Conclusions: Understanding how treatments are tolerated in patients outside of clinical trials is critical. These data provide a snapshot of how people experience 12 months of their treatment, with regularly collected PROs. It is important to use real-world data such as these, alongside clinical trial data, to better understand people's ability and desire to tolerate their treatment.

P1.17.72 Clinical and Dosimetric Predictors for Post-Radiotherapy Lung Cancer Recurrence: A Model for Resource-Limited Settings

R.A.B. Aguiar[1],[2], T.R. Dias[3], J.S. Pavão[3], L.B. Assunção[3], M.L.T. Bento[3], G.L.F. Cunha[3], R. Ferrari[1], G. Barbosa[1], E. Fuks[1], L. Oliveira[1], P. Canary[1], C.E. De Almeida[1], M. JV.[4], D. Przybysz[1]
[1]RadioSerra Radiation Therapy, Petrópolis/BR ,[2]Petropolis Medical School - FMP, Petrópolis/BR ,[3]RadioSerra Radiation Therapy, Petropolis Medical School, Petrópolis/BR ,[4]Centro de Terapia Oncológica, Petrópolis/BR

Introduction: Optimizing post-radiotherapy surveillance for lung cancer recurrence is crucial, especially in developing countries where healthcare resources andup-to-date technology are limited. This study aims to create a predictive model integrating clinical and dosimetric factors to accurately enhance personalizedsurveillance and recurrence control in resource-constrained settings.

Methods: We retrospectively analyzed lung cancer patients treated with radiotherapy between 2018 and 2023. Clinical variables, tumor staging, and dosimetric parameters were evaluated to explore factors associated with survival, recurrence, and pulmonary toxicity and recurrence data were collected from clinical records. Logistic regression and AUC curve analysis were used to assess predictive factors and model performance.

Results: A total of 207 lung cancer patients were analyzed, with a median age of 66 years (range 29-92) and a balanced gender distribution. Smoking history was reported in 81,16 % of patients, and 56.04% were diagnosed at stage IV. The cohort included 191 NSCLC (92.3%) and 16 SCLC (7.7%) patients. Overall mortality was 24.6% (51 deaths), and recurrence occurred in 65,22% (133 of 207) of patients. SCLC patients showed unexpectedly higher survival rates (75.4%, 12 patients) and minimal recurrence (37,5%, 6 patients) compared to NSCLC patients (74,87% survival, 143 patients; 67,54% recurrence, 129 patients). This finding contrasts with existing literature, where SCLC typically demonstrates rapid recurrence and poor 5-year survival (<10%). Dosimetric analysis revealed a mean V5% of 9.01%, a mean V20% of 16.78%, a mean lung dose (MLD) of 1764 cGy, and a mean maximum dose (Dmax) of 4195 cGy." Patients with V20% >35% and MLD >2000 cGy had a significantly higher recurrence risk. Advanced cancer stage (III and IV) was significantly associated with recurrence (p=0.002). Patients with a history of smoking had a 3.2-fold higher recurrence rate compared to nonsmokers. Furthermore, higher Dmax values correlated with increased recurrence, highlighting the impact of radiation exposure on local tumor control. The predictive model achieved strong discriminative performance with an AUC of 0.83.

Conclusions: Integrating clinical and dosimetric parameters provides an effective and clinically relevant model for predicting recurrence following radiotherapy in lung cancer patients. In resource-constrained healthcare environments, such a model is instrumental in tailoring surveillance protocols, prioritizing high-risk individuals, and facilitating timely intervention. Implementation of this predictive strategy can substantially enhance recurrence detection, optimize healthcare resource utilization, and ultimately improve patient outcomes.

P1.17.73 Misperception of Unintentional Weight Loss and Anorexia More Prevalent in Lung Cancer Among Other Solid Tumors in a Mexican Cohort

S. Campos-Gomez, A. Gonzalez-Santana, E. Jaimes-Alpizar
Centro Oncológico Estatal ISSEMyM, Toluca/MX

Introduction: Cancer is a catabolic inflammatory disease that causes patients to often experience weight loss, or even cachexia in severe cases. Undernourishment in patients with cancer impairs the quality of life and therapeutic response, further leading to poor prognosis. Anorexia is seen in 30% of cancer patients, leading to reduced food intake or reduced nutrient absorption and, consequently, to a worsening of quality of life, as well as to increased morbidity and mortality. Unintentional pre-treatment weight loss, which can be a consequence of anorexia, is also associated with a worsening of functional capacity and tolerance to prognosis. Objective: To evaluate the prevalence of anorexia and weight loss at diagnosis (pre-treatment) in different solid tumors, and identify the frequency and factors associated with pre-treatment weight loss, and to determine the malnutrition risk in patients with advanced solid tumor diagnosis.

Methods: This was a prospective observational cohort study. Patients over 18 years old from the State Oncology Center of ISSEMyM, diagnosed with solid tumor, from April 1st 2019 to July 31st 2019, Once the informed consent was signed by the patient, the Malnutrition Screening Tool (MST) and NUTRISCORE nutritional screenings were applied. The patients were stratified by the presence/absence of anorexia and of pre-treatment weight loss, which generated a measure composed of four categories, which were the independent variables. Data analysis was performed with the statistical program SPSS 22. For descriptive analysis of qualitative variables, frequency and percentage distributions were used, while quantitative variables were described by measurements of central tendency and dispersion analyzed and compared using the two-way ANOVA test with a confidence level of 95%.

Results: The total sample consisted of 312 patients including cases of lung, breast, cervical, colorectal, ovarian and prostate cancer, which were the most prevalent diagnoses during the study period. The average age of the total sample was 57.94 ± 12.92 year old, Among the 312 patients included in the study, anorexia and pre-treatment weight loss were present in 37% and 38.5%, respectively. Most cases with involuntary weight loss are reported in the breast, cervical and colorectal cancer groups, however, 29% of patients with lung cancer report no know about lost while patients with other diagnoses have lower or no percentages of ignorance. However, although fewer lung cancer patients report not having lost weight involuntarily, 11.7% who lost weight were considered moderate to severe (11 or > 15 kg).Lung cancer was the tumor group with highest nutritional risk, followed by ovarian, cervical, colorectal, prostate and breast cancer, with significant differences p 0.000

Conclusions: Anorexia and pre-treatment weight loss appear to be relevant problems in patients with solid tumor but mainly in lung cancer with more severe grade even lung cancer patients misperceive them. Specific interventions are of crucial importance in individualized treatment plans, even within the context of palliative care.

Keywords: Lung cancer, weight loss, anorexia

P1.17.74 Bridging Data Gaps in Brazilian Lung Cancer Surgery Care: The Evolution of the Brazilian Lung Cancer Registry (RBCP)

M.T. Tzukazan[1], L.L. Lauricella[1], P.D. D'Ambrosio[1], L.B. Rodrigues[3], T.R. Tsukazan[4], J.L. Gross[5], F.E.G.C. Cipriano[6], F.M.d. Silva[7], R.M. Terra[8]
[1]Hospital São Lucas da PUCRS, Porto Alegre/BR ,[1]Instituto do Câncer do Estado de Sao Paulo (ICESP), Sao PAULO/BR ,[3]Hospital Madre Tereza, Belo Horizonte/BR ,[4]Hospital Sao Lucas (PUCRS), Porto Alegre/BR ,[5]Hospital ACCamargo, Sao Paulo/BR ,[6]Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto, Ribeirao Preto/BR ,[7]Imperial Hospital de Caridade, Florianopolis/BR ,[8]Instituto do Cancer do Estado de Sao Paulo, Sao Paulo/BR

Introduction: Reliable data on lung cancer in Brazil are scarce. Existing sources offer basic epidemiology but lack detail on surgical quality and outcomes. To address this, the RBCP was created in 2014. Initially a state-level effort, it expanded into a national, multicenter clinical registry aimed at monitoring surgical practice and improving care. RBCP data also supported Brazil's contribution to the 3rd IASLC Lung Cancer Staging Project.

Methods: The RBCP collects standardized data on demographics, risk factors, procedures, complications, staging, treatment, molecular profile, survival, and recurrence. Hosted on REDCap, it relies on voluntary participation and trained local teams. Quality control includes real-time validation and periodic audits assessing completeness, consistency, and accuracy. As of 2024, data from 20 institutions were analyzed.

Results: By the end of 2024, 3,109 surgeries were recorded, with numbers rising steadily post-2015 (Figure 1A). Most patients were women (57.32%), with median ages of 62.8 (women) and 66.6 (men). Racial distribution: 80.95% White, 12.04% Mixed, 4.21% Black, 2.8% Asian. A smoking history was present in 60.2%. Comorbidities included hypertension (49.7%), coronary disease (9.3%), and COPD (33%). Surgeries were conducted via the public health system (43%) and private insurance (55%). Diagnosis was incidental in 47.4%, symptom-driven in 29.2%, during follow-up of other cancers in 15.7%, and via screening in 7.7%. Figure 1B illustrates a shift from thoracotomy to minimally invasive approaches—mainly RATS and VATS—reaching 88.8% in 2024. Figure 1C shows lobectomy as the main procedure, with a consistent rise in segmentectomies and wedge resections, indicating broader use of parenchyma-sparing techniques. Early-stage tumors predominated: IA1 (14.8%), IA2 (21.0%), IA3 (11.7%), IB (14.6%), and IIA (4.4%). Advanced stages included IIB (12.5%), IIIA (12.3%), and IIIB (2.3%). Molecular testing was available in 15.8%, with EGFR mutation most frequent (23%). Data quality analysis showed 83% completeness and 7% inconsistency.

Conclusions: The RBCP is an emerging source of oncologic thoracic surgery data in Brazil. It enables detailed evaluation of patient demographics, treatment trends, and clinical outcomes. The widespread adoption of minimally invasive and robotic techniques reflects modernization in surgical care. Ongoing quality assessment strengthens the reliability of the registry for research and policy. Despite being a non-funded, researcher-led initiative, the RBCP demonstrates the potential of structured databases to drive improvements in lung cancer care. However, the registry is still expanding and does not yet encompass all Brazilian states, reflecting both the country's vast geography and the need for broader institutional engagement.

P1.17.75 Realizing Digital Transformation in Health: Findings From the TRANSITION Project

A. Charalambous, T. Tsitsi, N. Dodlek
Cyprus University of Technology, Limassol/CY

Introduction: Technology has rapidly infiltrated many aspects of healthcare changing the landscape of cancer care in numerous ways across the disease continuum. Despite the potential of technology to impact cancer care it is pivotal that the drivers of such digital transformation, namely healthcare professionals (HCPs) and health managers need to achieve and maintain adequate levels of digital health literacy. This requires a specific set of digital skills of various levels of expertise that will allow them to assume roles in designing, developing, and utilising digital solutions as a means of high-quality and efficient services. The European Commission funded TRANSiTION Project was developed to support the EU Beating Cancer Plan through fostering up-skilling and reskilling in the context of digital health solutions for the oncology workforce.

Methods: The TRANSiTION training has been made primarily available to 14-European Member States. The project allowed recruitment through participating cancer centers and from eligible individuals. Eligible participants to the program met specific pre-defined requirements. Following the introduction of the training in the EU, the project has been globally released allowing participants to sign up for the training. The program has been comprehensively evaluated through the adoption of the CIPP Evaluation Model (Context, Input, Process, and Product) that included measurements before and after the training on the following: o Learning Objective Review Instrument (LORI). o Online Readiness Questionnaire for learners (provides feedback and readiness score). o Technology Acceptance Model (TAM v1) questionnaire to assess acceptability. o Post-Study System Usability Questionnaire (PSSUQ v3) for usability

Results: Over 1000 participants from over 53 countries have been recruited to the program, undertaking different learning pathways according to their specialty/profession. The analyses demonstrated statistically significant ($P < 0.05$) results of the training across all the assessment domains. Statistically highly significant results ($P < 0.001$) were recorded in terms of the impact of the training on the trainees' ability to introduce and utilized digital solutions in diverse clinical pathways across the cancer continuum.

Conclusions: There is a pressing need for comprehensive digital skill training for oncology healthcare professionals across diverse backgrounds and healthcare systems. Healthcare systems around the world undergo a digital transformation to facilitate the use of technology for innovative solutions to improve healthcare delivery and efficiency, to achieve improvement in medical problems and overcome consistent challenges posed by a growing need for healthcare services, a shrinking and burdened workforce and reduced funding. A smooth digital transformation requires an adequately prepared workforce that acts as the driver of implementation and sustainability. The findings provide evidence that designing digital skills training programs that support a holistic approach can significantly impact cancer care delivery across the disease continuum. Commitments on the policy, clinical practice, research and education fields are needed to increase the digital transformation preparedness of the oncology workforce. The overall work of the TRANSiTION Project serves as an innovative training programme in oncology that reflects the needs and preferences of HCPs and health managers.

Introduction: Advances in lung cancer diagnostics, staging and treatment have markedly improved outcomes, but also increase the complexity of care delivery, potentially worsening geographic disparities. Improved care and outcomes requires facilities, equipment and a skilled workforce. This can be particularly challenging in LMICs. We took a national inventory of material and human resources available for lung cancer care in Nigeria, a Sub-Saharan African country.

Methods: In February and March 2025, we surveyed tertiary care institutions categorized as Federal University Teaching Hospitals (FUTH), Federal Medical Centers (FMCs), State University Teaching Hospitals (SUTH) and Specialty Hospitals (SH). We inventoried available care delivery facilities, services and workforce at respondents' institutions, summarized data with standard statistical methods.

Results: We received responses from 38 institutions, including 21 of 33 (64%) FUTH, 7 of 24 (29%) FMCs, 4 SUTH and 6 SH, from 26 of 36 States (72%) and all 6 geopolitical regions (100%). Institutions had a median of 500 (IQR 300-670; range 10 - 1350) beds; 3 of 38 institutions (8%) were privately owned. A summary of the available facilities, services and workforce is summarized in Table 1. Strikingly, only 1 facility had a PET-CT scanner, EBUS was available at only 1 facility and no facility had genomic testing. Only 9 facilities had a linear accelerator. Nevertheless, most institutions had available specialists for care delivery. 31 of 41 respondents (76%) provided 67 responses detailing challenges to care delivery (Table 2); 39 (95%) respondents indicated interest in contributing patient-level data to an observational registry.

Conclusions: Despite nominally available facilities and a workforce, services for contemporary lung cancer care were limited. Affordability, lack of equipment, workforce inadequacies and delayed patient presentation were the most frequently reported challenges. Existing resources provide opportunity for partnerships to test corrective interventions.

Facilities Available	N (%)	Services Available	N (%)	Workforce Available	Median (IQR; Range)

P1.17.77 Lung Cancer Consensus: Uniting for a Healthier World

M.E. Bussell[1], K.N. Syrigos[2], L. Corrales[3], R.U. Osarogiagbon[4]
[1]TriMar Strategies, Inc., New York/NY/USA ,[2]National and Kapodistrian University of Athens Medical School, Athens/GR ,[3]Centro de Investigacion y Manejo del Cancer - CIMCA, San Jose/CR ,[4]Baptist Memorial Healthcare Corporation, Memphis/TN/USA

Introduction: As health professionals, ratify Bridging the Gap in the Diagnosis & Management of Lung Cancer, presented at International Lung Cancer Network (2023), Emirates Oncology Society Conference (2024), & Pan-African Conference on Lung Cancer (2025). This Consensus Statement outlines 5 core principles to guide health professionals, policy-makers, patient organizations, and stakeholders in improving global lung cancer outcomes:

1. Improve & expand prevention; 2. Focus on early detection; 3. Ensure equitable & sustainable access to treatment; 4. Build partnerships & promote investment; 5. Combat stigma, recognizing it as a social determinant of public health

Methods: Practices analyzed across Africa, Asia-Pacific, Gulf States, & Latin America using a benchmarking framework informed by WHO, OECD, and published literature. Findings discussed in regional expert panels and meetings. Our approach highlights barriers in knowledge, service delivery, access, & governance, underscoring the need for global ratification of the Consensus Statement to drive awareness, policy, & action.

Results: While good practices exist, no country excels across all principles:

1. Prevention: 24 of 29 countries studied are FCTC signatories, yet none have fully implemented its commitments. Only 4 have national agencies for tobacco control.

2. Early detection: National screening programs exist in Korea (2019), Croatia (2020), Taiwan (2022), and Australia (2025). Outreach gaps persist in 18 countries, particularly among marginalized groups, while 17 countries fail to address never-smokers' risks. In sub-Saharan Africa and Asia-Pacific lung cancer results more from solid fuel use than tobacco.

3. Equitable Access to Treatment: Of 17 countries with clinical guidelines, only 8 have updated them in the past 5 years, missing opportunities to fully align with best practices.

4. Partnerships: 14 countries have lung cancer-specific patient organizations. General cancer organizations exist in 25 countries, but they often lack a specific focus on lung cancer.

5. Stigma: Stigma remains pervasive, largely due to smoking's association with lung cancer. 14 countries have published literature recognizing this challenge. Destigmatization efforts help address unconscious bias across society & within healthcare settings.

These findings emphasize the urgent need for coordinated global action to close gaps in prevention, detection, treatment, investment, and stigma.

Conclusions: Despite progress, access remains inequitable. Disadvantaged populations, particularly in low-income countries, face disproportionately poor outcomes. Unifying global efforts through the Lung Cancer Consensus Statement can drive meaningful change, highlight opportunities for improvement & ensure those at-risk for and living with lung cancer receive the care they need. There is neither time nor room for complacency.

P1.17.78 Living Systematic Review Linked to Guidelines and Regulatory Approvals as a Treatment Decision Support Tool in NSCLCy

H. Borghaei[1], A. Forsythe[2], S. Grieve[3], R. Liu[3], J. Rege[2], S. Sarkisian[4]
[1]Fox Chase Cancer Center, Philadelphia/PA/USA ,[2]Oncoscope-AI LLC, Miami/FL/USA ,[3]Eviviz, Toronto/ON/CA ,[4]Frederick Health, Frederick/MD/USA

Introduction: A Systematic Literature Review (SLR) of interventional clinical trials in Non-Small Cell Lung Cancer (NSCLC) projects > 2,500 publications in 2025, alongside > 6 NCCN updates and numerous regulatory approvals. For oncologists with demanding schedules, staying updated is a challenge. A clinical data system integrating automated NCCN treatment paradigm with a real-time SLR, regulatory approvals, and ongoing trials can support evidence-based decisions. This study leveraged Artificial Intelligent (AI) and automation to create a comprehensive Decision Support Tool (DST) for NSCLC.

Methods: A Cochrane-compliant SLR protocol was automated for daily updates. A Large Language Model trained on > 20,000 annotated clinical trial records (across six cancer types, including NSCLC) extracted 32 variables per publication (e.g., TNM staging, histology, biomarker, risk factors, treatment line, interventions, interventions; randomization, study phase and sample size; analysis type, follow-up period; reported outcomes (median and landmark overall survival (OS), progression-free survival (PFS) and other progression measures, response data, quality of life); subgroup analyses, safety/toxicity). Extracted data were standardized and integrated with established guidelines treatment paradigm. A software tool was built to filter this database, linking treatment pathways to real-time SLR, FDA approvals, and ongoing clinical trials.

Results: The real-time SLR identified 110 interventional NSCLC trial publications, of which 356 were since January 2024. In a test-case query for treatments in NSCLC patients with EGFR alterations, 114 studies were identified in < 1 minute. Of these, 62 focused on post-TKI progression with 39 reporting on Phase 2 or 3 studies. Fourteen randomized controlled studies investigated nine Immune checkpoint inhibitors, two antibody drug conjugates, and three targeted therapies. Two studies showed significant OS, and 5 studies showed significant PFS improvement vs. comparators, of which only one study was included in NCCN guidelines. Traditional SLR would require 3 weeks and multiple researchers to achieve similar results.

Conclusions: By selecting key patient criteria (e.g., biomarkers, metastatic stage, treatment path), our Decision Support System links real-time clinical data to established guidelines. Implementation in clinical practice could enable oncologists to make timely, informed decisions, potentially improving patient outcomes.

P1.17.79 Assessing Radiotherapy Access and Patient Experience in Lung Cancer Treatment:A Survey on Financial and Logistical Challenges

D. Khosla, A. Jamwal, R. Kapoor, N. Singh, A. Bal, N. Gupta, R. Madan
Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh/IN

Introduction: Lung cancer treatment is complex and typically involves multiple modalities. Radiotherapy, uniquely applicable across all disease stages, plays a crucial role in the treatment spectrum. While the medical efficacy of radiotherapy is well-documented, there is a lack of comprehensive assessment regarding patient perspectives and overall treatment experiences. This audit seeks to evaluate patient-related factors comprehensively, focusing on understanding patient satisfaction, and access to radiotherapy, and identifying areas for potential improvement.

Methods: A cross-sectional survey was conducted involving 252 lung cancer patients receiving radiation treatment at PGIMER, Chandigarh, India. Data were collected through structured questionnaires capturing various aspects of their journey including demographics, facility accessibility, waiting times, travel and accommodation issues, financial burden, and satisfaction levels.

Results: The majority of patients reported significant financial strain due to travel and accommodation costs. About 72% of patients indicated a significant or moderate financial burden, with unexpected expenses contributing to the overall cost. Family members reported significant economic strain, with 45% indicating a moderate to significant financial impact. About 85% of family members had to reduce their work hours or leave their jobs to support the patient, while 31% of patients themselves had to stop working or take extended leave due to treatment. Despite the high patient workload, 65% of patients were started radiation treatment within two weeks. Waiting times for appointments and treatment varied, with 42% of patients experiencing occasional delays and 30% reporting never having to wait. Patients faced considerable travel challenges, with 48% travelling daily and 37% covering distances of over 200 km. Travel time was often more than 2 hours for 62% of patients. Accommodation was a concern for 53% of patients, with a significant percentage reporting high costs. Access to radiotherapy facilities near home was limited, with 50.79% reporting no nearby facility, leading to significant travel burdens—36.51% of patients travelled over 200 km, and 62% had travel times exceeding two hours. Financial support was available for 63% of patients, mainly through government programs. While 63% received financial aid through government programs, 38.5% incurred unexpected costs due to machine breakouts, extended stays, or additional travel. Out-of-pocket expenses persisted, with 40.08% of patients reporting a significant impact on their financial stability. Patient satisfaction with treatment was high, with 92% rating their overall experience as good or excellent.

Conclusions: The audit highlights the substantial financial burden and logistical challenges faced by lung cancer patients during treatment. While government programs and financial support have alleviated some costs, there remains a significant impact on patients' finances and daily lives. The availability of cancer care facilities in India is markedly uneven, with a concentration of advanced care in specific centres leading to overburdening and strain on resources. This disparity adversely affects the quality of care and patient outcomes, highlighting the need for a more equitable distribution of cancer care resources.

Keywords: Radiotherapy, cancer care access, patient experience

Complejo hospitalario Universitario de Canarias, Instituto de Investigación Sanitaria de Canarias (IISC), La Laguna (Tenerife)/ES ,[5]Hygeia Consulting S.L., Madrid/ES ,[6]Roche Farma, Madrid/ES ,[7]Hospital de la Santa Creu i Sant Pau, Barcelona/ES

Introduction: Adjuvant alectinib has shown a significant benefit with respect to disease-free survival as compared with adjuvant platinum-based chemotherapy (PbCH) in early-stage ALK rearranged non-small cell lung cancer (NSCLC) patients, as well as a mainly low-grade safety profile. The aim of this analysis was to estimate the economic burden of disease management with current adjuvant PbCH after complete resection of ALK+ NSCLC in Spain, focusing on the costs of patients with recurrent disease.

Methods: A two-round consensus panel was conducted with six Spanish experts. First, the experts completed a questionnaire designed to capture expert opinion on the epidemiology, treatment pathways and healthcare resource use associated with disease management in patients with ALK+ NSCLC. The responses were then shared in a second round to reduce variability and reach a common consensus. Afterward, a 3-states Markov model was built to estimate the 5-years costs after complete resection of ALK+ NSCLC (IB ≥4cm - IIIA), from the Spanish National Health System (NHS) perspective. The efficacy data used to model transitions between health states were obtained from the ALINA study and other published articles on NSCLC. Unit costs were obtained from national databases and expressed in euros of 2025. To account for uncertainty in the model parameters, a one-way sensitivity analysis was performed, generating a range of possible outcomes around the mean cost estimates.

Results: A target population of 98 hypothetical patients with resected ALK+ NSCLC was estimated, of which 62 would experience recurrence after 5 years from treatment with adjuvant PbCH. In Spain, the total cost in absolute terms of managing these 62 relapses would amount €8,519,175 and the total cost of 35 disease-free patients would be €707,500. Therefore, the total cost for the target population of the analysis was 9,2 million €. The average cost of ALK+ NSCLC recurrences in Spain over a 5-year period would be €137,026 (€9,576 and €172,973 for recurrences managed with local or systemic treatment, respectively). Figure 1 summarises the average cost of recurrences by type. Sensitivity analyses reinforced the robustness of the results obtained.

Conclusions: Although the number of patients with ALK+ early-stage NSCLC is low, the cost of recurrences (particularly those requiring systemic therapies) represents a substantial burden for the National Health System. Early intervention and the incorporation of more efficacious adjuvant therapies to mitigate recurrence risk are critical to optimize disease management.

P1.17.81 Unveiling the Natural History of Lung Cancer by Sex, Histology, and Nodule Type Using Mathematical Modeling

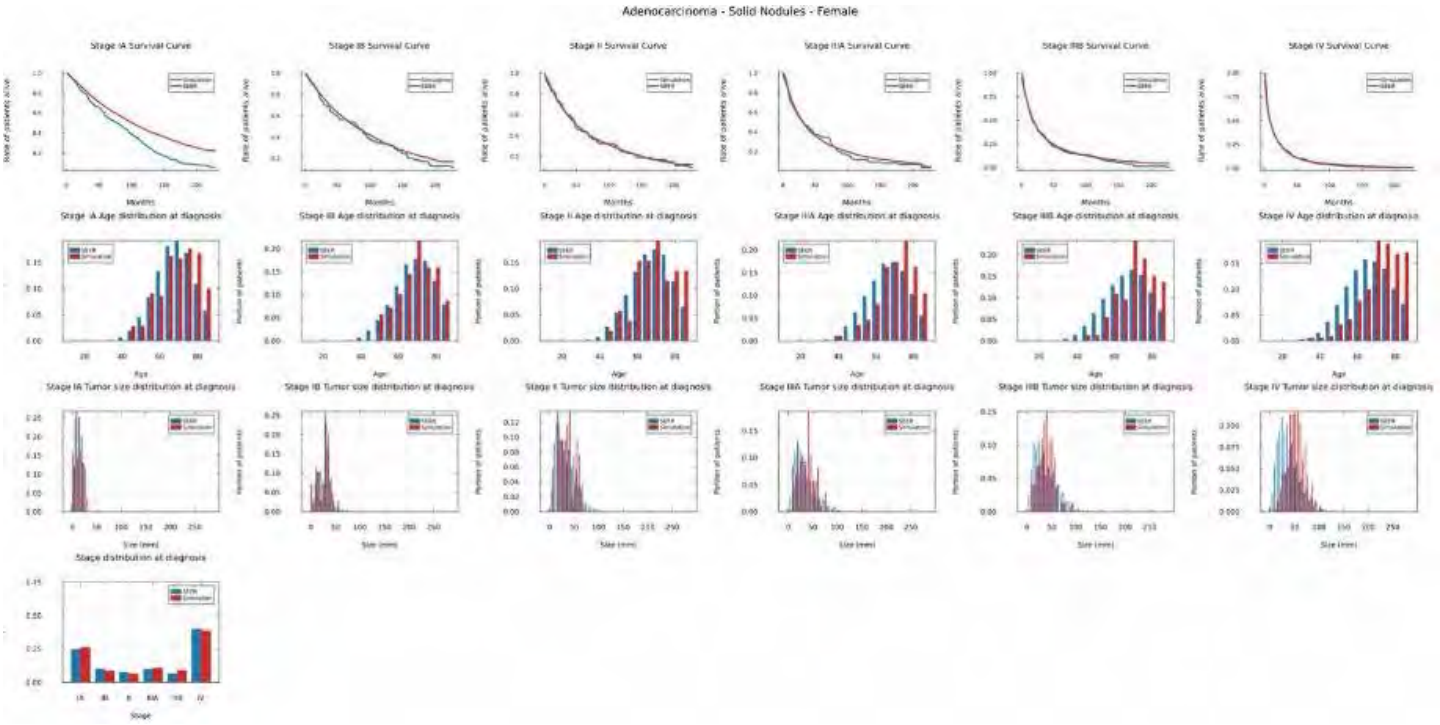
S. Ishizawa[1], R.S. Naargund[1], M. Eghbalizarch[1], C.M. Tammemagi[2], R. Meza[3],[4], I. Toumazis[1]
[1]The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[2]Brock University, St. Catharines/ON/CA ,[3]BC Cancer Research Institute, Vancouver/BC/CA ,[4]University of British Columbia, Vancouver/BC/CA

Introduction: Lung cancer is the leading cause of cancer-related death globally. Mathematical models that simulate the natural course of the disease, commonly referred to as natural history models (NHMs), have been developed and used to provide insights into the effectiveness of interventions. In a recent scoping review of the literature focusing on existing NHMs, we found that no existing lung cancer NHM accounts for the differences in the disease progression by nodule type, and very few explicitly model tumor growth. We thus developed and validated a sex-, histology-, and nodule type-specific NHM for lung cancer that explicitly models tumor growth.

Methods: We developed sex-specific state-transition lung cancer NHMs for the most common histological subtypes (small cell, squamous cell, adenocarcinoma, and other non-small cell) using the AJCC staging system. Adenocarcinomas were further stratified by nodule type into solid, part-solid, and non-solid. We assumed that tumors grow according to Gompertz models, which were calibrated to observed data from the Surveillance, Epidemiology, and End Results (SEER) 17 registry from 2000-2021. Because SEER does not provide information on nodule type, we assumed all adenocarcinomas in SEER are solid nodules and adjusted the progression rates for part-solid and non-solid nodules based on estimates of tumor volume doubling time from the literature. Each of the NHMs had a similar structure. We used the observed stage-specific survival after diagnosis, stage distribution at diagnosis, stage-specific tumor size distribution at diagnosis, and stage-specific age distribution at diagnosis as calibration targets. We assessed the goodness of fit of each model using the weighted sum of root mean squared error (RMSE) and validated the NHMs on the control arms of the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial (PLCO) and the National Lung Screening Trial (NLST) trials.

Results: The number of parameters for each model ranged between 27-33 parameters estimated through calibration. The calibrated NHMs successfully reproduced the observed data from SEER in terms of all calibration targets by sex and histological subtype (Figure 1). The RMSE for all models was less than 3%. The NHMs reproduced the observed outcomes of the PLCO and NLST control arms.

Conclusions: The NHMs accurately simulate the sex-, histology-, and nodule type-specific progression of lung cancer while explicitly modeling tumor growth. The resulting NHMs will inform future microsimulation studies to evaluate the effectiveness of alternative lung cancer screening strategies by nodule type.



Keywords: natural history, tumor growth, nodule type

P1.17.82 Lung Cancer's Price Tag: Escalating Hospitalization Costs in Brazil Over the Past Two Decades

J.H. Maselli Schoueri[1], A.C. Viana[1], M. Magalhães Filho[2], J. Favoretto Neto[3], L.V. de Alcantara Sousa[1], L. da Silva Paiva[1], J.J. Namura[1], C. Vaz de Melo Sette[1], A. del Giglio[1], P. Nazareth Aguiar Jr[4]
[1]ABC Medical School, Santo André/BR ,[2]Beneficência Portuguesa - SP, São Paulo/BR ,[3]Hospital do Amor Amazônia, Rondônia/BR ,[4]Grupo Oncoclínicas, Santo André/BR

Introduction: Lung cancer (LC) is the leading cause of cancer-related death worldwide. In Brazil, despite the universal healthcare system (SUS), regional and demographic disparities may influence both access to care and treatment outcomes. Economic analyses focusing on hospitalization costs are essential to understanding the burden of LC on the public healthcare system. This study aimed to analyze trends in average hospitalization costs for LC in Brazil.

Methods: Ecological study in which LC was classified according to ICD-10. Average In-Hospital Admission costs were collected from the Hospital Information System for each administrative region of Brazil, and stratified by year, sex and age group of involvement. Values were first adjusted for inflation, using the Broad Consumer Price Index (IPCA), obtained from the Accumulated Variation in the year during the Real Plan by the Brazilian Institute of Geography and Statistics (IBGE). Then, the values were adjusted by the annual exchange rate for US dollars, obtained from the Institute of Applied Economic Research (IPEA), allowing for international comparison. The period studied was defined between the years 2001 and 2024, taking 2020 as the basis for starting inflation calculations. Since the data did not follow a linear distribution, quadratic regression was used to evaluate its behavior over time. The program used was Stata 15.0. The confidence level was 95%.

Results: From 2001 to 2024, average hospitalization costs (in USD, not adjusted for inflation) were consistently higher among women compared to men. This difference may reflect sex-based variations in clinical presentation, resource utilization, or treatment strategies. Quadratic regression demonstrated nonlinear patterns in in-hospital costs for LC in Brazil between 2001 and 2024. Increasing trends were observed until the mid-2010s, followed by a subsequent decline in both sexes (especially women), regions, and age groups ($p < 0.001$). The highest cost curves occurred in the 20-34 age group, and the lowest among the elderly. The North region presented a lower adjusted R^2, which may suggest greater local variability.

Conclusions: There was a parabolic behavior in hospital costs for lung cancer in Brazil, with growth until approximately 2011, followed by a decline. The analysis by subgroups reinforces regional, age and gender inequalities, with a potential impact on public policies.

P1.17.83 Implementation of Lung Cancer Screening by Family Physicians in the U.S.: Results of a National Survey

R. Volk[1], J. Eberth[2], M.P.B. Brietzke[1], J. Lettieri[1], K. Maki[3], N. Tan[4], M. Monroe[5], K.N. Reid[5], L. Rosenthal[6], E.A. Kazerooni[7], R.A. Smith[6]
[1]The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[2]Drexel University, Philadelphia/PA/USA ,[3]Wayne State University, Detroit/MI/USA ,[4]Rutgers University, New Brunswick/NJ/USA ,[5]American Academy of Family Physicians, Leawood/KS/USA ,[6]American Cancer Society, Atlanta/GA/USA ,[7]University of Michigan Medical School, Ann Arbor/MI/USA

Introduction: Lung cancer screening (LCS) rates in the U.S. remain low despite endorsements from professional organizations and broad insurance coverage with no co-pay. Family physicians play an essential role in LCS, in having long-term relationships with their patients that emphasize preventive care, established screening protocols for other cancers, routinely screening for tobacco use, and providing cessation resources to their patients who smoke. Understanding what family physicians know about LCS, how they are implementing it their practices and their preferences for doing so, is critical to increasing the uptake of this life saving screening test.

Methods: An online, self-administered survey (Alchemer©) of active members of the American Academy of Family Physicians (AAFP) was conducted between February and August 2024. Sampling involved stratification of members by the nine geographic Census Divisions in the U.S., and then taking random samples until the target sample size per division was achieved. Recruitment was conducted in two waves, with four reminders sent to AAFP members with valid email addresses. Survey items captured participants' practice and demographic characteristics; lung cancer screening attitudes, practices, and resources; and attitudes and practices around smoking cessation and new screening technologies. Data are reported descriptively with sample weight adjustments for gender, years since residency, urban/rural status, and Census Division.

Results: The sample included 1,183 family physicians, with balanced participation across the nine Census Divisions. Participants' practice and demographic characteristics mirrored the overall AAFP membership. Among survey participants, 22.7% completed residency training within the past seven years, while 37.1% completed training more than 21 years ago. Nearly all (95.9%) used an electronic health record (EHR), with Epic® (43.7%) being the most common. Familiarity with the 2021 United States Preventive Services Task Force recommendation and current American Cancer Society guideline was high. Participants "agreed/strongly agreed" that the benefits of lung cancer screening (LCS) outweighed the risks (85.2%). The majority (89.6%) had ordered LCS for their patients, with 53.6% referring at least 11 patients for LCS over the past year. Nearly two-thirds (63.5%) indicated their center/clinic had a decentralized approach to LCS, where family physicians were responsible for ordering LCS, tracking results, and coordinating follow-up care, while 11.1% were supported by a centralized LCS program that coordinates care after the order was placed, and 15.8% relied on a hybrid approach (i.e. some centralized support was available). Most (71.3%) had clinical protocols for collecting smoking histories from patients, and 50.1% used EHR alerts to prompt them about a patient's LCS eligibility. Use of standardized protocols for follow-up of abnormal findings (38.7%) and incidental findings (35.5%) were less common. Only 26.4% had access to care navigators to facilitate the screening process.

Conclusions: Nearly all U.S. family physicians agreed that LCS was beneficial for patients and refer eligible patients for LCS. Approximately 2 in 3 physicians coordinate LCS themselves, without resources such as a navigator or provided in a centralized screening program. This lack of support is a major barrier to implementing high quality LCS uptake.

P2.02.01 Characterizing UPP1 Expression in Non-Tumor Cells of Lung Cancer and Its Clinical Implications

Y. Li, C. Lu, D. Ge
Zhongshan Hospital, Fudan University, Shanghai/CN

Introduction: Uridine phosphorylase 1 (UPP1) is a key enzyme in uridine metabolism, recently reported to promote tumor cell proliferation through metabolic reprogramming (Nature, 2023). Our previous study demonstrated its tumor-promoting role in lung adenocarcinoma and its potential as a prognostic biomarker (Nature Communications, 2024). However, the functional role of UPP1 in non-malignant cells within the tumor microenvironment (TME) and its impact on immune regulation in lung cancer remain largely unknown.

Methods: We conducted an integrative analysis using single-cell RNA sequencing data from nearly 200 lung cancer patients, combined with clinical and transcriptomic data from over 500 patients. Multiplex immunofluorescence and spatial transcriptomics were applied to validate spatial distribution and cellular localization of UPP1. Functional roles were assessed through conditional knockout mouse models targeting macrophages and neutrophils. A tumor organoid-UPP1+TAM-CD8+T cell co-culture system was developed to examine immune interactions. Additionally, high-throughput drug screening was performed using organoids and immune cells to identify potential UPP1-targeting agents.

Results: UPP1 was significantly upregulated in several non-malignant cell populations, particularly tumor-associated macrophages (TAMs), neutrophils (TANs), and endothelial cells within the TME. High UPP1 expression in these populations was associated with poor overall survival, increased tumor progression, and reduced response to immune checkpoint blockade (ICB). Mechanistically, UPP1 expression was induced under hypoxic conditions and by cytokines such as GM-CSF and IL-6. Functionally, UPP1 upregulation in TAMs contributed to the establishment of an immunosuppressive TME by promoting secretion of inhibitory mediators such as G-CSF and CCL9, leading to impaired CD8+T cell cytotoxicity. Conditional deletion of UPP1 in myeloid populations inhibited tumor growth, enhanced CD8+T cell activation, and sensitized tumors to anti-PD-L1 therapy in vivo. In ex vivo organoid co-culture systems, UPP1+TAMs suppressed CD8+T cell-mediated cytotoxicity, a phenotype reversible by targeting UPP1.

Conclusions: This study uncovers a previously underappreciated role of UPP1 in shaping the immunosuppressive microenvironment of lung cancer through its expression in non-malignant stromal and immune cells. UPP1 serves as a critical metabolic-immune regulator and a promising therapeutic target to enhance anti-tumor immunity and improve immunotherapy outcomes. Our findings provide novel insights into metabolic regulation within the TME and offer translational strategies for targeting non-malignant components of lung tumors.

P2.02.02 R-Loop-Associated DNA Damage Facilitates Chemosensitivity of NSCLC

H. Chen[1], G. Yu[2], H. Lin[2], J. Liu[2], X.A. Zhou[2], H. Liu[2], Y. Luo[2], K. Cheng[2], Z. Mao[2], Y. Ma[2], J. Wang[1], K. Chen[1], J. Wang[2], Y. Li[1]
[1]Peking University People's Hospital, Department of Thoracic Surgery, Beijing/CN ,[2]Department of Radiation Medicine, Institute of Systems Biomedicine, School of Basic Medical Sciences, Peking University Health Science Center, Beijing/CN

Introduction: Aberrant accumulation or impaired resolution of R-loops compromise genome stability, leading to DNA damage and contributing to tumorigenesis, including NSCLC(non-small cell lung cancer). Notably, Several R-loop-associated proteins serve as critical regulators of R-loop structures across the genome, which are essential for mRNA metabolism and genome stability. In this study, we aimed to identify novel regulators of R-loops associated to NSCLC and to underscore their potential roles in modulating chemotherapeutic response.

Methods: RNA/DNA hybrids were immunoprecipitated from HeLa cells using the S9.6 antibody and subjected to mass spectrometry to identify R-loop-associated proteins. FTSJ3 function was evaluated via siRNA knockdown, overexpression, and rescue with RNase H1 overexpression. R-loop accumulation and DNA damage were assessed by immunofluorescence, comet assay, and proximity ligation assay. Cell viability and chemosensitivity to CPT or cisplatin were measured in lung cancer cell lines. TCGA and IHC analyses were used to evaluate FTSJ3 expression and its association with prognosis in NSCLC patients.

Results: FTSJ3 was identified as a novel R-loop-binding protein. Its depletion led to R-loop accumulation, increased DNA damage, and reduced cell viability. These phenotypes were reversed by RNase H1 overexpression, confirming their R-loop dependence. Loss of FTSJ3 enhanced sensitivity to CPT and cisplatin in vitro. Clinical analysis including TCGA and IHC showed FTSJ3 was upregulated in multiple cancers and correlates with poor prognosis in NSCLC, suggesting its potential as a predictive biomarker for NSCLC chemotherapy response.

Conclusions: Our study identifies FTSJ3 as a critical regulator of R-loop homeostasis, given its role in modulating DNA damage and chemotherapy sensitivity, FTSJ3 represents a potential therapeutic target and prognostic biomarker for improving treatment outcomes in NSCLC.

P2.02.03 Ferroptosis-Induced SUMO2 Lactylation Counteracts Ferroptosis by Enhancing ACSL4 Degradation in Lung Adenocarcinoma

G. Shan, H. Fan, C. Zhan
Fudan University, Shanghai/CN

Introduction: Lactylation, a lactate-mediated post-translational modification, has garnered significant attention for its pivotal role in epigenetic modulation. However, the intricate interplay between lactylation and ferroptosis in lung adenocarcinoma (LUAD) remains to be fully elucidated.

Methods: In this study, we employed metabolomic profiling and metabolic library screening to identify metabolites related to ferroptosis. Lactylation proteomics analysis was conducted to determine the proteins and residue sites that undergo lactylation during ferroptosis. Furthermore, we utilized immunofluorescence, cycloheximide chase assays, and sumoylation proteomics to assess the effects of lactylation on SUMO2. Cell viability assays, lipid peroxidation quantification, transmission electron microscopy of mitochondrial damage, malondialdehyde, and glutathione measurements were employed to evaluate the influence of SUMO2 lactylation on ferroptosis. Additionally, we designed a cell-penetrating peptide targeting SUMO2 lactylation and validated its efficacy in promoting ferroptosis in cellular, patient-derived organoid, and xenograft models.

Results: Utilizing metabolomic profiling and metabolic library screening, our study uncovered that ferroptotic stress markedly enhances glycolysis and lactate accumulation, which in turn confers resistance to ferroptosis in LUAD cells. Subsequently, we demonstrated that ferroptosis induction elevates protein lactylation levels within LUAD, especially SUMO2 at the K11 residue. Cell viability, lipid peroxidation detection, malondialdehyde, and glutathione measurements, collectively revealed that SUMO2-K11 lactylation contributes to ferroptosis resistance. The sumoylation proteomics and co-immunoprecipitation assays indicated that SUMO2-K11 lactylation hinders the interaction between SUMO2 and ACSL4. This disruption facilitates ACSL4 degradation, thereby mitigating ferroptosis. Furthermore, we identified AARS1 as the lactyltransferase and HDAC1 as the delactyltransferase for SUMO2. Based on these findings, we developed a cell-penetrating peptide capable of entering cells independently of cell membrane receptors or transfection reagents. By selectively inhibiting SUMO2-K11 lactylation, this peptide promotes ferroptosis and sensitizes LUAD to cisplatin treatment in vitro and in vivo.

Conclusions: This study suggests a promising therapeutic approach of targeting SUMO2-K11 lactylation to potentiate ferroptosis-based cancer therapies.

P2.02.05 CXCL12/CXCR4 Axis Mediates M2 Monocyte Polarization-Induced Immune Resistance in NSCLC Liver Metastasis

Q. Wang, X. Liu, C. Su
Shanghai Pulmonary Hospital, Tongji University, Shanghai/CN

Introduction: The low response rate to PD-1/PD-L1 inhibitors in patients with NSCLC liver metastasis limits the benefit of immunotherapy in this population. The patients may have their own unique immune escape mechanism, and the analysis of this mechanism will help to explain the reasons for the poor efficacy of immunotherapy in these patients.

Methods: The differences of gene expression, cytokines, number of immune cell infiltration and function of immune cell subsets in lung primary disease in patients without liver metastasis, lung primary disease in patients with liver metastasis and lung primary disease in patients with liver metastasis were compared based on clinical samples. Luminex multifactor assay to validate differences in cytokine and immune cell function. OLINK technique was used to detect proteomic expression difference and related function in serum of patients with liver metastasis. Difference of intestinal flora and serum metabolome in 16S. The mechanism hypothesis of poor efficacy of immunotherapy was proposed. To establish a mouse model of liver metastasis of non-small cell lung cancer. Bioinformatics analysis, flow cytometry, in vitro co-culture, key target RNA interference, PCR and other techniques were used to further analyze the key targets related to liver metastasis and immunotherapy efficacy of NSCLC and their regulatory mechanisms.

Results: At the transcriptome level, gene expression profile and protein-protein interaction network analysis showed that CD36 and CXCR4 were the core proteins responsible for differences in the expression of liver metastasis genes in NSCLC. The results of enrichment analysis suggest the activation of lipid metabolism-related pathways in patients with liver metastasis. It was found that the immune cell diversity of liver metastases was lower than that of the primary lesions, and the T cell subtype analysis showed that CD8+T cell infiltration was significantly reduced. The expression of M2-TAM was mainly increased in the myeloid cell population. By establishing a mouse model of lung adenocarcinoma liver metastasis, M2-TAM has been preliminarily confirmed to mediate tumor immune escape by inhibiting CD8+T cell function in NSCLC liver metastasis TME. The secretion of CXCL12 increased in patients with NSCLC liver metastasis, and the expression of CXCR4 increased on the surface of TAM in liver metastasis, which participated in and promoted the recruitment of monocytes into M2 liver metastasis. The number of intestinal microbial species in patients with NSCLC liver metastasis was more abundant. Lipid deposition and increased fatty acid uptake of TAM were found in liver metastatic specimens. CD36 can promote lipid accumulation in TAM, activate PI3K/AKT pathway by regulating fatty acid metabolism reprogramming, and enable macrophages to have a tumor-promoting phenotype.

Conclusions: CXCL12/CXCR4 axis participated in and promoted the recruitment of monocytes to M2 in liver metastases. Increased lipid deposition and fatty acid uptake in TAM were detected in liver metastasis specimens, which was consistent with previous studies on the M2-polarization characteristics of TAM with high lipid levels. CD36 is the core protein of differences in liver metastases, which can promote lipid accumulation in TAM, activate PI3K/AKT pathway and promote M2 polarization by regulating fatty acid metabolic reprogramming.

P2.02.06 Functional Impact of Missense Mutations Affecting Immune Response Genes in Human Cancer

C.A. Diaz, J.M. Morillas, P. Navajas-Chocarro, F. Setien, O.A. Romero, M. Sanchez-Cespedes
Josep Carreras Leukaemia Research Institute, Badalona/ES

Introduction: In recent years, immunotherapy has emerged as a promising therapeutic approach to stimulate the immune response against cancer cells. Immune Checkpoint Blockade (ICB) therapies, based on the use of monoclonal antibodies targeting programmed cell death protein 1 (PD-1) or its ligand (PD-L1), have demonstrated durable antitumor effects, particularly in non-small cell lung cancer (NSCLC). However, these therapies can fail in patients who are expected to benefit from them, underlining the need of identifying reliable biomarkers to select those patients who will truly benefit from ICBs. Our research group has pioneered the discovery of tumor-specific mutations in genes involved in tumor immune evasion, which is the ability of the tumor cell to evade the action of the immune system. These alterations may predict resistance to ICB therapies. Our study aims to characterize the landscape and functional impact of previously uncharacterized amino acid changes in genes involved in immune response.

Methods: We characterized the mutational landscape and assessed the functional impact of amino acid substitutions in key immune response genes (B2M, CALR, IFNGR1, IFNGR2, JAK1 and JAK2), in more than 12,000 tumors. Missense mutations with potential functional impact in genes involved in immune response were identified using public databases (cBioPortal, UniProt, ClinVar, Cosmic, PolyPhen2, SIFT and Alphamissense). Wild-type IFNGR1, IFNGR2, JAK2 cDNAs were cloned and targeted mutagenesis was performed to assess the effect of selected missense mutations on protein functionality. Lentiviral vectors were used to ectopically express the generated constructs in cell lines. We tested the response to IFNγ using western blot, RT-qPCR and toxicity assays and the positioning of the HLA-I complex in the cell surface uisng immunofluorescence.

Results: We detected mutations in the aforementioned genes in 11% of the tumors, of which 58% were classified as missense, with B2M having the highest mutation frequency per base pair, predominantly truncating variants. We also identified colorectal and endometrial cancers with the highest mutation rates, followed by melanoma and lung cancer. We predicted the pathogenicity of a curated list of 226 amino acid substitutions at B2M, IFNGR1, IFNGR2, and JAK2, evaluated by SIFT, PolyPhen2, and AlphaMissense, from which we performed the functional characterization of 18 mutations with potential impact on the functionality and assembly of IFNGR1 (n=3), IFNGR2 (n=3), JAK2 (n=7), and B2M (n=5). This revealed that 43% and 33.3% of selected JAK2 and IFNGR1 mutations impaired transcriptional activation and did not suppress cell growth by IFNγ, while 80% of B2M mutations disrupted HLA-I complex, indicating pathogenicity. When computational predictions were compared to experimental data, AlphaMissense aligned best.

Conclusions: We provide a comprehensive mutational profile of HLA-I complex and IFNγ response components in human cancer, along with functional insights into selected missense mutations that may aid in patient stratification for ICB.

P2.02.07 Targeting SLC4A7 Reprograms the Acidic Tumor Microenvironment to Overcome Immunotherapy Resistance in NSCLC

H. Qin[1], X. Liu[2], F. Yang[1], J. Wang[1], D. Tang[1], W. Gao[1]
[1]Fudan university, huadong hospital, shanghai/CN ,[2]Tongji university, shanghai pulmonary hospital, shanghai/CN

Introduction: Solid tumors maintain an acidic tumor microenvironment (TME) that drives cancer progression, therapy resistance, and immune evasion. However, the molecular mechanisms linking TME acidosis to metabolic-immune crosstalk in non-small cell lung cancer (NSCLC) remain incompletely understood. Here, we investigated the role of bicarbonate transporters in regulating TME pH dynamics and its functional consequences.

Methods: Through single-cell transcriptomic profiling of NSCLC specimens, we identified solute carrier family 4 member 7 (SLC4A7) as the predominant bicarbonate transporter. Functional studies combined genetic ablation and pharmacological inhibition of SLC4A7 in preclinical NSCLC models. Immune landscape remodeling was assessed via flow cytometry and functional T cell assays. Mechanistic insights into SLC4A7 regulation were derived from integrated RNA-seq and ATAC-seq analyses.

Results: SLC4A7 was broadly expressed across malignant and stromal cells. Its suppression attenuated extracellular bicarbonate accumulation, ameliorating TME acidosis, while promoting intracellular acidification to suppress glycolytic metabolism. In vivo, SLC4A7 inhibition enhanced cytotoxic T cell infiltration and function, suppressing tumor growth and metastasis. Combinatorial therapy targeting Slc4a7 with PD-1/CTLA-4 checkpoint blockade synergistically improved therapeutic efficacy and survival. Mechanistically, BACH1 was identified as the transcriptional regulator of SLC4A7 expression.

Conclusions: Our study establishes SLC4A7 as a dual metabolic-immune regulator in NSCLC, orchestrating TME pH homeostasis and immune evasion. The synergistic effect of Slc4a7 targeting with immune checkpoint blockade provides a novel strategy to overcome immunotherapy resistance. These findings highlight pH modulation as a promising therapeutic axis for precision oncology in NSCLC.

P2.02.08 A Unique VEGFA-Expressing CAF Subpopulation Emerges in TKI-Resistant Lung Cancer to Mediate Immunotherapy Sensitization and Adverse Outcomes

J. Wang[1], S. Lu[1], Y. Wang[2]
[1]Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, shanghai/CN ,[2]Shanghai Institute of Immunology, Department of Immunology and Microbiology, Key Laboratory of Cell, Shanghai Jiaotong University School of Medicine, shanghai/CN

Introduction: Resistance to EGFR tyrosine kinase inhibitors (EGFR-TKIs) represents a major challenge in targeted treatment for lung cancer patients harboring EGFR mutations. While emerging evidence suggests that immunotherapy yields superior efficacy in TKI-resistant patients compared to those with EGFR-mutant tumors, the underlying mechanisms remain elusive. Elucidating the mechanisms driving immunotherapy responsiveness in TKI-resistant patients is critical for designing post-resistance therapeutic strategies.

Methods: We collected lung cancer biopsy samples from EGFR wild-type, EGFR-mutant, and TKI-resistant patients for single-cell sequencing to analyze compositional alterations in the tumor microenvironment (TME). Comparative analysis of TME components before and after TKI resistance was performed to identify potential target cell populations. Multicolor immunofluorescence and flow cytometry were employed to validate the presence of these cells in human and murine tumors. An in vitro cell line model was established to mimic the identified cells, followed by co-implantation with tumor cells to investigate their effects on tumor progression and immunotherapy response.

Results: Single-cell sequencing analysis of cancer-associated fibroblasts (CAFs) revealed a distinct subpopulation characterized by high VEGFA expression, designated as VEGF_CAFs. Their existence was confirmed in both human and murine TMEs using multicolor immunofluorescence and flow cytometry. Differential gene expression analysis between VEGF_CAFs and other CAFs identified key variable genes, which were used to infer VEGF_CAF abundance in the TCGA lung adenocarcinoma cohort. Elevated VEGF_CAF levels correlated with poor patient prognosis. We established a murine fibroblast cell line stably overexpressing VEGFA (validated by qPCR and ELISA) to model VEGF_CAFs. Co-implantation of VEGF_CAFs with LLC cells in mice demonstrated their tumor-promoting effects. Flow cytometry revealed increased PD1 expression on CD8+ T cells in VEGF_CAF-bearing tumors, suggesting potential immunotherapy sensitization. Notably, high expression of VEGF_CAF-specific variable genes was associated with improved immunotherapy outcomes in patients. Among major VEGFA-expressing cell types in the TME (tumor cells, myeloid cells, CAFs), only CAF-derived VEGFA was significantly reduced in EGFR-mutant patients and further diminished post-TKI resistance, implicating VEGF_CAFs in patients with enhanced immunotherapy responsiveness.

Conclusions: Our study identifies a unique CAF subpopulation within the TME that exhibits high VEGFA expression, associates with unfavorable prognosis, emerges in TKI-resistant patients, and potentially sensitizes tumors to immunotherapy. These findings provide mechanistic insights into the superior efficacy of immunotherapy in TKI-resistant populations and inform therapeutic strategies for overcoming EGFR-TKI resistance.

P2.02.09 Early-Stage Lung Adenocarcinoma: PLVAP-Driven Regulation of the Tumor Microenvironment

L. Xie1, M. Sun1, Y. Zheng1, Z. Yu1, H. Kong1, J. Yu1, S. Lu1, Y. Zhang1, J. Hu1, H. Xin2, J. Zhou1, X. Wang1, M. Xiang3, B-S. Ding4, C.A. Powell5, F.R. Hirsch6, C. Bai1, Y. Song1, J. Yin1, D. Yang1

Introduction: Early-stage neovascular infiltration emerges as a critical determinant of tumor advancement. Anti-angiogenic therapy induces a dynamic reduction in the prevalence of tip-like endothelial cells (TECs), a specialized tumor-associated endothelial subpopulation. However, mechanistic investigations into TEC phenotypic plasticity and their gene regulatory networks during incipient vascular co-option remain sparse, particularly regarding how TEC-specific molecular signatures functionally orchestrate microvascular remodeling and metastatic priming.

Methods: Surgical specimens from patients with CT-confirmed pulmonary nodules, alongside lung tissues from KrasG12D (K) and KrasG12DTgfbr2-/- (KT) murine models, were subjected to integrated single-cell RNA sequencing (scRNA-seq) and 10x Visium spatial transcriptomic profiling. PLVAP's functional relevance was systematically validated through multi-modal approaches: prognostic meta-analysis of clinical databases, immunofluorescence-based spatial mapping, transwell invasion/migration assays, endothelial tubulogenesis models, and tumor-endothelial co-culture systems.

Results: Integrated analysis of single-cell RNA sequencing (scRNA-seq) and 10x Visium spatial transcriptomics in both human and murine models revealed elevated proportions of tip cells in human tumor tissues and KT mice, potentially originating from type I capillaries. PLVAP, a molecular marker characteristic of tip cells, demonstrated a significant inverse association with clinical outcomes in lung adenocarcinoma patients. In vitro investigations further identified heightened PLVAP expression in tumor-associated endothelial cells, with its activation regulated by TGFβ1 signaling. Functional studies implicated PLVAP in modulating endothelial cell behaviors, including invasion, migration, and angiogenic tube formation, while also influencing tumor cell metastatic activity. Cell-cell communication analysis uncovered a mechanistic role for TGFβ1-expressing tip cells during early tumorigenesis, wherein paracrine TGFβ1 signaling enhances tumor cell invasiveness.

Conclusions: During early-stage lung adenocarcinoma progression, a marked elevation in tip cell populations originating from type I capillaries was observed, with their molecular signature gene PLVAP demonstrating an inverse correlation with survival outcomes. Mechanistically, tumor-derived TGFβ1 secretion upregulated PLVAP expression in endothelial cells, driving pro-angiogenic endothelial invasion/migration and vascular remodeling. Notably, scRNA-seq trajectory analysis suggested that a limited subset of tip cells in incipient tumors autonomously produce TGFβ1, which paracrinely amplifies tumor cell invasiveness through epithelial-mesenchymal transition pathways, thereby accelerating malignant progression.

P2.02.10 Emotional Distress Following Lung Cancer Surgery and Tandospirones Dual Benefits for Chemotherapy

X. Qin, X. Liu, Y. Fan, S. Ma
shanghai pulmonary hospital, Shanghai/CN

Introduction: Patients undergoing lung cancer surgery face a significantly heightened risk of emotional distress (ED), including anxiety and depression, which severely impacts their quality of life and may compromise treatment outcomes. Effective management of ED is crucial in postoperative care, yet the interaction between anti-ED medications and cancer therapy remains poorly understood.

Methods: This study systematically evaluated the mental health status of 1,185 non-small cell lung cancer (NSCLC) patients post-surgery, identifying chemotherapy as an independent risk factor for ED. Additionally, we investigated the safety and therapeutic effects of six commonly prescribed anti-ED drugs in NSCLC cell lines (A549 and H1299) and animal models. Cell viability, apoptosis, and cholesterol metabolism were assessed using CCK-8 assays, flow cytometry, RNA sequencing, and functional enrichment analyses.

Results: The prevalence of ED was significantly higher in postoperative NSCLC patients (32.2%) compared to healthy controls (8.9%). Chemotherapy was strongly associated with increased ED incidence. Among the tested anti-ED drugs, tandospirone exhibited no tumor-promoting effects and unexpectedly enhanced cisplatin's cytotoxicity. Mechanistically, tandospirone reduced cholesterol levels in tumor cells, activating feedback pathways involving SREBP2 and HMGCR, thereby promoting apoptosis and chemosensitivity. In vivo experiments confirmed that tandospirone synergized with cisplatin to inhibit tumor growth and metastasis.

Conclusions: Our findings highlight the dual role of tandospirone in alleviating ED and enhancing chemotherapy efficacy through cholesterol metabolism modulation. Furthermore, our study provides a scientific basis for integrating psychological support with metabolic interventions in lung cancer treatment, offering a novel strategy to improve patient outcomes.

P2.02.11 SRC Activation Drives Acquired Pemetrexed Resistance in Non-Small Cell Lung Cancer and Is Targetable by Dasatinib

J. Seo, K-J. Kim, S.H. Kim, S-H. Hwang, W. Park, M-S. Kang, E.H. Jung, S-A. Kim, K.J. Suh, J.Y. Lee, J-W. Kim, J-O. Lee, J.W. Kim, Y.J. Kim, K-W. Lee, J.H. Kim, S-M. Bang, J.S. Lee
Seoul National University Bundang Hospital, Seongnam-si/KR

Introduction: Pemetrexed, a standard antifolate chemotherapy for non-squamous non-small cell lung cancer (NSCLC), is often limited by acquired resistance. This study investigated the role of SRC kinase in mediating pemetrexed resistance and evaluated whether SRC inhibition impairs the viability of pemetrexed-resistant NSCLC cells.

Methods: Pemetrexed-resistant cell lines (PC9 R, NCI-H460 R, and NCI-H3122 R) were generated through continuous exposure to pemetrexed for 12 months. Protein phosphorylation profiling and Western blot analyses were conducted to identify key signaling alterations. SRC was abrogated using both transient and doxycycline-inducible CRISPR/Cas9 systems to evaluate its role in cell viability and survival signaling. We assessed the efficacy of three SRC inhibitors—dasatinib, bosutinib, and saracatinib—using cell viability assays, colony formation assays, apoptosis detection, and cell cycle analyses.

Results: All pemetrexed-resistant cell lines demonstrated significant upregulation of phosphorylated SRC (p-SRC Y416) accompanied by enhanced activation of downstream effectors. SRC knockout significantly reduced p-SRC Y416 and downstream signaling (including p-STAT3 and p-FAK), while increasing markers of DNA damage (γ-H2AX) and apoptosis (cleaved caspase-3), resulting in reducing cell viability and clonogenic capacity. Among the SRC inhibitors tested, dasatinib showed the most potent, dose-dependent suppression of SRC activation and downstream signaling, including p-AKT, p-GSK3β, and p-FAK. Furthermore, dasatinib treatment promoted cell cycle arrest predominantly at sub-G1 and G0/G1 phases, accompanied by increased DNA damage and apoptosis, ultimately reducing colony formation. These findings indicate that SRC inhibition disrupts pro-survival pathways and triggers DNA damage-mediated cell death in pemetrexed-resistant cells.

Conclusions: Our findings identify SRC activation as a critical mechanism that drives acquired pemetrexed resistance in NSCLC. Targeting SRC, particularly with dasatinib, effectively impairs the survival of pemetrexed-resistant cells by promoting DNA damage, apoptosis, and cell cycle arrest. These findings provide a strong rationale for further preclinical and clinical investigation of SRC inhibitors, either as monotherapy or in combination with pemetrexed, as a therapeutic strategy to overcome resistance in NSCLC patients.

P2.02.12 hUC-MSC-Derived Exosomes Mitigates Immune Checkpoint Inhibitor-Associated Lung Injury by Suppressing GSDME-Mediated Pyroptosis

F. Wang[1], Z. Chenli[1], X. Xie[1], H. Deng[1], Y. Yang[1], W. Guan[1], X. Lin[1], M. Liu[1], C. Zhou[1]
[1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Immune checkpoint inhibitors (ICIs) targeting PD-1/PD-L1 and CTLA-4 enhance anti-tumor immunity but can cause immune-related lung injury (ICI-LI) in 3-18.5% of patients, with glucocorticoids often ineffective in 10% of cases. Our previous research suggests pyroptosis via CASPASE/GSDME contributes to ICI-LI, and mesenchymal stem cell-derived exosomes (MSC-exos)—known to inhibit pyroptosis and treat lung injuries—may offer a novel therapy.

Methods: We isolated and characterized human umbilical cord-derived mesenchymal stem cell exosomes (hUC-MSC-exos), then administered them to ICI-LI mouse models and pyroptosis-induced alveolar epithelial cells (HBE). Through small RNA sequencing of exosomes, we identified candidate miRNAs, predicted and validated their target genes. Finally, we verified the inhibitory effect on pyroptosis using miRNA mimics/agomir in both in vivo and in vitro experiments.

Results: 1. Exosomes purified from hUC-MSC through ultracentrifugation were rigorously characterized and validated to meet established quality criteria(FIG.A).

2. hUC-MSC-exos alleviate lung injury in ICI-LI mouse models and suppress pyroptosis in HBE cells in vitro by inhibiting GSDME-mediated pyroptosis(FIG.B-D).3. MiR-21-5p is highly expressed in hUC-MSC-exos and targets the APAF1 gene(FIG.E-F).

4. MiR-21-5p in hUC-MSC-exos mitigates lung injury in ICI-LI mice and reduces damage in the HBE cell pyroptosis model by suppressing the APAF1/CASPASE3/GSDME/IL1β pathway(FIG.G-H).

Conclusions: hUC-MSC-derived exosomal miR-21-5p suppresses APAF1 expression, inhibiting CASPASE3/GSDME activation both in vivo and in vitro, demonstrating the therapeutic potential of hUC-MSC-Exos for ICI-LI treatment.

P2.02.13 Macrophages Exhibit Enhanced Cholesterol Efflux in Early-Stage Lung Adenocarcinoma

Y. Zheng[1], M. Sun[1], Y. Wang[1], J. Zhou[1], X. Wang[1], Y. Song[1], C. Bai[1], C.A. Powell[2], D. Yang[1]
[1]Zhongshan Hospital Fudan University, Shanghai/CN ,[2]Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: Macrophages have been proved an important part in the microenvironment of many cancer types including lung adenocarcinoma (LUAD) and play a major regulatory role in promoting malignant development. However, most attempts to block their infiltration and function failed to bring clinical benefits. Notably, the majority of these studies focus on advanced tumor, in which stage the immune microenvironment has been reshaped to favor the progress of tumor. How macrophages exert their role in early-stage tumor, a question associated with improvement of macrophage-targeted therapy, remains less well studied.

Methods: We profile cells from 6 treatment-naïve patients with stage IA LUAD by single-cell RNA sequencing (scRNA-seq). After unsupervised graph-based clustering, monocyte / macrophage (MM) clusters based on canonical marker genes were identified. Then all these MM clusters were turned into re-clustering and we performed further analysis including KEGG enrichment analysis on them. To validate our results from local database, we also obtained scRNA-seq data released previously and characterized the MM clusters. Also, in vitro cell co-cultures were used to evaluate the effects of lung tumor cells on macrophages.

Results: Followed quality control, we collected approximately 100,000 high-quality cells from 6 paired samples, of which around 6,000 cells were from tumor and 4,000 were from adjacent normal tissue. In MMs, while the fraction of alveolar macrophages was strongly reduced in tumor, a cluster expressed SEPP1 and LGMN (SEPP1+ macrophages) demonstrated a significant increase. The differential expression analysis of SEPP1+ macrophages from tumor compared to para-tumor showed upregulation of genes involved in cholesterol metabolism, lysosome and complement and coagulation cascades. Of note, up-regulated genes related to cholesterol were responsible for cholesterol efflux (such as APOC1, APOE and ABCA1) instead of synthesis. Analysis of database from prior studies on of early-stage LUAD also showed an enrichment of macrophages associated with cholesterol-efflux in early-stage LUAD. Furthermore, in vitro experiment showed that ABCA1 expression was significantly increased in THP-1-derived macrophages upon co-culture with A549.

Conclusions: Our results reveal a cluster of macrophages with enhanced cholesterol efflux in early-stage lung adenocarcinoma.

P2.02.14 Urolithin a Alleviates Radiation Pneumonitis by Activating PINK1-PRKN-Mediated Mitophagy

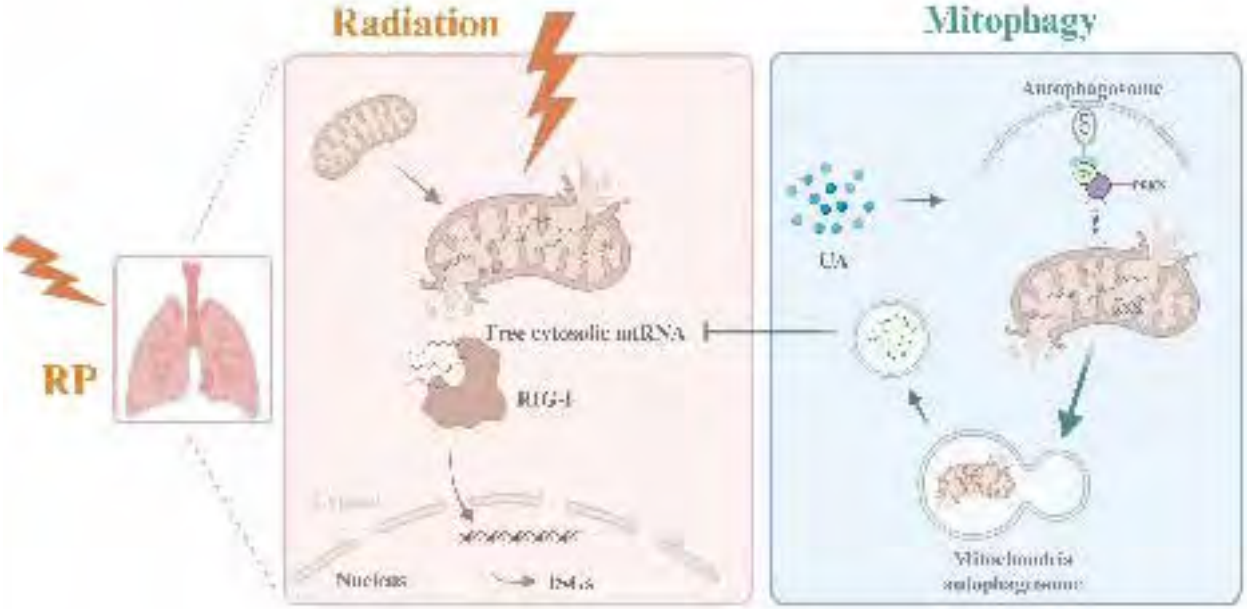
X. Gong
Shanghai pulmonary hospital, Shanghai/CN

Introduction: Radiation pneumonitis (RP) is a common and severe complication of radiotherapy. Currently, effective treatments for RP are lacking. This study aims to investigate the role of radiation-induced PINK1/PRKN-mediated mitophagy and type I interferon responses in RP, and to evaluate the pharmacological effects of Urolithin A (UA) in regulating inflammation through mitophagy activation.

Methods: We established RP mouse models (20 Gy thoracic irradiation) and radiation-induced BEAS-2B cell models (6 Gy). Histopathological analysis, transcriptomic analysis, immunofluorescence, Micro-CT, Western blot, confocal microscopy, and RT-qPCR were used to systematically investigate mitochondrial damage, mtRNA release, RIG-I/MDA5-MAVS pathway activation, and changes in PINK1/PRKN-mediated mitophagy. Moreover, the effects of mitophagy inducers (UA) on inflammation regulation were analyzed.

Results: Radiation significantly caused mitochondrial damage in lung tissues, inducing mtRNA release and RIG-I/MDA5-MAVS-mediated type I interferon response. PINK1/PRKN-mediated mitophagy was significantly enhanced, clearing damaged mitochondria and reducing cytosolic mtRNA release, thereby suppressing inflammation. UA activation of mitophagy significantly alleviated pathological damage, reduced inflammatory cytokine levels, and inhibited excessive activation of the RIG-I/MDA5-MAVS pathway. Knockdown of PINK1 or PRKN weakened the protective effects of UA. Both in vitro and in vivo, UA reduced radiation-induced inflammation and improved lung tissue structure and function through mitophagy.

Conclusions: Radiation-induced mtRNA release activates the RIG-I/MDA5-MAVS pathway and triggers a type I interferon response, leading to inflammation. PINK1/PRKN-mediated mitophagy significantly alleviates inflammation by reducing cytosolic mtRNA release. As a mitophagy inducer, UA demonstrates therapeutic potential for RP, providing a new direction for the development of anti-inflammatory strategies.



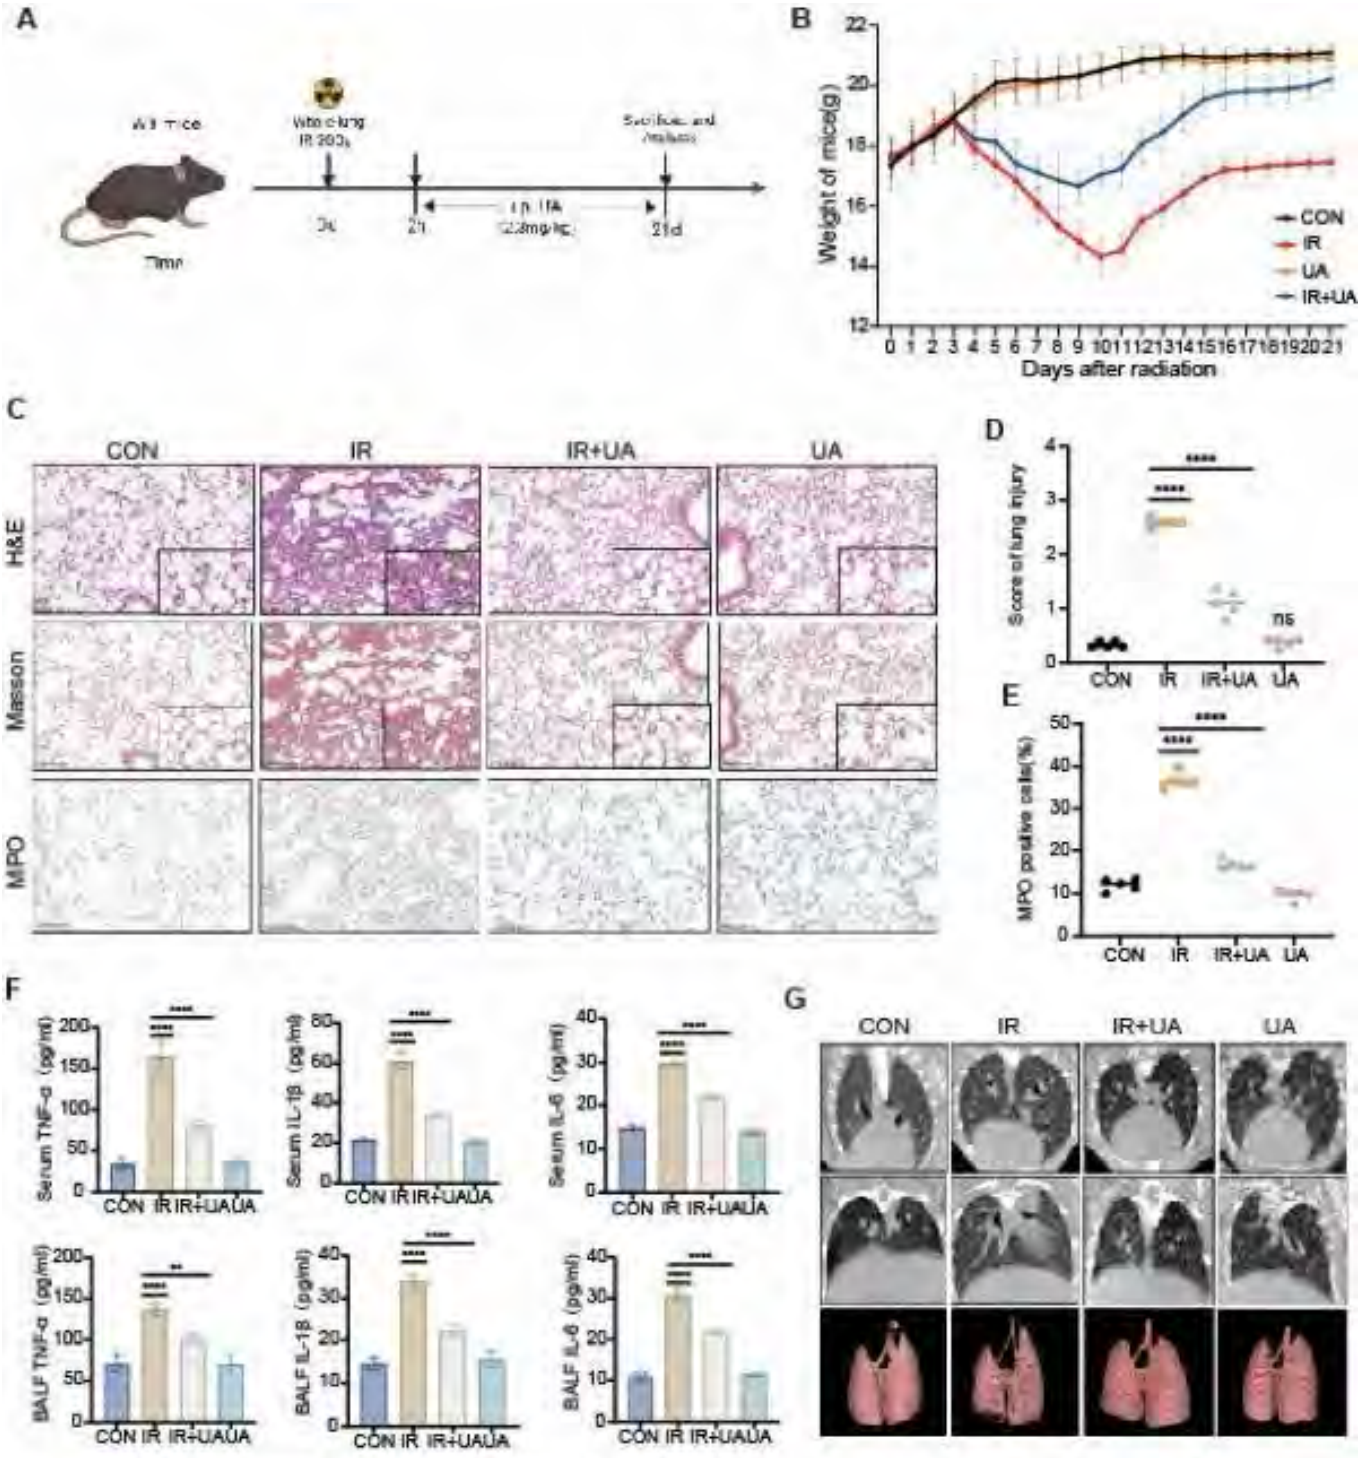


Fig. UA induces PINK1/PRKN-dependent mitochondrial autophagy to alleviate radiation-induced pneumonia in RP mice. P2.02.15 Drug Tolerance and Persistence to EGFR Inhibitor Treatment Are Mediated by an ILK-SFK-YAP Signaling Axis in Lung Adenocarcinoma

R. Shi[1,2], D. Farnsworth[1,2], C. Febres-Aldana[3], J. Chow[1], R. Sheena[1], T. Atwal[1], J.L. Gomez Marti[3], S. Li[1], K. Thomas[1,2], C-M. Lee[1,2], S. Awrey[1], P. McDonald[1], R. Somwar[3], S. Dedhar[1,2], M. Ladanyi[3], K. Bennewith[1,2], W. Lockwood[1,2]
[1]BC Cancer Research Institute, Vancouver/BC/CA ,[2]University of British Columbia, Vancouver/BC/CA ,[3]Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Lung cancer is the leading cause of cancer-related deaths world-wide. Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have extensively improved patients outcomes. However, patients inevitably develop resistance against EGFR-TKIs. Epithelial-mesenchymal transition (EMT) in tumour cells is a known non-genetic resistance mechanism to EGFR tyrosine kinase inhibitors (TKI) that is also associated with worse outcome in patients. The progression towards EMT-mediated resistance exist a key transitory state of drug-tolerant-persistence (DTP), in which permits cancer cells to survival during drug treatment. Integrin-linked kinase (ILK) has been implicated in the pathogenesis of other cancers through the promotion of EMT and has recently been shown to be associated worse outcomes in patients treated with EGFR-TKIs. Therefore, we hypothesize that ILK may be an important mediator of DTP survival to EGFR-TKI treatment of lung adenocarcinoma (LUAD).

Methods: Gene Set Enrichment Analysis was performed on LUAD patient databases. Genetic and pharmacological manipulation of ILK were used to regulate ILK's function in lung cancer cells. Cell viability and clonogenic assays were used to evaluate osimertinib (Osi) sensitivity. Osi-resistant (OsiR) cells were made by dose-escalation. RNAseq, qPCR, and western blots were performed to assess expression levels. Confocal microscopy was used to evaluate YAP activity. Subcutaneous tumour were implanted in NRG mice to assess response to Osi in vivo. Immunohistochemistry and MSK-IMPACT sequencing were used correlate ILK staining with resistance mechanisms in patient samples.

Results: High ILK expression was found to be significantly correlated with an EMT expression signature in patients. Genetic suppression of ILK in LUAD cells reduced the viability of DTP cells by impairing SFK-YAP activation, ultimately improving Osi response. In addition, we found that LUAD cells in extracellular-matrix rich microenvironments have increased dependences on ILK-mediated cytoprotective effects during Osi treatment. These LUAD cells with high ILK expression are able to persist during EGFR-TKI treatment, progressing through EMT to develop EGFR-TKI resistance. To improve the translatability of our findings, we showed that pharmacological inhibition of ILK suppressed EMT, improved Osi response, and delayed the onset of Osi resistance in LUAD cells. Lastly, we found that high ILK expression in patient biopsies was associated with receptor tyrosine kinase-independent mechanisms of resistance to EGFR-TKIs and may be exploited as a biomarker for acquired resistance in LUAD.

Conclusions: Our results suggest that ILK is an important regulator of EGFR-TKI response and may be exploited as a predictor for acquired resistance, providing evidence for co-targeting ILK with EGFR to better control minimal residual disease and EGFR-TKI resistance in lung cancer.

P2.02.16 Identification of Deruxtecan-Induced Methylome Signature in NSCLC Cell Lines

A. Gower, S. Li, N. Kamranpour, T. Grogan, C. Shen, S. Park, A. Han, A. Lisberg, M.A. Velez, W. Zeng, Y. Zhou, A. Cummings, D. Elashoff, D. Slamon, X. Zhou, E. Garon
UCLA, Los Angeles/CA/USA

Introduction: Antibody drug conjugates (ADCs) with topoisomerase I (Topo-I) inhibitor payloads represent a promising therapeutic approach for lung cancer. However, predictive biomarkers of response to this new class of therapeutics remain undefined. In this study, we evaluated non-small cell lung cancer (NSCLC) cell lines treated with deruxtecan, a Topo-I inhibitor, using a validated cell-free DNA Methylome Sequencing (cfMethyl-Seq) assay to identify a unique methylome signature associated with response to deruxtecan.

Methods: Ten NSCLC cell lines were treated with deruxtecan (D), cisplatin (P), or control (C) at their IC50 concentrations. Methylation profiling was conducted using an improved cf-MethylSeq, covering 144,400 analyzable genomic regions (Stackpole et al, Nature Communications, 2022). The average methylation levels were calculated for every profiled genomic region, and Wilcoxon signed-rank tests (W) were utilized to identify differentially methylated regions (DMRs), focusing on relative changes in the sample pairs (comparing D vs. C and D vs. P). We used two replicates for each sample, and to avoid duplicated samples in the statistical testing, we performed analysis on the first replicate (r1) and second replicate (r2) independently. To confirm the signature is specific to deruxtecan, rather than being a marker of chemotherapeutic effect in general, we selected DMRs based on the following criteria: 1) P-value < 0.01 in the one-sided W of r1 or r2 between D and C. 2) P-value < 0.05 in the one-sided W of r1 or r2 between D and P. 3) In replicate, P-value < 0.05 in the one-sided (same directionality) W between D and C. 4) In replicate, P-value < 0.1 in the one-sided (same directionality) W between D and P. Identified DMRs were mapped to gene promotor regions annotated using the GeneHancer database to determine associated genes within the DMRs.

Results: Whole methylome sequencing identified 30 hypermethylated DMRs specific to deruxtecan-treated NSCLC cell lines. These regions were linked to 64 genes. Cross-validating these genes with genecards.org, 25 genes (39%) encode recognized proteins (Table 1).

Conclusions: In vitro analysis of NSCLC cell lines treated with deruxtecan revealed a unique methylation signature characterized by 30 DMRs and 25 associated genes encoding recognized proteins. This represents the first methylome signature associated with deruxtecan response, offering guidance for treatment strategies, including potential ex vivo assays or a theranostic approach using small doses of ADC. We aim to validate this signature in patient plasma samples to evaluate its potential as a predictive biomarker for response to deruxtecan-based ADCs.

P2.02.17 GNAZ as a Tumor Suppressor Marker Inhibits Tumor Development Through Interaction With the KIF11 Protein

S. Kong
shanghaijiaotong university, shanghai/CN

Introduction: Current research on lung cancer primarily focuses on immunotherapy and targeted therapy, while studies on small molecule inhibitors remain limited. GNAZ is a subunit of the G protein involved in the MAPK pathway mediated by EGFR and plays a role in vesicular transport within the body. Clinical data analysis reveals that lung adenocarcinoma patients with high GNAZ expression have a higher five-year survival rate. In the EGFR-resistant cell lines PC-9 and H1975, overexpression of GNAZ significantly reduces cell proliferation, invasion, and migration. Immunofluorescence analysis indicates that GNAZ overexpression is associated with vesicular transport and may be involved in autophagy. We performed mass spectrometry and transcriptome sequencing, which revealed that GNAZ interacts with the KIF11 gene and plays a regulatory role in the WNT signaling pathway, potentially involving the WNT-Ca2+ pathway.

Methods: Mass spectrometry was used to detect protein interactions, while transcriptome sequencing was conducted to identify upstream genes. Cell proliferation, migration, and invasion abilities were assessed using scratch assays, colony formation assays, CCK-8 assays, EdU proliferation assays, and Transwell assays. Western blot (WB) was employed to validate protein expression, and quantitative PCR (Q-PCR) was used to verify RNA-level expression.

Results: Our findings suggest that GNAZ functions as a tumor suppressor gene by interacting with KIF11 and regulating the WNT signaling pathway. KIF11 plays a role in endoplasmic reticulum stress regulation and contributes to tumor progression by promoting invasion and metastasis. Therefore, KIF11 inhibitors hold significant potential as small molecule inhibitors for cancer treatment.

Conclusions: In summary, our study identifies GNAZ as a potential tumor suppressor gene that inhibits lung cancer progression by interacting with KIF11 and regulating the WNT signaling pathway. Functional experiments demonstrate that GNAZ overexpression significantly suppresses tumor cell proliferation, migration, and invasion, while KIF11 is implicated in endoplasmic reticulum stress and tumor metastasis.

P2.02.18 Crosstalk Between Oncogenic Signaling Pathways and Immune Checkpoint Proteins in Pleural Mesothelioma

M. Hashim[1], A. Ries[1], C. Pirker[1], L. Koszik[1], M. Pinós Ruiz[1,2], B. Mosleh[1], M.A.R. Hoda[1], K. Schelch[1], B. Döme[1], W. Berger[1], M. Grusch[1]
[1]Medical University of Vienna, Vienna/AT ,[2]University of Barcelona, Barcelona/ES

Introduction: Pleural mesothelioma (PM) is an aggressive malignancy primarily associated with asbestos exposure. It is characterized by an inflammatory tumor microenvironment, poor prognosis, and resistance to conventional therapies. Chronic inflammation-induced reactive oxygen species (ROS) are believed to play a key role in PM development. However, very little is known about the mechanism of PM development and immune checkpoint protein (ICP) expression. Understanding the molecular mechanisms underlying PM development and ICP expression is crucial for developing more effective strategies for PM prevention and management. This study aims to elucidate mechanisms that link ROS exposure to oncogenic signaling pathways and immune checkpoint protein (ICP) expression.

Methods: Mesothelial (Met5a and NP2-hTERT) and PM (SPC212 and MSTO-211H) cells were treated with xanthine (X) and xanthine oxidase (XO) to produce ROS. Dichlorodihydrofluorescein Diacetate (DCDFA) assay was performed to assess ROS generation using the X/XO system. Hoechst-33342 and PI staining were done to check ROS-induced cytotoxicity. Oxidative stress-mediated changes in cell migration and behavior were evaluated using live cell imaging microscopy. Protein expression levels and phosphorylation of MAPK, AKT, and YB-1 were determined by immunoblotting. Expression of the ICPs PDL1, PDL2, PVR, PVRL1, and VISTA was investigated by qRT-PCR. Furthermore, pharmacological inhibitors for AKT, MEK, and RSK were used to check for pathway dependencies of ROS-induced changes.

Results: X/XO treatment resulted in dose-dependent ROS induction in all four cell models. ROS mediated an increase in cell migration and changes in cell morphology at concentrations that resulted in only minimal toxicity in the investigated models. Moreover, it increased the phosphorylation of ERK, AKT, and YB-1, indicating the activation of key oncogenic signaling pathways. With respect to ICPs, the expression of PDL1 and PDL2 was increased after ROS treatment in PM as well as in mesothelial cells. The MEK and RSK inhibitors not only abolished the effect of ROS but also restored the expressions of PDL1 and PDL2.

Conclusions: This study demonstrates that ROS activates MAPK, AKT, and YB-1 signaling and also increases cell migration and immune evasion in PM cells. Importantly, these effects are also present in mesothelial cells, from which PM development ensues. Furthermore, the study also observed a notable crosstalk between YB-1 phosphorylation and PDL1/2 expression, suggesting YB-1 as a new potential target to interfere with immune evasion in PM.

P2.02.19 SIN3A/MIR22HG/Beclin1 Axis Regulates Both Autophagy and Ferroptosis in Lung Adenocarcinoma

Y. Chen[1], X. Huang[1], M. Yin[1], W. Su[1]
[1]Affiliated Hospital of Guangdong Medical University, Zhanjiang/CN

Introduction: Long non-coding RNAs (lncRNAs) have been implicated in tumourigenesis. Our previous study found that the lncRNA MIR22HG was significantly underexpressed in lung adenocarcinoma by RNA-seq analysis and was associated with poor prognosis. MIR22HG is located on chromosome 17p13.3, and MIR22HG is susceptible to loss and methylation during tumourigenesis, and its dysfunction has been implicated in a variety of human diseases. However, how dysregulation of MIR22HG expression and activity affects the progression of lung adenocarcinoma (LUAD) remains unknown.

Methods: Lentiviral-mediated gene overexpression and in vivo experiments were carried out to confirm the tumor-suppressive effect of MIR22HG. LC3-GFP-RFP adenovirus was transfected into LUAD cells, followed by siRNA-mediated gene silencing, and formation of autophagic vesicles was observed through confocal microscopy. Western blotting was used to analyze the levels of key autophagy proteins after gene overexpression and silencing. ROS levels were measured using siRNA-mediated flow cytometry. The levels of autophagy and ferroptosis key proteins were analysed by Western blotting after overexpression or silencing of genes. The direct binding of SIN3A to MIR22HG was confirmed through a RIP assay. Response experiments confirmed the upstream position of SIN3A with respect to MIR22HG and its inhibitory effect on MIR22HG expression.

Results: In vivo experiments showed that overexpression of MIR22HG significantly inhibited lung adenocarcinoma proliferation. Mechanistic analysis showed that overexpression of MIR22HG increased the expression of autophagy-associated proteins LC3B and Beclin1, and decreased the expression of p62 protein and iron oxidation-regulated proteins GPX4 and SLC7A11. Knocking down MIR22HG had the opposite effect. What's more, the MIR22HG and Beclin1 replication assay showed that MIR22HG exerts oncogenic effects by mediating the combined effects of autophagy and ferroptosis activation of Beclin1. In addition, the combination of RIP and reversion experiments indicated that the low expression of MIR22HG in lung adenocarcinoma was due to the inhibition of the binding protein SIN3A, which binds to MIR22HG and inhibits its expression.

Conclusions: The findings suggest that MIR22HG has a synergistic oncostatic impact by inducing autophagy and ferroptosis through Beclin1. Additionally, The reduced expression of MIR22HG in lung adenocarcinoma arises from the binding of SIN3A to it and subsequent inhibition of expression.

P2.02.20 Targeting BTN1A1 in Pd=D-L1-Negative NSCLC: A Clinically Actionable Immune Checkpoint for Docetaxel-Based Combination Therapy

S.S. Yoo[1], S-H. Lee[1], Y-S. Kim[1], C. Wu[1], B-k. Hong[1], S-H. Lee[2]
[1]STCube Pharmaceuticals, Inc, Rockville/MD/USA ,[2]Samsung Medical Center/Sungkyunkwan University School of Medicine, Seoul/KR

Introduction: Non-small cell lung cancer (NSCLC) remains challenging to treat due to its high heterogeneity, intrinsic resistance, and refractoriness to current immunotherapies. BTN1A1 has recently been identified as a novel immune checkpoint predominantly expressed in dormant or chemoresistant cancer cells, with expression patterns mutually exclusive to PD-L1. This study aimed to evaluate the therapeutic efficacy of anti-BTN1A1 and anti-PD-L1 antibodies, combined with docetaxel, in relation to BTN1A1 and PD-L1 expression in NSCLC patient-derived organoids (PDOs).

Methods: Patient-derived organoids (PDOs) were generated from NSCLC patient samples to investigate the differential expression of BTN1A1 and PD-L1. The therapeutic efficacy of monoclonal antibodies targeting BTN1A1 and/or PD-L1, administered alone or in combination with docetaxel, was evaluated by measuring organoid viability and apoptosis induction. Docetaxel, a microtubule-stabilizing chemotherapeutic agent known to disrupt tumor cell proliferation and enhance immunogenic cell death, was tested to determine potential synergistic effects when used alongside checkpoint inhibitors.

Results: Combination therapy involving docetaxel significantly reduced PDO viability and robustly induced apoptosis compared to antibody monotherapy alone. The mutually exclusive expression of BTN1A1 and PD-L1 was confirmed in PDOs, resulting in differential responses to either anti-BTN1A1 or anti-PD-L1 antibodies. Notably, docetaxel treatment increased BTN1A1 expression, enhancing the response to anti-BTN1A1 antibody treatment relative to anti-PD-L1 therapy, indicating a potential mechanism for synergistic effects.

Conclusions: Combining anti-BTN1A1 or anti-PD-L1 antibodies with docetaxel markedly enhanced therapeutic outcomes in NSCLC PDO models. The elevated BTN1A1 expression observed post-docetaxel treatment highlights anti-BTN1A1 therapy as a promising strategy for PD-L1-negative NSCLC patients refractory or resistant to current PD1/PD-L1 treatments. These findings suggest significant clinical potential for combination strategies targeting diverse immune evasion pathways in treatment-resistant NSCLC.

P2.02.21 CTNNB1 Activates LINC01426 to Promote Metabolic Reprogramming in Lung Adenocarcinoma Cells by Regulating NFAT5 Nuclear Translocation

J. Yu[1], S. Chen[1], Q. Li[2], S. Yang[1], B. Chen[1], Q. Fang[1]
[1]Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University Medical School Cancer Institute, Tongji University School of Medicine, Shanghai/CN ,[2]Department of Respiratory and Critical Care Medicine,Wanbei Coal-Electricity Group General Hospital, suzhou/CN

Introduction: Lung adenocarcinoma (LUAD) is mainly detected at advanced stages, with poor prognosis. This paper elucidated the mechanism of LINC01426 in regulating LUAD cells.

Methods: LncRNAs with differential expression in LUAD tissues were analyzed from the GEO database and the TCGA-LUAD database, and the upstream elements of LINC01426 were predicted by the TFBS R package and the JASPAR website. Subsequently, we screened the genes similar to LINC01426 in the TCGA-LUAD database by R Corr package and used KEGG enrichment analysis to derive the pathways that these genes were enriched on. Finally, we analyzed the screened genes by functional validation experiments to verify their effects on malignant behaviors and glycolysis.

Results: LINC01426 was raised in LUAD, and Tissue microarray analysis uncovered that the staining intensity of LINC01426 was notably higher in LUAD tissues. Patients with high LINC01426 expression had lower survival cycles. LINC01426 was regulated by CTNNB1, and CTNNB1 could bind to the LINC01426 promoter and transcriptionally activate LINC01426 expression. Moreover, LINC01426 could regulate the glycolysis of LUAD cells through NFAT5. Knockdown of LINC01426 or NFAT5 substantially inhibited the metabolic reprogramming, which in turn hindered LUAD cell growth.

Conclusions: CTNNB1 transcriptionally activates LINC01426, which binds to NFAT5 in the cytoplasm and thus promotes NFAT5 nuclear translocation, leading to metabolic reprogramming and accelerating LUAD progression.

P2.02.22 Analysis of FGF19 in Lung Squamous Cell Cancer Tissue and Cell Models

L. Koszik[1], K. Sinn[1], C. Pirker[1], M. Pinós[1,3], M. Hashim[1], M.A. Hoda[1], K. Schelch[1], D. Balázs[1], W. Berger[1], M. Grusch[1]
[1]Medical University of Vienna, Vienna/AT ,[3]University of Barcelona, Barcelona/ES

Introduction: Fibroblast growth factor 19 (FGF19) is a member of the FGF family of growth factors and signals via binding to the cell surface receptor tyrosine kinase fibroblast growth factor receptor 4 (FGFR4). Overexpression of FGF19 caused by gene amplification has been identified as an oncogenic driver in several types of malignancies including lung squamous cell carcinoma (SCC). However, the link between FGF19 gene amplification, transcript expression, protein expression, protein secretion and sensitivity of SCC cells to FGFR inhibitors has not been well established. The aim of the current study was to identify possible gene dose alterations of FGF19 in a panel of SCC cell lines and in surgical specimens of SCC patients from Central Europe. Gene dose data were compared to gene and protein expression data. Additionally, the sensitivity of SCC cell lines against a specific FGFR4 inhibitor and a pan-FGFR inhibitor was evaluated in 2D and 3D cell culture.

Methods: FGF19 gene dose levels were evaluated by fluorescence in situ hybridization (FISH), array comparative genomic hybridization (aCGH) and qPCR. FGF19 transcripts were analyzed by qRT-PCR. Protein levels of FGF19 were analyzed by immunohistochemistry and ELISA. Testing of SCC cell lines for their sensitivity against a selective FGFR4 inhibitor (BLU9931) and a pan-FGFR inhibitor (Erdafitinib) was done in 2D monolayer and in 3D spheroid culture. Selected cell lines with high and low FGF19 levels were additionally tested for their stemness, sprout formation and migratory ability.

Results: Gene dose data analyzed by FISH, aCGH and qPCR showed a good overall agreement. Two of 14 SCC cell lines displayed gene amplifications with all three detection methods. In contrast, none of the 23 tissue specimens showed FGF19 gene amplification. Several SCC cell lines showed very high FGF19 transcript and protein expression in absence of gene amplification. FGF19 cellular protein levels, secreted protein levels and mRNA levels showed significant correlations but neither value correlated with gene dose. IC50 values of SCC cell lines varied between 1.5 µm - 12.8 µm and between 1.0 µm - 14.7 µm for BLU9931 and Erdafitinib, respectively, in 2D cultures and were generally higher in 3D spheroid growth assays. All cell lines were able to form spheroids and treatment with both inhibitors at concentrations above the IC50 values did not block the formation of spheroids. No significant correlations between inhibitors and FGF19 mRNA expression, protein expression and gene dose values were observed except for the correlation between BLU9931 sensitivity and FGF19 amplification assessed by FISH.

Conclusions: Taken together, our results suggest that FGF19 amplification is not as common in SCC of Central European patients as the 37% previously found in Chinese SCC patients. High FGF19 mRNA and protein expression in SCC cell lines is independent of FGF19 gene amplification but may not be a good predictor of FGFR inhibitor sensitivity.

P2.02.23 Screening of Autophagy Related Genes in Lung Squamous Cell Carcinoma and Study of Their Mechanisms of Action

S. Lu[1,2], K. LI[1], L. CHEN[3,4], Q. SHI[2], Y. Han[1], X. LENG[5]
[1]Department of Thoracic Surgery, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu/CN ,[2]Chongqing Medical University, Chongqing/CN ,[3]Department of Oncology, Sichuan Provincial People's Hospital, Chengdu/CN ,[4]University of Electronic Science and Technology of China, Chengdu/CN ,[5]Department of Thoracic Surgery, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Chengdu/CN

Introduction: Lung squamous cell carcinoma (LUSC) is a common, aggressive lung cancer subtype with high recurrence and metastasis rates, despite treatment advances. Autophagy-related genes are crucial in cancer progression and treatment response, but their roles in LUSC prognosis are unclear. This study explores these genes' impact on LUSC prognosis, focusing on the key gene SLC39A8, and seeks potential targeted drugs. The goal is to offer new insights and therapeutic targets for precise LUSC treatment.

Methods: The study analyzed transcriptomic data from LUSC patients using TCGA and GEO datasets (GSE12472, GSE157010, GSE157009) to identify autophagy-related genes. Consensus clustering divided patients into four subgroups, with subgroup A having the worst prognosis. Immunohistochemistry confirmed high SLC39A8 expression in subgroup A. LUSC cell models with altered SLC39A8 expression were created to study its impact on the transcriptome through RNA sequencing. SLC39A8's biological effects were further examined using Western blotting, dual fluorescence reporter systems, migration and proliferation assays, and tumorigenesis experiments in mice. Finally, AutoDock Vina was used for virtual screening.

Results: This study highlighted SLC39A8's key role in LUSC development, showing its high expression linked to poor prognosis. Silencing SLC39A8 increased autophagy and reduced cell growth and movement. Six potential small-molecule inhibitors were identified for targeted LUSC treatment.

Conclusions: This study highlights the crucial role of SLC39A8 in LUSC and suggests potential small-molecule inhibitors for targeted therapy. The findings offer important theoretical insights and propose new directions for drug development and precision therapy in LUSC.

P2.02.24 Zongertinib Has Activity Against NRG1 Fusion Positive Tumor Cells

Y. Shibata[1], M. Nilsson[1], H. Udagawa[1,2], A.G. Paula[1], J. He[1], H. Jiang[1], Q. Huang[1], A. Poteete[1], J.V. Heymach[1]
[1]UT M.D. Anderson Cancer Center, Houston/TX/USA ,[2]National Cancer Center Hospital East, Kashiwa/JP

Introduction: Neuregulin 1 (NRG1) gene fusions are clinically actionable oncogenic driver mutations in non-small cell lung cancer (NSCLC) and other tumors, promoting tumor growth by binding to HER3 and inducing HER2-HER3 heterodimerization, which enhances downstream signaling. Therapeutic strategies targeting HER2-HER3 signaling have so far shown only modest activity in patients with NSCLC bearing NRG1 fusions. A better understanding of the signaling networks in cancer cells expressing NRG1 fusions is essential for developing effective therapeutic strategies for this patient population. Zongertinib, a HER2-specific tyrosine kinase inhibitor (TKI), has demonstrated notable clinical activity against HER2 mutant tumors. However, it is unclear whether blockade of HER family signaling with zongertinib is effective against NRG1 fusion-positive cancer cells.

Methods: We investigated the efficacy of zongertinib and other TKIs in NRG1 fusion-positive cancer cells using a panel of 16 Ba/F3 models engineered to express various HER family members in combination with NRG1 fusions as well as human cell line models of NRG1 fusion-positive cancer, LUAD0061AS3 (SLC3A2-NRG1) and MDA-MB-175-VII (DOC4-NRG1).

Results: We observed that zongertinib inhibited downstream signaling and tumor cell growth in NRG1 fusion-positive cells, most notably in those expressing HER2 and HER3, while sparing wild-type EGFR. EGFR signaling can also be activated in cells expressing NRG1 fusions, and we observed that dependency on EGFR and HER2 signaling varied among NRG1 fusion-positive cancer cell lines. Likewise, pan-HER family TKIs, poziotinib and afatinib, showed activity against NRG1 fusion-positive cells that expressed EGFR. This preclinical activity is consistent with the clinical responses in NRG1 fusions previously reported in the phase 1A of zongertinib.

Conclusions: Our findings indicate that zongertinib is a promising therapeutic approach for patients with NRG1 fusion-positive malignancies, particularly those expressing HER2 and HER3.

P2.02.25 Elevated SGO2 Expression in Lung Adenocarcinoma Promotes Migration and Invasion by Regulating MAD2, Correlating With Poor Prognosis

M. sun[1], W. Zhou[1], G. Wei[1], M. LV[1], Y. Sun[2], C. Zhu[1]
[1]The Second Hospital of Nanjing, NanJing/CN ,[2]Jiangsu Cancer Hospital, NanJing/CN

Introduction: Lung adenocarcinoma represents a globally prevalent malignant tumor characterized by its high mortality rate, primarily attributed to its aggressive invasive and metastatic potential. SGO2, a critical protein involved in the regulation of cell division, has been implicated in the progression of multiple malignancies. Despite its recognized role in various cancers, the biological functions of SGO2 in the context of Lung adenocarcinoma remain underexplored, necessitating further investigation to elucidate its potential mechanisms and therapeutic implications.

Methods: The Cancer Genome Atlas (TCGA) database was utilized to analyze the expression levels of SGO2 in a cohort of 206 lung adenocarcinoma patients compared to 200 non-neoplastic control samples. Subsequently, immunohistochemical staining was performed on a subset of 21 LUAD tissue samples obtained from Nanjing Second Hospital to validate the findings from the TCGA database. The functional role of SGO2 in the H1299 cell line was assessed through a series of in vitro experiments, including Western blotting to evaluate protein expression, CCK-8 assays to measure cell proliferation, Transwell assays to assess cell invasion, wound healing assays to analyze cell migration, and flow cytometry to examine cell cycle distribution. Additionally, the influence of SGO2 on the regulation of MAD2 expression was explored to further investigate the molecular mechanisms underlying SGO2's role in LUAD progression.

Results: The enhancement of SGO2 expression in Lung adenocarcinoma tissues is significantly associated with a poor prognosis in patients. A reduction in SGO2 expression markedly decreases the proliferative, migratory, and invasive capabilities of H1299 cells, a phenomenon that may be attributed to the regulation of MAD2 expression by SGO2.

Conclusions: SGO2 plays a critical role in regulating the malignant behaviors of lung adenocarcinoma cells, including proliferation, migration, and invasion, by modulating the expression of MAD2, thereby significantly contributing to the molecular pathogenesis of lung adenocarcinoma.

P2.02.26 Establishment of a HER2 Overexpressing Lung Squamous Cell Carcinoma Cell Line Sensitive to Targeted and Cytotoxic Therapies

S. Suzuki, M. Yashiro, K. Kishimoto, H. Kinoshita, T. Tanimura, K. Hara, H. Inoue, N. Izumi, T. Tsukioka, J. Soh
Osaka Metropolitan Univercity Graduate School of Medicine, Osaka city/JP

Introduction: Lung squamous cell carcinoma (LSCC) accounts for approximately 30% of non-small cell lung cancer (NSCLC) cases and is often characterized by distinct genomic alterations compared to lung adenocarcinoma. While HER2 mutations, amplifications, and overexpression are well-documented in lung adenocarcinoma, their presence and therapeutic implications in LSCC remain poorly understood. Targeted therapies against HER2 have primarily shown efficacy in HER2-driven lung adenocarcinomas; however, their role in LSCC has not been clearly established. Here, we report the development and characterization of a novel LSCC cell line derived from resected patient specimens, which exhibits HER2 overexpression and sensitivity to HER2-targeted therapies, including trastuzumab deruxtecan and afatinib. This study aims to provide insights into the therapeutic potential of HER2 inhibition in LSCC and explore the feasibility of HER2-directed treatment strategies for this histological subtype.

Methods: A primary LSCC cell line was successfully established from surgically resected tumor specimens of a previously untreated 47-year-old Japanese male patient with a heavy smoking history. The cells were cultured and characterized for HER2 expression levels using quantitative PCR (qPCR). Whole genome sequencing (WGS) were conducted to evaluate additional genomic alterations and transcriptomic profiles. To evaluate drug sensitivity, an MTT assay was performed to assess the efficacy of trastuzumab deruxtecan and afatinib, along with standard chemotherapy agents, including carboplatin and paclitaxel, which are commonly used in LSCC treatment. The half-maximal inhibitory concentration (IC50) values for each drug were calculated to determine the degree of drug responsiveness. Furthermore, the clinical course of the parental patient, who later experienced recurrence post-surgery, was reviewed to correlate in vitro findings with actual treatment outcomes.

Results: The established LSCC cell line exhibited strong HER2 overexpression and amplification as confirmed by qPCR and WGS, but HER2 exon 20 mutations were not detected. Drug sensitivity assays demonstrated a significant reduction in cell viability upon exposure to trastuzumab deruxtecan and afatinib, with IC50 values of 65 nM and 57 nM, respectively, indicating strong HER2 dependency in this LSCC model. In addition, the cytotoxic agents carboplatin and paclitaxel significantly inhibited cell proliferation, with IC50 values of 8 μM and 10 nM, respectively. Notably, the patient from whom the LSCC cell line was derived later experienced disease recurrence and demonstrated a good clinical response to the combination of carboplatin and paclitaxel, supporting the translational relevance of our in vitro findings.

Conclusions: This study reports the first HER2-overexpressing LSCC cell line with confirmed sensitivity to HER2-targeted therapies and cytotoxic agents. The correlation between HER2 overexpression and therapeutic response suggests that a subset of LSCC patients may benefit from HER2-directed treatment strategies. These findings underscore the need for biomarker-driven therapeutic approaches in LSCC and advocate for HER2 testing as part of the molecular characterization of LSCC. Our newly established model provides a valuable platform for future research on HER2-driven oncogenesis in LSCC and potential clinical trials exploring HER2-targeted interventions in this histological subtype.

P2.02.27 Osimertinib Increases Expression of HER2 and Combination With T-DXd, a HER2-Directed ADC, Enhances Its Efficacy in PDX Models of EGFR Mutant NSCLC

N. Floch[1], A. Koers[1], M. Martin[1], F.J. Calero-Nieto[1], S. Talbot[1], B. Phillips[1], L. Ireland[1], E. Panditharatna[2], J. Kent[1], A. Hughes[1], L. Magiera[1], J. Mettetal[3]
[1]AstraZeneca, Cambridge/GB ,[2]AstraZeneca, Mississauga/ON/CA ,[3]AstraZeneca, Waltham/MA/USA

Introduction: Osimertinib is a third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor that has demonstrated efficacy in the first-line treatment of advanced or metastatic EGFR-mutant non-small cell lung cancer. Despite clinical benefit, most patients become refractory to osimertinib, highlighting the need for combination strategies to maximize the duration of response or address osimertinib resistance. Trastuzumab deruxtecan (T-DXd; DS-8201) is a human epithelial growth factor receptor 2 (HER2)-directed antibody drug conjugate (ADC) with demonstrated antitumor activity against a range of tumor types.

Methods: Using multiomic studies, including proteomics and scRNAseq, we identified a cell surface marker whose levels are increased upon acute and chronic osimertinib treatment, both in vitro and in vivo. We then assessed the effect of an ADC against the cell surface marker identified in combination with osimertinib across 18 patient-derived xenografts (PDX) in vivo.

Results: Our research revealed that both acute and prolonged exposure to osimertinib leads to a significant upregulation of HER2. Furthermore, osimertinib treatment promotes increased EGFR-HER2 heterodimerization and enhances HER2 internalization. Single-cell RNA sequencing analysis of tumors treated with osimertinib identified a specific cell subpopulation with upregulated HER2 expression, which was eradicated when xenograft-bearing animals received a combination treatment of osimertinib and T-DXd. Importantly, the combination of T-DXd and osimertinib demonstrated superior in vivo efficacy compared to osimertinib alone in one of three Ex19del, three of six L858R, and four of five Ex20Ins EGFR TKI naïve mutant PDX models. Furthermore, in four PDX models derived from osimertinib-resistant patients, T-DXd treatment resulted in regression in all the models tested.

Conclusions: Our preclinical data emphasizes that prolonged osimertinib treatment can increase HER2 expression, showcasing the potential of a new combination treatment strategy with T-DXd. This approach could strengthen osimertinib's effectiveness as first-line treatment or address resistance to osimertinib.

Keywords: NSCLC, Osimertinib, T-DXd

P2.02.28 Proteasome Inhibitor Causes Proteotoxic Death and Reshapes TME in LKB1-Deficient NSCLC by Blocking Er-Stress Repair Addiction

Z-Y. Dong[1], Z-P. Xu[1], H-T. Qu[2], X-T. Cai[1], Y-P. Zhang[1], Z-Q. Guo[1], Z-N. Wu[1], K-M. Zhuang[1], Z-X. Rong[1]
[1]Nanfang Hospital, Southern Medical University, Guangzhou/CN ,[2]Southern Medical University, Guangzhou/CN

Introduction: STK11/LKB1 loss-of-function mutation is associated with extremely poor prognosis and multi-therapy resistance in non-small cell lung cancer (NSCLC), yet effective treatments remain elusive.

Methods: Integrated transcriptomic analyses were performed on human lung adenocarcinoma (LUAD) cohorts, Lkb1-knockout/rescue murine cell lines, and KrasLSL-G12D/+ Trp53flox/flox GEMMs with lentiviral Cre-induced Lkb1 deletion. The efficacy of proteasome inhibitor was assessed in vitro through proliferation assays and flow cytometry, and in vivo using syngeneic tumor models. Mechanistic insights were derived from bulk mRNA sequencing and immune deconvolution analyses.

Results: LKB1-deficient LUAD patients exhibited significantly reduced survival. Transcriptomic profiling revealed heightened reliance on endoplasmic reticulum (ER) stress resolution via unfolded protein response (UPR) in LKB1-deficient tumors, validated across murine models and human systems. The proteasome inhibitor bortezomib demonstrated selective cytotoxicity against murine TC1-shLkb1 and LKB1-null human A549 cells. In syngeneic in vivo models, bortezomib specifically inhibited Lkb1-deficient tumor growth and extended survival without affecting Lkb1-proficient tumors. Molecular analyses revealed bortezomib-mediated apoptosis restoration in Lkb1-deficient tumors, concomitant with rescued interferon-α/γ signaling. Immune profiling showed enhanced CD8+ T cell infiltration and reduced M2-polarized macrophages in treated tumors, indicating tumor immune microenvironment (TIME) reprogramming.

Conclusions: LKB1-deficient lung adenocarcinoma exhibits UPR pathway addiction to mitigate lethal ER stress. Proteasome inhibitor selectively targets this vulnerability through dual mechanisms: direct induction of proteotoxic crisis and TIME remodeling toward anti-tumor immunity. These findings position proteasome inhibition, either as monotherapy or in rational combinations, as a promising strategy for this aggressive NSCLC subset.

P2.02.29 CXCR2 Inhibitor Plus KRAS G12C Inhibitor Remodels Immunosuppressive Tumor Microenvironment in KRAS G12C-Mutant NSCLC?

D. He, N. Chen, C. Niu, W. Yang, F. Chen, X. Zhou, J. Cui
Cancer center, The First Hospital of Jilin University, Changchun/CN

Introduction: Sotorasib (AMG510), a first-in-class KRAS G12C inhibitor, demonstrates constrained clinical efficacy as monotherapy, with intrinsic/acquired resistance emerging as a critical barrier in patients with KRAS G12C-mutant non-small cell lung cancer (NSCLC). KRAS oncogenic activation triggers profound remodeling of the tumor immune microenvironment (TIME), establishing immunosuppressive networks that potentiate immune evasion. These mechanistic insights underscore the imperative to develop rationally designed combination therapies that co-target KRAS-driven signaling and reverse TIME dysregulation, thereby overcoming the therapeutic limitations of current KRAS G12C inhibitors.

Methods: The study systematically analyzed immune suppression-related pathways in KRAS G12C mutant lung adenocarcinoma samples from the TCGA database, with comparative profiling of KRAS wild-type tumors and normal lung tissues. Basing on these findings, a novel combination therapy strategy leveraging AMG510 to simultaneously reduce tumor burden and remodel the TIME in KRAS G12C-driven Lewis lung carcinoma (LLC) models in C57BL/6N mice we explored. The potential mechanisms underlying the combination strategy were further investigated. Complementary in vitro studies extend these observations to human KRAS G12C- mutant NSCLC cell lines, rigorously evaluating combination efficacy across multiple AMG510 resistance lung cancer cells.

Results: We observed that pathways associated with polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs) were enriched in KRAS G12C-mutant lung adenocarcinomas (LUAD). Hence, co-administration of SB225002, a C-X-C motif chemokine receptor 2 (CXCR2) antagonist targeting PMN-MDSCs, significantly enhanced the inhibitory effect of AMG510 on tumor burden in LLC-bearing mice. However, the same combination strategy did not exert a synergistic therapeutic effect in LLC model in severely immunodeficient NCG mice, suggesting that the combination strategy depends on the TIME. Further analysis revealed that the combination of SB225002 and AMG510 markedly reduced the infiltration of PMN-MDSC and enhanced the activity of CD4+ T cells within the TIME. Depleting CD4+ T cells using an anti-CD4 antibody significantly reversed the anti-tumor effects of the combination strategy. Consistently, depletion of PMN-MDSCs with an anti-Ly6G antibody, in combination with AMG510, resulted in antitumor effects and TIME remodeling similar to those observed with SB225002. Mechanistic studies revealed that AMG510 inhibited the MAPK pathway, the expression of the transcription factor myelocytomatosis oncogene (MYC) and its downstream targets, C-X-C motif chemokine ligands (CXCL) 1/2 in tumor cells, thereby reducing their chemotactic attraction to PMN-MDSCs. This mechanism synergized with SB225002, which targets PMN-MDSCs via the ligand-receptor axis. Surprisingly, increasing the dosage of SB225002 showed a trend toward reduced tumor burden in NCG mice compared to the monotherapy group, implying that the combination strategy also exerts effects on tumor cells. In vitro experiments demonstrated that the combination regimen exhibited synergistic inhibition of clonal formation, apoptosis resistance, and proliferation in multiple human lung cancer cells resistant to AMG510. Further investigations revealed that the combination strategy synergistically suppressed the MAPK signaling pathway.

Conclusions: The combination therapy demonstrates dual efficacy by potently remodeling the immunosuppressive tumor microenvironment and directly inhibiting tumor cells proliferation. These findings establish a robust experimental foundation for advancing this therapeutic approach into clinical trials.

Keywords: KRAS G12C, non-small cell lung cancer, CXCR2

P2.02.30 Targeting MTA2 Lactylation as a Therapeutic Strategy to Overcome Chemoresistance in Lung Adenocarcinoma

R. Shencheng, D. Ge, C. Zhan
Zhongshan Hospital, Fudan University, Shanghai/CN

Introduction: The primary objective of conventional chemotherapeutic agents is to directly or indirectly induce DNA damage, leading to tumor cell death. To evade this, cancer cells must rapidly mobilize mechanisms to counteract genotoxic stress. This process is central to the development of chemoresistance in cancer. Chemoresistance in lung adenocarcinoma (LUAD) remains a critical barrier to effective treatment, requiring elucidation of molecular drivers. The Warburg effect is a hallmark of cancer that refers to the preference of cancer cells to metabolize glucose anaerobically rather than aerobically. This results in substantial accumulation of lactate. Lactylation is a lactate-induced post-translational modification. While lactylation is increasingly implicated in epigenetic regulation, its functional relevance to therapeutic resistance remains incompletely defined. Matastasis-associated protein 2 (MTA2) is the core component of the Nucleosome Remodeling and Deacetylase (NuRD) complex, which plays a critical role in mitigating DNA damage, yet its regulatory interplay with metabolic stress signaling is still unexplored.

Methods: Metabolomics and transcriptomics quantified lactate flux in LUAD. Proteomics and retrospective analysis pinpointed MTA2-K539la as a chemotherapy response mediator. Electrostatic modeling and immunofluorescence mapped MTA2-K539la-importin α interactions. Co-immunoprecipitation and comet assays dissected the NuRD complex dynamics and DNA damage. RNA-seq and molecular docking screen out the writer of MTA2 lactylation. An engineered cell penetrating peptide targeting MTA2-K539la was developed and functionally validated in cells, patient-derived organoids, and spontaneous lung cancer models under cisplatin and immunotherapy regimens.

Results: Cisplatin treatment exacerbated lactate accumulation, driving widespread protein lactylation and fostering chemoresistance. Mechanistically, MTA2 lactylation at K539 strengthened its binding affinity to importin α, enhancing nuclear translocation and subsequent stabilization of the NuRD complex. This mechanism suppressed cisplatin-induced DNA damage. KAT2A was identified as the writer catalyzing MTA2 lactylation. Pharmacological disruption of MTA2-K539la via a rationally designed peptide restored cisplatin sensitivity across preclinical models and synergized with immune checkpoint blockade to augment tumor regression.

Conclusions: This study establishes MTA2 lactylation as a metabolic checkpoint that safeguards genomic stability under genotoxic stress, thereby promoting chemoresistance in LUAD. By demonstrating the therapeutic efficacy of targeting this pathway, our findings position lactylation inhibition as a translatable strategy to resensitize refractory tumors to conventional and immunotherapeutic agents.

P2.02.31 The Changes of Macrophage in EGFR Mutant TKI-Resistant Patients With Lung Cancer

S. Zhu, S. Lu
Shanghai Chest Hospital, Shanghai Jiao Tong University school of Medicine, Shanghai, China, Shanghai/CN

Introduction: Lung cancer patients harboring epidermal growth factor receptor (EGFR) mutations typically exhibit limited sensitivity to immune checkpoint inhibitors (ICIs) and are prone to developing resistance to first-line tyrosine kinase inhibitors (TKIs). However, effective therapeutic options for patients with TKI resistance remain limited. Notably, our team's ORIENT31 clinical trial demonstrated that ICI-based combination therapy can significantly improve progression-free survival in TKI-resistant patients. The underlying immune mechanisms contributing to the enhanced response to immunotherapy after TKI resistance require further investigation.

Methods: We performed single-cell RNA sequencing on lung cancer biopsy samples from three groups: EGFR wild-type, EGFR-mutated, and TKI-resistant. Comparative analyses were conducted to characterize the differences in immune cell subsets and molecular features of the tumor immune microenvironment among these groups.

Results: Our analysis revealed that macrophages comprise over 20% of the tumor microenvironment. Notably, TKI-resistant tumors exhibited a reduction in SPP1^{+} macrophages, a subset frequently associated with immunosuppression in previous single-cell studies. Conversely, we observed an increased proportion of SLC40A1^{+} macrophages in TKI-resistant patients. These macrophages exhibited elevated expression of MHC class II molecules, indicating enhanced antigen-presenting capacity. Importantly, high infiltration of SLC40A1^{+} macrophages was associated with improved overall survival in lung adenocarcinoma (P=0.031), highlighting their potential role in antitumor immunity.

Conclusions: Our study underscores the pivotal role of macrophages in shaping the immune microenvironment of TKI-resistant lung cancer. Notably, SLC40A1^{+} macrophages may serve as a key biomarker for predicting immunotherapy efficacy in this patient population. These findings offer valuable insights that could guide the future clinical application of ICIs in TKI-resistant lung cancer.

P2.02.32 Homeostatic Dysregulation of Systemic CD8+ T Cell Compartment in Lung Cancer Patients

J.S. Yun, J-H. Cho, I-J. Oh, S-W. Lee
Chonnam National University Medical School, Hwasunup, Jeollanamdo/KR

Introduction: Suppression of tumor-reactive CD8+ T cells is a well-known feature of the tumor microenvironment. However, the extent to which tumors exert systemic effects on the overall CD8+ T cell compartment remains unclear. This study investigates the systemic homeostatic dysregulation of CD8+ T cells in lung cancer patients and its implications for immune responses and therapy outcomes.

Methods: Peripheral blood samples from 349 lung cancer patients and 53 healthy donors were analyzed using flow cytometry, single-cell RNA sequencing, and T cell receptor (TCR) sequencing. We examined the composition and functional characteristics of CD8+ T cell subsets, focusing on differentiation states, proliferation capacity, and gene expression signatures associated with immune homeostasis. Clinical outcomes of immune checkpoint inhibitor (ICI) therapy were assessed in four independent patient cohorts.

Results: Lung cancer patients exhibited a progressive alteration in CD8+ T cell composition, characterized by an increased frequency of more differentiated effector memory T cells (DN-Tem) with diminished proliferative capacity. Single-cell RNA sequencing revealed reduced quiescence and increased spontaneous activation, indicative of systemic homeostatic dysregulation. Furthermore, a higher proportion of DN-Tem was associated with poor response to ICI therapy, suggesting that systemic CD8+ T cell dysregulation impairs effective antitumor immunity.

Conclusions: Our findings reveal that lung cancer induces widespread homeostatic dysregulation of the systemic CD8+ T cell compartment, leading to an accumulation of dysfunctional effector memory subsets. This phenomenon correlates with poor clinical response to ICI therapy, highlighting a novel immune evasion mechanism. Understanding this systemic alteration could inform the development of improved immunotherapeutic strategies for lung cancer patients.

P2.02.33 Radiotherapy Induces Ferroptosis and Activates STING Pathway to Reverse Immunotherapy Resistance in LKB1-Mutant Lung Cancer

Y-P. Zhang, D-Y. Zheng, D-h. Wu
Shunde Hospital, Foshan/CN

Introduction: LKB1 mutations are associated with primary resistance to immune checkpoint inhibitors (ICIs) in non-small cell lung cancer, but the underlying mechanism remains unclear.

Methods: KrasG12D/+-sgLkb1 (KL) driven lung adenocarcinoma mouse model was established and analyzed by single-cell RNA sequencing (scRNA-seq) to decode the characteristics of LKB1-mutant lung cancer cells. The ferroptosis resistance score of lung cancer cells was constructed and validated in transcriptomic, cellular, and vivo levels. Relevant inducers and inhibitors were utilized to verify the ferroptosis resistance phenotype in LKB1-mutant lung cancer. TCGA database and multiple immunotherapy cohorts were leveraged to explore the relationship between ferroptosis resistance and immune-related pathways and the efficacy of immunotherapy. The impact of radiotherapy on ferroptosis resistance, the activation of the STING pathway and immunotherapy in LKB1-mutant lung cancer were explored in vitro and vivo experiments.

Results: The integrated analysis of single-cell data of KL and KrasG12D/+ TP53fl/fl (KP) driven lung adenocarcinoma mouse model revealed that the ferroptosis-related pathways were significantly enriched in KL tumors compared with the KP tumors. LKB1-mutant lung cancer cells owned higher ferroptosis resistance score and were resistant to ferroptosis in vitro and in vivo. Ferroptosis resistance was negatively correlated with immune-activating pathways and the efficacy of immunotherapy. LKB1 mutation might induced ferroptosis resistance via upregulating NRF2 signaling pathway. Radiotherapy could reverse ferroptosis resistance, activate the STING pathway and ignite the tumor immune microenvironment in LKB1-mutant lung cancer. The LKB1-mutant tumor was significantly shrunk in the combination of ICIs and radiotherapy group, which could be restored by a ferroptosis inhibitor.

Conclusions: Radiotherapy could reverse the immunotherapy resistance of LKB1-mutant lung cancer by inducing ferroptosis in tumor cells and activating the STING signaling pathway.

P2.02.34 Synergistic Antitumor Effect of an XPO1 Inhibitor And/Or Sotorasib With V-ATPase Inhibitors Pretreatment in KRAS G12C NSCLC

J. González[1], M. Zhou[1], K. València-Clua[1], D. Olmo-González[2], J. Nilsson[3], J. Codony-Servat[1], R. Rosell[2]
[1]FIOR group, IGTP - Institut d'Investigació Germans Trias i Pujol, Badalona/ES ,[2]FIOR group. IOR, Dexeus University Hospital, Barcelona/ES ,[3]Umeå University | UMU, Umeå/SE

Introduction: Non-small cell lung cancer (NSCLC) bearing KRAS G12C mutation has demonstrated limited clinical efficacy to KRAS G12C selective inhibitors, such as the covalent inhibitor sotorasib, due to primary and acquired resistance mechanisms. A major focus has been placed on developing combined therapies to avoid resistance. Selinexor, a selective inhibitor of Exportin-1 (XPO1), has shown promising efficacy in KRAS-mutant lung cancer cell lines. Additionally, the V-ATPase inhibitor omeprazole, has been demonstrated to increase cytoplasmic retention of cytotoxic drugs when pretreated, increasing the sensitivity of cells to chemotherapy and some targeted therapies. This study aims to evaluate the efficacy of combining selinexor or sotorasib with omeprazole pretreatment in KRAS G12C NSCLC cell lines and to identify the mechanism of action of these drug combinations.

Methods: Four KRAS G12C-mutated NSCLC cell lines (H358, H23, H358R [sotorasib-resistant], and H2030) were used in this study, ranging from more sotorasib-sensitive to resistant phenotypes, respectively. All experiments were performed administering omeprazole to cells 24 hours before treatment with selinexor or sotorasib for 72 hours. Cell viability was assessed by MTT assays using varying doses of omeprazole pretreatment. Synergy was studied using Loewe, Bliss and HSA models with Combenefit and SynergyFinder programs. Cell viability in H358 spheroids (3D conditions) was evaluated using CellTiter-Glo 3D Assays. Colony Formation Assays (CFA) were performed by treating cells for 15 days. Western blot analyses were conducted to analyze the protein levels of XPO1, the KRAS signaling pathway, the MRAS-PP1C-SHOC2 complex, and markers such as pEphA2, RanGAP1, IRE1α, DLC1, and AURKA.

Results: Combined therapy of selinexor with omeprazole pretreatment and sotorasib with omeprazole pretreatment increases sensitivity to both drugs across the four cell lines used in the study. Furthermore, omeprazole pretreatment can overcome resistance to selinexor or sotorasib in the resistant cell lines, as observed in the cell viability assays. Evidence suggests synergistic effects of selinexor/sotorasib with omeprazole pretreatment. Likewise, synergy of these drug combinations was also observed in 3D conditions using H358 spheroids and in the CFA. The CFA highlighted the effectiveness of the triple combination of selinexor and sotorasib pretreated with omeprazole, as it was able to almost eliminate all colonies. Regarding the mechanism of action of these drug combinations, selinexor significantly reduced the protein levels of XPO1, and sotorasib markedly reduced pEphA2 in all lines. The combination of selinexor/sotorasib with omeprazole reduced the levels of RanGAP1 and AURKA across all cell lines, as well as IRE1α in the two most sotorasib-sensitive cell lines, H358 and H23. Combination treatments increased DLC1 levels in the H23 and H2030 cell lines but were not detected in H358 or H358R.

Conclusions: This study highlights the synergistic antitumor effect of selinexor or sotorasib with omeprazole pretreatment in KRAS G12C NSCLC cell lines. It should be noted that pretreatment with omeprazole has demonstrated to potentially overcome resistance to both treatments. Future in vivo studies are necessary along with unveiling the role of XPO1 since XPO1 expression was present in cell lines and was not decreased by sotorasib, only by selinexor.

P2.02.35 Association of Intratumoral Microbiota Composition With Tertiary Lymphatic Structure of Lung Adenocarcinoma

H. Zhou[1], Z. Zhao[1], Y. Wang[2,3], L. Yao[1], C. Cai[1], Y. Lei[1], G. Liao[1], W. Zhan[1]
[1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Youth Innovation Team of Medical Bioinformatics, Shenzhen University Health Science Center, Shenzhen/CN ,[3]Department of Cell Biology and Genetics, College of Basic Medicine, Shenzhen University Health Science Center, Shenzhen/CN

Introduction: Emerging evidence implicates intratumoral microbiota in lung adenocarcinoma pathogenesis, though its functional consequences remain poorly characterized. Tertiary lymphoid structures (TLS) demonstrate clinical associations with survival outcomes and therapeutic responses across malignancies. This study employs sequencing-based microbial profiling to investigate potential crosstalk between intratumoral microbiota and TLS in lung adenocarcinoma.

Methods: We analyzed transcriptome profiles from The Cancer Genome Atlas (TCGA)-LUAD project and matched intratumoral microbiota abundance data from TCMbio. Our study employed stringent selection criteria: treatment-naive primary tumors with multi-omics data, excluding multiple samples per patient. Patients were stratified into TLS-high and TLS-low groups using a predefined threshold based on TLS-50 signature scores. Microbiota composition was systematically characterized across TLS subgroups. Differentially abundant genera between TLS groups underwent correlation analysis with tumor immune infiltration scores. External validation cohorts from GEO databases assessed reproducibility of TLS-associated microbial features.

Results: The analysis included 510 patients from the TCGA-LUAD cohort, with 109 (21.4%) stratified as TLS-high. Notably, TLS-high prevalence progressively decreased with advancing TNM stage (I: 26.7%, II: 22.0%, III: 9.8%, IV: 4.0%). TLS-high patients demonstrated significantly improved overall survival (Log-rank p=0.006). Comparative immune profiling revealed elevated tumor infiltration scores for B cells, T cells, Th1 cells, and NK cells in TLS-high patients, contrasted by reduced macrophage and neutrophil infiltration scores. Comparative analysis of microbiota diversity revealed distinct patterns between TLS-high and TLS-low groups. In alpha diversity indices, while Shannon and Simpson indices showed no significant differences (Wilcoxon rank test $p > 0.05$), Richness indices demonstrated marked variation (p=0.02). Beta diversity assessed through PCoA exhibited significant group separation (PERMANOVA test p=0.006). Differential abundance analysis using LEfSe (Wilcoxon rank test $P < 0.05$, LDA ≥ 2) identified Staphylococcus as significantly enriched in TLS-low specimens, whereas Priestia showed preferential abundance in TLS-high specimens. Notably, Priestia abundance displayed significant negative correlations with tumor-infiltrating immune cells through Pearson correlation analysis: macrophages (r=-0.12, p=0.006) and neutrophils (r=-0.12, p=0.007). Analysis of two independent validation cohorts reinforced the clinical relevance of Priestia-TLS associations. In Cohort 1 (n = 44), TLS-high specimens exhibited median Priestia abundance of 0.119 compared to 0.066 in TLS-low specimens. While between-group comparisons only disclosed marginally significant difference (Wilcoxon rank test p=0.066),Priestia abundance demonstrated significant positive correlation with TLS scores (Pearson's r=0.38, p=0.01). Cohort 2 (n=27) mirrored this pattern, showing median abundances of 0.026 (TLS-high) versus 0.007 (TLS-low) with borderline statistical separation (p=0.055), yet revealing stronger correlation coefficients with TLS scores (r=0.41, p=0.03).

Conclusions: This study establishes a significant association between intratumoral microbiota composition and TLS in lung adenocarcinoma. The elevated microbial richness and Priestia enrichment observed in TLS-high tumors may modulate TLS formation through immune microenvironment regulation. Notably, the identified negative correlations of Priestia with macrophages and neutrophils suggest a potential association with reduced immunosuppressive cell infiltration, which may create favorable conditions for TLS development. Importantly, the consistent positive correlations between Priestia abundance and TLS scores across independent validation cohorts highlight its promise as an emerging biomarker candidate for TLS-related immune activation.

P2.02.36 Canakinumab Interception Trial and Preclinical Studies Reveal Stage-Dependent Biology in Lung Cancer and Precancers

J.J. Zhang, B. Zhu, M. Salehjahromi, S. Heeke, M. Godoy, M.V. Negrao, N. Vokes, X. Le, J.V. Pozadzides, C.M. Gay, L. Byers, T. Cascone, H.T. Tran, S.H. Lin, B. Carter, A. Tam, R. Rajaram, M. Antonoff, E. Ostrin, H. Chen, G. Blumenschein, D. Rice, G.L. Walsh, W. Hofstetter, R.J. Mehran, C.C. Wu, A. Vaporciyan, B. Zhang, H. Araujo, S.J. Moghaddam, I. Wistuba, J.J. Lee, J. Wu, J.V. Heymach
MD Anderson Cancer Center, Houston/TX/USA

Introduction: Multiple clinical trials testing canakinumab, an interleukin-1β (IL-1B) antibody in lung cancers have yielded negative results. However, our work has highlighted the critical role of innate immunity in lung adenocarcinoma (LUAD) precancers, and demonstrated that IL-1B inhibition can delay the progression of precancers into invasive LUAD. These findings have led to the development of Can-Prevent-Lung (NCT04789681), a single-arm phase II trial evaluating whether canakinumab can enhance regression rates of persistent high-risk (presumably precancerous) pulmonary nodules to prevent invasive LUAD.

Methods: In the Can-Prevent-Lung trial, patients with persistent high-risk pulmonary nodules (nodules showing no regression on at least two CT scans three months apart, with a predicted malignancy risk >10% based on the Brock model) were enrolled to receive canakinumab subcutaneously. The initial dosing regimen was 200 mg every 3 weeks for up to eight doses, which was modified to 300 mg every three months for up to four doses following a planned interim analysis. CT scans were performed to evaluate response using modified RECIST (mRECIST) criteria, assessing both solid and ground-glass opacity components. A propensity-matched non-treatment control group was analyzed in parallel. Peripheral blood samples were collected for T cell receptor sequencing, cytokine profiling, and plasma cell-free DNA (cfDNA) analysis at multiple time points during the treatment. Additionally, in vivo IL-1B blockade experiments were conducted in LUAD mouse models, and single-cell and spatial transcriptomics profiling were utilized to investigate mechanisms of action and the impact of IL-1B inhibition on the tumor microenvironment.

Results: At the planned interim analysis, 15 patients had completed treatment and safety follow-up. No Grade 3 or higher drug-related toxicities were observed, with Grade 2 neutropenia without active infections (n=4) being the most common toxicity. According to mRECIST criteria, 11 patients exhibited pulmonary nodule shrinkage, with the best response being a 27% reduction, while 13 patients showed a slower growth trajectory post-canakinumab treatment compared to pre-treatment. In 3D volumetric analysis, the treatment group demonstrated a median annual growth rate of -6.7%, in contrast to a +14.8% annual growth rate in the control group. Pulmonary nodules in the IL-1B group exhibited fewer cells (P=0.024), lower intra-lesion spatial heterogeneity (P=0.049), and reduced density (P<0.001). Notably, abnormal cfDNA signals detected before treatment became negative following canakinumab therapy. An additional 10 patients received the revised 300 mg every three months regimen, with no Grade 2 or higher toxicities observed. In both genetically engineered and carcinogen-induced LUAD mouse models, IL-1B blockade significantly reduced tumor burden when administered at the precancerous stage, but not at the advanced cancer stage. Correlative analyses from the Can-Prevent-Lung trial, and single cell and spatial transcriptomics profiling from mouse models treated with anti-IL-1B or IgG controls—are ongoing.

Conclusions: Cancer biology, including immune response and evasion patterns, as well as therapeutic efficacy, is stage-dependent. Canakinumab has demonstrated a favorable safety profile and promising efficacy in patients with high-risk pulmonary nodules, despite previous negative trials in invasive lung cancer. These findings support the IL-1B pathway as a promising target for immune interception of high-risk (precancerous) pulmonary nodules.

P2.02.37 ERBB3-BCAR4 Is a Recurrent and Oncogenic Fusion in Lung Adenocarcinoma Cases That Lack Other Driver Alterations

K. Levine[1], C. Baik[1], S. Liu[2], J. Riess[3], A. Berger[4]
[1]University of Washington / Fred Hutch, Seattle/WA/USA ,[2]Georgetown University, Washington DC/WA/USA ,[3]University of California Davis, Sacramento/CA/USA ,[4]Fred Hutch, Seattle/WA/USA

Introduction: There has been great progress recently for patients with metastatic lung adenocarcinoma whose tumors harbor common driver alterations. However, there remains a subset of patients with rare variants of unknown significance, for which the treatment options are severely lacking. There have been two previous case reports of patients with lung adenocarcinoma for which an ERBB3-BCAR4 fusion was identified, including one in TCGA. Importantly both cases had WGS and were negative for known driver alterations. In addition, the TCGA case had elevated RNA expression of the fusion transcript, including the full extracellular and kinase domains of the ERBB3 gene, which encodes for the EGFR family member HER3. The objective of the study is to better understand the function and clinical relevance of the ERBB3-BCAR4 fusion. We hypothesize that ERBB3-BCAR4 is a driver fusion that can be targeted with drugs that bind to the HER3 extracellular domain.

Methods: UW-Oncoplex is a next-generation sequencing assay used at the University of Washington / Fred Hutch. The current assay has > 400 genes and includes ERBB3 in the panel. For in vitro work, overexpression of the fusion was performed in NCI-H3122 cells, an ALK-fusion positive lung adenocarcinoma cell line. The cells were then treated with lorlatinib to suppress growth of the parental cells, thereby testing if the ERBB3-BCAR4 fusion could function as a driver in a lung adenocarcinoma context. For RNA-Sequencing of the fusion case, RNA was extracted from FFPE, library prep performed using Illumina's TruSeq RNA Exome hybrid capture technique, and sequencing completed on a NovaSeq.

Results: Via UW-Oncoplex sequencing, we report the identification of the third case of an ERBB3-BCAR4 fusion. This patient is a young woman who lacks a significant smoking history, and like the two previous cases, had a tumor negative for other driver alterations. The breakpoint identified is nearly identical to the TCGA case, with RNA-Sequencing confirming high expression of an in-frame transcript that includes the extracellular and kinase domains of ERBB3 and exon 4 of BCAR4. Preliminary in vitro work shows that overexpression of this fusion in lung adenocarcinoma cells rescues cell growth when the endogenous driver is inhibited. Use of patritumab deruxtecan in vitro, a HER3 antibody drug conjugate, reverses the growth advantage of ERBB3-BCAR4, suggestive of a potential treatment option for patients with this rare fusion. Ongoing work includes assessing the signaling mechanisms of the fusion via in vitro studies and IHC of the patient tumor, testing other EGFR-family kinase inhibitors in vitro, and querying a large clinical database to better define the fusion frequency.

Conclusions: Here, we report the identification of ERBB3-BCAR4 as a recurrent fusion in lung adenocarcinoma cases. Data suggestive that this fusion is functional include the lack of other driver alterations, the elevated RNA expression, and in vitro studies showing a growth advantage. Ongoing research includes additional work to define the signaling mechanisms of the fusion and potential therapeutic options to aid in the care of this rare patient population.

P2.02.38 Single-Cell RNA-Sq Reveals Potential Mechanism of RUNx3 Reshaping TME in NSCLC

X. Chen[1], J. Zheng[2], W. Xiao[1], Y. Deng[3]
[1]Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou/CN ,[2]The Second Affiliated Hospital of Fujian Medical University, Quanzhou/CN ,[3]The First Affiliated Hospital of Fujian Medical University, Fuzhou/CN

Introduction: RUNX3 plays an important role as a tumor suppressor gene (TSG) in NSCLC, but its specific biological mechanism is not yet clear. The aim of this study is to reveal the changes in tumor microenvironment (TME) in NSCLC with different RUNX3 expression status using single-cell RNA sequencing.

Methods: 7 NSCLC patients with detailed pathological data were included in this study, among which 3 patients provided samples of paracancerous tissue as well as cancerous tissue. After obtaining the sequencing results, the "Seurat" package was used to screen for differentially expressed gene profiles, annotate the cell cluster based on marker genes, and analyze the differences in cell proportions under different RUNX3 expression status. The ratio of observed over expected cell numbers (Ro/e) was used to explore the enrichment tendency of different cell types in three pathological types.

Results: According to immunohistochemical staining of RUNX3, 3 patients were divided into RUNX3 negative group (RUNX3_Neg) and the other 4 RUNX3 positive group (RUNX3_Pos). Based on marker genes, all cells were classified into 13 types. The results of Ro/e showed that the only cell type enriched in RUNX3_Pos cancer tissue was fibroblasts, while the cell types that enriched in RUNX3_Neg cancer tissue were club cells, ciliated cells, fibroblasts, plasma cells, B cells, neutrophils, mast cells and pDCs. From the perspective of immune cells, RUNX3_Neg tissues are more likely to accumulate plasma cells, B cells, mast cells and plasmacytoid dendritic cells compared to RUNX3_Pos tissues. Results of Ro/e demonstrated that RUNX3_Neg cancer tissues are more prone to macrophage depletion, while RUNX3_Pos tissues are more prone to macrophage enrichment.

Conclusions: Via single-cell sequencing technology our findings revealed that the expression status of RUNX3 is highly correlated with TME of NSCLC, and mononuclear phagocytes (MPs) may be an important target cell population for RUNX3 to alter TME, and altering the enrichment status of MPs may be a promising cancer treatment strategy. This study provides valuable insights into the anti-cancer mechanism of RUNX3.

P2.02.39 Fulzerasib, a KRAS-G12C Inhibitor, Has Synergistic Antitumor Effect With Omeprazole Pretreatment in KRAS G12C NSCLC

M. Zhou[1], J. Codony-Servat[1], D. Olmo-González[2], J. González[1], K. València-Clua[1], Y. Wang[3], J. Zhang[3], F. Zhou[3], F. Yang[3], H. Shen[3], R. Rosell[2]
[1]FIOR group, IGTP - Institut d'Investigació Germans Trias i Pujol, Badalona/ES ,[2]FIOR group. IOR, Dexeus University Hospital, Barcelona/ES ,[3]GenFleet Therapeutics (Shanghai) Inc., Shanghai/CN

Introduction: Non-small cell lung cancer (NSCLC) harboring the KRAS G12C mutation poses a major challenge for effective and durable treatment. Fulzerasib (GFH925, IBI351), an irreversible KRAS G12C inhibitor, has demonstrated superior efficacy compared to sotorasib and adagrasib, achieving an objective response rate of 49.1% and a median progression-free survival of 9.7 months. Omeprazole, a proton pump inhibitor, has been shown to enhance cytoplasmic retention of cytotoxic drugs and sensitize cancer cells to chemotherapy and some target therapy, such as tepotinib. The current study aims to explore the antitumor effect and underlying mechanisms of fulzerasib in combination with omeprazole pretreatment in KRAS G12C-mutated NSCLC cell lines.

Methods: Three KRAS G12C-mutated NSCLC cell lines (H358, H23 and H2030) were selected to represent fulzerasib-sensitive, mildly resistant and resistant phenotypes, respectively. Cells were treated with varying doses of omeprazole pretreatment (administered 24 hours before fulzerasib) and subsequently treated with fulzerasib. Cell viability was assessed using MTT assays, and synergy was evaluated using Loewe, Bliss, HSA and ZIP models. Western blotting was performed to analyze the expressions of proteins and the regulations of pathways, including KRAS pathway, the MRAS-PP1c-SHOC2 complex, Met pathway, Wnt pathway, and markers like SLUG, HES1, and pEphA2.

Results: Synergistic effects of Fulzerasib and omeprazole pretreatment were observed across all models and cell lines. Combination treatment significantly reduced MRAS expression in the MRAS-PP1c-SHOC2 ternary complex. In cancer-related pathways, pMet and pAKT expression were markedly decreased, while MAPK pathway components (pRaf and pERK1/2) showed no significant changes. Wnt pathway analysis revealed decreased β-catenin expression without notable changes in pLRP6. SLUG, HES1 and pEphA2 expression were also significantly reduced.

Conclusions: This study highlights that fulzerasib exhibits synergistic antitumor effects with omeprazole pretreatment, potentially through the suppression of multiple cancer-related proteins and pathways. Future studies will explore additional mechanisms, including autophagy and ferroptosis, to further elucidate the therapeutic potential of this combination.

P2.02.40 Multiomics Assessment of Lung Adenocarcinoma Subtypes Defined Through Tumor Purity-Adjusted DNA Methylation

D. F. Nacer de Oliveira, E. Arbajian, S. Veerla, M. Aine, M. Jönsson, F. Rosengren, A. Karlsson, A. Salomonsson, S. Isaksson, M. Planck, J. Staaf
Lund University, Lund/SE

Introduction: Molecular subtypes of lung adenocarcinoma (LUAD), the most common histological subtype of lung cancer, have been proposed based on one or two-dimensional studies and different defining characteristics have been proposed for each of them. LUAD molecular subtypes have been shown to have prognostic value but have not yet been implemented as part of clinical routine. Epigenetic modifications in cancer cells are independent of sequence variants, directly linked to gene and genome regulation, and provide important information to guide subclassification efforts. However, DNA methylation data obtained from tumor samples are influenced by their tumor composition and analyses are often performed without regard for where in the genome such modifications occur.

Methods: We adjusted DNA methylation data from 95 primary LUAD samples from a Swedish cohort to better reflect values from tumor cells alone according to sample purity and subdivided the data according to genomic locations relative to gene coordinates. These data were used to classify samples into four clusters that were then contrasted based on clinicopathological, epigenomic, genomic, transcriptomic, proteomic, and metabolomic data. Findings were validated in two larger independent cohorts containing 418 and 322 samples each. Lastly, 62 LUAD cell lines were classified into the methylation clusters to verify which characteristics were intrinsic to tumor cells.

Results: Of the four methylation clusters, two (M1 and M4) were associated with previously proposed mRNA/protein subtypes showing similar characteristics to what has been published, such as higher percentages of persons without smoking history in M1, the cluster with the best prognosis. The remaining two clusters, however, were a combination of other proposed subtypes. Despite showing similar mRNA/protein subtype compositions, clusters M2 and M3 differed from each other through e.g., higher expression of a napsin A/surfactant metabolism expression metagene in M3, a marker of the LUAD histology. Genes included in this metagene showed lower DNA methylation in M3 compared to M2 despite an aggregate promoter hypermethylation phenotype seen in the former cluster. M2-like and M3-like cell lines recapitulated the metagene expression patterns seen in M2 and in M3 clusters from the three cohorts analyzed. Finally, patients with M3 tumors seemed to have poorer overall prognosis.

Conclusions: Focusing on tumor cell epigenomics, we were able to identify important characteristics of the different LUAD methylation clusters. Dissecting this disease based on combined biological information from multiomics data results in a deeper understanding of the heterogeneity in this complex disease and can hopefully lead to future treatments guided by molecular subtypes.

P2.02.41 Feasibility of Flow Super RCA for KRAS Mutation Detection in Liquid Biopsies of Advanced Lung Adenocarcinoma: Pilot Study

L. Posado-Domínguez[1], A. Olivares Hernández[1], M. Jara-Acevedo[2], M. Jiménez-López[3], E. Del Barco-Morillo[1], M. Gonzalez-Tablas[2], P. Paula Navarro-Navarro[2], J.G. García[2], T. Gómez-Hernández[3], L. Bellido-Hernández[1], D. Santamaría-Velilla[2], A.O. Orfao[2]
[1]University Hospital of Salamanca, Salamanca/ES ,[2]Cancer Research Center, Biomedical Research Institute of Salamanca (IBSAL), Salamanca/ES ,[3]Department of Thoracic Surgery, University Hospital of Salamanca, Salamanca/ES

Introduction: KRAS mutations are the most frequent oncogenic alterations in non-small cell lung cancer (NSCLC), particularly in adenocarcinoma. In recent years, considerable research efforts have focused on developing specific KRAS inhibitors. Agents targeting the G12C variant —such as sotorasib and adagrasib— have already been approved, and pan-KRAS inhibitors are currently under investigation. As treatment strategies increasingly rely on molecular profiling, liquid biopsy has emerged as a promising non-invasive tool for real-time mutation detection. In this context, we evaluated the feasibility of a novel rolling circle amplification-based technique (Flow SuperRCA) to detect KRAS mutations in plasma samples and compared its results with conventional tissue biopsy.

Methods: Ten patients with advanced lung adenocarcinoma were included. KRAS mutations (codons G12C, G12D, G12V, and Q61H) were previously analyzed in tumor tissue using conventional molecular methods. Plasma samples were tested using Flow-SuperRCA, which involves target-specific padlock probe ligation, signal amplification, and flow cytometric detection. Cell-free DNA (cfDNA) concentration was quantified, and concordance between tissue and plasma results was assessed.

Results: KRAS mutations were identified in primary tumor tissue in 5 of 10 patients (3 G12C, 1 G12D, 1 G12V). Flow-SuperRCA detected mutations in 3 of these 5 patients (60% concordance), successfully identifying two G12C and one G12D mutation. The G12V and Q61H mutations present in tissue were not detected in blood; both cases had the lowest cfDNA concentrations (0.71 and 2.22 ng/µL, respectively) and a limited number of evaluable variant allele events. Interestingly, Flow SuperRCA detected a third G12C mutation and one Q61H mutation in patients without corresponding tissue alterations. Given that liquid biopsies were performed 4 to 6 weeks after tissue sampling, these findings may reflect temporal tumor evolution or spatial heterogeneity within the (primary vs metastatic) tumor landscape. In total, KRAS mutations were identified in plasma in 5 out of 10 patients.

Conclusions: Flow Super RCA is a promising minimally invasive technique for detecting KRAS mutations in advanced lung adenocarcinoma. The method showed partial concordance with tissue testing and the capacity to reveal additional mutations that may emerge over time or arise in distinct tumor subclones and/or at distinct tumor sites. These preliminary findings support further exploration of this technique in larger prospective cohorts.

P2.02.42 Effect of MTHFR Gene Mutation on the Efficacy of Tyrosine Kinase Inhibitor Treatment in Lung Cancer Patients

X. Huang, J. Huang, Z. Huang, Z. Yang, W. Su, Y. Chen
Affiliated Hospital of Guangdong Medical University, Zhanjiang/CN

Introduction: Worldwide, lung cancer is the second most commonly diagnosed cancer and the leading cause of cancer-related deaths. A groundbreaking development in the treatment of lung cancer was achieved with the discovery of mutations that activate the epidermal growth factor receptor (EGFR) gene in non-small cell lung cancer (NSCLC). These mutations include a missense mutation in exon 21 and a short frame deletion in exon 19. EGFR-targeted tyrosine kinase inhibitors (TKI) have shown to be more effective than cytotoxic treatment in enhancing tumor response and improving progression-free survival outcomes in NSCLC patients with EGFR mutations. However, targeted therapy eventually leads to drug resistance in patients with EGFR gene mutation, and the underlying molecular mechanism of TKI resistance remains unclear. The MTHFR gene plays an important role in many biological processes. It encodes an enzymatic protein that catalyzes the irreversible reaction of 5-10-methyltetrahydrofolate to 5-methyltetrahydrofolate. This reaction is essential for the conversion of homocysteine to methionine by methionine synthase, where 5-methyltetrahydrofolate is used.

Methods: The Affiliated Hospital of Guangdong Medical University conducted a genetic analysis of 64 patients using next-generation sequencing (NGS) to determine their gene mutation status. In addition, the study also assessed the MTHFR mutation and the baseline characteristics of patients, along with the treatment outcomes such as overall survival (OS) and progression-free survival (PFS).

Results: The study involved 64 patients with advanced non-small cell lung cancer, out of which 30 (46.9%) had EGFR 19 mutations, and 34 (53.1%) had EGFR 19 mutations. The frequency of MTHFR gene mutation in these patients was found to be 31.3% (20/64). The study also revealed that patients with MTHFR gene mutation had a significantly increased median progression-free survival (PFS) of 28.50 months as compared to those without the mutation (11.30 months). However, there was no significant difference in the median overall survival (OS) between the two groups (31.50 months vs. 42.50 months). Furthermore, in NSCLC patients receiving EGFR-TKIs treatment, the study observed significant differences in PFS and MTHFR mutations (p= 0.023).

Conclusions: In NSCLC patients with MTHFR mutation, the benefits of EGFR-TKIs treatment are more significant. MTHFR gene is a predictor for first-line treatment of advanced NSCLC with EGFR-TKIs.

P2.02.43 Multi-Omic Approach Elucidates the Underlying Mechanism of HA-Coated Neohesperidin Nanoparticles Against Lung Cancer

R. Pandey, P. Nikhil, V. Gaikwad, P. Ramalingam
National Institute of Pharmaceutical Education and Research, Hajipur, Hajipur/IN

Introduction: Lung cancer (LC) is the leading cause of cancer-related deaths, with an average five-year survival rate of just 13%. Although many synthetic treatments are available, their effectiveness is often compromised by significant resistance issues, making them unsuitable. This therapeutic limitation is largely due to a lack of understanding of the metabolic and mechanistic processes involved in LC. To address this, it is crucial to identify potential molecular metabolites in pre-malignant LC. Therefore, we propose the use of natural products, which may help to mitigate toxicity and resistance-related limitations. In this context, neohesperidin (NHP), a flavonoid, has demonstrated strong anticancer potential. However, its limited bioavailability reduces its therapeutic efficacy. Thus, an NHP polymeric nanoparticle was formulated, and its therapeutic efficacy and underlying mechanisms were evaluated. Additionally, we employed proteomic and metabolomic approaches to investigate the biochemical and molecular differences between malignant LC tissue and normal lung samples in mice.

Methods: Here, we develop the hyalauronic acid (HA) coated PLGA nanoparticle of NHP and comprehensively evaluated its protective effects through histopathological examination of LC mice induced by urethane (1g/kg). Further, proteomics and metabolomics profiling was performed through LC-Orbitrap MS to offer a systematic view of the dynamic alterations in proteins and global endogenous metabolites, together with their disrupted pathways, acquired by applying log≥2 fold change and statistical significance of fold change ($p<0.005$). Later, western blotting was performed to confirm the expression of specific proteins and validate the pathway.

Results: The results demonstrated HA coated NHP nanoparticles could synergistically exert significant preventive effects against LC by notably ameliorating lung histopathological damage in LC mice. Further, approximately 364 differently expressed proteins (DEPs) and 25 differently expressed metabolites (DEMs) were identified, showing significant variation when compared to normal, diseased, and formulation-treated lung tumor tissue. Pathway enrichment analysis of DEMs revealed perturbations in the apoptotic pathway, with the involvement of lipid and amino acid biosynthesis pathways, which are primarily responsible for the therapeutic action of the formulation. Moreover, the expression of proteins involved in the apoptosis pathway (COX6A1, Bcl213, P11103) was confirmed by western blotting.

Conclusions: This research offers valuable insights into therapeutic strategies involving HA-coated NHP nanoparticles and enhances our understanding of antitumor mechanisms, which could be beneficial for future investigations in the clinical treatment of LC. We offer a comprehensive multi-omics foundation for assessing, managing, and detecting health risks associated with lung cancer.

P2.02.44 Research on the Mechanism of Gut Microbiota Promoting NSCLC Distant Metastasis Through Its Metabolite Testosterone

C-G. Liu, M-X. Lin, D. Zang, J. Chen
The Second Hospital of Dalian Medical University, Dalian/CN

Introduction: Lung cancer ranks among the malignant tumors with the highest morbidity and mortality worldwide, with non-small cell lung cancer (NSCLC) accounting for approximately 80-85% of all cases. Over half of NSCLC patients present with metastasis at the time of initial diagnosis, resulting in extremely poor survival rates. Growing evidence suggests that the gut microbiota and its metabolites play crucial roles in tumor initiation, progression, and treatment. However, the underlying mechanisms by which the gut microbiota and its metabolites regulate NSCLC metastasis remain unclear.

Methods: By collecting baseline fecal samples from NSCLC patients prior to treatment for metagenomic and non-targeted metabolomic analysis, multi-omics integrated analysis was performed to identify testosterone as the key metabolite promoting NSCLC metastasis. Wound healing and transwell assays were conducted to verify the effects on migration and invasion of testosterone in NSCLC cell lines. Mendelian randomization demonstrated that testosterone promoted AKT phosphorylation at the genetic level, which was further validated by Western Blot analysis. Tumor metastasis was investigated in a mouse model to reveal whether testosterone could promote NSCLC metastasis in vivo.

Results: Compared to patients with non-metastatic NSCLC, those with distant metastasis exhibited significant gut microbiota dysbiosis and distinct metabolic characteristics. The correlation analysis revealed that Fusobacteria was negatively associated with NSCLC metastasis, suggesting a potential protective role. The metabolite testosterone and its related pathways might play key roles in NSCLC metastasis. Testosterone significantly enhanced the migration and invasion abilities of PC9, A549, and H1299 cells. Testosterone accelerated epithelial-mesenchymal transition (EMT) progression through activation of AKT/mTOR pathway phosphorylation. Additionally, intraperitoneal injection of testosterone promoted malignant progression of NSCLC in mice.

Conclusions: The gut microbiota metabolite testosterone may promote NSCLC metastasis by inducing EMT through activation of AKT/mTOR pathway phosphorylation. This study may provide clinical targets and evidence for the prediction and interventional treatment of NSCLC metastasis.

P2.02.45 Modulated Electro-Hyperthermia Enhances Tumor Cell Susceptibility to Gamma Delta T Cell-Mediated Cytotoxicity and Tumor Infiltration

C.Y. Chiu
Taoyuan General Hospital, Taoyuan/TW

Introduction: Numerous studies reported gamma delta T cell (γδ T cell) therapy as a promising immunotherapy for treating tumors, but little research explored the potentials of γδ T cell in combination with other treatments. Modulate electro-hyperthermia (mEHT) is a significant technological development in hyperthermia, autofocusing electromagnetic power on the cell membrane to create massive apoptosis. However, the synergetic effects of mEHT and γδ T cells for treating tumors remain unclear.

Methods: Therefore, in this study, we hypothesized that mEHT could enhance the therapeutic effects of γδ T cells against tumors. By recruiting γδ T cells to tumor cells, mEHT-treated tumors were more sensitive to these cells and thus increased the cytotoxic functions. The γδ T cells were isolated and co-cultured with mEHT-treated tumors.

Results: The cytotoxic rates were significantly increased compared with control and a conventional heating device. In tumor-bearing NOD/SCID mice, the tumors remained stable until the end of the experiment with intravenous injections of γδ T cells and mEHT treatment. Furthermore, the increased γδ T cell infiltrations within the tumor microenvironment were found in these mice compared with monotherapy.

Conclusions: These results suggested that γδ T cells could mediate a potent anti-tumor effect when combined with mEHT, providing insight for future clinical development of combinational immunotherapy as a novel anti-tumor strategy.

P2.02.46 V-Atpase Inhibitors Enhance the Effect of Tepotinib (c-Met Inhibitor) or RMC-6236 (Pan-Ras(ON) Inhibitor) in KRAS-Mutant NSCLC

K. València-Clua[1], J. Codony-Servat[1], J. González[1], M. Zhou[1], D. Olmo-González[2], R. Rosell[2]
[1]FIOR group, FIGTP - Fundació Institut d'Investigació Germans Trias i Pujol, Badalona/ES ,[2]FIOR group. IOR, Dexeus University Hospital, Barcelona/ES

Introduction: KRAS G12C inhibitors (sotorasib or adagrasib) in monotherapy have short-lived response in metastatic KRAS G12C NSCLC patients. Resistance to KRAS G12C inhibitors appear due to the presence of coexisting KRAS mutations, activation mutations of other RAS isoforms, and amplifications or activation mutations upstream or downstream of RTK pathways. We previously reported that targeting c-Met (tepotinib), upstream growth factor signal transducer of KRAS, decreased cell viability in a broad panel of KRAS G12C and non-G12C NSCLC cell lines. The proliferation inhibition was increased when tepotinib was combined with omeprazole, known to act as a V-ATPase proton pump inhibitor. The aims were to first assess the half maximal inhibitory concentration (IC50) of tepotinib versus RMC-6236 in KRAS G12C and non-G12C-mutant NSCLC cell lines. Secondly, the potential synergism of omeprazole + tepotinib versus omeprazole + RMC-6236. Finally, by western blot analysis, to see the behaviour of MRAS and YAP1 among other proteins as biomarkers of adaptive resistance.

Methods: In vitro studies were conducted in NSCLC cell lines, including NCI-H358, a generated H358 line resistant to sotorasib (H358R), NCI-A549, and NCI-H23. Cell lines were treated with tepotinib (c-Met inhibitor) or RMC-6236 (pan-RAS(ON) inhibitor) alone and in combination with omeprazole pre-treatment. Cell viability assays were performed by MTT, and synergism/antagonism analysis was carried out using Combenefit and Sinergy finder + computational programs. Western blot analysis was performed to characterize total and phosphorylated proteins.

Results: RMC-6236 showed a stronger inhibitory effect in H358 than in H358R and H23 cell lines. Omeprazole increased the cell growth inhibition effect of RMC-6236 and showed synergism in all cell lines. RMC-6236 and omeprazole pre-treatment decreased activation of several tyrosine kinase receptors: MET, EGFR, and LRP6, as well as downstream proteins such as AKT, ERK1/2, and YAP1. RMC-6236 treatment alone enhanced the expression of MRAS and translocated β-catenin to the nucleus, however, when omeprazole pre-treatment was added, the upregulation of MRAS and β-catenin disappeared. Of interest is the fact that tepotinib + omeprazole pre-treatment decreased the expression of MRAS, the cancer stem cell marker (Hes1), ERK1/2, AKT, STAT3, and YAP1, as well as EGFR, EphA2, and LRP6.

Conclusions: Early evidence of data points out that omeprazole increases the anticancer effect of either tepotinib or RMC-6236 in KRAS G12C-mutant and non-G12C-mutant NSCLC cell lines. Western blot analysis shows several hints that the combination of omeprazole pretreatment + tepotinib or omeprazole + RMC-6236 both combinations can avoid upregulation of MRAS and YAP1 and several receptor tyrosine kinases. To further discern is the leverage of tepotinib in front of RMC-6236.

P2.02.47 Hypoxia-Driven SERBP1-SLC25A5-ND6 Axis Regulates Mitochondrial Metabolic Reprogramming to Promote Metastasis in Non-Small Cell Lung Cancer

D. Lu[1], J-a. Huang[1], Z. Liu[1], C. Mu[2]
[1]the First Affiliated Hospital of Soochow University, Suzhou/CN ,[2]Department of Respiratory and Critical Care Medicine, First Affiliated Hospital of Soochow University, Suzhou/CN

Introduction: Metastasis of non-small cell lung cancer (NSCLC) is the core reason for the low survival rate of patients, with metabolic reprogramming serving as a critical adaptive mechanism for tumor survival. SERPINE1 mRNA binding protein 1 (SERBP1), as an RNA-binding protein, is abnormally expressed in a variety of cancers, but its role in NSCLC metastasis has not been clearly defined. By integrating various omics data, this study revealed for the first time the specific mechanism of NSCLC metastasis driven by SERBP1 translocation to mitochondria (mtSERBP1) by binding mitochondrial transporter SLC25A5 under hypoxia conditions, and targeted regulation of mitochondrial metabolism of mt-ND6 mRNA. The clinical translational value of SERBP1 as a potential biomarker was evaluated, and the functional application of SERBP1 as a potential therapeutic target in cancer research was expanded.

Methods: The First Affiliated Hospital of Soochow University collected cancer tissue and matched para-cancer tissue from NSCLC patients to detect SERBP1 expression. The regulatory effect of SERBP1 on NSCLC metastasis was investigated by mouse tail vein lung metastasis model, transwell and wound healing experiments. The OCR and ECAR values of NSCLC cells were measured by Agilent Seahorse XFe24 analyzer. Mitochondrial protein was isolated and the expression of SERBP1 in mitochondria was detected under hypoxia condition. The effect of SERBP1 expression on mitochondrial morphological changes was detected by immunofluorescence and transmission electron microscopy. The mechanism of SERBP1 entering mitochondria was investigated by RIP-seq and Co-IP techniques.

Results: Analysis of 126 clinical cohort studies combined with public databases showed that SERBP1 was highly expressed in cancer tissues and significantly negatively correlated with TNM stage, metastasis, and survival prognosis. Functional phenotype experiments demonstrated that SERBP1 overexpression enhances the migration and invasion ability of NSCLC cells. In the lung metastasis model of nude mice, the number of metastatic nodules increased in SERBP1 high expression group. Mechanistcally,based on high-throughput omics analysis, overexpression of SERBP1 inhibited oxidative phosphorylation and promoted glycolysis. Co-IP experiment confirmed that hypoxia triggers SERBP1 translocation to mitochondria via interaction with the transporter SLC25A5. RIP-seq confirmed that mtSERBP1 targeted regulation of mt-ND6 mRNA, impairing electron transport chain complex I activity and shifting energy production to aerobic glycolysis.

Conclusions: In this study, a complete research system of RNA-binding protein-mitochondrial metabolic axis was established. By focusing on the molecular mechanism that SERBP1 drives NSCLC metastasis by regulating mitochondrial metabolic reprogramming under hypoxic conditions. Under hypoxia conditions, SERBP1 binds to mitochondrial transporter SLC25A5 and transits to mitochondria (mtSERBP1), which degrades the expression of mitochondrial coding gene mt-ND6, destroys the function of electron transport chain complex I, inhibits oxidative phosphorylation, promotes the occurrence of aerobic glycolysis, and accelerates the malignant metastasis of NSCLC.

P2.05.01 The Role of Robotic-Assisted Bronchoscopy and Endobronchial Ultrasound in Diagnosing and Staging Pulmonary Carcinoid

S. Podder, E. Harris, A. Esposito, C. Bestvina, S. Murgu
University of Chicago, Chicago/IL/USA

Introduction: Pulmonary carcinoids account for less than 2% of all lung cancers and can present as endobronchial or as parenchymal nodules. The diagnostic yield of robotic-assisted bronchoscopy (RAB) and the accuracy of endobronchial ultrasound-transbronchial needle aspiration (EBUS-TBNA) for lymph node staging in pulmonary carcinoids have not been systematically evaluated.

Methods: In this IRB-approved retrospective study (IRB24-2156), we reviewed consecutive patients who underwent RAB evaluation at the University of Chicago for pulmonary nodules and were subsequently diagnosed with pulmonary carcinoids. Records reviewed included demographics, clinical characteristics, nodule imaging features, bronchoscopic techniques, lymph node stations sampled, surgical intervention, and final pathological staging.

Results: Twenty-three patients were diagnosed with pulmonary carcinoids from 2020 until 2024. Most patients were female and white, with a median age of 68 years (Table 1). The mean nodule size was 17.46 mm, predominantly located in the inner or middle third of the lung. Only 6 patients underwent Ga-68 Dotatate scans, all post-bronchoscopic diagnosis. RAB successfully reached the nodules in 100% of cases. A definitive diagnosis was achieved in 21 of 23 patients (91%) (Table 2). Atypical carcinoid diagnosis was made in 3 patients, while a diagnosis of typical carcinoid was made in 20 patients. The tumor was accurately staged by EBUS-TBNA in 17/23 (87%) of cases. Of the three patients with EBUS-TBNA and surgical staging discrepancies, two had non-diagnostic RAB (EBUS-TBNA staging was not performed), and one had intraoperative pleural involvement but not nodal metastasis. Nodal metastases were diagnosed in 4 patients. Bronchoscopic procedures were well tolerated with one case of pneumothorax.

Conclusions: RAB offers a high diagnostic yield for pulmonary carcinoids and EBUS-TBNA, when performed, provides reliable intrathoracic lymph node staging. These findings support the use of RAB and EBUS-TBNA as safe and effective tools for the diagnosis and staging of pulmonary carcinoid tumors.

P2.05.02 Evolution and Survival Impact of Endobronchial Ultrasound (EBUS) Adequacy in Two Population-Based Lung Cancer Cohorts

O.A. Akinbobola[1], M. Smeltzer[2], J. Zhao[3], T. Ng[3], A. Mehrotra[3], M. Ray[2], C. Fehnel[1], A. Saulsberry[1], K. Dortch[1], A. Patel[1], R. Osarogiagbon[1]
[1]Baptist Cancer Center, Memphis/TN/USA ,[2]University of Memphis School of Public Health, Memphis/TN/USA ,[3]Baptist Memorial Hospital, Memphis/TN/USA

Introduction: EBUS is the standard for mediastinal staging in NSCLC, but variability in nodal sampling adequacy may impact staging accuracy, treatment decisions, and survival.

Methods: We analyzed the pattern of use of EBUS in a Multidisciplinary Thoracic Oncology Program cohort from 2014-2024. EBUS adequacy was categorized as low-adequacy (sampling of 0 or 1 station), partial-adequacy (sampling of 2 or 3 stations), and high-adequacy (examination of all four stations: 4R, 4L, 7, and 10/11). Although other stations (e.g., 2R/L, 12/13) are important, we focused on examination of these hilar/mediastinal stations as a minimum quality standard. We analyzed temporal trends using the Cochran-Armitage test, survival with Kaplan-Meier plots, log-rank tests, and proportional hazards models. Adjusted hazard ratios (aHR) controlled for age, sex, race, insurance, smoking, PET/CT imaging, and clinical stage, with low-adequacy as the reference. Nodal upstaging was calculated by comparing pre-EBUS clinical staging with post-EBUS staging based on nodal sampling results.

Results: Of 971 patients, 26% had EBUS with low-adequacy, 47% had partial-adequacy, and 27% had high-adequacy. Median age was 67 vs 67 vs 70 (p=0.002); commercial insurance use increased across groups, respectively (35% vs. 44% vs. 49%, p=0.0144). EBUS adequacy significantly improved over time (P<0.0001 Figure 1b). Nodal upstaging was lower within low-adequacy group (2%) compared to partial and high-adequacy groups (8% vs 4%; p=0.0024). EBUS adequacy was associated with improved OS (partial: aHR=0.77, p=0.034; high: aHR=0.75, p=0.022). Stage-stratified analysis showed significant survival benefits for stage III (aHR=0.58, p=0.0329) and intermediate benefits in stage IV (partial: aHR=0.60, p=0.0153; high: aHR=0.58, p=0.0508).

Conclusions: EBUS adequacy significantly improved over time, reflecting advancements in procedural training and feedback. High adequacy was associated with improved OS in stage III-IV disease.

P2.05.03 Minimizing Atelectasis in ENB: A Propensity-Matched Study of Laryngeal Mask Ventilation Strategy

Y. Xu, H. Liu
peking union medical college hospital, Beijing/CN

Introduction: Atelectasis during electromagnetic navigation bronchoscopy (ENB) can compromise diagnostic accuracy and hamper lesion localization. While endotracheal intubation (ETI) is the traditional airway management approach during ENB, its limitations in ventilation optimization, especially with large-diameter bronchoscopes, have prompted exploration of alternatives. This study aimed to evaluate the feasibility and effectiveness of a laryngeal mask airway-assisted ventilation strategy for atelectasis prevention (LMA-VSAA) during ENB.

Methods: We conducted a single-center, propensity score-matched cohort study comparing LMA-VSAA with conventional ETI in patients undergoing ENB for peripheral pulmonary lesions. Propensity matching was performed based on age, sex, lesion location, and FEV1%. The LMA-VSAA group received optimized ventilation including lung recruitment maneuvers, 6-8 cmH_2O PEEP, and FiO_2 titrated to 40%. The primary outcomes were the degree of atelectasis (measured by CBCT lung volume change) and nodule displacement distance (3D distance between planned and actual lesion position). Secondary outcomes included ENB operation time and complication rates.

Results: Eighty patients were included (40 in each group). Baseline characteristics were well balanced. The LMA-VSAA group showed significantly lower atelectasis compared to the ETI group (8.2 ± 3.4% vs. 28.3 ± 7.6%, P < 0.001). Nodule displacement distances were also significantly smaller in the LMA-VSAA group for both upper (3.2 ± 1.8 mm vs. 11.2 ± 3.4 mm, P < 0.001) and lower lobe lesions (7.4 ± 2.3 mm vs. 24.1 ± 5.2 mm, P < 0.001). ENB procedure times were comparable (25.4 ± 6.8 vs. 27.1 ± 7.5 minutes, P = 0.40). No hypoxemia or serious complications occurred in either group.

Conclusions: The LMA-VSAA strategy significantly reduced intraoperative atelectasis and improved lesion localization accuracy during ENB compared to conventional ETI. These findings demonstrate that LMA-VSAA is a feasible and effective alternative for airway and ventilation management in ENB, with potential to enhance diagnostic yield and patient outcomes. Further randomized trials are warranted to validate these results and explore broader applicability in interventional pulmonology.

Subgroup analysis of primary outcomes stratified by lesion location.

Outcome		LMA-VSAA Group (n=40)	Control Group (n=40)	P
Degree of atelectasis, %	Overall	8.2 ± 3.4	28.3 ± 7.6	<0.001

P2.05.04 Electromagnetic Navigation-Guided 3D Conformal Microwave Ablation for High-Risk Peripheral Pulmonary Nodules

Y.L. Yawei Liu, L.M. Liurong Mao, K.L. Kongjia Luo
Sun Yat-Sen University Cancer Center, Guangzhou/CN

Introduction: Clinically, high-risk peripheral pulmonary nodules (PPNs) identified through imaging follow-up often necessitate surgical resection for pathological diagnosis and therapeutic intervention. However, 5%-10% newly diagnosed patients are not candidates for surgery owing to cardiopulmonary insufficiency or other comorbidities. Traditional alternative therapies exhibit notable limitations in terms of efficacy and safety, underscoring the urgent need for a novel approach. This study aimed to assess the clinical feasibility and safety of electromagnetic navigation-guided three-dimensional conformal microwave ablation (ENB-DCMA) in patients with high-risk PPNs.

Methods: This retrospective study was conducted on consecutive patients who underwent ENB-DCMA of high-risk PPNs between March 2021 and August 2023. Inclusion criteria encompassed medically inoperable patients or those refusing surgery, with PPNs highly suspicious for malignancy. Primary endpoints include local control rate(LCR) and safety.

Results: Sixty-two high-risk PPNs(mean long-axis diameter of 12.26 ± 6.18 mm) in 50 patients were treated with 65 sessions of ablation. All nodules achieved planned ablation zones. No procedure-related mortality occurred. Postoperative complications included pneumothorax 12% (6/50; only 2 cases requiring drainage), post-procedural fever 2%(1/50) and self-limited hemorrhage 4%(2/50). The mean length of hospital stay after surgery was 2.91±1.31 days. Local disease progression occurred in 11 cases during the follow-up. The 1-year local control rate (LCR) was 82.3% (51/62). Median progression-free survival (PFS) was not reached,and the mean PFS for primary NSCLC and metastatic lesions was 40.7 months (95% CI 39.44 to 42.01) and 15.9 months (95% CI 10.58 to 21.31) respectively with a significant difference.(log-rank P<0.001).

Conclusions: ENB-DCMA represented a paradigm-shifting, safe, and effective minimally invasive alternative for the management of high-risk PPNs in medically inoperable patients. This transbronchial approach integrated navigational accuracy with precise 3D thermal field control and may redefine minimally invasive ablation paradigms potentially. Further prospective multicenter trials are needed to confirm its broader clinical applicability and long-term outcomes.

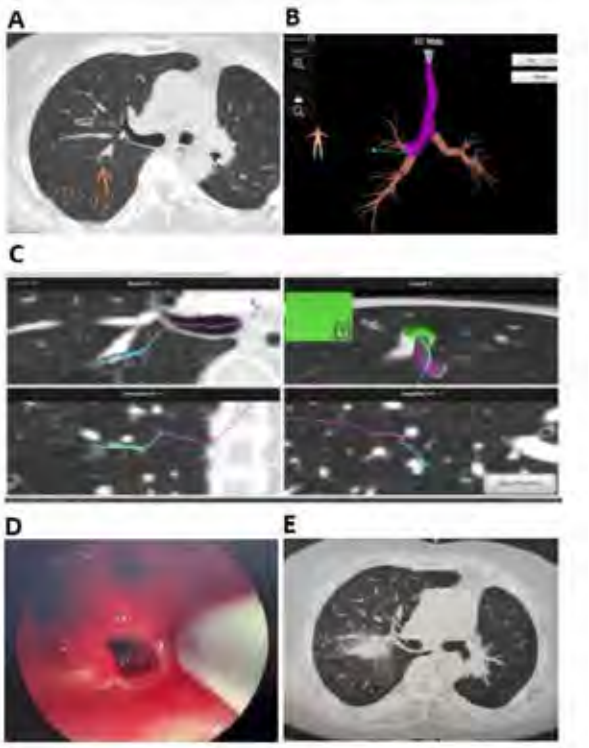

Figure 1: ENB-DCMA procedure: chest computed tomography before microwave ablation (A); planning of targeting nodule (B); real-time electromagnetic navigation screen of the sensor probe aimed at nodule (C); BTPNA was utilized (D); 48h after the microwave ablation (E). *ENB-DCMA*, Electromagnetic navigation-guided three-dimensional conformal microwave ablation; *BTPNA*, Bronchoscopic Trans-Parenchymal Nodule Access

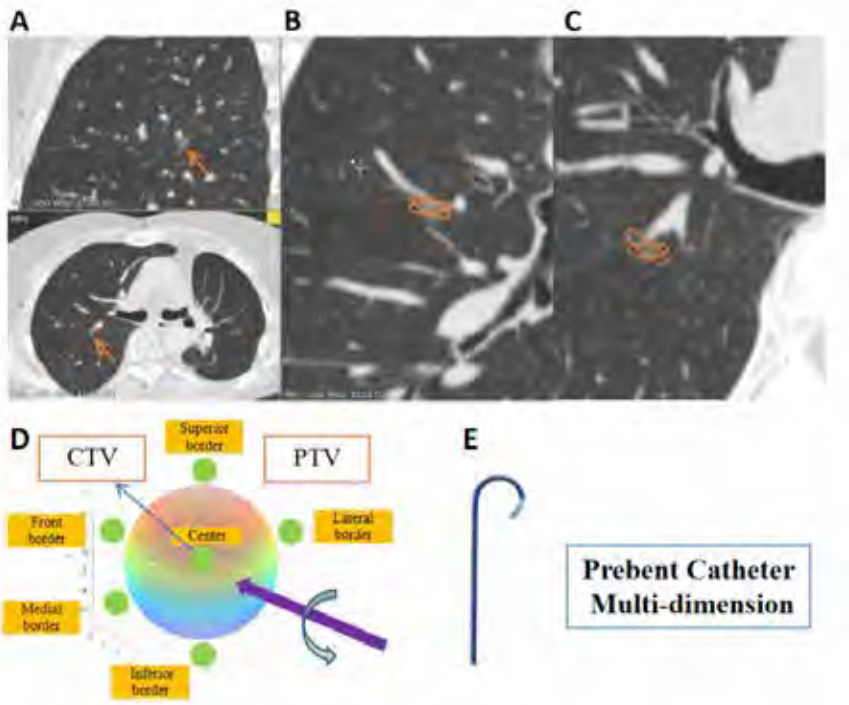

Figure 2: ENB-DCMA concrete operations: chest computed tomography before microwave ablation (A)(B); the nodule was adjacent to vascular structure, a prebent catheter was used for the procedure. the distal end of the catheter could be adjusted by turning the knob until it was parallel to the vascular structure(C); The 3D calibration method was used to ensure the catheter reached the center, superior,inferior,front,medial and lateral margin of the target lesion, thus pathological sampling and sufficient ablation range were confirmed(D); Multi-dimension operation with prebent catheter(E).

P2.05.05 Prediction of Distant Metastasis Using CT/PET-Based Radiomics in Non-Small Cell Lung Cancer: A Systematic Review and Meta-Analysis

N.N. Al-Bzour[1], A.N. Al-Bzour[2], M.N. Samarah[2], N.R. Othman[2], B.M. Alsarayrah[2], T.E. Alzaher[2], M. Hashki[2], Y.M. Alajlouni[2], R.A. Sawafta[3], O.M. Younis[3], J. Alrawabdeh[3], F. Abu Rous[4]
[1]Jordan University of science and techology, Irbid/JO ,[2]Jordan University of Science and Technology, Irbid/JO ,[3]University of Jordan, Amman/JO ,[4]Henry Ford Health, Detroit/MI/USA

Introduction: Non-small cell lung cancer (NSCLC) is associated with high rates of distant metastasis (DM), which significantly impacts patients' outcomes. The use of CT/PET-based radiomics has emerged as a promising tool to predict DM, potentially offering more accurate predictions compared to traditional clinical models. We aim to evaluate and compare the predictive performance of radiomics and clinical models in predicting DM in NSCLC patients.

Methods: We conducted a systematic review and meta-analysis following the PRISMA guidelines through PubMed and Scopus databases for studies on radiomics in NSCLC. The protocol was registered on PROSPERO (CRD42025628953). Observational studies and randomized clinical trials on NSCLC patients who underwent CT/PET-based radiomics with distant organ metastasis were included. Non-English articles, reviews, case reports, and animal studies were excluded. Primary outcome included accuracy of CT/PET-based radiomics in predicting DM in NSCLC. Pooled analysis was performed using the inverse variance weighting meta-analysis of single means on evaluation metrics including the area under curve (AUC), and the concordance index (C-index). Secondary outcomes included the comparison of radiomics vs. clinical models in DM prediction.

Results: Seventeen studies, including 1,550 NSCLC patients, were analyzed. Among them, 559 patients had distant metastasis. The mean age was 69.6 ± 7.7 years, and 733 were males. Stage I, II, and III diseases were reported in 450, 316, and 291 patients, respectively. Six studies assessed DM prediction using the C-index, and 11 used the AUC. For radiomics models evaluated with the AUC, low heterogeneity was observed (I^2 = 42%, p = 0.07), with a pooled AUC of 0.73 (95% CI: 0.70-0.77) using a fixed-effect model. Radiomics models evaluated with the C-index showed no heterogeneity (I^2 = 0%, p = 0.83), with a pooled C-index of 0.65 (95% CI: 0.61-0.70). Clinical models assessed using the AUC displayed high heterogeneity (I^2 = 90%, p < 0.01), with a pooled AUC of 0.70 (95% CI: 0.61-0.79) using a random-effect model. In contrast, clinical models evaluated with the C-index showed no heterogeneity (I^2 = 0%, p = 0.61), with a pooled C-index of 0.60 (95% CI: 0.55-0.65).

Conclusions: Our results indicate that radiomics models outperformed clinical models in predicting DM in NSCLC patients, as evidenced by higher pooled AUC and C-index values. Radiomics models also exhibited low heterogeneity across studies, suggesting consistent and reproducible performance. In comparison, clinical models showed greater variability and slightly lower predictive accuracy. These findings suggest that radiomics has the potential to serve as a reliable tool for DM prediction in NSCLC, offering more consistent performance than clinical models.

P2.05.06 Mature Results of a High-Precision Clinical Protocol for Staging Non-Small Cell Lung Cancer (NSCLC) of the Left Lung

S. Call, L.R. Cabanillas-Paredes, C. Obiols, A.M. Andrei, J.M. Ochoa-Alba, L. Luizaga, M. Serra Mitjans, R. Rami-Porta
Hospital Universitari Mútua Terrassa, Terrassa/ES

Introduction: Video-assisted mediastinoscopic lymphadenectomy (VAMLA) allows a bilateral mediastinal ymphadenectomy from the superior paratracheal to the hilar nodes. Extended cervical mediastinoscopy (ECM) allows to explore the subaortic and the para-aortic nodal stations. In 2010, VAMLA was included in our staging protocol, based on European Society of Thoracic Surgeons (ESTS) guidelines, for patients with normal mediastinum. We aimed to assess: 1) the accuracy of VAMLA+ECM; 2) the rate of unsuspected (u) N2 in a cohort of patients with left-side NSCLC and normal mediastinum by integrated positron emission tomography (PET) - computed tomography (CT).

Methods: Prospective observational single-center study of 229 consecutive VAMLAs and ECM for staging left clinical (c) N0-1 NSCLC from 2010 to 2023. Systematic nodal dissection (SND) performed during lung resection was considered the reference standard test to validate negative VAMLAs and negative ECM. Those patients with negative VAMLA but without lung resection were excluded (n=29). uN2-3 rates were analyzed in the global series and in the subgroups of tumors according to their clinical nodal and tumor categories by PET-CT. Pathologic findings were reviewed, and staging values, calculated using the standard formulas (including 95% confidence interval [CI]).

Results: 200 patients (152 men; median age 60, range 45-86) underwent VAMLA + ECM. A mean of 4,2 nodal stations and a mean of 16.7 lymph nodes (range 6-39) were sampled. Staging values of the whole protocol (VAMLA + ECM) were: sensitivity, 0.89 (95% CI, 0.74-0.95); negative predictive value, 0.97.6 (95% CI, 0.94-0.99); and diagnostic accuracy, 0.98 (95% CI, 0.98-1). The uN2-3 rate for the whole series was 18%. The uN2-3 rates according to presurgical cT and cN categories by PET-CT were: 6.1% (4/65) in cT1N0; 10.1% (6/59) in cT2N0; 10% (2/20) in cT3N0; 40% (4/10) in cT4N0; 45.6% (21/46) in cN1. Complications related to VAMLA occurred in 9/200 (4.5%) patients, being temporary left recurrent laryngeal nerve palsy the commonest, 3/9 (33%).

Conclusions: This clinical protocol for staging NSCLC of the left lung and normal mediastinum by PET-CT demonstrated a high rate of unsuspected N2-3 disease (specially in cN1 and cT4N0) and a high accuracy. With these results, and especially for the mentioned subgroups, it seems recommendable to increase the precision of invasive staging methods (ideally with a bilateral transcervical lymphadenectomy) to identify the best candidates for neoadjuvant treatments.

P2.05.07 The Effect of Adrenal Gland Metastasis on the Course of Lung Cancer

S. Hajiyeva[1], G. Ak[1,2], S. Metintas[1], M. Metintas[1]
[1]Eskisehir Osmangazi University, Medical Faculty, Eskisehir/TR ,[2]Eskisehir Osmangazi University, Eskisehir/TR

Introduction: Approximately half of lung cancer patients already have metastases at diagnosis. The adrenal gland is one of the most common metastatic sites for lung cancer. The aim of this study was to investigate the frequency, characteristics and impact on survival of adrenal metastases in patients with lung cancer.

Methods: A total of 1,253 patients with lung cancer were examined between January 1, 2011 and December 31, 2015. All radiologic examinations (chest CT including upper abdomen, PET-CT, dynamic adrenal CT) of all patients from diagnosis to death were retrospectively reviewed. Adrenal lesions were divided into the groups < 1 cm and ≥ 1 cm at diagnosis. Adrenal lesions were classified as benign or malignant based on the compatibility of clinical and radiologic data. However, adrenal lesions in patients with less than one year of follow-up due to death were assessed as indeterminate lesions. The relationship between adrenal metastases and clinical and survival data was analyzed.

Results: The mean age of the patients ± SD was 63.05 ± 9.54 (33 - 90) years, and 89.2% were male. Of the patients with an adrenal lesion of less than 1 cm, 0.7% (7/971) had adrenal metastases at diagnosis and 6% (59/971) during follow-up. Of the patients with an adrenal lesion of 1 cm or more, 54.6% (154/282) had an adrenal metastasis at diagnosis and 45.4% (128/282) had a benign adrenal lesion. The survival time was 12.0 ± 12.5 (11.0 - 13.0) months in patients without metastases at diagnosis, 10.0 ± 3.1 (4.0 - 16.0) months in patients with metastases only in the adrenal gland and 7.0 ± 0.6 (5.9 - 8.1) months in patients with metastases in the adrenal gland and other organs. The survival of patients without metastases was similar to the survival of patients who only had metastases in the adrenal gland (p=0.119). However, the survival of both patients without metastases and patients who only had metastases in the adrenal gland was longer than that of patients who had metastases in other organs in addition to the adrenal gland (p<0.001 and p=0.002 respectively). On multivariate analysis, the determinants of adrenal metastases at diagnosis were nodular structure of the adrenal lesion (OR; 95%CI: 4.97; 2.10-11.87), SUVmax value ≥ 2.5 (5.57; 3.25-9.53), brain (OR: 3.24; 1.17-8.18), bone (3.87; 1.59-9.43) and pleural metastases (2.55; 1.02-6.38). The variables that predicted malignant or benign adrenal lesions were adrenal lesion size (2.98; 1.33-6.67) and SUVmax (8.25; 5.00-13.61).

Conclusions: Although adrenal metastases are common in lung cancer patients, clinical outcomes are better than for metastases in other organs. Curative treatment approaches can have a positive impact on the survival of patients with adrenal metastases.

P2.05.08 Discordance Between Clinical and Pathological Invasive Size in Early Stage Non-Small Cell Lung Cancer

T. Yun[1], S. Park[1], J.H. Park[1], B. Na[1], C.H. Kang[1], I.K. Park[1], Y.T. Kim[1]
[1]Seoul National University Hospital, Seoul/KR

Introduction: The radiological solid size of part-solid nodules (PSN) is often used to estimate the invasive portion of tumors in non-small cell lung cancer (NSCLC). Consequently, the clinical T stage is defined based on the solid size of PSNs. However, discrepancies between clinical and pathological T staging have been observed. This study aims to analyze the discordance between clinical and pathological staging in NSCLC.

Methods: We retrospectively analyzed early-stage clinical adenocarcinoma lung cancer patients who underwent curative surgery between January 2018 and December 2020. Patients with visceral pleural invasion were excluded. Concordance was defined as matching clinical T stage (based on PSN size) and pathological T stage, while discordance was defined as a mismatch between the two. Among the discordant group, we further classified patients into up-staged and down-staged T status groups. All staging was reviewed according to the ninth edition of the AJCC TNM staging system.

Results: A total of 1,141 patients were included, with 444 (38.9%) in the concordance group and 697 (61.1%) in the discordance group. Among the discordant group, 155 (13.6%) had up-staged T status, and 542 (47.5%) had down-staged T status. Discordance with upstaging was predominantly observed in patients with clinical T1a status. Notably, only pure ground-glass nodules (GGNs) exhibited upstaging discordance. The radiological mean total tumor size in the up-staged group was the largest across all groups, although the solid component size was the smallest (1.9 ± 0.8 cm vs. 1.0 ± 0.9 cm, p < 0.001). The invasive portion's pathological size in the up-staged group was also the largest (1.6 ± 0.9 cm vs. 0.7 ± 0.5 cm and 1.8 ± 0.9 cm, p < 0.001). The acinar type of adenocarcinoma was most frequent in both the concordance and up-staged groups, while the lepidic type was predominant in the down-staged group. Lymphatic invasion was observed in both the concordance and up-staged groups, but none were found in the down-staged group (5.2% vs. 25.8%, p < 0.001). Although the recurrence rate was higher in the up-staged group, no significant difference was found between the concordance and discordance groups (p = 0.004).

Conclusions: Discordance between clinical and pathological staging was particularly notable in pure GGN nodules. For lung nodules close to 2 cm in size, the pathological invasive portion may exceed the radiological solid size, emphasizing the importance of considering both clinical and pathological assessments in staging early-stage NSCLC.

Table. Baseline characteristics

N=1141	Concordance (N=444)	Discordance (N=697)		P value

P2.05.09 Proposed Modification of Clinical T Categorization for Early-Stage Lung Adenocarcinoma:A Data-Driven Multicenter Quantitative Analysis

Q. LI[1], Y. ZHU[2], B-y. Rao[2]
[1]Sun Yat-sen University Cancer Center, Guangzhou/CN ,[2]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou/CN

Introduction: The postoperative survival rate for patients with clinical stage I non-small cell lung cancer (NSCLC) remains unsatisfactory even after complete tumor resection. The current clinical T categorization (cT8) may not be optimized for guiding treatment decisions as it does not take into account the ground-glass opacity (GGO) component. This study aim to improve cT8 by considering GGO component that could further optimize the current treatment protocols of early-stage lung adenocarcinoma (LUAD).

Methods: A total of 1289 patients diagnosed with stage I LUAD were included from three hospitals between 2014 and 2017. The study comprised a discovery cohort (DC: n=830) from center I and three external validation cohorts (EVC1: n=186; EVC2: n=176; EVC3: n=97) from centers II, III, and TCIA, respectively. The optimal thresholds for defining GGO and solid components in CT images were determined by a quantitative CT feature predicting both pathological grade and recurrence-free survival (RFS) using a data-driven quantitative analysis method. A modified clinical T category (cTm) was then derived by adjusting the cT8 of patients based on the feature value. The performances of the cTm in predicting pathological grade and RFS were assessed using the concordance index (C-index).

Results: The optimal attenuation thresholds for identifying GGO and solid components on CT were determined to be -650 HU and -250 HU, respectively. The percentage of solid-mass to total-mass (SM%) was the best predictor of both pathological grade and RFS (C-index=0.704). The cTm was derived by downstaging the patients with SM%<45% and upstaging those with SM%>75%, resulting in significantly enhanced C-indexes compared to cT8 in all external validation cohorts: EVC1 (pathological grade: 0.722 vs. 0.686, p<0.001; RFS: 0.654 vs. 0.629, p<0.001), EVC2 (pathological grade: 0.774 vs. 0.720, p<0.001; RFS: 0.831 vs. 0.724, p<0.001), and EVC3 (RFS: 0.613 vs. 0.539, p<0.001).

Conclusions: The proposed cTm has the potential to more precisely tailor surgical interventions and treatment protocols for early-stage LUAD, thus enhancing the prospects for favorable clinical outcomes.

[1]MAGNA GRAECIA UNIVERSITY, CATANZARO/IT ,[2]Università Cattolica del Sacro Cuore- Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome/IT ,[3]San Raffaele Hospital IRCCS, Milan/IT ,[4]IRCCS National Cancer Institute Regina Elena, Rome/IT ,[5]University of Pisa, Pisa/IT ,[6]San Camillo Forlanini Hospital, Rome/IT ,[7]Humanitas Hospital, Milan/IT ,[8]University of Turin, Molinette Hospital, Turin/IT ,[9]hospital Cochin, Paris/FR

Introduction: The 9thTNM proposal introduced the N2a(single N2 station) and N2b(multiple N2 stations)category as descriptors in stages with nodal involvement and revised the stage groups with new combination of T and N characteristics. However, prognostic factors among these stages are not been investigated yet. Aim of this study is to evaluate different prognostic factors among the new proposed stages.

Methods: Data of patients underwent anatomical surgical resection and lymphadenectomy from 8 centres from 1/1/202015 to31/12/2023 were collected and retrospectively analysed. Only patients with hilar or mediastinal nodal involvement without neo-adjuvant therapy were included. Pathological reports were adapted to the 9thTNM proposal generating the following staging groups: IIB(pT2N1,T1N2a), IIIA(T1N2b,T2-3N2a,T3N1,T4N1), IIIB(T2-3N2b,T4N2a,T4N2b).Pathological factors were correlated to overall survival(OS) and Disease free survival(DFS) using Kaplan-Meier curves.The log-rank test and Cox-regression analysis was used to assess differences between subgroups. The analysis was conducted on the entire population and among the different stages.

Results: The final analysis was conducted on 318 patients. Pathological Stage resulted IIb in108(34.0%),IIIa in168(52.8%) and IIIb in42(13.2%) cases. During follow-up, 132(42.5%) patients experienced a recurrence and 76(20.8%) died. Adenocarcinoma resulted the most frequent histology, resulting in the 67.9% of cases. Pathological T-stage resulted 1 in 137(43.0%),2 in 103(32.4%), 3 in 48(15.1%) and 4 in 30(9,4%) cases, respectively, while pN1 resulted in 138(43.4%) and pN2 in 180(56.6%) patients. Radical mediastinal dissection was performed in 223(70.1%) of cases and Spread through air spaces(STAS) resulted in 64(20.1%) of cases.In the entire cohort, infiltration presence(p=0.008),pN2 (p<0.001),p-stage(p<0.001), total metastatic nodes(p=0.021) and adjuvant therapy resulted significant negative prognostic factors for DFS, while pT(p<0.001), infiltration(p=0.025), vascular invasion (p=0.007), lymphatic invasion (p=0.010),pStage(p=0.002),N2 metastases(p=0.022),total number of metastatic nodes(p=0.044) and adenocarcinoma subtype(p=0.021) significantly correlate with worse OS.Considering the different stages(table),advanced pT stage resulted a significant negative prognostic factor for OS in IIB stages. In stage IIIA, STAS(p=0.022),N2 resected station<3(p=0.041) and N2 metastatic nodes(p=0.046) resulted negative prognostic factors for DFS and lymphatic invasion for OS(p=0.029). In stage IIIB, high grade adenocarcinoma resulted negative prognostic factor for DFS, while pneumonectomy(p=0.019),squamous cell carcinoma (p<0.001),advanced pT(p=0.016), pN2b(p=0.017) and concomitant pN1 involvement(p=0.002) resulted negative prognostic factors for OS.

Conclusions: Our study showed different prognostic factors among the new stages proposed in the new TNM staging system. In this way, it would be possible to stratify the prognosis and plan ad hoc therapies and follow-up schedules tailored on tumor characteristics

P2.05.11 Prognostic Impact of Organ-Specific Metastasis in Non-Small Cell Lung Cancer

W.K. Ryu[1], N. Park[1], H-C. Kim[2], J-S. Ryu[1], J.H. Lim[1]
[1]Inha University Hospital, Incheon/KR ,[2]Inha University College of Medicine, Incheon/KR

Introduction: Prognostic stratification is essential in non-small-cell lung cancer (NSCLC) to guide treatment decisions. While the TNM staging system has evolved to refine the M category based on metastatic burden, it does not account for differences in prognosis based on the specific organ affected. This study evaluates whether incorporating organ-specific metastasis improves prognostic discrimination in stage IV NSCLC.

Methods: We conducted a retrospective cohort study using data from the Korean Central Cancer Registry (2014-2018). Patients with stage IV NSCLC were classified according to the 9th edition TNM classification: M1b (single-organ, single metastasis), M1c1 (multiple metastases within a single organ), and M1c2 (multiple organ metastases). Survival outcomes were compared across groups using Kaplan-Meier analysis and Cox proportional hazards modeling.

Results: Among 3,165 patients, 56.5% had single-organ metastases, while 43.5% had multiple organ metastases. Median overall survival (OS) was longest in M1b (8.0 months), followed by M1c1 (6.0 months), and shortest in M1c2 (5.9 months) ($p < 0.001$). However, survival varied by metastatic organ. Liver, adrenal, and uncommon-site metastases were associated with significantly worse OS, even among M1b patients. Some M1b and M1c1 patients with high-risk organ metastases had worse survival than M1c2 patients, challenging the TNM-defined prognostic hierarchy.

Conclusions: The current TNM M category does not fully capture the prognostic impact of metastatic organ involvement. Incorporating organ-specific metastases into staging and prognostic models could refine risk stratification and improve personalized treatment approaches for stage IV NSCLC.

P2.05.12 Lymph Node Pathologic Grading Strategy: Under the Backdrop of the IASLC Grading System for Invasive Lung Adenocarcinoma

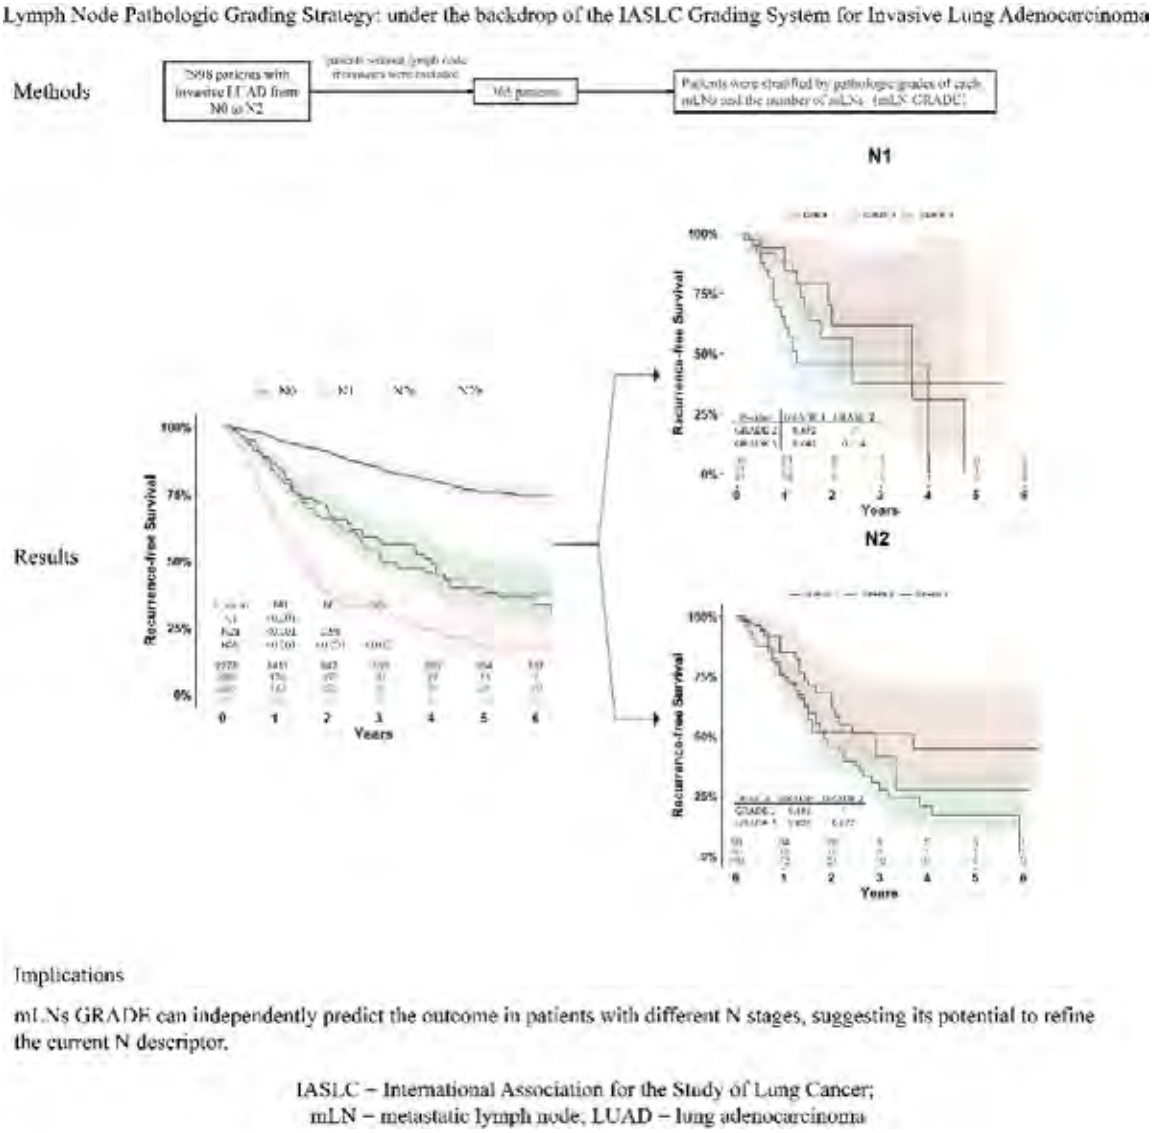
C. Deng
Fudan University Shanghai Cancer Center, Shanghai/CN

Introduction: We aimed to probe into the pathologic grading system in metastatic lymph nodes (mLNs) based on the IASLC grading system for supplementing the accuracy of N staging in patients with lung adenocarcinoma (LUAD).

Methods: From 2011 to 2021, a large cohort of 2998 patients with invasive LUAD were analyzed and classified according to their N stages. Patients were further stratified according to different pathologic grades for each mLN as well as the quantity of mLNs, which we named GRADEs. And we performed survival analysis to reveal the association between GRADEs and long-term outcomes.

Results: The prognostic differences between N categories were highly significant in terms of recurrence-free survival (RFS). High mLNs GRADE was robustly correlated with higher pathologic grade ($p < 0.001$) in primary tumors, higher p-TNM stage ($p < 0.001$), and worse RFS in patients with different N stages. High mLNs GRADE was linked to higher EGFR mutation ($p = 0.021$) in N1 patients, but not in N2 patients. Multivariate analysis revealed the independent prognostic significance of high mLNs GRADE, correlating with adverse outcomes in both N1 and N2 patients.

Conclusions: High mLNs GRADE is significantly associated with worse outcomes in patients with different N stages. mLNs GRADE may help supplement the current N descriptor.



Keywords: Lung adenocarcinoma, Lymph node, Grading system

P2.05.13 M1a With Pleural or Pericardial Effusion Have Worse Survival Than Those With Pleural or Contralateral Lung Metastasis When Receiving EGFR-TKIs

X. Chen[1,2], W. Li[2], Z. Li[2], H. Du[2], X. Wang[1,2], S. Ren[1,2], F. Wu[1,2]
[1]Tongji university School of Medicine, Shanghai/CN ,[2]Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: The M1a descriptors for non-small cell lung cancer (NSCLC) remain unchanged since 7th TNM staging classification. However, the data from the International Association for the Study of Lung Cancer (IASLC) Staging Project was limited in sample size and uniformity of treatment modalities and lines of treatment. The objective of this study was to evaluate the clinical outcome of NSCLC patients undergoing epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) in first-line setting with IVA staging across the different M1a descriptors and M1b descriptors, according to the 9th edition TNM staging manual.

Methods: An electronic medical record search was performed at Shanghai Pulmonary Hospital between Jan 2021 and Dec 2023. NSCLC Patients with IVA staging receiving first-line EGFR-TKIs were analyzed within this retrospective study. The Kaplan-Meier methods were used to evaluate the effect of the different M1a descriptors and M1b descriptors on progression-free survival (PFS) and overall survival (OS).

Results: In total, 450 NSCLC patients with EGFR mutations were evaluated. patients were classified into four groups, including tumors presenting with: 1) pleural or pericardial nodules without effusion ("M1a-Pleural", N=57), 2) contralateral pulmonary nodules with/without pleural or pericardial nodules ("M1a-Contralateral", N=54), 3) pleural or pericardial effusion with/without other M1a descriptors ("M1a-Effusion", N=216), 4) single metastatic lesion in one organ ("M1b", N=123). 274 patients (60.8%) were female and 74 (16.4%) were current or former smokers, with a median age 61 years (range, 19 - 88). Kaplan-Meier survival analyses showed that inferior PFS and OS was observed in patients with M1a-Effusion compared with those with M1a-Pleural (P < 0.001 and P = 0.009, respectively) or M1a-Contralateral (P = 0.016 and P = 0.014, respectively), while sharing a similar prognosis with patients with M1b disease (P = 0.230 and P = 0.130, respectively). Besides, patients with M1a-Pleural had better PFS than those with M1a-Contralateral (P = 0.046), though not significant statistically in OS (P = 0.830).

Conclusions: EGFR-mutated NSCLC patients with pleural, pericardial effusion had similar PFS and OS with M1b disease when treated with EGFR-TKIs, while worse than those with pleural, pericardial or contralateral pulmonary nodules without effusions. These findings may be taken into consideration for the next edition NSCLC staging guidelines.

P2.05.14 Clinical Versus Pathological T Staging in Lung Adenocarcinoma: Discrepancies and Prognostic Implications

L. Yang
Peking Union Medical College Hospital, Beijing/CN

Introduction: Accurate T staging plays a critical role in the management of lung adenocarcinoma, guiding surgical decisions and adjuvant therapy. While pathological T staging is regarded as the gold standard due to its basis in direct tissue examination, clinical T staging based on CT imaging is the primary reference in preoperative settings. However, discrepancies between clinical and pathological assessments are frequently observed and may lead to inappropriate treatment strategies. Despite previous investigations, large-scale studies systematically evaluating these discrepancies and their prognostic implications remain limited.

Methods: This retrospective study included 10,274 patients with resected invasive lung adenocarcinoma from a single tertiary center between 2015 and 2024. Preoperative CT reports and postoperative pathology records were reviewed to obtain tumor size and T stage data. Clinical and pathological measurements were compared to assess agreement in tumor diameter and T classification. A subset of 3,656 patients with available follow-up data was included for survival analysis. The predictive performance of clinical and pathological staging in relation to overall survival (OS) and disease-free survival (DFS) was assessed using Kaplan-Meier curves, log-rank tests, and concordance indices.

Results: Clinical tumor measurements derived from CT were generally larger than those obtained from pathology (mean: 1.80 cm vs. 1.49 cm). Although the two were strongly correlated ($r = 0.806$, $p < 0.001$), the regression line deviated from the identity line, indicating a systematic overestimation by CT. Accordingly, clinical T staging showed a general trend toward overclassification, with only moderate agreement compared to pathological staging ($\kappa = 0.30$). ROC analysis evaluating the ability of clinical T stage to predict pathological T stage revealed a bimodal pattern of performance: predictive accuracy was relatively higher in advanced tumors (T2b-T4), lowest in intermediate stages (T1b-T2a), and modest in early-stage tumors (T1a). Survival analysis further evaluated their prognostic utility, showing that clinical T staging provided slightly better risk stratification in early-stage disease, whereas pathological T staging demonstrated modestly greater prognostic separation in advanced-stage tumors.

Conclusions: Discrepancies between clinical and pathological T staging reflect both biological factors, such as lung tissue shrinkage and tumor heterogeneity, and technical differences in imaging and pathological processing. Although these inconsistencies exist, each staging method offers complementary strengths at different disease stages. Recognizing their respective advantages may improve the accuracy of preoperative assessment and enable more individualized, biology-informed treatment strategies for patients with lung adenocarcinoma.

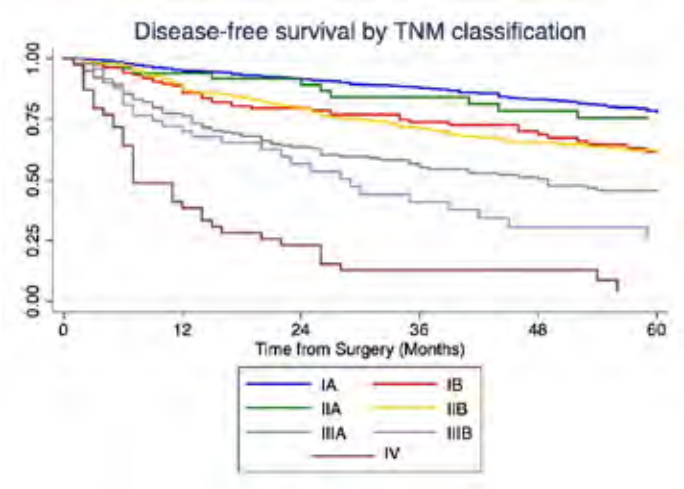
P2.05.15 Management-Oriented Classification of Lung Neuroendocrine Tumors Based on a French Surgical Cohort of 1,915 Patients From the EPITHOR Database

R. Vergé[1], L. Brouchet[1], P-B. Pages[2], P-E. Falcoz[3], P-A. Thomas[4]
[1]Toulouse University Hospital, Toulouse/FR ,[2]Dijon University Hospital, Dijon/FR ,[3]Strasbourg University Hospital, Strasbourg/FR ,[4]North Hospital Aix-Marseille University, Marseille/FR

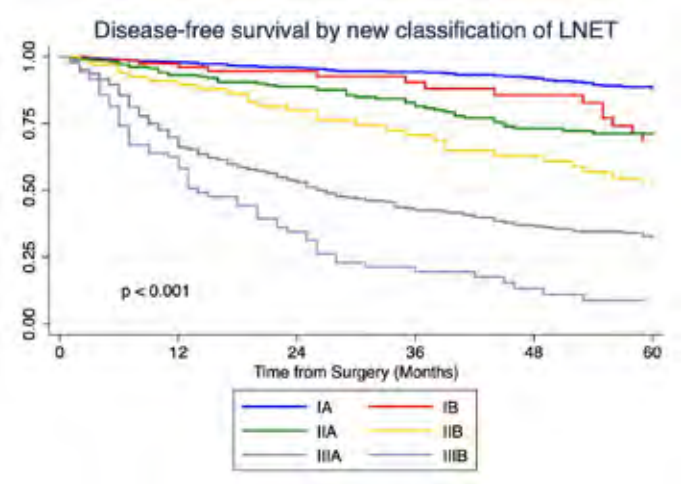
Introduction: Lung neuroendocrine tumors (LNET) are rare malignancies with heterogeneous management, as current strategies are not guided by the TNM classification used for other lung cancers. This study aimed to develop a histopronostic classification capable of predicting survival and recurrence in patients with LNET.

Methods: We conducted a retrospective multicenter study using data from the French national thoracic surgery registry, EPITHOR. The study included French patients who underwent anatomic lung resection or bronchial sleeve resection for LNET (typical carcinoid, atypical carcinoid, and large-cell neuroendocrine carcinoma, excluding small-cell lung carcinoma [SCLC]) between 2008 and 2019. Patients without available pathology reports were excluded. Uni- and multivariable analyses were performed to identify factors predictive of disease-free survival, followed by a recursive partitioning analysis to develop our classification system.

Results: A total of 1,915 patients were analyzed, with extended follow-up and recurrence-free survival data available for 1,406 patients.Our study confirmed that the TNM classification is inadequate for predicting survival in LNET, as some earlier-stage tumors exhibited poorer outcomes than those classified at higher stages.



We established our new classification, based on histological type, tumor size, lymph node involvement, and the proliferation marker Ki-67. The proposed classification is as follows: Stage IA: Typical carcinoid with Ki-67 ≤ 5% Stage IB: Typical carcinoid with Ki-67 > 5% Stage IIA: Atypical carcinoid with tumor size < 4 cm Stage IIB: Atypical carcinoid with tumor size ≥ 4 cm Stage IIIA: Large-cell neuroendocrine carcinoma without mediastinal lymph node involvement (N0 or N1)Stage IIIB: Large-cell neuroendocrine carcinoma with mediastinal lymph node involvement (N2). This classification demonstrated strong discriminatory power for both overall survival and recurrence-free survival(p<0.001).



Conclusions: Our classification system effectively predicts survival and recurrence in patients undergoing surgery for non-SCLC LNET. We propose its implementation in clinical practice to guide surveillance strategies and optimize patient management.

P2.05.16 Comparative Discriminative Performance of Number-Based and 9th Edition N Classifications in NSCLC: Exploring Statistically Valid Cut-offs

J.Y. Kim[1], J.K. Yun[1], G.D. Lee[1], S. Choi[1], H.R. Kim[1], Y-H. Kim[1], D.K. Kim[1], S-I. Park[1], Y. Kwon[1], D. Kim[1]
[1]Asan Medical Center, Seoul, Seoul/KR

Introduction: The 9th edition of the TNM classification for non-small cell lung cancer (NSCLC) revised the N stage and demonstrated improved prognostic stratification. Interest in number-based N classifications (nN, based on the count of positive lymph nodes) has persisted; however, prior proposals often lacked statistically grounded thresholds. This study aimed to define such thresholds and compare the discriminative ability of the nN classification with that of the 9th edition N stage.

Methods: We retrospectively analyzed NSCLC patients (TanyN0-2bM0) who underwent pulmonary resection between 2005 and 2022. A validation cohort (35%) was randomly selected with stratification by the 9th N stage, and the remaining 65% comprised the training cohort. In the training cohort, all integer threshold combinations were tested to define four nN classes. Combinations showing significant overall survival differences in pairwise log-rank tests were further evaluated using multivariable Cox proportional hazards (PH) models. Final thresholds were selected based on the lowest Akaike Information Criterion (AIC). The nN classification was compared with the 9th N stage using AIC, concordance index (C-index), and integrated discrimination improvement (IDI) in both cohorts.

Results: The training and validation cohorts included 4,802 and 2,586 patients, respectively. Optimal thresholds for the nN classification were 1 and 4, classified four classes: class 0 (0 positive nodes), class 1 (1), class 2 (2-4), and class 3 (≥5). Cox PH models confirmed significant survival differences across all adjacent classes, except class 1 vs. 2 in the validation cohort (p = 0.054).Compared with the 9th N stage, the nN classification showed comparable discrimination. In the training cohort, nN had a slightly lower AIC (17,703.27 vs. 17,726.96) and a higher C-index (0.7569 vs. 0.7539). In the validation cohort, AIC values were nearly identical (nN: 8,843.61; 9th N: 8,843.71), and the C-index was slightly higher for the 9th N stage (0.7368 vs. 0.7345). The IDI values, using the 9th N stage as reference, were 0.00243 at 36 months and -0.00294 at 60 months, indicating minimal overall difference.

Conclusions: The nN classification provided appropriate discriminatory performance and, in some metrics, outperformed the 9th N stage. However, differences were modest, supporting the continued validity of the 9th N stage. Future TNM revisions may benefit from incorporating number-based approaches, particularly in evaluating single-node metastasis.

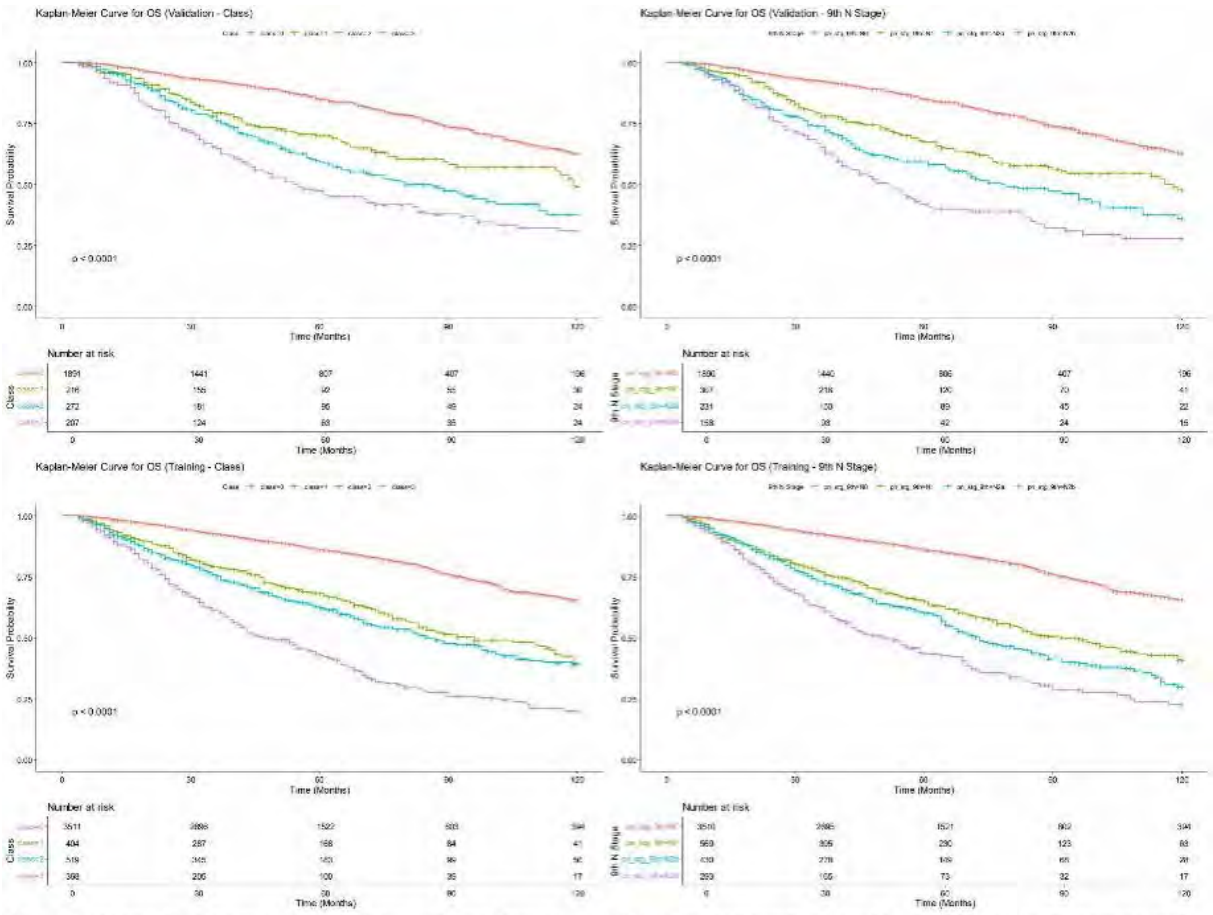

Figure 1. Kaplan–Meier curves for overall survival according to the 9th N stage and number-based N classification in the training and validation sets.

P2.05.17 European Single-Center Validation of the 9Th TNM Staging System in Over 3,300 Surgically Treated NSCLC Patients

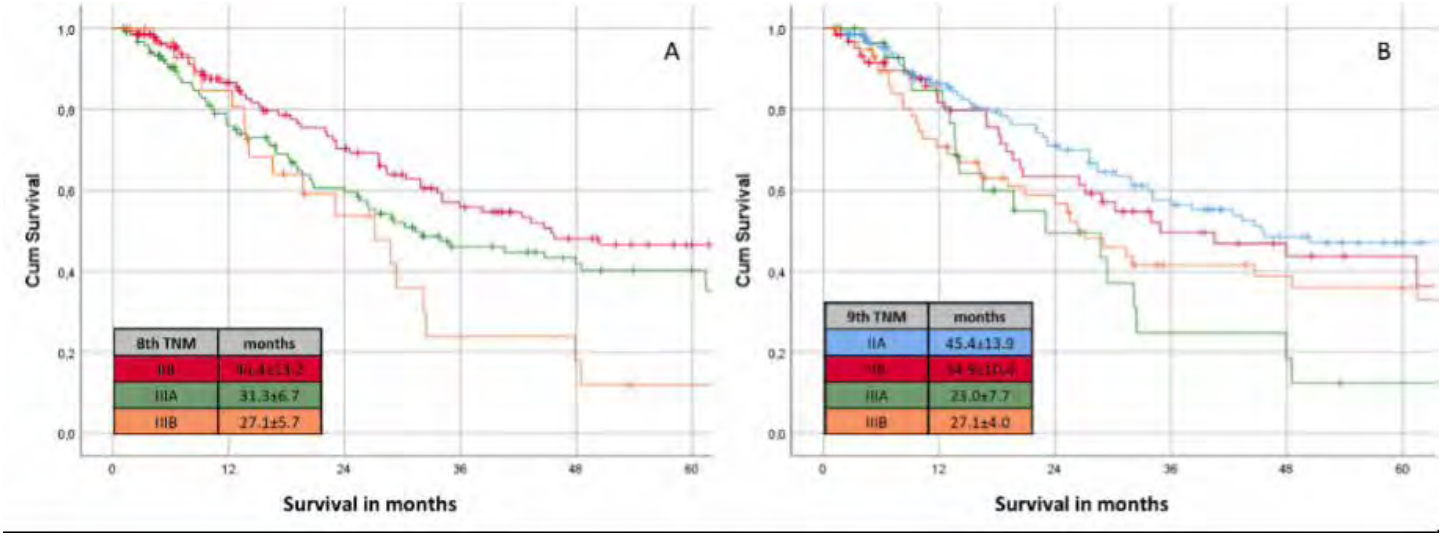
I. Schott[1,2], N. Achilleos[1,2], F. Doerr[1,2], K. Grapatsas[1,2], N. Baldes[1,2], C. Taube[1,2], D. Theegarten[2,3], N. Guberina[2,4], M. Stuschke[2,4], M. Wiesweg[2,5], M. Schuler[2,5], S. Bölükbas[1,2]
[1]University Medical Center Essen, Ruhrlandklinik, West German Cancer Center, University Duisburg-Essen, Essen/DE ,[2]National Center for Tumor Diseases (NCT), NCT West, a partnership between University Hospital Essen, University Duisburg-Essen, University Hospital Köln, University Köln, and DKFZ, Essen/DE ,[3]University Medical Center Essen, West German Cancer Center, University Duisburg-Essen, Institute of Pathology/DE ,[4]University Medical Center Essen, West German Cancer Center, University Duisburg-Essen, Essen/DE ,[5]University Medical Center Essen, West German Cancer Center, University Duisburg-Essen, Essen/DE

Introduction: IASLC recently introduced the 9th TNM-staging system for NSCLC. This study externally validates the new edition and compares its discrimination power with the previous 8th edition on a large European single-center database.

Methods: A retrospective analysis was conducted on stage I-IIIB patients who underwent anatomical resection and systematic lymph node dissection for NSCLC between 2010 and 2022 at a large European center certified for lung cancer treatment. All patients were treated over time according to applicable guidelines. Overall survival analysis by TNM stages was compared using the Kaplan-Meier method. Akaike Information Criterion (AIC), R2-measure and Concordance index (C-index) were used to compare the predictive ability between the 8th and 9th edition of the TNM-staging system.

Results: A total of 3,313 patients were included in this study. The patients' mean age at time of surgery was 65.6±9.7 years. 61.4% were male patients. The stage of 91.4% of patients (IA: n=1,282; IB: n=513; IIA: n=170; IIB: n=539; IIIA: n=447; IIIB: n=76) remained unchanged according to both TNM-staging systems. Due to the newly introduced changes to the N descriptor, 225 patients (6.8%) were down-staged according to the new TNM-staging system (IIB/IIA: n=134; IIIA/IIB: n=60; IIIB/IIIA: n=31). However, 61 patients (1.8 %) required up-staging from stage IIIA to IIIB. Both TNM-staging systems exhibit comparable predictive power and accuracy for the overall survival of NSCLC patients [8th versus 9th edition AIC: 21,733 vs. 21,146; R2: 0.362 vs. 0.417; C-index (p-value): 0.625 (0.002) vs. 0.627 (0.002)]. This finding remains valid even when analyzing only patients who were either down- or up-staged. In these cases, no significant long-term survival differences were observed.

Conclusions: This study externally validates the 9th TNM-staging system on a large European single-center database. The newly introduced changes to the N-descriptor do not appear to have any significant influence on its prognostic accuracy.



The figure shows the Kaplan-Meier curves of NSCLC patients who were either down- or up-staged according to the 8th edition (A) and 9th edition (B) of the TNM-staging system.

P2.06.01 Prognostic Value of a Combined Model Using CT and PET/CT Parameters for Predicting STAS in Stage I Lung Adenocarcinoma

K.S. Beck[1], Y.E. Sung[2], J.I. Jung[2], I.R. Yoo[2]
[1]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul/KP ,[2]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul/KR

Introduction: This study aimed to develop an imaging-based tumor spread through airspaces (STAS) prediction model using CT and PET/CT and assess its prognostic utility in stage I lung adenocarcinoma.

Methods: 453 patients with pathological stage I lung adenocarcinoma who underwent curative pulmonary resection were retrospectively analyzed. The predictive performance of consolidation-to-tumor ratio (CTR) on chest CT and tumor-to-liver ratio (TLR) on PET/CT for STAS was assessed using receiver operating characteristic (ROC) curve analysis. Kaplan-Meier survival analysis and Cox proportional hazards models were used to evaluate the prognostic significance of STAS, individual imaging parameters, and the proposed combined imaging-based risk model. Associations between the imaging-based risk stratification and established pathological prognostic factors, such as histological grade and lymphovascular invasion (LVI), were also investigated.

Results: STAS was identified in 92 (20.3%) patients and was significantly associated with higher pathological tumor stage ($p < 0.001$), aggressive histologic features, including Grade 3 tumors ($p < 0.001$), and higher rates of LVI ($p < 0.001$). Both CTR (AUC 0.745, cutoff 0.841, sensitivity 77.2%, specificity 68.1%) and TLR (AUC 0.641, cutoff 1.057, sensitivity 67.1%, specificity 72.4%) demonstrated significant predictive ability for STAS. Patients were categorized into four groups based on CTR and TLR cutoffs: G1 (TLR low & CTR low), G2 (TLR low & CTR high), G3 (TLR high & CTR low), and G4 (TLR high & CTR high). Kaplan-Meier analysis revealed that DFS significantly differed among these groups ($p < 0.001$), with no survival difference between G1 and G2 ($p = 0.359$). In multivariate analysis, both the TLR high & CTR low group (HR 8.036, $p = 0.030$) and the TLR high & CTR high group (HR 9.814, $p = 0.006$) remained independent predictors of poor DFS. Additionally, higher imaging-based risk groups correlated with increased Grade 3 tumors ($p < 0.001$) and LVI positivity ($p < 0.001$).

Conclusions: STAS prediction using preoperative CT and PET/CT can provide clinically relevant prognostic insights. The proposed imaging-based risk stratification model, integrating CTR and TLR, effectively identified patients at high risk of recurrence. This model may facilitate individualized treatment strategies, including consideration for more aggressive therapy in high-risk patients.

P2.06.02 Invading Through External Elastic Lamina Is Predictive of Poorer Outcomes in Pulmonary Non-Mucinous Invasive Adenocarcinoma

C. Chiang[1], Y.C. Yeh[2], T.Y. Chou[1], Y-C. Wu[1], P-K. Hsu[2], H-T. Lee[1]
[1]Taipei Medical University Hospital, Taipei/TW ,[2]Taipei Veterans General Hospital, Taipei/TW

Introduction: Visceral pleural invasion (VPI) of lung cancer is defined as involvement by tumor cells into the elastic laminae of visceral pleura. In both AJCC staging system and CAP cancer protocol, VPI is classified as below: PL-0 for tumors that do not invade the elastic lamina; PL-1 for tumors that invade the elastic lamina but not up to the pleural surface; PL-2 for tumors that invade up to the pleural surface without involvement of adjacent anatomic structures; and PL-3 for tumors that invade the parietal pleura; staging of tumors smaller than 3 cm in size will be upgraded from T1 to T2 if VPI (PL-1 or PL-2) is present. Currently, it is recommended that tumor cell penetration through the thickest and outmost (external/outer) elastic lamina, rather than the internal/inner elastic lamina, serves as the criterion for diagnosing VPI. Nevertheless, there is scarce evidence supporting this recommendation. This study aims to explore the clinical significance of lung cancer invading through internal versus external elastic lamina of visceral pleura with real world experiences.

Methods: We retrospectively reviewed clinicopathological characteristics of 1,217 patients with surgically resected non-mucinous invasive adenocarcinoma at Taipei Veterans General Hospital, Taiwan, between 2011 and 2016. With the scheme of two-layered elastic laminae, VPI was categorized into PL-n (no pleural invasion; tumor involvement beneath internal elastic lamina), PL-i (tumor invading into or beyond internal elastic lamina and beneath external elastic lamina), PL-e (tumor invading into or beyond external elastic lamina but not reaching parietal pleura), and PL-p (tumor invading through elastic laminae and reaching parietal pleura). We analyzed the relationship between categories of VPI and prognosis, along with other pertinent clinical and histopathological parameters.

Results: The 5-year overall survival rates were 89.7% for patients with PL-n, 89.5% for PL-i, 71.3% for PL-e, and 53.3% for PL-p, while 5-year recurrence-free survival rates were 88.1%, 85.8%, 55.8%, and 48.6%, respectively. PL-e showed significant differences in univariate analyses in overall survival analysis whereas in disease-free survival analysis, PL-e showed significant differences in both univariate and multivariate analyses.

Conclusions: Tumor cells invading into or beyond external elastic lamina (PL-e) was a significant prognostic factor for recurrence and associated with worse overall survival for pulmonary non-mucinous invasive adenocarcinoma, compared to tumor cells invading beneath external elastic lamina (PL-i). This study provides evidence supporting the use of external elastic lamina penetration as the landmark to classify pleural invasion in current clinical practice.

P2.06.03 Diagnostic Performance of Frozen Section in Determining Histological Patterns and Spread Through Air Spaces in Lung Adenocarcinoma

H. Si[1], H. Xie[1], L. Xu[1], H. Su[1], X. Xie[1], J. Fan[2], N. Xu[3], Y. Zhang[4], D. Zhao[1], C. Chen[1]
[1]Shanghai Pulmonary Hospital, Shanghai/CN ,[2]The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang/CN ,[3]Anhui Provincial Chest Hospital, Hefei, Anhui/CN ,[4]Shandong Public Health Clinical Center, Jinan, Shandong/CN

Introduction: Precise frozen pathology reports are vital to guide surgical decision-making on sublobar resection and lymphadenectomy selection. We aim to evaluate the accuracy of intraoperative frozen section (FS) in determining the histological patterns and spread through air spaces (STAS) among patients with lung adenocarcinoma.

Methods: In this post-hoc analysis of a randomized, phase 3 trial (STAR 001), patients with invasive peripheral lung adenocarcinoma ≤ 2 cm were randomly assigned to undergo segmentectomy or lobectomy following intraoperative confirmation of micropapillary (MP) and/or solid (S) patterns ≤ 5% by FS. Patients who were excluded due to invasive adenocarcinoma with MP and/or S pattern ≥ 5% by FS diagnosis were also included for post-hoc analysis. The primary outcome was the concordance between FS and final pathology (FP) diagnoses. Fleiss' kappa coefficients were employed to evaluate the inter-observer agreement among three pathologists for pathological diagnosis on FS.

Results: The post-hoc analysis evaluated a consecutive cohort of 900 invasive non-mucinous lung adenocarcinomas. The study population consisted of 645 eligible cases enrolled in STAR001 trial and 255 cases excluded based on MP and/or S patterns exceeding 5% by FS. All subjects were prospectively collected across 13 medical centers in China from August 2019 to December 2023. The best sensitivity for diagnosing the predominant pattern and presence of pattern was 89.6%, and 96.2% in acinar pattern, respectively. While highest specificity for identifying the presence of certain subtype was 93.8% in the evaluation of papillary pattern. The presence of complex glands pattern diagnosed by FS was an independent factor for the discrepancy between FS and FP. Remarkable consistency was demonstrated among the three pathologists in determining the predominant histological pattern on FS, with a kappa value of 0.846. Furthermore, substantial agreement among three pathologists for diagnosing the presence of each certain histological pattern on FS was revealed with all corresponding pattern-specific kappa value exceeding 0.7. The overall accuracy, sensitivity, and specificity of STAS diagnosis on FS were 89.6%, 70.4%, and 95.6%, respectively, with substantial inter-observer agreement (Fleiss' κ=0.707) among three pathologists. (Table 1)

Conclusions: FS demonstrated a favorable concordance in diagnostic accuracy and satisfactory interobserver agreement for intraoperative diagnosis of histological subtypes and STAS. FS may provide surgeons with valuable insights for optimal surgical decision-making.

Table 1. Diagnostic performance of frozen sections on presence of certain histologic pattern, predominant histologic pattern and spread through air spaces in comparison to final pathology.

Patterns	Accuracy	Sensitivity	Specificity	PPV	NPV	Kappa value between FS and FP[1]	Inter-observer Fliess Kappa value[2]
Presence of certain histologic pattern

P2.06.04 Artificial Intelligence-Led Characterisation of Lethal Morphologies in Lung Adenocarcinoma

K. Rakovic[1,2,3], N. Poulain[2], F. Ballantyne[2], C. Ficken[2], S. Martinelli[2], L. Officer-Jones[2], R. Pennie[2], I. Powley[2], K. Yuan[1,2], J. Le Quesne[1,2,3]
[1]University of Glasgow, Glasgow/GB ,[2]CRUK Scotland Institute, Glasgow/GB ,[3]Queen Elizabeth University Hospital, Glasgow/GB

Introduction: Histopathological grade is the cornerstone of pathological prognostication in lung adenocarcinoma (LUAD). Grade is a quantitative assessment of architectural patterns, but neglects a wealth of information encoded in the tissue such as the tumour microenvironment. Identifying novel morphological markers of risk is time-consuming, given the need for explicit definition of features of interest a priori and substantial manual effort required for the human observer to encode them. Self-supervised artificial intelligence, as applied to histopathological whole slide images (WSIs), has the potential to democratise histopathology and gives us the ability to identify recurrent morphological patterns in WSIs without an up-front hypothesis or human annotation.

Methods: We apply a self-supervised learning pipeline, histomorphological phenotype learning, to a highly characterised set of 4427 WSIs from 1007 patients with surgically resected primary LUAD. This gives us a library of morphological clusters spanning the morphological variance in the dataset. We encode the frequency of each cluster at the patient level and statistically link these to outcome and clinicopathological variables. Each cluster can be interpreted by a pathologist, and given a qualitative description.

Furthermore, we align these clusters to WSIs of tissue microarrays, allowing us to interrogate the local biology underpinning them. This allows us to add a volume of regional molecular signatures to our cluster library.

Results: We discovered 71 clusters which not only independently recapitulate known architectural patterns used in grading but also spotlight variant epithelial and stromal patterns. We group clusters into superclusters, defined by their lymphocyte density and tendency for epithelial discohesion.

In a univariate five-fold cross-validated Cox regression model using supercluster frequency, this achieves an internal test c-index of 0.6-0.65 and 0.61-0.62 in an external cohort (The Cancer Genome Atlas LUAD), exceeding the prognostic power of grade.

Immune-cold discohesive patterns are linked to adverse prognosis in a five-fold cross-validated multivariate Cox regression model (hazard ratio 1.17, 95% CI 1.06-1.28 $p < 0.001$) after adjusting for age, sex, grade and stage. These regions are high in extracellular matrix proteins such as collagen-1A. Immune-hot discohesive patterns are enriched in patients with PD-L1-positive tumours ($p < 0.01$). Additionally, we link the frequency of specific clusters to sex and driver mutations.

Conclusions: We present an unsupervised analysis of tumour morphology in LUAD, identifying under-recognised histopathological features strongly related to outcome. Many of these lethal appearances are of predominantly acinar architecture, highlighting an opportunity to refine the current clinical gold standard.

P2.06.05 Diagnosis of the Novel IASLC Grading System Using Intraoperative Frozen Section: A Prospective Multi-Center Trial

F. Fu, H. Chen, Y. Zhang
Fudan University Shanghai Cancer Center, Shanghai/CN

Introduction: The International Association for the Study of Lung Cancer (IASLC) recently proposed a novel grading system for invasive non-mucinous lung adenocarcinoma. This study aimed to assess the accuracy of intraoperative frozen section (FS) in diagnosing IASLC grades in early-stage lung adenocarcinoma and to identify factors associated with misdiagnosis.

Methods: This prospective, multi-center clinical trial (ECTOP-1014) was conducted from July 2022 to August 2023. The diagnoses of new grades were based on the newest grading system released by IASLC. FS diagnoses were compared with final pathology (FP) to evaluate diagnostic concordance. Logistic regression analysis was performed to identify predictors of FS misdiagnosis.

Results: The overall concordance rate between FS and FP for IASLC grading was 79.9%, with a weighted kappa of 0.627, indicating good agreement. Lepidic and micropapillary predominant patterns were independently associated with misdiagnosis of grades using FS ($P < 0.001$). Interobserver agreement among pathologists was excellent ($\kappa = 0.821$). Incorporating FS into a predictive model for Grade 3 tumors improved the Area Under the Curve to 0.907.

Conclusions: FS provides a reliable intraoperative assessment of IASLC grades and may aid in surgical decision-making. However, specific histological patterns, such as lepidic and micropapillary, are associated with increased misdiagnosis rates. Further studies are needed to validate these findings and assess the impact of FS-guided decisions on patient outcomes (NCT05794698).

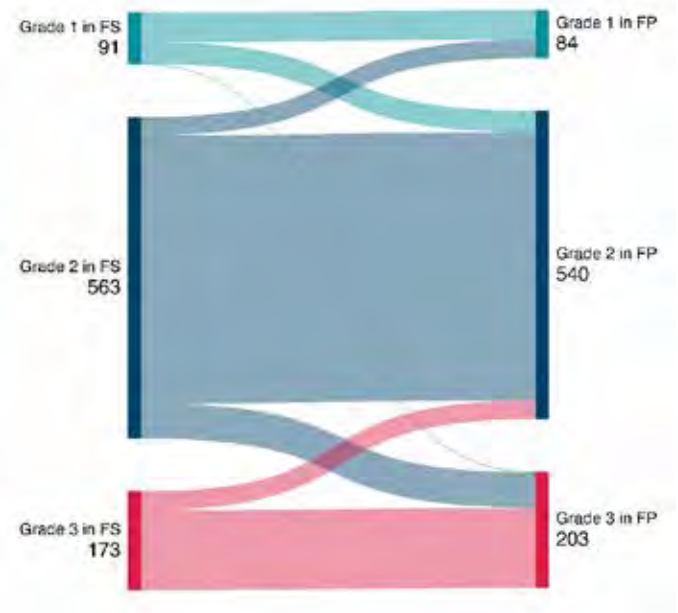

Table 1. The diagnosis of frozen section and final pathology for the IASLC grading system

IASLC grades by FP	IASLC grades by FS, n (%)			Sensitivity	Specificity	Accuracy
	Grade 1	Grade 2	Grade 3			
Grade 1 (N=84)	52 (57.1)	32 (5.7)	0 (0.0)	61.9%	94.8%	91.4%
Grade 2 (N=540)	38 (41.8)	469 (83.3)	33 (19.1)	86.9%	67.2%	80.0%
Grade 3 (N=203)	1 (1.1)	62 (11.0)	140 (80.9)	69.0%	94.7%	88.4%

P2.06.06 Bronchiolar Adenoma With Malignant Transformation? New Insights Based on Morphologic, Immunophenotypic, and Genomic Analysis of 13 Cases

Y. Huang[1], C. Wu[1], L. Hou[1], Z. Dong[1], J. Lin[1], W. Chen[1], S. li[1]
[1]Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai/CN

Introduction: In the wide histomorphological spectrum of BAs, it is confusing to pathologists whether there is a close relationship between BAs and lung cancer. Herein, we describe a series of BA with concurrent other lung cancer in the same lesion and to investigate the potential relationship between BA and tumours.

Methods: We described the histomorphological, immunohistochemical and molecular features of 13 cases of bronchiolar adenoma (BA)-like lesions, including four classic BAs, eight mixed type BAs, and one BA-like lesion with malignant transformation to adenocarcinoma (BLMTA). The different components in the mixed type BAs and BLMTA were enriched using the Millisect system. Whole exome sequencing (WES) was performed on the different components.

Results: Of these 13, four were classic distal type BAs with bilayered architecture, eight cases exhibited partial classic bilayered, leaving a monolayer of cuboidal epithelial cells in some areas (mixed type BAs), furthermore, the monolayered areas were diagnosed as AIS (n=4), MIA (n=2), and adenocarcinoma (n=2) base on the histological features. Of note, we also identified one case was composed of homogeneous cuboidal cells with cellular atypia in the BA-like region and cuboidal cells with apocrine secretion in the monolayered adenocarcinoma component (i.e. BLMTA). Immunohistochemical analysis revealed that the TTF1 expression of the luminal cells and basal cells of the bilayered regions of the mixed type BAs and the BLMTA is more heterogeneous than that in monolayered tumour components. Basal cells of BA-like regions expressed p40 continuously. The hotspot map and phylogenetic analysis displayed a distinct difference between the BA and tumour components and there were no branched driver mutations in the two components of the mixed type BAs. However, the two components of the BLMTA shared 459 common gene mutations, including EGFR G719C, TP53, ERBB2, and so on, while the branch driver gene EGFR S768I was only observed in the BA-like component.

Conclusions: Our study demonstrated that BAs and lung adenocarcinoma are entirely distinct entities based on histomorphological, immunohistochemical, and molecular features. BLMTA may represent either a BA-like lesion with malignant transformation potential or a common adenocarcinoma with unique morphological characteristics.

P2.06.08 ERBB2 Mutations in Non-Small Cell Lung Cancer - Findings From a Large UK Cohort

L. Williams[1], C. Gemma[2], B. Poskitt[2], K. Balbi[2], P. Bennett[2], D.A. Moore[3]
[1]University College London Hospitals NHS Trust, London/GB ,[2]Sarah Cannon Molecular Diagnostics, London/GB ,[3]University College London, London/GB

Introduction: ERBB2 driver mutations are reported in a small fraction of NSCLCs and are amenable to emerging targeted therapies. The rate of ERBB2 mutations has been reported between 1 and 6% in various cohorts. The aim of this project was to determine the frequency of ERBB2 driver mutations in a large retrospective cohort of NSCLCs tested by targeted NGS, predominantly representing samples from the UK's universal 'National Health Service'. There is also limited published data to suggest that certain lung adenocarcinoma morphological patterns of growth may be associated with ERBB2 mutation. Histology was available from a majority of samples and this was reviewed to determine whether particular morphologies were enriched in ERBB2 mutant NSCLC within this cohort.

Methods: The archival database of a molecular diagnostics laboratory, largely serving London and South East England, was interrogated. Samples underwent somatic variant analysis using a custom-built next generation sequencing panel, which included the relevant exons in ERBB2. All samples from patients with a diagnosis of NSCLC which were successfully sequenced were included in the retrospective cohort. All variants classified as being pathogenic from the cohort were exported and full details were extracted for those with ERBB2 mutations.

Results: 4862 NSCLC samples were successfully sequenced over a 5-year period, encompassing 2019-2023 inclusive. 57 ERBB2 mutations were identified within this cohort, representing a mutation rate of 1.2%. 39 Of the 57 ERBB2 driver mutations were insertions, duplications or insertion-deletions in exon 20. Histology was available and lung adenocarcinoma growth pattern assessable in 39 of the 57 samples. The commonest predominant growth pattern in these samples was micropapillary pattern (15/39, 38%) and a further 4 samples had a minor component of micropapillary growth pattern alongside another predominant patter. All 39 cases showed non-mucinous morphology.

Conclusions: This represents the first large cohort of UK NSCLC patients in which ERBB2 mutation rate has been described and, representing a broad cross section of the NSCLC population, is likely to be highly representative. ERBB2 mutation has a similar rate in this cohort to some other less common actionable alterations such as ROS1 fusion, RET fusion and BRAF V600E mutation. There was an enrichment for micropapillary growth pattern in the histology of those harbouring ERBB2 mutation.

P2.06.09 Clinical, Racial, and Genetic Differences in Non-Small Cell Lung Cancer Between Young and Older Patients in the AACR Project Genie Database

K.H. Al-rabi[1], y. Hamadneh[2], O. Younis[2], A. yaseen[3], M. Ma'koseh[3], Y. Talab[3], O. El Kahtib[3], F. Tamimi[3], T. Al-Batsh[3], A. Khater[3], L. Alshobaki[4], M. Al-Kasasbeh[4], S. Yaser[3], A. Al-Ibraheem[3], A. Zayed[3], H. Abdel-Razeq[3]
[1]KHCC, amman/JO ,[2]Jordan university, amman/JO ,[3]king Hussien cancer center, amman/JO ,[4]University of Jordan, amman/JO

Introduction: The median age for lung cancer diagnosis is 71 years. Approximately 5% of NSCLC cases occur in patients aged 50 years or less. Young patients have distinct clinical characteristics and genetic profiles. This study aims to investigate these differences to improve understanding and inform treatment strategies.

Methods: Data from the AACR, cBioPortal, and Genie databases were retrospectively analyzed. The entire cohort included 1,833 patients with genetic, clinical, and racial data available for analysis. Young patients (< 50 years) were compared with older patients (> 50 years) using Welch's t-test, Mann-Whitney U, chi-square, and Fisher's exact test to identify age-related differences in NSCLC features and their therapeutic implications.

Results: Of the 1,833 patients analyzed, 130 (7.1%) were under 50 years, mostly females 83 (63.8%). The median age was 45.6 years, compared to 67.9 years in older patients. Younger patients had higher proportions of Asians (13.1% vs. 5.9%), Blacks (6.9% vs. 5%), and other racial groups (10.8% vs. 4.5%), while older patients were more likely to be whites (84.6% vs. 69.2%; all p = 0.001). Squamous cell carcinoma is uncommon in young patients compared to older ones (1.5% vs. 11.9%; 2/130 vs. 202/1703; p = 0.005).Younger patients were more likely to present at an advanced stage: stage IV (67.4% vs. 41.2%; p < 0.001), while older patients were more often diagnosed earlier: stage I (28.5% vs. 8.5%), stage II (9.8% vs. 7.0%), and stage III (19.8% vs. 17.1%). Lung (34.5% vs. 22.8%; p = 0.01) and liver (21.8% vs. 13.3%; p = 0.03) were the predominant metastatic sites in younger patients.The prevalence of TP53 mutations was similar between the two groups (overall: 56.76%, older: 54.12%; p = 0.550). Older patients showed a higher prevalence of STK11 mutations (15.47% vs. 6.67%; p = 0.004), KEAP1 mutations (14.28% vs. 4.65%; p = 0.001), and KRAS mutations (31.95% vs. 17.57%; p = 1.96E-04). Among these, the KRAS G12C mutation was significantly more common in older patients (13.49% vs. 3.01%; p = 0.001). In contrast, RB1 mutations were more frequently detected in younger patients (11.11% vs. 6.00%; p = 0.027). Younger patients also exhibited higher rates of ALK rearrangements (20.95% vs. 7.37%; p < 0.001), ERBB2 mutations (11.49% vs. 4.14%; p = 0.0003), and a slightly greater frequency of EGFR mutations overall (27.03% vs. 25.50%; p = 0.696). Among these, the EGFR T790M mutation is notably more common in younger patients (6.77% vs. 2.98%; p = 0.0355)

Conclusions: Lung cancer in young adults has distinctive features, including a predominance of adenocarcinoma, Asian descent, advanced stage at diagnosis, and unique genomic profile. These findings support a tailored approach and comprehensive genetic profiling should be mandatory, as personalized treatment approach with targeted therapy may lead to superior outcomes

P2.06.10 Title: Prognostic Impact of TP53 Co-Mutations with EGFR vs KRAS in Advanced Non-Small Cell Lung Cancer: A cBioPortal Analysis

D. Chukkalore, W.Y. Aung, N. Cheranda, N. Puttagunta, A. Singhal, I. Chiang, N. Seetharamu
Northwell Heath, Manhasset/NY/USA

Introduction: Non-small cell lung cancer (NSCLC) is a genomically diverse cancer, with only a subset of driver mutations with prognostic or predictive significance. Epidermal growth factor receptor (EGFR) and Kisten rat sarcoma viral oncogene (KRAS) are among the most common actionable mutations. While TP53 mutations are generally associated with poor prognosis, their prognostic role in EGFR- and KRAS-mutated NSCLC is still being elucidated. Given distinct biological behaviors and therapeutic approaches for these mutations, we sought to explore the influence of concomitant TP53 mutations on the survival outcomes of patients with EGFR or KRAS mutated NSCLC.

Methods: Information regarding TP53, EGFR and KRAS alterations and patients' survival time in advanced NSCLC was downloaded from the Cancer Genome Atlas Database, an open access database available at http://www.cbioportal.org. We chose MSK-IMPACT Clinical Sequencing Cohort (MSKCC, Nat Med 2023 and MSK, Nat Commun 2023). Patients were stratified into two groups: (1) EGFR-mutated with or without TP53 alterations and (2) KRAS-mutated with or without TP53 alterations. Comprehensive genomic profiling, including next-generation sequencing (NGS) data, was analyzed to correlate mutational profiles with clinical outcomes, particularly overall survival (OS). Kaplan-Meier survival curves and log-rank tests were used to assess differences in survival outcomes between groups.

Results: As expected, overall survival differed by mutational status (log rank p <0.0001) with EGFR mutation positive NSCLC faring better. Among patients with EGFR mutated NSCLC, concomitant TP53 mutation was associated with a worse survival (median OS: 33 months, 95% CI 28-39) compared to those without (median OS: 42 months, 95% CI 33-58; p=0.01). In the KRAS-mutated cohort, median OS was worse in those without TP53 mutation (median OS:15 months, 95% CI:12-22) compared to with TP53 mutation (median OS:24 months, 95% CI:19-35; p=0.049). While TP53 co-mutation was associated with worse outcomes in EGFR-mutant NSCLC, this was not observed in the KRAS group.

Conclusions: Our findings showed mutation-specific prognostic role of TP53 in advanced NSCLC. TP53 mutations were associated with worse overall survival in EGFR-mutated NSCLC. Conversely, in KRAS-mutant NSCLC, TP53 co-mutations conferred a relative survival benefit compared to KRAS mutation alone—suggesting a distinct biological interaction that may influence disease course or therapeutic sensitivity. These results underscore the importance of evaluating TP53 mutational status in the context of the primary oncogenic driver in NSCLC. Specifically, TP53 mutations should be integrated into risk stratification and treatment planning for EGFR-mutated NSCLC, while their role in KRAS-mutant NSCLC suggests a distinct biological interaction warranting further investigation.

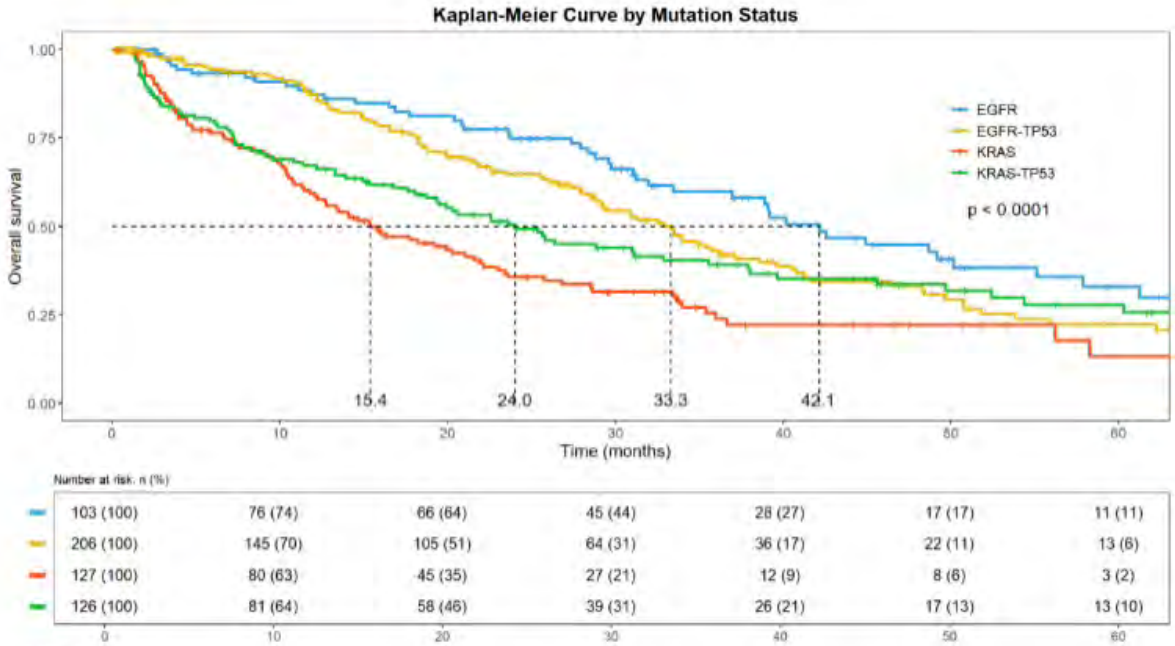

Figure 1:
Kaplan-Meier survival curves for *EGFR*- vs *KRAS*-mutated NSCLC patients with and without concurrent TP53 co-mutations.

P2.06.11 Factors Impacting Receiving EGFR Test Results Before Initial Treatment Among Stage Iv Non-Small Cell Lung Cancer Patients

D.P. Petro, MD[1], T. Patel, MD[2], S.". Divers, MD[3], B. Mulherin, MD[4], E. S. Santos, MD[5], R. Choksi, MD[1], M. Gart, MBA[6], A. Rui, MPH[6], D. Parris, PhD, MPH[6], A. Shrivastava, B. Tech[6], B. Wang, MBA[6], P. Varughese, PharmD, MBA[6], R. Geller, MD[6], J. Scott, MD[6]
[1]University of Pittsburgh Medical Center (UPMC), Pittsburgh/PA/USA ,[2]Zangmeister Cancer Center, Columbus/OH/USA ,[3]Genesis Cancer & Blood Institute/AON, Hot Springs/AZ/USA ,[4]Hematology Oncology of Indiana, Indianapolis/IN/USA ,[5]The Oncology Institute of Hope and Innovation, Fort Lauderdale/FL/USA ,[6]Integra Connect, West Palm Beach/FL/USA

Introduction: The study of Compromised Outcomes in Stage IV Non-Small-Cell Lung Cancer (NSCLC) With Actionable Mutations Initially Treated Without Tyrosine Kinase Inhibitors1 demonstrated survival benefit for patients (pts) who initiated targeted therapy for initial treatment compared to those who did not or switched to targeted therapy. We aim to show among stage IV NSCLC pts in the U.S. what factors impact receiving EGFR test results before initial treatment (RBIT).

Methods: Using Integra Connect PrecisionQ's de-identified database, the analysis comprised 1565 pts >=18 years of age who were confirmed via chart abstraction as newly diagnosed with stage IV NSCLC and initiated treatment between 1/1/2022 to 12/31/2024. Pts were assessed based on whether gender, age, race, Eastern Cooperative Oncology Group (ECOG) performance status, histology, stage, site of metastases (mets), testing approach, and test turnaround time (TAT) impacted receiving EGFR RBIT. Descriptive analyses were performed, and chi-squared analysis were used for comparisons.

Results: Among 1565 pts, 1191 (76%) received RBIT, 298 (19%) received results after initial treatment, and 76 (5%) were not tested. The mean age of pts who received RBIT was 70.2 compared to 68.4 for those who did not. Among females, 617/791 (78%) received RBIT compared to 570/769 (74%) for males and 4/5 (80%) for unknown gender pts. Based on race, pts receiving RBIT was 913/1210 (75%) among White pts, 131/172 (76%) among Black/African American pts, 35/39 (90%) among Asian pts, and 112/144 (78%) among other pts. Based on ECOG, pts receiving RBIT was 725/938 (77%) among ECOG 0-1 pts, 205/272 (75%) among ECOG 2+ pts, and 261/355 (74%) among pts with an unknown ECOG. Receiving RBIT by histology was 885/1110 (80%) for adenocarcinoma pts, 211/319 (66%) for squamous cell carcinoma pts, and 95/136 (70%) for pts with other subtypes or unknown histology ($p < 0.01$). Receiving RBIT among stage IVA was 425/577 (74%) compared to stage IVB at 407/512 (79%) ($p < 0.05$). Based on site of mets, receiving RBIT was 479/626 (77%) among pts with bone mets, 325/385 (84%) among pts with brain/central nervous system mets, and 197/250 (79%) among pts with liver mets ($p < 0.01$). Among tested pts, pts receiving RBIT with both solid and liquid testing was 443/509 (87%), those with liquid only testing was 239/285 (84%), those with solid tumor only testing was 325/455 (71%), and those with an unknown modality was 184/240 (77%) ($p < 0.01$). Among tested pts, pts receiving RBIT was 394/454 (87%) for TAT of <7 days, 584/740 (79%) for TAT of 7-to-14 days, and 209/290 (72%) for TAT of >14 days ($p < 0.01$).

Conclusions: The real-world data shows NSCLC stage IV pts who received EGFR RBIT more often had brain/CNS mets, liver mets, stage IVB, adenocarcinoma, both liquid and tissue testing, or results with a shorter TAT compared to those who did not. Factors such as gender, age, race, and ECOG did were not found to be statistically significant in whether patients received EGFR RBIT.

P2.06.12 TP53/RB1-Mutant Squamous Cell Lung Cancers: Clinicopathologic Features and Outcomes

P. Agrawal[1], A. Pupo[1], P. Clark[1], M. Offin[1], N. Rekhtman[1], B. Herzberg[2], J. Sui[3], A. Elkrief[4], K.C. Arbour[1], G. Riely[1], P.K. Paik[1], M.G. Kris[1]
[1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]Columbia University, New York/NY/USA ,[3]Mater Private, Dublin/IE ,[4]Centre hospitalier de l'Université de Montréal, Montreal/QC/CA

Introduction: Loss of TP53 and RB1 disrupts cell cycle regulation, impairs DNA damage repair, and evades apoptosis. Concurrent mutations in the tumor suppressor genes TP53 and RB1 are hallmarks of small cell and neuroendocrine lung carcinomas. Concurrent alterations in TP53 and RB1 also occur in patients with EGFR-mutant lung adenocarcinomas at high risk of histologic transformation to small cell lung cancers. The incidence and significance of TP53/RBI loss in non-small cell lung cancers without actionable oncogenic mutations remain undefined. In this report, we describe the clinicopathologic characteristics and course of patients with TP53/RB1-mutant squamous cell lung cancers with no histologic neuroendocrine features or actionable oncogenic drivers.

Methods: We identified patients at Memorial Sloan Kettering with squamous cell lung cancers with concurrent mutations in TP53and RB1 detected by next-generation sequencing (NGS) using MSK-IMPACT or MSK-ACCESS, performed between January 2014 and 2023. All patients had no actionable driver alterations and no neuroendocrine features noted on pathology reports by histologic examination or immunohistochemistry. Demographic characteristics, clinicopathologic features, treatment histories, survival outcomes, and NGS results were collected.

Results: Among 1011 patients with squamous cell lung cancers with NGS testing by MSK-IMPACT or MSK-ACCESS, we identified 93 patients (9.2%, 95% CI 7.5% to 11.1%) with concurrent TP53 and RB1 mutations with no actionable oncogenic drivers, no neuroendocrine differentiation, and adequate clinical documentation. Their median age at diagnosis was 69 years (range 51 to 91 years), 63% were male, and 97% were current or former cigarette smokers. Seventy-three percent of patients were diagnosed with stages I to IIIB squamous cell lung cancer at diagnosis. The median PDL1 expression was 2% (range 0 to 100%) and 28% had PDL1 values 50% or greater. The median tumor mutational burden (TMB) was 9.8 mutations/megabase (range 3 to 33) and 44% had a TMB score of 10 or greater. Among patients with stages I to IIIB at initial diagnosis, 43% developed progression or recurrence. Among 54 patients with metastatic disease at any time, 15 (28%) had brain metastases. The median overall survival from time of diagnosis of all patients with metastatic disease was 1.3 years, with a median follow up of 9.2 years. Twenty-six patients were treated with immune checkpoint inhibitors (ICI) in any line for metastatic disease. Their median time on treatment with any immunotherapy was 4 months.

Conclusions: We found that patients with TP53/RB1-mutant squamous cell lung cancer without oncogenic drivers, no treatment with target therapies, and no neuroendocrine differentiation by histology, represent a unique group of lung cancers. These individuals had tobacco exposure and a high median TMB. Patients with metastatic disease experienced a short time on ICI with a 15-month median overall survival. We plan to compare patients with squamous cancers with TP53/RB1 loss with matched controls with intact TP53/RB1. We will also analyze tumor tissues from individuals with TP53/RB1-deficient squamous cancers for transcriptional markers (ASCL1, YAP1, POU2F3, NEUROD1) characteristic of small cell lung cancers and markers of neuroendocrine differentiation (chromogranin, synaptophysin, DLL3) to uncover potential therapeutic vulnerabilities.

P2.06.13 Actionable Mutation Profiles and Survival Outcomes in Invasive Mucinous Adenocarcinoma of the Lung

J. Kim[1], M. Weitz[2], W. Woo[3], S. Kim[1], A. Dugan[2], Y.K. Chae[4]
[1]Metrowest Medical Center, Framingham/MA/USA ,[2]Tempus AI, Inc., Chicago/IL/USA ,[3]St. Joseph's Medical Center, Stockton/CA/USA ,[4]Northwestern University Feinberg School of Medicine, Chicago/IL/USA

Introduction: Invasive mucinous adenocarcinoma (IMA) is a rare subtype of lung adenocarcinoma with unique clinicopathologic features and limited therapeutic options. Comprehensive comparisons of genomic profiles and their survival impact between IMA and non-IMA are lacking. This study aimed to evaluate actionable and other clinically significant mutations and their prognostic relevance in IMA versus non-IMA.

Methods: De-identified records of 3,428 patients with primary lung adenocarcinoma and available survival data were retrieved from the Tempus database and stratified by histology into IMA (n=78) and non-IMA (n=3,350) groups. Clinical, biopsy, and molecular characteristics were compared using χ^2 and Fisher's exact tests for categorical variables. Actionable mutations were defined per current NCCN guidelines, including EGFR exon 19, L858R, or G719X mutations, ALK, ROS1, or RET fusions, and ERBB2 alterations. Real-world overall survival (rwOS) was analyzed using Kaplan-Meier curves and Cox proportional hazards models.

Results: IMA showed significantly higher frequencies of KRAS (54% vs. 27%, $p < 0.001$) and ERBB2 mutations (5.1% vs. 1.6%, $p = 0.044$) but a lower frequency of EGFR exon 19 deletions (1.3% vs. 9.6%, $p = 0.013$). Non-IMA patients with actionable mutations had longer median rwOS (35.73 vs. 16.47 months). A similar trend towards improved rwOS was observed for patients with actionable mutations in the IMA cohort (not reached vs. 12.98 months), although the sample size was small (n=14). Additionally, STK11 mutations appeared to be associated with poorer rwOS in non-IMA patients.

Conclusions: IMA exhibits a distinct mutational profile compared with non-IMA, showing differences in both frequency and prognostic impact. While actionable mutations were linked to improved survival in non-IMA, their prognostic value was less evident in IMA. Moreover, STK11 mutations suggested a potentially worse overall survival in non-IMA. Further analyses of clinically significant mutations in a larger IMA cohort will clarify the biological differences underlying these distinct tumor behaviors.

Table 1. Clinical, Demographic, and Molecular Characteristics of IMA vs. non-IMA Patients

Characteristic	Overall N = 3,428[1]	Non-IMA N = 3,350[1]	IMA N = 78[1]	p-value[2]

P2.06.14 Adoption of a 50-Gene Targeted Next Generation Sequencing Hotspot Panel in Non-Small Cell Lung Cancer in a Tertiary Institution in Singapore

K. Sooi[1], J. Nutzinger[2], K.N. Tan[1], V. Lee[1], Y.X. Gwee[1], M. Sachdeva[1], S. Wijaya[1], J.L. Low[1], Y. Ang[1], Y. Huang[1], R.A. Soo[1]
[1]National University Cancer Institute Singapore, Singapore/SG ,[2]Leiden University Medical Center, Leiden/NL

Introduction: Effective molecular profiling in non-small cell lung cancer (NSCLC) patients is essential to identify actionable genomic alterations (AGAs). Current guidelines recommend the use of next-generation sequencing (NGS) panels. Here we present the clinical outcomes of a newly adopted in-house NGS panel and compared with single gene testing (SGT) for EGFR/ALK/ROS1 alterations.

Methods: Since June 2023, a laboratory developed DNA- and RNA-based 50-gene targeted NGS hotspot panel (APEX Tissue, MiRXES) has been adopted as standard practice for all patients with advanced non-squamous (non-sq) NSCLC. Clinicopathological characteristics and molecular profiling were prospectively collected on all patients with newly diagnosed NSCLC between June 2023 and March 2025 who underwent APEX Tissue testing. The overall response rates (ORR), progression-free survival (PFS) and overall survival (OS) were compared between a subset of patients with advanced non-sq NSCLC with a historic cohort of similar patients who underwent SGT. Descriptive statistics were used to summarise patient demographics and clinical characteristics (SPSS Statistics version 26). Survival outcomes were analysed using the Kaplan-Meier method, and differences between groups were assessed with the log-rank test. A p-value of <0.05 was considered statistically significant.

Results: Of the 268 patients who underwent APEX Tissue testing, 227 (84.7%) were successfully sequenced; the remainder had inadequate samples. Of the 227 evaluable patients, the median age was 70 years, majority were males (57.8%), non-smokers (56.8%), Chinese ethnicity (78.0%), adenocarcinoma histology (91.6%) and advanced disease (66.1%) at the time of diagnosis. NGS testing revealed 208/227 (91.6%) patients harboured at least 1 molecular alteration. The commonest alterations were EGFR (44.1%), TP53 (24.7%) KRAS (17.2%), MET (5.3%), ALK (5.3%) and CTNNB1 (5.3%). Some 148 patients (65.2%) had an AGA as defined by NCCN guidelines of which 102/148 (68.9%) patients received molecular targeted therapy during the course of their treatment. A comparison was performed between patients with advanced disease tested with NGS (n=150) and SGT (n=100). Baseline characteristics were well-balanced. The NGS cohort had more AGAs (62.7% vs 23.0%, p<0.01) and received targeted therapy in the 1st line setting (56.7% vs 24.0%, p<0.01). The testing turnaround time was similar (9.01 days vs 7.89 days, p=0.051) between the two groups. In terms of clinical outcomes, patients who underwent NGS testing had a higher ORR (58.9% vs 39.6%, p<0.01). longer PFS (12.4 months vs 5.8 months, HR 0.56, 95% CI 0.40-0.79, p<0.01) and longer OS (21.6 months vs 14.0 months (HR 0.56, 95% CI 0.37-0.85, p<0.01) than patients who underwent SGT.

Conclusions: The integration of a 50-gene targeted NGS hotspot panel was successful in our centre, identifying more AGAs and ultimately improving patient clinical outcomes. To our knowledge, this is also the first study conducted in Asia that has shown improvement in survival of NGS vs SGT in NSCLC. The adoption of broad genomic profiling is essential to optimise therapeutic decision-making.

P2.06.15 Genomic Alterations in Lung Cancers Associated With Fibrosing Interstitial Lung Diseases in a French Multicentric Cohort

E. GUENZI[1], A. Guyard[1], N. Theou-anton[1], A. Mailleux[2], G. Zalcman[1], B. Crestani[1,2], A. Cazes[1], N. Pote[1]
[1]CHU Bichat Claude Bernard, AP-HP, Paris/FR ,[2]Inserm U[1149], Paris/FR

Introduction: Fibrosing interstitial lung diseases (f-ILDs) are rare conditions characterized by chronic inflammation and progressive destruction of the lung parenchyma, leading to end-stage respiratory failure. Epidemiological data indicate that f-ILDs are associated with an increased incidence of lung cancer (LC). However, detailed molecular characteristics of LC associated with f-ILDs (LC/f-ILDs) are lacking. Using Next Generation Sequencing (NGS), we aimed to investigate the genomic alterations of LC/f-ILDs in a large French multicentric cohort, and to compare these genomic alterations with LC from a public database.

Methods: This retrospective study was based on a French multicentric cohort of patients with LC/f-ILD. Histological tumor types were classified according to the 5th edition of WHO classification of thoracic tumours. The pattern of pulmonary fibrosis was based on TDM and/or histopathological criteria according to the ATS/ERS/JRS/ALAT guidelines. DNA and RNA alterations were explored by NGS using using the Oncomine Comprehensive Assay V3 (OCAV3) (Life Technologies, Thermo Fisher Scientific). The genomic alterations of LC/f-ILDS were then compared to the TCGA database of LC. Using Reactome database, we also compared the signalling pathways impacted by the genetic alterations.

Results: A total of 107 samples from 101 patients, representing 102 tumors, were included. Among the 102 LC/f-ILD, 46 (45.1%) were adenocarcinomas (ADC), 43 (42.2%) were squamous cell carcinomas (SCC), 10 (9.8%) were small cell lung cancer (SCLC) and 3 (2.9%) were large cell neuroendocrine carcinoma (LCNEC). DNA NGS was conducted on 95 tumour samples, encompassing 44 ADC, 38 SCC, 10 SCLC, and 3 LCNEC. RNA NGS was conducted on 70 tumor samples. In ADC-SCC/f-ILD, TP53 was the most frequently mutated gene (59.76%), followed by ATM (20.67%), NF1 (17.07%), KRAS (12.20%), and NOTCH1 (10.98%). Mutation of EGFR and KRAS were found in 2 (4,5%) and 9 (20,45%) cases of ADC, respectively. We did not find any fusion transcript of ALK or ROS1 genes. We found a significantly ($p<0,05$) higher frequency of mutations in ADC-SCC/f-ILD compared to TCGA for ATM (20.67% versus 7.17%), NOTCH1 (10.98% versus 5.94%), BRCA1 (13.64% vs 3.16%), PMS2 (6.10% versus 1.33%), TSC2 (6.10% versus 2.77%) and FANCI (6.10% versus 1.43%). Regarding signaling pathways, we found a significantly higher proportion of tumors with molecular alterations in pathways related to DNA repair (especially homolozygous recombination repair, HRR), NOTCH and BRCA pathways in ADC/f-ILD compared to TCGA. In SCCs/f-ILD, we also found a significantly higher proportion of alterations DNA repair pathway compared to TCGA, notably non-homologous end-joining and Homology directed repair pathways.

Conclusions: This study provides significant insights into the genomic alterations of LC/f-ILD. In this large multicentric cohort, we found that ADC/f-ILD seems to harbour specific molecular features, involving NOTCH, HRR and BRCA pathways. These data pave the way for the developpement of new targeted therapies in LC/f-ILD, some of which are currently being investigated in clinical trials.

P2.06.16 Identification of Molecular Signatures Linked to Early-Stage Lung Adenocarcinoma With STAS Using Spatial Transcriptomics

K. Hisamatsu[1], K. Shien[1], S. Tomida[2], A. Matsuoka[1], R. Fujiwara[1], K. Ishimura[1], R. Fujii[1], R. Yoshichika[1], Y. Fukumoto[1], K. Okada[1], M. Yoshikawa[1], H. Torigoe[1], K. Suzawa[1], S. Toyooka[1]
[1]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama/JP ,[2]Okayama University Hospital, Okayama/JP

Introduction: Spread through air spaces (STAS) is recognized as an invasive histological pattern for tumor invasion in non-small cell lung cancer (NSCLC). It is defined as micropapillary clusters, solid nests, or single cells in the airspaces beyond the edge of the main tumor. STAS has been associated with worse prognosis in patients undergoing surgically resection for NSCLC. However, the molecular basis and potential biomarkers remain unclear. This study utilized spatial transcriptomics to identify the gene expressions patterns specific to STAS, aiming to elucidate its molecular mechanisms and identify candidate biomarkers to support preoperative diagnosis.

Methods: This retrospective, single-center study included 188 patients with pathological stage I lung adenocarcinoma (8th edition TNM classification) who underwent surgical resection at our institution between 2020 and 2021. Overall survival (OS) and recurrence-free survival (RFS) were compared between STAS-positive and STAS-negative patients. A subset of 61 patients (28 STAS-positive, 33 STAS-negative) was selected for spatial transcriptomic profilling using GeoMx Digital Spatial Profiler (DSP). Region of interest (ROIs) were defined in the tumor core, tumor border, tumor microenvironment (TME), and adjacent normal lung tissue. Transcriptomic data were analyzed using R (version 4.4).

Results: Among the 188 patients, 56 (29.8%) were identified as STAS-positive. While OS did not differ significantly between the two groups, RFS was significantly worse in STAS-positive patients ($p < 0.01$). In univariate analysis, both STAS and the papillary histologic subtype were associated with an increased risk of tumor recurrence. In multivariate analysis, only STAS remained as an independent prognostic factor for recurrence ($p = 0.01$). Spatial transcriptomic analysis was conducted on 791 ROIs from STAS-positive and STAS-negative tumors. Differential gene expression analysis revealed that specific pathways and molecular signatures, particularly those associated with tumor proliferation and invasion, were enriched in the STAS-positive tumor and TME ROIs.

Conclusions: STAS is an independent prognostic factor for recurrence in early-stage NSCLC patients following surgical resection. Spatial transcriptomic analysis identified distinct molecular features, including changes in the TME of STAS-positive tumors, that may contribute to recurrence. These findings enhance our understanding of the molecular basis of STAS and may aid in identifying biomarkers to support preoperative diagnosis.

P2.06.17 Cellular Heterogeneity and Tertiary Lymphoid Structure Dynamics Predict Overall Survival in Immune Checkpoint Therapy-Treated NSCLC Patients

H. Grover[1], A. Kumar[1], M. Krishna[1], P. Kumari[1], S. Chandrashekaraiah[1], A. Chakraborty[1], J. Chauhan[1], V. Patil[1], V.P. Shyamasundar[1], S. Kulkarni[1], S. Kapoor[1], J. Wingrove[1], Y. Mundkur[1], T. Patil[2], C. Aggarwal[3]
[1]Cellworks Group, Inc, South San Francisco/CA/USA ,[2]University of Colorado, Aurora/CO/USA ,[3]University of Pennsylvania, Philadelphia/PA/USA

Introduction: Despite the promise of immune checkpoint inhibition (ICI) in non-small cell lung cancer (NSCLC), precise methods for predicting patient response remain limited. An understanding of each patient's tumor microenvironment (TME) is essential for identifying robust biomarkers to improve treatment outcomes. We present a novel framework integrating patient-specific TME composition and Tertiary Lymphoid Structure (TLS) dynamics from bulk RNA-sequencing to predict immunotherapy response.

Methods: Methods: Cellworks previously developed and cross-validated an algorithm for deconvolution of cell proportions and cell-type-specific gene expression from bulk transcriptomic data. This approach was enhanced by incorporating a TLS Score derived from 34 key genes representing various facets of TLS dynamics, including cellular interplay and maturity. A Cox proportional hazards model was trained to predict OS in primarily advanced NSCLC patients treated with ICI (n=63, SU2C-MARK cohort), using TME cell proportions (TCP) and TLS score derived from tumor-derived bulk transcriptomic data. The model was then locked and validated on an independent set of 66 ICI-treated NSCLC patients from the same study.

Results: The integrated TCP and TLS model demonstrated high predictive significance for overall survival (OS) in the training cohort (HR=0.36, C-Index=0.768, p < 0.001) and retained significance in the independent validation cohort (HR=0.66, C-Index=0.628, p < 0.001). When dichotomized, the model demonstrated clinically meaningful separation in the validation cohort (HR=0.45, p=0.025; median OS: 12 vs. 30.8 months, Figure 1). Analysis of TLS components revealed that expression of genes involved in immune cell recruitment (CCL19, CCL21, CXCL13, CXCR3), T-cell infiltration and activation (CD3D, CD3E, ICOS, IL21R), and mature B-cell/dendritic cell presence in germinal centers (CD19, CD79B, CD20, FCER2, CR1/CD35, CD83) was significantly associated with improved survival. Notably, the survival benefit was not limited to fully mature TLS but extended to intermediate-mature TLS, suggesting that organized B-cell follicles, even without fully developed germinal centers, may confer ICI benefit. Among TME cellular components, a high ratio of CXCL9+ M1-like macrophages to SPP1+ M2-like macrophages was positively correlated with OS across both sets. A specific cluster of antigen-experienced CD8 + T-cells (CXCR6+ CXCR3+ KLRK1+) strongly predicted favorable outcomes, while tumor-associated neutrophils predicted poor survival. Both structural (TLS) and cellular (TCP) parameters contributed independently and complementarily to predictive accuracy.

Conclusions: The integration of TLS dynamics with specific immune and stromal cell populations provides collective insight into how structural organization and cellular composition cooperatively determine ICI efficacy. Further validation in larger cohorts is necessary to translate these findings into clinical practice.

P2.06.18 Computational Modeling of Comprehensive Genomic Profiling to Predict Chemotherapy Benefit in Advanced NSCLC

C. Aggarwal[1], D. Watson[2], P. Nair[2], A. Kumar[2], S. Khandelwal[2], J. Chauhan[2], S. Khanna[2], S. George[2], A. Dey[2], M. Patil[2], N. Ganesh[2], R. Purushottam[2], S. Kulkarni[2], P. G[2], D.A. Lala[2], S. Basu[2], S. Kapoor[2], M. Castro[2], J. Wingrove[2], T. Patil[3]
[1]University of Pennsylvania, Philadelphia/PA/USA ,[2]Cellworks Group, Inc, South San Francisco/CA/USA ,[3]University of Colorado, Aurora/CO/USA

Introduction: Combination chemo-immunotherapy is a primary treatment option for patients with advanced non-small cell lung cancer (NSCLC). Although PD-L1 is a biomarker for selecting patients for therapy, it is imperfect, and the benefit of adding chemotherapy varies among patients. To address this, Cellworks developed a mechanistic computational biology model that integrates a patient's tumor-specific genomic profile, identified through comprehensive genomic profiling (CGP). This model reveals signaling pathway dysregulation and predicts variable immune checkpoint inhibitor (ICI) and ICI + chemotherapy (ICI+C) responsiveness. The model's output is translated into a quantitative score called the delta Therapy Response Index (ΔTRI), which represents the likelihood of chemotherapy benefit regardless of PD-L1 status.

Methods: The TRI algorithm was developed using two real-world retrospective cohorts (total n=1519) of patients with metastatic NSCLC who underwent CGP using the Foundation One CDx panel1. The TRI, computational model and clinical thresholds were locked and then prospectively tested in an independent set of 222 advanced NSCLC treatment naïve patients receiving either ICI monotherapy (n = 66) or ICI+C combination therapy (n = 156) with complete clinical and genomic information, derived from the nationwide (US-based) de-identified ConcertAI Genomics360 database. All patients in the validation cohort had Foundation One CDx CGP associated with first-line (1L) therapy. Right-censored survival times were generated as the difference between the date of diagnosis and the last date of clinical observation. The ΔTRI clinical threshold was selected to represent 1.5 standard deviations from the estimated standard deviation in ΔTRI observed in the clinical development set.

Results: In the overall, independent validation population, continuous TRI was significantly associated with OS after adjustment for clinical and genomic risk factors in a multivariable model, including across PD-L1 levels (LR p = 0.022). Patients in the ΔTRI High Benefit Group (ΔTRI ≥ 16, n = 86), had an incremental benefit in median OS of ~ 7.63 months with the addition of chemotherapy to ICI (logrank p = 0.002, median OS ICI = 6.84 months vs ICI+C = 14.47 months, Figure 1). In contrast, patients in the ΔTRI No Benefit Group (ΔTRI < 16, n = 136) showed no improvement in OS when receiving ICI+C (logrank p = 0.78, median OS ICI = 11.02 months vs ICI+C = 12.63 months). After adjustment for clinical and genomic risk factors, a likelihood ratio test of interaction between ΔTRI and treatment (ICI versus ICI+C) was significant (LR p = 0.036).

Conclusions: In this study, continuous TRI predicted overall survival (OS) while ΔTRI predicted the incremental benefit of chemotherapy in an independent real-world cohort of patients with NSCLC receiving 1L ICI or ICI+C. These findings support the use of CGP in conjunction with computational modeling to identify patients who may benefit from combination immunotherapy and chemotherapy, as well as those unlikely to respond to ICI alone, regardless of PD-L1 levels. Future studies will aim to prospectively validate the hypothesis that ΔTRI can guide decisions on whether to add chemotherapy. 1Klein, M. et al. P2.06.19 A Multi-Source Pathology-Based Model for Gene Mutation and Recurrence Risk Prediction in Lung Cancer

H. Li[1], F. Xing[2], J. Xie[2], Y. Li[1]
[1]Fudan University Shanghai Cancer Center, Shanghai/CN ,[2]Department of Algorithm, Shanghai Aitrox, Shanghai/CN

Introduction: Histopathologic analysis remains the cornerstone of lung cancer diagnosis, yet morphological patterns alone cannot reliably predict gene mutations or clinical outcomes. Gene sequencing, while informative, relies on high-quality tissue samples and is further limited by prohibitive costs, prolonged turnaround times, and restricted accessibility, particularly in economically underdeveloped regions. To address these challenges, we propose a deep convolutional neural network (DCNN)-based multi-source pathology model.

Methods: We collected 2,767 hematoxylin and eosin (H&E)-stained whole slide images (WSIs) from surgical resection samples (447 cases) at Fudan University Shanghai Cancer Center with complete genetic mutation profiles. A subset of 1,150 WSIs (336 cases) contained progression free survival (PFS) data. Utilizing a clustering-constrained attention multiple instance learning (CLAM) framework with cross-attention, we fused histopathological features, pathologist-annotated regions of interest (ROIs), tumor invasion patterns, and TNM staging. Histopathological annotations and ROIs identification were performed by two pathologists and reviewed by a senior pathologist. Mutations were classified into four categories based on sequencing results: epidermal growth factor receptor (EGFR) hotspot mutation (EGFR Exon 19), EGFR rare mutation (EGFR non-Exon 19), other mutations (non-EGFR), and negative (no mutation). Model performance was evaluated using confusion matrices, receiver operating characteristic curves, classification maps, and heatmaps.

Results: The prediction model based on DCNN exhibited outstanding performance, achieving an overall accuracy of 0.89 across the four categories of mutation classification within the test dataset. Specifically, the area under the receiver operating characteristic curve (AUC) for predicting EGFR hotspot mutations, EGFR rare mutations, other mutations, and negative samples was 0.80, 0.89, 0.79, and 0.74, respectively. In contrast, the baseline model, which lacked ROIs, cancer cell invasion information, and staging information, only achieved an accuracy of 0.81 and an average AUC of 0.68. Furthermore, our DCNN model demonstrated robustness in WSIs of lung cancers for the prediction of five-year PFS, achieving an overall accuracy of 0.89. The AUC for predicting five-year PFS was 0.89 in the validation set and 0.85 in the test set. In contrast, the baseline model achieved an accuracy of 0.70 and an AUC of 0.65 in the test set.

Conclusions: Our study highlights the potential of a DCNN-based multi-source pathology model for predicting both gene mutation and recurrence risk, providing a cost-effective tool to guide clinical decisions in resource-limited settings.

P2.06.20 Assessment of Molecular Testing in Stage IV Non-Small Cell Lung Cancer Patients Across American Oncology Network

B. Mulherin, MD[1], T. Patel, MD[2], S.". Divers, MD[3], M. Gart, MBA[4], E. Alwon, MS[4], D. Kanovsky, MHSA[4], K. Henn, MHA[4], P. Dave, MHA[4], L. Kunst, MS[4], B. Wang, MBA[4], P. Varughese, PharmD, MBA[4], R. Geller, MD[4], J. Scott, MD[4], E. Santos[5]
[1]Hematology Oncology of Indiana, Indianapolis/IN/USA ,[2]Zangmeister Cancer Center, Columbus/OH/USA ,[3]Genesis Cancer & Blood Institute/AON, Hot Springs/AZ/USA ,[4]Integra Connect, West Palm Beach/FL/USA ,[5]The Oncology Institute of Hope and Innovation, Fort Lauderdale/FL/USA

Introduction: The NCCN guidelines recommend non-small cell lung cancer (NSCLC) patients (pts) who are stage IV receive comprehensive biomarker testing that includes evaluating for EGFR, ALK, ROS1, RET, MET, NTRK1/2/3, KRAS, ERBB2, and BRAF. The American Oncology Network (AON) has conducted quality initiatives (QI) with Integra Connect PrecisionQ focused on improving testing for stage IV pts. This study aims to show testing practices over the past 4 years in pts with stage IV NSCLC at AON.

Methods: 915 newly diagnosed stage IV pts from AON were randomly selected among 4,841 pts >=18 years of age who started first-line treatment between 1/1/2021 and 12/31/2024. The 915 pts were evaluated through manual chart abstraction to confirm their stage, diagnosis, and molecular testing results. In 2023, Integra Connect worked with AON medical leadership to generate an initial analysis of testing in stage IV and those results were shared with the practice. Testing rates were evaluated in each calendar year and additional analyses were performed to assess testing by histology, smoking status, gender, race, and age. Descriptive analyses were performed to analyze the data.

Results: Among the 915 stage IV NSCLC pts the median age was 70 (IQR 62.5-77), 49.5% were female, 76.2% identified as White, 11.8% identified as Black/African American, and 3.3% identified as Asian. Among the pts, 71% had adenocarcinoma, 21% had squamous cell carcinoma, and the remainder were undefined. In 2021, 84.9% (N = 218) of pts received comprehensive testing, which increased to a high of 93.8% (N = 194) in 2023 and was 89.8% (N = 177) in 2024. Among pts with adenocarcinoma, 91% (N = 652) received comprehensive testing compared to 81% (N = 193) in pts with squamous cell carcinoma. In 2021, 72% (N = 50) of squamous cell carcinoma pts received comprehensive testing which increased to 89% (N = 35) in 2024. No noticeable changes in testing rates over time were found among pts with adenocarcinoma. Comprehensive testing rates by smoking status were as follows: those who never smoked at 88.6% (N = 140), those who were previous smokers at 89.4% (N = 463), and those who identified as active smokers 86.5% (N = 311). Among male pts, 88.5% received comprehensive testing whereas among female pts 87.9% received comprehensive testing. Comprehensive testing rates by race were as follows: 88.2% for White (N = 697), 88% for Black/African American (N = 108), 90% for Asian (N = 30), and 87.5% for Other (N = 80). Comprehensive testing by age was as follows: pts <=50 at 92.7% (N = 41), pts 51-60 at 85% (N = 120), pts 61-70 at 88.3% (N = 300), pts 71-80 at 88.1% (N = 328), and pts >=81 at 89.7% (N = 126).

Conclusions: AON has driven increases in comprehensive testing among stage IV NSCLC pts, notably improving testing rates in pts with squamous cell carcinoma. While pts who were <=50 years of age had the highest rates of testing, no noticeable differences were observed by race, smoking status, or gender.

P2.06.21 Differential Gene Expression and Pathway Analysis of Invasive Mucinous Adenocarcinoma

S. Kim[1], M. Weitz[2], J. Kim[1], W. Woo[3], A. Dugan[2], Y.K. Chae[4]
[1]Metrowest Medical Center, Framingham/MA/USA ,[2]Tempus AI, Inc., Chicago/IL/USA ,[3]St. Joseph's Medical Center, Stockton/CA/USA ,[4]Northwestern University Feinberg School of Medicine, Chicago/IL/USA

Introduction: Invasive mucinous adenocarcinoma (IMA) is a distinct lung adenocarcinoma subtype with unique clinical behavior, including immunotherapy resistance and high metastatic potential. However, the molecular pathways linking these pathological features to clinical outcomes remain unclear. In this study, we conducted a comprehensive gene expression and pathway analysis to investigate whether mucin-related genes are associated with survival outcomes, evaluating their potential roles as prognostic biomarkers and therapeutic targets in IMA.

Methods: De-identified data records from 17,885 patients with lung adenocarcinoma were identified, including 558 with IMA and 17,327 with non-IMA subtypes. Differential gene expression (DGE) was assessed using Wilcoxon rank-sum tests with Benjamini-Hochberg correction ($|\log_2 FC| \geq 1.0$; $q \leq 0.05$ considered significant), excluding genes with low expression (TPM sum ≤ 20). Real-world overall survival (rwOS) was evaluated with Kaplan-Meier curves and Cox proportional hazards models. Gene set enrichment analysis was conducted via the Enrichr-KG platform using GO, KEGG, and Reactome libraries ($q \leq 0.05$ considered significant).

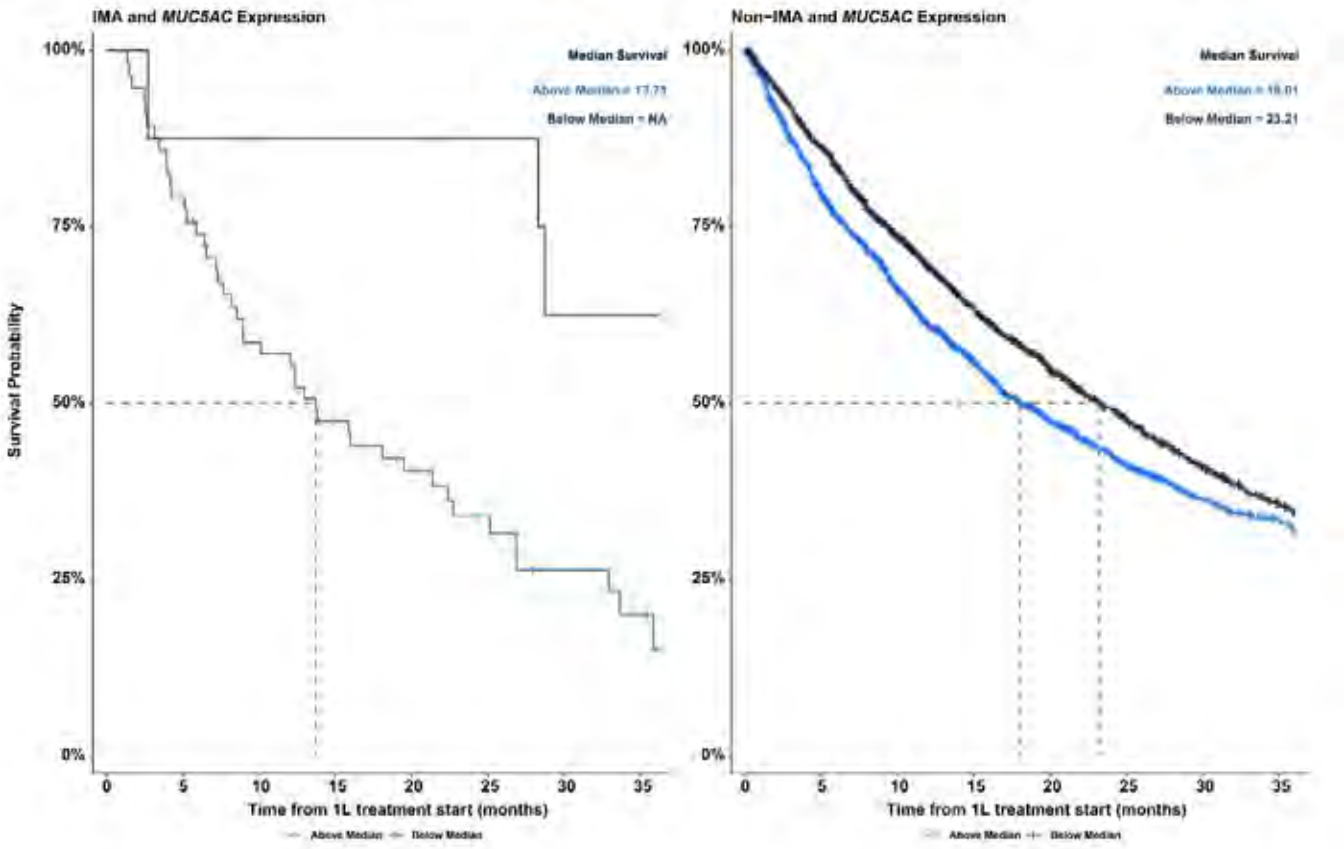
Results: DGE analysis identified 366 genes that were significantly differentially expressed in IMA (342 upregulated, 24 downregulated). Subsequent enrichment analyses identified 96 significantly enriched pathways: 94 linked to upregulated genes and two with downregulated genes. Furthermore, pathway analysis indicated that MUC5AC is closely linked to IL33 and SOX9, while MUC13 shares pathways with CXCL3 and CXCL5, all four of which were significantly upregulated in IMA (Table 1). Among the upregulated genes, elevated MUC5AC expression correlated with poor survival in both IMA and non-IMA cohorts (Figure 1).

Conclusions: These findings suggest that mucin-related genes in IMA modulate immune and metabolic pathways beyond mucin production, as evidenced by their strong network connectivity to regulators such as IL33, SOX9, CXCL3, and CXCL5. Our data highlight that the interconnected pathways among these upregulated genes could underlie the aggressive clinical behavior observed in IMA, warranting further mechanistic and clinical investigation.

Table 1. Selected Differentially Expressed Genes in IMA vs. Non-IMA

Gene	Log_2 Fold Change	*q*-value	Regulation
MUC5AC	4.44358	<0.001	Upregulated
MUC13	3.15044	<0.001	Upregulated
SOX9	1.33527	<0.001	Upregulated
IL33	1.32646	<0.001	Upregulated
CXCL5	1.22091	<0.001	Upregulated
CXCL3	1.00121	<0.001	Upregulated

Figure 1. Kaplan-Meier survival curves for MUC5AC overexpression in IMA and non-IMA patients



Strata	Number of Obs.	Number of Events	Median rwOS	Lower 95% CL	Upper 95% CL
Non-IMA, Above Median	1646	804	18.01	16.57	20.15
Non-IMA, Below Median	1704	816	23.21	21.47	25.28

P2.06.22 Pathological Characterization of Molecularly Screened Diffuse Pleural Mesothelioma

G.A. Impalà[1], A. Listì[2], F. Benso[2], F. Napoli[2], V. Zambelli[2], G. Farinea[2], M. Balbi[2], P. Bironzo[2], M. Volante[2], S. Novello[2], G.V. Scagliotti[2], F. Passiglia[2], L. Righi[2]
[1]University of Turin, Turin/IT ,[2]University of Turin, S. Luigi Gonzaga Hospital, Orbassano/IT

Introduction: The genetic landscape of pleural mesothelioma (PM) exhibits a significant degree of heterogeneity, with BAP1, NF2, and CDKN2A recognized as the most frequently altered tumor suppressor genes. Histology remains the paramount factor in determining prognosis and guiding treatment selection. However, information about the correlation between pathological and genomic features is lacking.

Methods: Between June 2020 and December 2024, 217 PM cases were prospectively screened for the UNITO-001 study (NCT04940637) using a DNA-based NGS assay. The Oncomine Comprehensive Assay v3, which identifies point mutations, deletions, insertions, and copy number variations in 161 genes, including BAP1, NF2, CDKN2A, and genes associated with homologous recombination repair (HRR), was used. All cases were reviewed for comprehensive morphological analysis of growth variants and grading.

Results: A total of 161 patients were male, and 56 were female. The average age was 71 years. Of the 217 patients, 176 (81%) were classified as epithelioid, 16 (7%) as biphasic, and 8 (4%) as sarcomatoid (the remaining were not available). 108/217 (50%) cases harbored genetic alterations. The most common altered gene was BAP1 (42/108, 39%), followed by NF2 (21/108, 19%) and CDKN2A (12/108, 11%). Other altered genes included TP53 (6/108, 6%), common BRAF, KRAS and STK11 oncogenes (13/108, 12%) and nonconventional genes (ARID1A, ATM, BRCA2, CHEK2, FBXW7, FGFR1, IDH1, MSH6, NF1, PALB2, PIK3CA, POLE, RAD51, SLX4 and SMAD4) in 23/108 (21%) cases. Co-mutations occurred in 14/108 cases (13%), primarily involving BAP1 (11/14 cases, 78%). Additionally, 2/108 were germline mutations in the MSH6 and BAP1 genes, and 26/108 (24%) were somatic mutations in HRR genes. Overall, 86/176 (49%) epithelioid, 11/16 (69%) biphasic, and 2/8 (25%) sarcomatoid cases harbored mutations. Histological slides from 176 surgical pleural biopsies were available for revision. Among the epithelioid tumors, the main architectural variants were solid (73/156, 47%), tubule-papillary (68/156, 44%), and trabecular (18/156, 11%). The solid pattern characterized the majority of mutated cases (42/73, 58%), while the tubule-papillary growth pattern was found in 29/68 (42%) mutated cases, and the trabecular pattern in 9/18 (50%) mutated cases (Fisher test p=not significant). No significant correlation between mutated genes and growth patterns was found. Regarding grading, 56/156 (36%) cases were high, and 100/156 (64%) were low-grade cases. The high-grade cases exhibited the highest mutation rate (31/56, 55%), while among the low-grade cases, 49/100 (49%) were mutated cases (Fisher test p= not significant). No significant correlation between mutated genes and grade was found.

Conclusions: Although a significant correlation between growth patterns, grading, and molecular profiles was not established, the high heterogeneity of PM highlights the need for further studies to explore alternative genetic pathways, identify surrogate biomarkers, and evaluate the potential for novel personalized therapies.

P2.06.23 CDKN2A Deletion Is an Independent Predictive Biomarker for Immunotherapy Response in Patients With Advanced NSCLC

H.S. Shim, K.A. Kim, C. Lee
Severance Hospital, Yonsei University College of Medicine, Seoul/KR

Introduction: While immune checkpoint inhibitors (ICIs) have transformed the treatment landscape of non-small cell lung cancer (NSCLC), identifying reliable predictive biomarkers remains a critical challenge. Currently used markers such as PD-L1 expression and tumor mutational burden (TMB) offer limited predictive value when applied in isolation. Genomic alterations that influence the tumor immune microenvironment may provide additional insights into immune resistance. In this study, we focused on CDKN2A deletion as a candidate biomarker and evaluated its clinical impact using real-world data.

Methods: We retrospectively reviewed clinical and genomic data from 321 NSCLC patients treated with ICIs at Severance Hospital between July 2019 and February 2023. All patients underwent targeted next-generation sequencing using the TSO500 panel. Associations between genomic alterations and progression-free survival (PFS) were assessed using univariate, subgroup, and multivariate analyses. In addition, H&E-stained tissue sections were reviewed to assess immune cell infiltration in relation to CDKN2A status.

Results: CDKN2A alterations were identified in 14% of patients, with deletions accounting for 6.5%. CDKN2A deletions were significantly associated with shorter progression-free survival (PFS) compared to cases without deletion (p = 0.002). The adverse prognostic effect of CDKN2A deletion was comparable to that of other poor-risk features, including nonsquamous histology (p = 0.001), low PD-L1 expression (≤50%, p = 0.001), low tumor mutational burden (<20/Mb, p = 0.001), and receipt of chemoimmunotherapy versus immunotherapy alone (p = 0.007). Notably, despite these associations Multivariate Cox regression analysis confirmed CDKN2A deletion as an independent poor prognostic factor (HR 2.24, 95% CI 1.38-3.65, p = 0.001) showing a greater adverse effect than even low PD-L1 expression (HR 1.42, 95% CI 1.08-1.89, p = 0.014), one of the most established poor-risk biomarkers. Moreover, histopathological review revealed reduced immune infiltration in tumors harboring CDKN2A deletion, consistent with an immune-cold tumor microenvironment. Although the TSO500 panel does not include the MTAP gene, its close genomic proximity to CDKN2A on 9p21.3—coupled with prior reports of frequent co-deletion—suggests a broader immunogenomic mechanism. Importantly, we also observed concurrent deletion of CDKN2B in 6.2% of patients, further supporting the hypothesis that large-scale chromosomal loss in the 9p21.3 locus contributes to immune evasion.

Conclusions: Our findings suggest that CDKN2A deletion is a clinically meaningful and potentially predictive biomarker for resistance to immune checkpoint therapy in NSCLC. The concurrent loss of neighboring genes such as MTAP and CDKN2B reinforces the role of the 9p21.3 chromosomal region in modulating the tumor immune landscape. As next-generation sequencing becomes increasingly integrated into clinical care, incorporating 9p21.3 status may enhance patient stratification and guide the development of rational combination strategies, including agents targeting epigenetic or innate immune pathways.

P2.06.24 Primary Pulmonary Neuroendocrine Immunophenotype Carcinoma Harboring Driver Gene Mutation/Fusions: Neuroendocrine Neoplasm?

B. Zhang, Y. Wang, Z. Huang, Y. Li
Fudan University Shanghai Cancer Center, Shanghai/CN

Introduction: Driver mutations in tyrosine kinase receptors are key genomic alterations in a subset of lung adenocarcinomas. However, these mutations are extremely rare in primary pulmonary neuroendocrine carcinomas (NECs), with only a few cases reported. We identified multiple cases of primary pulmonary neuroendocrine immunophenotype carcinoma harboring driver gene mutations or fusions, which could be classified into adenocarcinoma with neuroendocrine differentiation (ANED) and neuroendocrine-like carcinoma (NELC). Notably, NELC exhibited morphologic characteristics that do not align with the current classification system. To clarify its classification, we conducted a comprehensive clinicopathologic and molecular analysis of all identified cases at our institution.

Methods: A retrospective review was conducted using the electronic pathology database of a tertiary hospital between January 2018 and June 2024 identify cases of primary pulmonary neuroendocrine immunophenotype carcinoma harboring driver gene mutations or fusions. Diagnoses were confirmed by a pathologist, and specimens were analyzed for EGFR mutations, ALK translocations, and KRAS/RET expression. Clinical data were also collected and analyzed.

Results: Seventy-eight cases of pulmonary neuroendocrine immunophenotype carcinoma with EGFR, ALK, and other receptor tyrosine kinase mutations or fusions were identified. Among them, 34 were classified as ANED, with EGFR mutations detected in 50% of cases and additional occurrences of KRAS, RET, and ALK alterations. The remaining cases were high-grade NELC (HNELC), where TP53 mutations were present in 79% of advanced cases (A-H). Histological findings revealed that ANED exhibited typical adenocarcinoma patterns, including lepidic, acinar, papillary, micropapillary, and solid growth (I). In contrast, low-grade NELC (LNELC) displayed atypical morphologic features, such as irregular trabecular and nest-like growth with a fibrotic rather than sinus-rich interstitium (J). HNELC differed from conventional neuroendocrine neoplasms and exhibited a higher nuclear-to-cytoplasmic ratio than large cell neuroendocrine carcinoma but lower than small cell lung carcinoma, with spindle-shaped and polygonal cells and irregular nest-like structures (M). Clinically, most cases of HNELC were diagnosed at Stage III-IV, while ANED and LNELC cases were more evenly distributed across disease stages (N). Compared with ANED, HNELC showed significantly worse progression-free and overall survival (K-L). The majority of patients who received targeted therapy exhibited partial responses, reinforcing the need for routine driver gene testing in neuroendocrine-like tumor.

Conclusions: Lung NELC with driver gene mutations or fusions differs clinically and molecularly from traditional lung neuroendocrine neoplasms. However, it remains appropriate to classify these tumors within the neuroendocrine category. The findings emphasize the necessity of routine molecular testing in tumors with neuroendocrine features and atypical morphology.

P2.06.25 Clinical Implications of TROP2 Expression in Lung Adenocarcinomas

K. Takamochi, T. Hayashi, H. Terukina, H. Tomita, K. Suzuki
Juntendo University School of Medicine, Tokyo/JP

Introduction: Trophoblast cell surface antigen 2 (TROP2) is a cell surface glycoprotein expressed in various types of cancers, and its overexpression is associated with a negative prognosis. Antibody-drug conjugates targeting TROP2 show potential of treating TROP2-expressing cancers. Recently, TROP2 overexpression has been linked to poorer progression-free and overall survival (OS) after PD-L1 blockade therapy in patients with non-small cell lung cancer. In addition, TROP2 overexpression has been reported to correlate with gefitinib resistance in EGFR-mutated lung cancers. However, the clinical implications of TROP2 expression in lung adenocarcinoma (LUAD) remain unclear.

Methods: Immunohistochemical staining with an anti-TROP2 antibody (SP295) was performed on 1067 surgically resected LUAD tissue microarrays. The intensity of TROP2 expression was scored as 0 (absent), 1 (weak-to-moderate), or 2 (strong). The H-score was calculated as the product of the intensity and proportion of positive tumor cells. TROP2 expression positivity was evaluated based on the intensity (0 vs. 1/2), proportion of positive tumor cells (<25% vs. ≥25%), and H-score (<50 vs. ≥50). Statistical analysis was performed to examine the association of TROP2 overexpression with clinicopathological and molecular characteristics and prognosis. Subset analyses of the role of TROP2 expression were performed in PD-L1 positive LUADs and EGFR mutated LUADs.

Results: TROP2 overexpression was observed in 823 patients (77%) showing intensity 1/2, 373 (35%) with ≥25% positive tumor cells, and 273 (22%) with H-score ≥50. TROP2 overexpression was significantly associated in males, individuals partaking in smoking, elevated serum CEA level, advanced pathological stage, larger tumor size, histologically high-grade tumors, lymphatic permeation, pleural invasion, EGFR wild-type, and PD-L1 positive expression. The OS and relapse-free survival (RFS) of patients with TROP2 positive LUADs were worse than those with TROP2 negative LUADs. No differences were found in clinicopathological and molecular characteristics, OS, and RFS between TROP2 positive and negative cases of PD-L1 positive LUADs and EGFR-mutated LUADs.

Conclusions: TROP2 overexpressed LUADs are biologically aggressive tumors and good candidates for TROP2-targeting therapy. There were no biological differences between TROP2 positive and negative cases of PD-L1 positive LUADs and EGFR mutated LUADs.

P2.06.26 The Clinicopathological Characteristics and Prognostic Analysis of SMARCA4-Deficient Non-Small Cell Lung Cancer

J. Zhang
Shanghai Geriatric Medical Center, shanghai/CN

Introduction: To investigate the clinicopathological features of SMARCA4 deficient non-small cell lung cancer (NSCLC), and to evaluate the value of SMARCA4 gene mutation and its protein expression loss in clinical prognosis.

Methods: Advanced NSCLC patients diagnosed from January 2022 to January 2024 were selected, including 32 cases with BRG1 deficient and 64 cases with BRG1 intact expression. TCGA and MSKCC databases contained SMARCA4 gene mutation profile, mRNA expression level and the clinical prognostic information were downloaded.

Results: The main mutation types of SMARCA4 gene included missense mutation (52%), nonsense mutation (23%), frameshift deletion (12%), frameshift insertion (3%), and splice site mutation (10%). BRG1-deficient NSCLC is predominantly male (68.8%) with a history of tobacco exposure (65.6%) and a poor prognosis (Median OS of 12.0 months). The histopathological types were diverse, with poorly differentiated adenocarcinomas, The tumor stroma exhibits significant inflammatory cell infiltration and necrosis, with easily observable mitotic figures in tumor cells. Additionally, TTF-1 is negatively expressed in 76.1% of cases. The median level of proliferation index Ki-67 was 70%, and the positive rate of PD-L1 expression accounted for 68.7% (53.1% of which had an expression range of 1-49%, and 25% showed high expression). The co-deficient rate of BRG1 and BRM was 6.2%, and no co-deficient of BRG1 and ARID1A/ARID1B were found. In 954 NSCLC patients, there was no significant difference in overall survival between the SMARCA4 mutant group and the non-mutant group ($p>0.05$), while low expression of SMARCA4 mRNA ($p<0.05$) , especially BRG1 protein deficient ($p<0.0001$) predicted a worse clinical prognosis.

Conclusions: SMARCA4/BRG1-deficient NSCLC exhibits a highly aggressive clinicopathological phenotype. The loss of BRG1 protein serves as a more robust prognostic stratification factor compared to SMARCA4 gene mutations, warranting in-depth basic research and clinical trials to identify precise and effective therapeutic strategies.

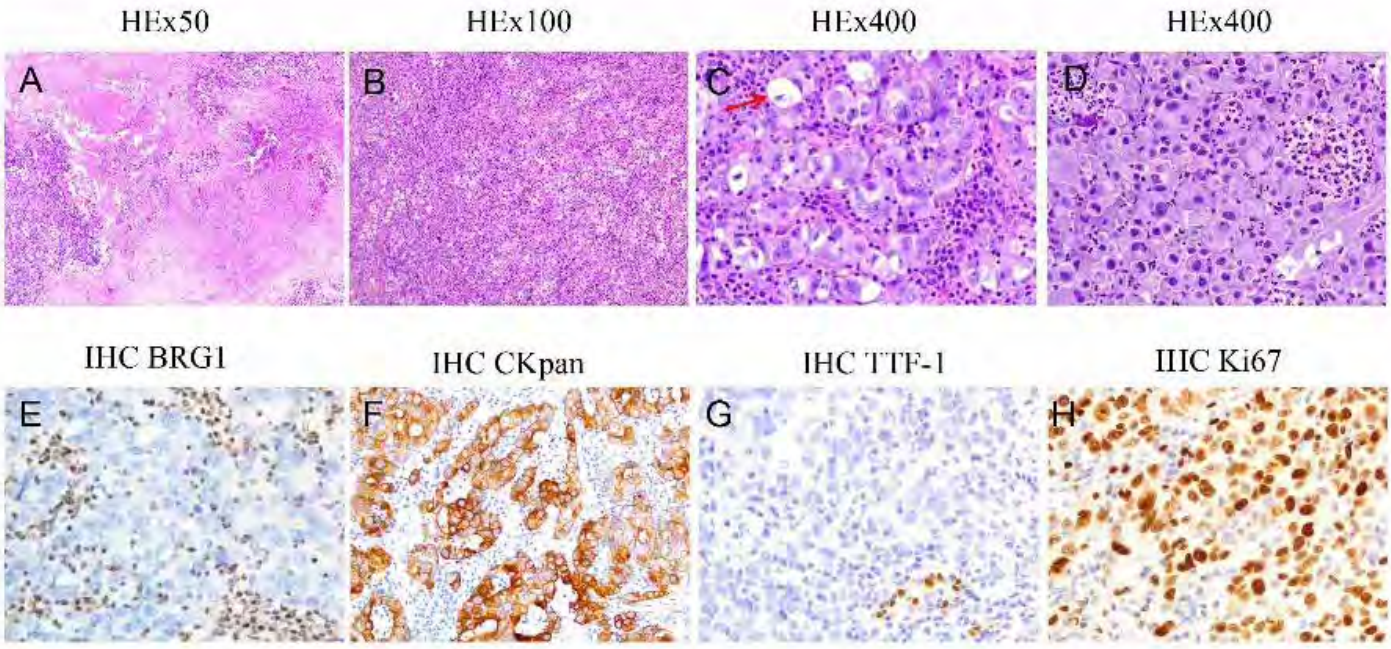

Figure 1. Pathological characteristics of BRG1-deficient adenocarcinoma. (A) HE staining shows poorly differentiated morphology with solid sheet-like arrangement and extensive necrosis (50× magnification). (B) HE staining shows some tumor cells with clear cytoplasm and an inflammation-rich background (100× magnification). (C) HE staining shows significant cellular atypia, prominent nucleoli, frequent mitotic figures, and poorly formed glandular structures (red arrow) (400× magnification). (D) Rhabdoid tumor cells with distinct eosinophilic nucleoli and a high mitotic rate (400× magnification). (E) Immunohistochemical staining shows loss of BRG1 expression in tumor cells with positive expression in background inflammatory cells (400× magnification). (F) Immunohistochemical staining shows CKpan is positive in tumor cells (400× magnification). (G) Immunohistochemical staining TTF-1 is negative in tumor cells (400× magnification). (H) immunohistochemical staining shows approximately 80% Ki67 positivity in tumor cells (400× magnification).

Introduction: The EGFR T790M mutation in non-small cell lung cancer (NSCLC) is most commonly acquired and associated with resistance to first-and second-generation EGFR tyrosine kinase inhibitors (TKIs). However in less than 1% of NSCLC cases, this mutation occurs as a germline alteration, significantly increasing the risk of developing lung cancer, particularly in non-smokers. Third-generation EGFR TKIs like osimertinib are effective for acquired T790M mutations, but their role in germline mutations is underexplored. The INHERIT trial showed that germline EGFR mutations can lead to an earlier age of diagnosis and may impact clinical outcomes. This study presents four rare cases of NSCLC patients with germline EGFR T790M mutations, providing insights into treatment responses, familial screening, and potential for region-specific genetic counseling and early detection.

Methods: This retrospective study analyzes four female patients who do not smoke diagnosed with NSCLC between 2017 and 2022, all with germline EGFR T790M mutations identified through tissue and plasma circulating tumor DNA biopsies. First-line therapy with osimertinib was initiated for all patients, and genetic screening was offered to first-degree relatives to assess familial risk. CT scans were recommended for relatives with positive test results. Clinical data were collected to evaluate disease progression, response to therapy, and the impact of genetic findings on clinical practice. Descriptive statistics were used to analyze treatment responses, survival outcomes and the correlation between variant allele frequencies (VAF), and treatment efficacy.

Results: All four patients demonstrated the germline EGFR T790M mutation. Patient A, diagnosed in 2022, initially responded well to osimertinib but developed pneumonitis, leading to treatment cessation. After disease progression, reduced-dose osimertinib was reintroduced, leading to disease stabilization. Patient B, diagnosed in 2020, achieved stable disease on osimertinib combined with stereotactic radiosurgery for brain metastasis. Patient C, diagnosed in 2021, showed progression despite osimertinib monotherapy, but responded favorably to osimertinib and amivantamab. Patient D, diagnosed in 2017, remained stable on osimertinib after radiation therapy. Genetic testing of family members revealed several first-degree relatives who tested positive for the T790M mutation and were enrolled in CT screenings for early detection. Although genetically unrelated, these patients were suspected to have inherited the mutation based on high VAFs observed in molecular testing of their tumors.

Conclusions: Germline EGFR T790M mutations, though rare, significantly impact NSCLC management. Osimertinib was effective for these patients, with most achieving disease stability, though the responses were not always sustained. This study emphasizes the importance of genetic testing for patients with suspected germline mutations and their first-degree relatives. Given the increased 50-60% risk of lung cancer in these individuals, as reported in the literature, we recommend family members undergo lung cancer screening to facilitate early detection. The findings suggest the need for region-specific genetic counseling and targeted screening programs for high-risk families. Further research into osimertinib's efficacy in germline EGFR T790M mutations is essential. Larger cohort studies and clinical trials are needed to establish standardized protocols for familial screening and treatment strategies. Enhanced understanding of germline EGFR T790M mutations will improve both treatment outcomes and early detection in at-risk families.

P2.06.28 GPC3 Upregulation After Neoadjuvant Chemoimmunotherapy Associates With Adverse Outcomes and Tumor Heterogeneity in Squamous NSCLC

L. Jiang, C. Wan, J. Nie, w. Zhong
hospital, guangzhou/CN

Introduction: Lung squamous cell carcinoma (LUSC) accounts for approximately 20%-30% of non-small cell lung cancer (NSCLC). With breakthroughs from studies such as KEYNOTE-671, neoadjuvant immunochemotherapy has become the standard treatment for resectable LUSC. However, current efficacy evaluation systems (e.g., major pathological response, MPR) exhibit significant individual variability in predicting long-term outcomes. Glypican-3 (GPC3), a member of the heparan sulfate proteoglycan family, has been confirmed as a prognostic biomarker in hepatocellular carcinoma, yet its role in the tumor microenvironment (TME) remodeling of LUSC and therapy-induced expression dynamics remain unclear.

Methods: This study enrolled 24 LUSC patients who underwent direct surgical resection (without neoadjuvant therapy) and 44 patients who received neoadjuvant immunochemotherapy followed by surgery at Guangdong Provincial People's Hospital between 2021 and 2024. Additionally, 15 patients with histopathologically confirmed LUSC bone metastases were included. GPC3 expression was independently assessed by two blinded pathologists (positivity defined as H-score ≥10). Statistical analyses included Fisher's exact test (categorical variables) and Mann-Whitney U test (continuous variables). Survival analysis was performed using Cox proportional hazards models adjusted for clinical staging factors.

Results: In the direct surgery group (n=24), 13 (54%) were GPC3-positive, whereas in the neoadjuvant immunochemotherapy group (n=44), 32 (73%) were GPC3-positive. In contrast, only 2 (13%) of the bone metastasis cases (n=15) exhibited GPC3 positivity. Statistical analysis revealed that GPC3 positivity increased post-neoadjuvant therapy, though not significantly (p=0.18, 95% CI [0.14, 1.43]). Notably, GPC3 expression was significantly lower in bone metastases compared to primary lung lesions (p=0.017, 95% CI [1.23, 80.32]). Using the Mann-Whitney U test, we compared GPC3+ cell proportions between the direct surgery and neoadjuvant groups. The neoadjuvant group exhibited significantly higher values (W=702, p=0.013). Descriptive statistics showed that the median GPC3+ cell proportion in the neoadjuvant group was 50 (IQR: 5-70), significantly higher than that in the direct surgery group (median=15, IQR: 0-40), suggesting that neoadjuvant immunochemotherapy induces GPC3 upregulation. To assess prognostic differences, patients were stratified by GPC3 IHC results. Among 24 GPC3-positive patients, 18 (75.0%) experienced recurrence, whereas only 1 of 11 (9.1%) GPC3-negative patients relapsed (p=0.00056, 95% CI=[2.84, 1358.96]). Postoperative adjuvant therapy did not influence recurrence risk (overall p=1.0; within the GPC3-positive subgroup, p=0.649). Kaplan-Meier analysis (median follow-up: 20.1 months) showed that the GPC3-positive group had a median event-free survival (EFS) of 17.7 months (95% CI: 14.6-not reached), whereas the negative group did not reach median EFS. The log-rank test confirmed significant survival curve divergence (p=0.0117).

Conclusions: This study is the first to demonstrate that neoadjuvant immunochemotherapy induces GPC3 upregulation in the LUSC TME, with GPC3+ phenotype strongly associated with early postoperative recurrence. The heterogeneity in GPC3 expression between primary and metastatic lesions suggests potential epigenetic reprogramming during metastatic progression. However, due to the limited sample size (n=83) and lack of multi-omics validation, future studies integrating single-cell RNA sequencing and spatial transcriptomics are warranted to elucidate the functional role of GPC3.

P2.06.29 Bridging Histopathology and Molecular Profiling: AI-Powered Virtual Multiplex Immunofluorescence Staining for LUAD Prognosis

H. Zhou[1], Y. Lei[1], Q. Li[2], Q. Zhang[3], C. Cai[1], W. Zhan[1], Y. Zhang[1]
[1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]The Second Affiliated Hospital Zhejiang University School of Medicine, Hangzhou/CN ,[3]Guangdong Cardiovascular Institute, Guangdong Provincial People's Hospital , Guangdong Academy of Medical Sciences, Guangzhou/CN

Introduction: Multiplex immunofluorescence (mIF) is widely used in tumor research to simultaneously visualize multiple biomarkers, providing detailed insights into the tumor immune microenvironment. However, mIF is costly and time-consuming, with limited histopathological context. Consequently, hematoxylin and eosin (H&E)-staining remains the primary method for cancer diagnosis. Here, we introduce HEMIFuse, a generative artificial intelligence-based platform that rapidly synthesizes virtual mIF images solely from routine H&E images.

Methods: The HEMIFuse platform was developed using the pix2pixHD generative adversarial network model. A total of 133 patients with stage I-III lung adenocarcinoma (LUAD) who underwent surgery were retrospectively enrolled and randomly divided into the training (n=100) and validation set (n=33). Formalin-fixed, paraffin-embedded (FFPE) tumor tissue sections were initially subjected to mIF staining, followed by high-resolution whole-slide imaging. The same sections were then restained with H&E and scanned. This procedure yielded spatially aligned, cell-level paired H&E and mIF images from identical histological regions (Fig. 1a), providing a high-quality dataset for applying AI to integrate histopathology with multiplex molecular information.

Results: Comprehensive image evaluation demonstrated that virtual mIF images generated by the HEMIFuse platform were of high quality and showed strong concordance with ground-truth images (Fig. 1c and d). Specifically, the highest SSIM and corresponding PSNR values on the validation set for the four LUAD-related biomarkers—CD3 (0.91 ± 0.05, 32.86 ± 4.13), CD20 (0.88 ± 0.08, 35.21 ± 3.05), CD68 (0.90 ± 0.05, 33.61 ± 3.55), and PD-L1 (0.85 ± 0.06, 31.26 ± 5.78). Additionally, the biomarker expression levels derived from virtual mIF images enabled prognostic stratification in LUAD patients ($p < 0.05$), achieving performance comparable to chemically stained mIF images. (Fig. 2).

Conclusions: The HEMIFuse platform enables rapid and accurate conversion of routine H&E images into virtual mIF images, significantly reducing cost of mIF staining and streamlining histopathology workflows.

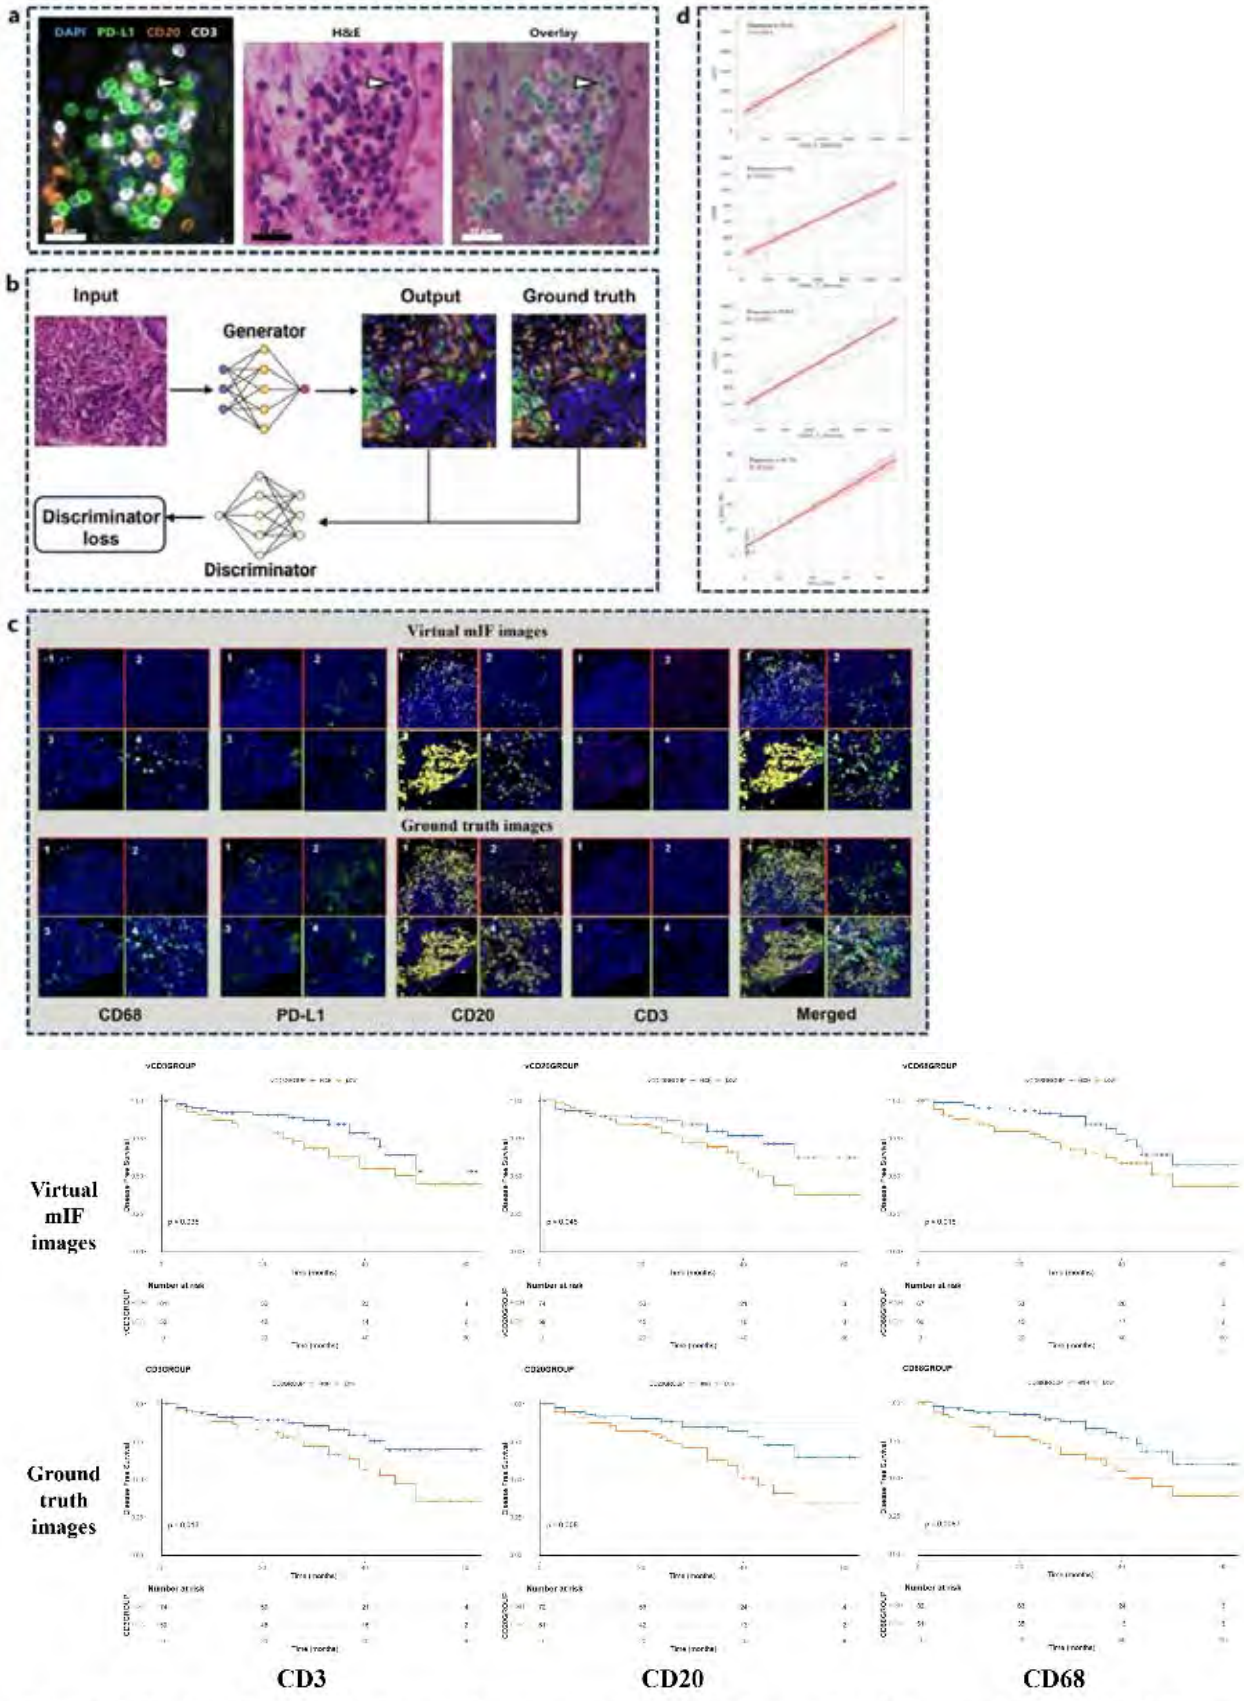

Figure 2: Kaplan–Meier survival curves based on virtual mIF and ground truth images, labeled with different biomarkers, for patients with LUAD.

P2.06.30 ITGBL1: A Predictive Biomarker for IPF-LUSC Comorbidity Risk in Lung Transplant Candidates

Z. Yang[1], H. Yang[1], Z. Wang[2], Q. Yu[1], K. Su[1], J. Zhang[1], F. Xiao[1], C. Liang[1]
[1]China-Japan Friendship Hospital, BeiJing/CN ,[2]China-Japan Friendship Institute of Clinical Medicine, BeiJing/CN

Introduction: Lung transplantation has become a primary treatment for end-stage lung diseases, including idiopathic pulmonary fibrosis (IPF), chronic obstructive pulmonary disease (COPD), and cystic fibrosis (CF). IPF patients face a significantly elevated risk of developing lung squamous cell carcinoma (LUSC), though the underlying mechanisms remain unclear. Since lung cancer is an absolute contraindication for transplantation, there is an urgent need for biomarkers to assess malignant transformation risk in IPF patients pre-transplant. This study aims to identify predictive biomarkers for lung cancer risk in transplant candidates.

Methods: Using single-cell RNA sequencing data from IPF-LUSC lung samples, IPF datasets from GEO, and LUSC data from TCGA, we identified common differentially expressed genes (DEGs) between two diseases. LASSO regression and SVM-RFE algorithms were applied to screen core candidate genes. SHapley Additive exPlanations (SHAP) interpretability analysis evaluated gene importance and model contribution. Kaplan-Meier survival analysis assessed prognostic impacts. PPI networks, GSEA functional enrichment, and immune cell infiltration analyses were performed for core genes. Single-cell RNA data further validated gene specificity in IPF-LUSC tumor tissues. All analyses used R language (v4.4.1).

Results: Cross-analysis revealed 409 shared DEGs. LASSO and SVM-RFE identified five core genes: BCHE, C1orf210, ITGBL1, PLLP, and SCG5. The XGBoost model (AUC-ROC=0.982) highlighted ITGBL1 as a key gene via SHAP analysis. Survival analysis showed high ITGBL1 expression correlated with reduced overall survival in LUSC patients (p=0.0014) but not in IPF cases. GSEA linked high ITGBL1 to cell cycle and proliferation pathways. Immune infiltration analysis revealed positive associations between ITGBL1 and naïve B cells/M1 macrophages in IPF (p<0.05). Single-cell data confirmed ITGBL1 overexpression in smooth muscle cells of IPF-LUSC tumor samples.

Conclusions: High ITGBL1 expression in IPF-LUSC patients may serve as a critical risk factor for malignancy. This finding could refine lung transplant recipient selection and enable perioperative interventions to improve long-term outcomes.

P2.06.31 Translational Analysis of NSD3 Gene Amplification in Lung Squamous Cell Carcinoma: Clinical Impact and Prognostic Insights From Histopathology

S. Takahashi
National Cancer Center Hospital East, Kashiwa/JP

Introduction: Nuclear receptor-binding SET domain 3 (NSD3), a histone H3 lysine 36 methyltransferase, has been implicated as a driver of lung squamous cell carcinoma (LUSC) in preclinical studies. However, the clinicopathological characteristics and prognostic significance of NSD3 amplification in LUSC remain unclear. To address this, we performed histopathological analysis of patient tissue samples.

Methods: The NSD3 gene copy number was evaluated using fluorescence in situ hybridization in 268 surgically resected LUSC cases, categorized into the amplification (Amp) and diploidy (Diploidy) groups. Clinicopathological characteristics were compared, and artificial intelligence-based image analysis was used to investigate the correlation between NSD3 amplification and protein expression, cancer cell proliferation, and tumor-infiltrating lymphocytes through immunohistochemistry.

Results: NSD3 amplification was detected in 106 (39.6%) patients. NSD3 protein expression was positively correlated with the NSD3 gene copy number ($R = 0.528$, $P < 0.001$). The Amp group exhibited higher mitotic counts ($P = 0.004$) and MIB-1 labeling index ($P = 0.009$) than the Diploidy group. No significant differences in the numbers of CD8-, Forkhead box P3-, or CD20-positive tumor-infiltrating lymphocytes were observed between the two groups. The Amp group had shorter overall survival than the Diploidy group ($P = 0.030$), and multivariable analysis revealed that NSD3 amplification is an independent poor prognostic factor ($P = 0.049$).

Conclusions: Our study highlights the clinical relevance of NSD3 amplification in LUSC using patient tissue analyses. These findings emphasize the potential of NSD3 as a prognostic biomarker and therapeutic target, bridging the gap between preclinical research and clinical application.

P2.06.32 Impact of piR_004530 Reactivation in Lung Cancer: Implications for Recurrence and Survival of Lung Squamous Cell Carcinoma Patients

Y. He[1], M. Acosta-Plasencia[1], D. Sánchez-Lorente[2], N. Viñolas[2], D. Martínez[2], T. Díaz[1], A. Altuna-Coy[1], R. Na[1], M. Boada[2], A. Guirao[2], L. Molins[2], R.M. Marrades Sicart[2], A. Navarro Ponz[1]
[1]Universitat de Barcelona, Barcelona/ES ,[2]Hospital Clinic de Barcelona, Barcelona/ES

Introduction: PIWI-interacting RNAs (piRNAs) are germline-characteristic small non-coding RNAs whose reactivation has been recently observed during carcinogenesis as a consequence of the germline reactivation program, which can be considered a hallmark of cancer. We have evaluated the prognostic impact of piR_004530 reactivation in non-small cell lung cancer (NSCLC) patients and studied its functional role in cell lines and organoid models.

Methods: A total of 243 NSCLC resected patients were analyzed. PiR_004530 expression was quantified in tumor (n=243) and normal tissue (n=31) using qRT-PCR. Tumor recurrence after surgery, disease-free survival (DFS), and overall survival (OS) were used as clinical endpoints in survival analysis. Cox regression models were generated and decision curve analysis for assessment of clinical benefit on disease prognosis was used. The effect of piR_004530 overexpression was assessed in squamous cell carcinoma (SCC) cell lines by cell migration, invasion, proliferation, apoptosis, and colony formation analysis. Patient-derived organoids from SCC patients were generated and cell viability was evaluated after piRNA overexpression.

Results: PiR_004530 became reactivated on the tumor compared to normal tissue and was overexpressed in SCC patients. The prognosis analysis in the whole cohort showed that patients with high levels of piR_004530 had shorter DFS and OS. However, the subanalysis by histology revealed that the true prognostic impact of piR_004530 was specifically on SCC patients. SCC patients with high piR_004530 had a higher relapse rate and shorter DFS and OS. piR_004530 emerged as an independent prognostic factor in the multivariate analysis. Since the SCC patients that received adjuvant treatment had the best post-surgical prognosis, we focused on the role of piR_004530 on non-treated patients, which allowed us to identify a high-risk group where the piRNA ameliorated patient's risk stratification, highlighting superior clinical benefit in postsurgical relapse prediction. piR_004530 overexpression was associated with increased migration, invasion, and proliferation, while apoptosis was inhibited in SCC cell lines. Moreover, the overexpression induced stem cell gene activation. In patient-derived organoids, the overexpression boosted organoid cell viability.

Conclusions: PiR_004530 became reactivated in NSCLC where it played a role as an oncogene and its higher levels correlated with disease recurrence and shorter survival in SCC patients.

P2.06.33 Prognostic Significance and Therapeutic Potential of LILRB4 in Mdsc-Mediated Immunosuppression in NSCLC

S. Kumata[1,2], H. Notsuda[1,2], M-T. Su[2,3], R. Saito-Koyama[4,5], R. Tanaka[1,2], Y. Suzuki[1,2], J. Funahashi[2], S. Endo[2], I. Yokota[6], T. Takai[2], Y. Okada[1,2]
[1]Tohoku University Hospital, Sendai/JP ,[2]Institute of Development, Aging and Cancer, Tohoku University, Sendai/JP ,[3]National Yang Ming Chiao Tung University, Taipei/TW ,[4]Tohoku University Graduate School of Medicine, Sendai/JP ,[5]National Hospital Organization, Sendai Medical Center, Sendai/JP ,[6]Hokkaido University Graduate School of Medicine, Biostatistics/JP

Introduction: Recently, a pro-tumor role of immunosuppressive MDSCs (myeloid-derived suppressor cells) is, at least partly, attributed to the presence of leukocyte Immunoglobulin-like receptor B4 (LILRB4/ILT3 in humans and its murine ortholog, gp49B) which are expressed on MDSCs, and some recent pieces of literature report that B4 is associated with cancer progression and prognosis. Previously, we investigated the mechanism by which B4 expressed on MDSCs promotes cancer progression in a mouse model and reported that inhibition of the B4 immune checkpoint suppresses metastasis (Su MT, Kumata S, et al. Oncoimmunology. 2022;11:2060907). However, no studies were examined the significance of the B4 immune checkpoint in non-small cell lung cancer (NSCLC) patients.

Methods: A retrospective study was conducted on 239 patients who underwent curative lung resection for NSCLC between 2011 and 2017. B4 expression levels in tumor-infiltrating stromal cells were assessed by immunohistochemistry and scored. The relationship between B4 expression and clinicopathological factors, as well as prognosis, was analyzed retrospectively. Whether the blocking of B4 on human PBMC-derived CD33+ MDSCs inhibited the migration ability of lung cancer cells was also examined using transwell migration assay.

Results: The median age of the patients was 70 years (range: 41-86 years), and 85 (35.6%) were female. The predominant histological type was adenocarcinoma (142 cases, 59.4%). High: B4 expression was observed in 75 patients (31.4%), including 26 (34.7%) with adenocarcinoma. The median follow-up period was 69.5 months (range: 1.7-119.6 months). Patients with high B4 expression had significantly shorter overall survival (OS) and recurrence-free survival (RFS) ($p = 0.013$ and $p < 0.005$, respectively). Multivariate analysis identified high B4 expression as an independent prognostic factor for poor OS and RFS ($p = 0.04$ and $p < 0.005$, respectively). Even in the cohort background aligned by propensity score matching, OS ($p = 0.023$) and RFS ($p = 0.0046$) in the B4 high group were shorter than in the B4 low group. Some of the B4 positive cells were positive for MDSC markers, CD33 and CD14. Transwell migration assay demonstrated that blocking B4 significantly inhibited the migration of human lung cancer cells cocultured with CD33+ MDSCs.

Conclusions: The results suggested that B4/gp49B participates in MDSC-mediated immunosuppression in the tumor microenvironment and that the targeting of B4 could be a novel strategy to improve immune checkpoint therapy.

P2.06.34 Tumor Heterogeneity Based Prognostic Score: What the Specimen Tells Us in the Intelligent Era?

Z. Huang[1], S. Wang[2], M. Zhang[1], B. Zhang[1], S. Shi[3], L. Wang[4], S. Wang[1], Y. Li[1]
[1]Fudan University Shanghai Cancer Center, Shanghai/CN ,[2]Butiange Co., Ltd, Shanghai/CN ,[3]Nanjing University, Nanjing/CN ,[4]University of Science and Technology of China, Hefei/CN

Introduction: Tumor heterogeneity plays key role in regulating tumor recurrence and therapy resistance. Especially microenvironmental heterogeneity is clearly suggestive of recurrence and death risk. Further studies are needed to determine whether tumor heterogeneity-based score can predict prognosis and guide future treatment strategies.

Methods: To investigate the relationship between prognostic outcome and tumor heterogeneity-based score, a total of 205 non-small cell lung cancers (NSCLCs) are collected. First, the specimen is measured and recorded as a novel macro-parameter (YOU parameter, optimal from Young modulus). Then we build an optimized AI model for micro-parameters detection, including tumor-infiltrating lymphocytes (TILs) and tertiary lymphoid structure (TLS). The percentage of TILs/tumor area is scored as 1 point (<0.25), 2 points (≥0.25 and <0.5) and 3 points (≥0.5). Cordon model between TILs and tumor is marked as 1 point. Intra-tumor gathering model is marked as 2 points. Other spatial models are marked as 0. Besides, no TLS, immature TLS and mature TLS are marked as 0, 1, 2 separately. The TLS number/10HPF is identified as 0 (1-5), 1 point (6-10) and 2 points (>10). The spatial construction model is defined as the inside model (inside tumor area=2), boundary model (0.785mm2 area centered on the tumor border =1), and exclusive model (outside tumor area=0). Finally, the multi-dimensionality Fu-TOP-Pro scoring is built to predicate recurrence risk post-operation. This Fu-TOP-Pro scoring consists of the macro-parameter (YOU parameter) and micro-parameters (TILs+TLS).

Results: Differences in tumor composition result in different macro-parameter (YOU parameter) values. Obviously, YOU parameter performs well in distinguishing tumor and non-neoplastic adjacent tissues. It shows a dramatically high level in tumor (A). Progressed cases tend to have higher YOU parameter, especially in early stage cases (B-F). Besides, for micro-parameters, AI-based reorganization accuracy of TILs and TLS reach 98.53% and 97.23% respectively (G and H). Both gathering model and cordon model of TILs, and inside model of TLS are positively related to good prognosis (I-L). Finally, the Fu-TOP-Pro scoring model performs better in PFS prediction compared to TNM stage (M-O). Fu-TOP-Pro score is an independent prognostic factor (P, Fu-TOP-Pro=1, HR=3, p=0.007).

Conclusions: To sum up, the findings of both macro- and micro-parameters are of great significance to identify the post-operation recurrence risk. It provides new ideas and AI views for prognosis prediction, indicating the potential of broad application prospects.

P2.06.35 Extracellular Vesicle RNA Diversity in Lung Adenocarcinoma: Driving Immunosuppression and Metastasis

Z. Chen[1], S. Lao[2], Y. Zhao[2]
[1]The Affiliated Qingyuan Hospital of Guangzhou Medical University, Qingyuan/CN ,[2]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Lung adenocarcinoma (LUAD), the predominant subtype of non-small cell lung cancer (NSCLC), utilizes lymph node involvement as a key prognostic determinant. Although tumor-draining lymph nodes (TDLNs) coordinate antitumor immunity, the spatial heterogeneity of extracellular vesicle (EV) RNA profiles across primary tumors, TDLNs, and systemic circulation remains undefined. This study investigates EV RNA dynamics to elucidate their roles in establishing immunosuppressive niches.

Methods: We conducted multi-tissue EV RNA profiling of primary tumors, TDLNs (node-positive: TDLN+), and plasma from LUAD patients. Integrated bioinformatics analyses characterized RNA diversity, functional pathways, and immune-stromal crosstalk.

Results: Primary tumor-derived EVs (Ti-EVs) preferentially retained long non-coding RNAs (lncRNAs) and transfer RNAs (tRNAs) within the tumor microenvironment (TME), whereas plasma EVs displayed distinct mRNA and miRNA profiles. Functionally, primary Ti-EVs promoted neutrophil extracellular trap (NET) formation and systemic dissemination, while TDLN+ Ti-EVs activated insulin-like growth factor (IGF) signaling. Both primary and metastatic niches exhibited stromal-epithelial-myeloid enrichment but lacked immune infiltration. Strikingly, EV-mediated LGALS9-HAVCR2 signaling in TDLN+ engaged activated dendritic cells (aDCs), monocyte-derived macrophages (mo-Macs), and exhausted CD8+ T cells, establishing a potent immunosuppressive axis.

Conclusions: Our study uncovers EV RNA heterogeneity as a driver of multidimensional immunosuppressive TME in LUAD. Conserved lncRNA/tRNA signatures in Ti-EVs and plasma EVs highlight their potential as liquid biopsy biomarkers. Therapeutic targeting of the LGALS9-HAVCR2 axis may disrupt immunosuppressive signaling in nodal metastases, offering clinical translation opportunities. These findings illuminate EV-mediated intercompartmental crosstalk in cancer progression.

P2.06.36 Proteomic Atlas Reveals Organ-Specific Metabolic and Functional Shifts in Preclinical Icb-Related Pneumonitis and Colitis

Z-X. Rong, Z-N. Wu, X-T. Cai, K-M. Zhuang, Z-P. Xu, H-T. Qu, Y-P. Zhang, Z-Y. Dong
Nanfang Hospital, Southern Medical University, Guangzhou/CN

Introduction: Immune checkpoint blockade (ICB)-associated colitis and pneumonitis are clinically significant immune-related adverse events (irAEs), yet insights in their systemic and tissue-specific proteomic alterations remain unclear.

Methods: We performed label-free 4D-DIA proteomic analysis on colon, lung, and splenocytes from murine models of radiation-induced pneumonitis (radiation ± ICB) and DSS-induced colitis (DSS ± ICB). Gene Ontology (GO) and KEGG enrichment analyses were used to identify altered pathways.

Results: In pneumonitis, lung tissues exhibited adaptive immune activation, dysregulated complement/coagulation cascades, and enhanced intracellular pathogen processing (symbiont-containing vacuole membrane and TAP binding). Spleens showed systemic metabolic reprogramming with upregulated nucleoside, carbohydrate, and cysteine/methionine metabolism. In colitis, inflamed colons displayed neuron-epithelial alterations (synapse, neuron-projection, and cell adhesion) concurrent with immune activation, while spleens exhibited enriched carbohydrate and arachidonic acid metabolism.

Conclusions: This study maps organ-specific proteomic landscapes of irAEs, highlighting systemic metabolic rewiring and functional alterations of local proteins. These findings underscore the tissue-specific nature of irAE pathogenesis and potential therapeutic targets.

P2.06.37 NGS Testing in Lung Cancer Within the Catalan Precision Oncology Program: The ICO-HUB Comprehensive Cancer Center Experience

M. Mosteiro Lamas[1], M. Varela[2], A. Alay[1], S. Villatoro[2], D. Cordero[1], D. Barroso[3], M. Gausachs[3], M. Ajenjo-Bauza[1], S. Otero[1], S. Padrones[2], S. Aso[2], I. Brao[1], M. Arellano[1], N. Baixeras[1], L. Pijuan[2], D. Azuara[1], M. Jove[1], R. Palmero[1], L. Capdevila[4], M. Plana[1], L. Moliner[1], J. Brenes[1], A. Cuellar[1], J. Saldaña[1], C. Mesía[1], A. Solanes[1], A. Teulé[1], A. Vidal[2], X. Matías-Guiu[2], C. Lázaro[1], E. Nadal[1]
[1]Catalan Institute of Oncology, L'Hospitalet de Llobregat/ES ,[2]Bellvitge Universitary Hospital, L'Hospitalet de Llobregat/ES ,[3]IDIBELL, L'Hospitalet de Llobregat/ES ,[4]Hospital Santa Tecla, Tarragona/ES

Introduction: NGS testing is essential for the clinical management of patients with NSCLC, and equitable access to molecular diagnosis, especially NGS, should be ensured. In Catalonia, the public payer (CatSalut) launched the Precision Oncology Program (POP) to cover NGS testing costs for adult patients diagnosed with stage IB-IV non-squamous NSCLC or squamous NSCLC if younger than 50y or those with low tobacco exposure.

Methods: This observational study aimed to capture the clinicopathological and molecular characteristics of patients with NSCLC who participated in the POP within our campus. Molecular testing was conducted at the Molecular Core of the Bellvitge Universitary Hospital (HUB) and the Catalan Institute of Oncology (ICO), covering a large population area and collaborating with eight affiliated regional hospitals. Patients were eligible if they underwent a single NGS test to identify actionable genomic alterations. All cases were discussed in a multidisciplinary tumor board.

Results: 1653 patients were registered who participated in the POP from February 2020 to March 2025. Two sequencing platforms were used: Trusight Oncology 500 (TSO500) in 299 patients (18.1%) and Oncomine Precision Assay (OPA) in 1354 patients (81.9%). Median age was 67 years and most patients were males (66.1%), ECOG PS 0-1 (66.5%) and had stage IV disease (61%). Most patients were current or former smokers (84.1%). The most frequent histology was lung adenocarcinoma (74.5%), followed by squamous (7.2%). The median tumor cell infiltration was 40% (range, 5-100%) and NGS was not informative only in 37 cases (2.2%). The following drivers were detected in the whole cohort: KRAS mutations 526 (31.8%), being G12C 217 (13.1%); EGFR mutations 192 (11.6%), including exon 19 deletions in 97 (5.9%), L858R in 57 (3.4%) and other mutations 38 (2.3%); BRAF mutations 77 (4.7%), being V600E 24 (1.5%); ALK fusions 33 (2.0%); ERBB2 mutations 33 (1.9%); MET exon 14 skipping mutations 28 (1.7%); ROS1 fusions 14 (0.8%), RET fusions 8 (0.5%), NTRK fusions (0.06%). Actionable drivers were detected in 550 patients (33.3%) and were more frequently observed in patients with non-squamous histology (35.1%) compared with those with squamous cell carcinoma (9.3%). More information on clinical outcomes will be presented at the conference.

Conclusions: NGS testing is feasible in a public health system to enable equitable access to treatment. The frequency of actionable driver alterations is consistent with the known prevalence in Europe. The POP of Catalonia allowed the identification of patients to receive targeted therapy within the ICO-HUB network.

Table 1. Frequency of actionable driver alterations according to histology

Actionable genomic alterations	Non squamous NSCLC (n=1534)	Squamous NSCLC (n=119)
KRAS G12C	213 (13.9%)	4 (3.4%)
EGFR	187 (12.2%)	5 (4.2%)
ALK fusions	33 (2.2%)	0 (0.0%)
ERBB2 mutations	32 (2.1%)	1 (0.8%)
MET ex14 mutations	27 (1.8%)	1 (0.8%)
BRAF V600E	24 (1.6%)	0 (0.0%)
ROS1 fusions	14 (0.9%)	0 (0.0%)
RET fusions	8 (0.5%)	0 (0.0%)
NTRK fusion	1 (0.06%)	0 (0.0%)

P2.06.38 BTN1A1 and Nuclear YAP1 Co-Expression as Predictive Biomarkers for Nelmastobart Efficacy in Lung Cancer: Findings From a Phase 1 Trial

S.S. Yoo, B-K. Hong, C. Wu, S.H. Lee, Y. Kim
STCube Pharmaceuticals, Inc, Rockville/MD/USA

Introduction: Butyrophilin 1A1 (BTN1A1) is a novel immune checkpoint protein expressed in various human tumors and immune cells. It has been shown to be co-expressed with Yes-associated protein 1 (YAP1), a central effector of the Hippo signaling pathway that translocates to the nucleus under stress conditions. The co-expression of BTN1A1 and nuclear YAP1 is thought to promote tumor growth, immune evasion, and chemoresistance. High levels of BTN1A1 and nuclear YAP1 expression have been observed in lung cancer, highlighting their potential as therapeutic targets. Recently, a first-in-human Phase 1 clinical trial of Nelmastobart, a BTN1A1-targeting antibody, was completed. This study compared immunohistochemical profiles and tumor microenvironment characteristics between responders and non-responders to Nelmastobart in a cohort of patients with small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC). The goal was to inform the design of future clinical trials based on BTN1A1 and YAP1 expression and CD8+ T cell infiltration.

Methods: Tissue samples from four lung cancer patients (three SCLC and one NSCLC) were analyzed to evaluate BTN1A1 expression and tumor microenvironment features. A non-small cell lung cancer tissue microarray (TMA) was included for broader comparative analysis. Multiplex immunofluorescence staining was performed using the Akoya OPAL 6-color system, with a panel including BTN1A1, PD-L1, CD8, Ki-67, PanCK, and YAP1. Slides were scanned using the Akoya PhenoImager HT 2.0, and image analysis was conducted using QuPath and R.

Results: Analysis of the NSCLC TMA revealed BTN1A1 expression in approximately 60% of cases. Co-expression analyses showed that tissues with strong BTN1A1 expression had a higher proportion of cells co-expressing nuclear YAP1 (8-12%), while co-expression with PD-L1 was rarely observed. Treatment with Nelmastobart was well-tolerated, with the most common adverse events being low-grade fatigue and infusion-related reactions. Among enrolled SCLC and NSCLC patients, those with high nuclear YAP1 expression and BTN1A1 positivity in baseline tissue achieved stable disease (SD). Notably, patients with high nuclear YAP1 expression demonstrated improved progression-free survival compared to those with low YAP1 expression.

Conclusions: Preliminary results from the TMA analysis and Phase 1 trial suggest that targeting BTN1A1 with Nelmastobart is safe and shows early signs of clinical activity in lung cancer, particularly among patients with high nuclear YAP1 expression. These findings support further investigation in larger, biomarker-enriched clinical trials to validate BTN1A1 and YAP1 as predictive biomarkers and confirm the therapeutic efficacy of Nelmastobart in lung cancer.

Keywords: BTN1A1, YAP1, Nelmastobart

P2.06.39 Predicting Relapse and TKI Response Using DNA and RNA EGFR VAF in EGFR-Mutant Lung Adenocarcinoma

R. Espinoza[1], Y-H. Chang[2], J-W. Chen[3], H-Y. chen[1]
[1]Academia Sinica, Taipei/TW ,[2]National Health Research Institutes, Zhunan/TW ,[3]National Chung Hsing University, Taichung/TW

Introduction: Driver mutations in the epidermal growth factor receptor (EGFR) gene are highly prevalent in non-smoking lung adenocarcinoma (LUAD) patients, particularly in Asian populations; however, their impact on relapse-free survival (RFS) remains controversial. While some studies associate EGFR mutations with a better prognosis, others report no significant difference or even worse outcomes, suggesting that a binary classification of EGFR genotype may be insufficient for patient stratification. Emerging evidence highlights the role of EGFR variant allele fraction (VAF) in predicting tyrosine kinase inhibitor (TKI) efficacy in advanced LUAD, yet its relevance for prognosis or TKI response in early-stage disease remains unexplored. Moreover, previous studies have exclusively relied on DNA VAF, overlooking potential insights from RNA VAF, which may reflect allele-specific expression or other transcriptional influences. In this study, we aim to analyze both DNA and RNA VAF in resected LUAD patients to evaluate their prognostic value for relapse risk and TKI response. This study marks the first investigation of RNA VAF as a clinical biomarker in this context.

Methods: We analyzed 133 untreated stage I-III EGFR-mutant LUAD patients for relapse-free survival (RFS). Additionally, we evaluated progression-free survival (PFS) under TKI treatment in a subset of 48 patients. Whole-exome sequencing data from tumor and adjacent normal tissue (NAT) were used for somatic variant calling, and these data were integrated with tumor RNA sequencing to estimate mutant and wild-type gene expression using a newly developed bioinformatic pipeline. Cox proportional hazards models were applied to calculate hazard ratios (HR) adjusted for clinical variables (sex, age, smoking status, and pathological stage) and molecular profiles (EGFR mutation types, and TP53 genotype).

Results: Both DNA and RNA EGFR VAFs significantly stratified patients' RFS (log-rank tests, $p < 0.0001$), but they identified distinct high- and low-risk subsets. Integrating both models resulted in a three-tier risk group classification with significant adjusted hazard ratios (adj. HR [95% CI]: mid-risk, 3.03 [1.15-7.99]; high-risk, 4.42 [1.56-12.54], compared to low-risk). EGFR-wildtype patients exhibited an intermediate risk (2.03 [0.6-6.89]), underscoring the heterogeneity of EGFR-mutant LUAD. Our model also identified high-risk stage I patients who may require more urgent intervention ($p = 0.0021$). In TKI-treated patients, those who relapsed prior to therapy exhibited the same PFS trend as observed in RFS ($p = 0.047$), whereas non-relapsed patients showed an inverse trend.

Conclusions: These findings highlight the clinical relevance of VAFs beyond EGFR genotype alone and emphasize the importance of evaluating both DNA and RNA VAFs to enable more precise and informed TKI treatment decisions.

P2.06.40 Integrated Molecular Analysis of Advanced NSCLC Depicts Molecular Signatures Associated With Tyrosine Kinase Inhibitors Efficacy

P. Bironzo[1], V. Zambelli[1], F. Napoli[1], E. Garbo[1], S. Poletto[1], G. Farinea[1], S. Cappia[2], A. Merlini[1], I. Rapa[1], L. Righi[1], G.V. Scagliotti[1], M. Volante[1], S. Novello[1]
[1]University of Torino, Orbassano/IT ,[2]AOU S. Luigi Gonzaga, Orbassano/IT

Introduction: Tyrosine kinase inhibitors (TKI) are the mainstay of treatment for advanced oncogene addicted non-small cell lung cancer (NSCLC). However, resistance to TKI invariably occurs during treatment course but data on drug resistance-related mechanisms are largely missing. Therefore, we designed a retrospective study to deeply characterize the genomic and epigenetic signatures associated with TKI response in epidermal growth factor receptor mutation positive (EGFR+) and anaplastic lymphoma kinase rearranged (ALK+) advanced NSCLC patients.

Methods: Samples from patients with advanced NSCLC treated with first-line next-generation TKIs (osimertinib or alectinib) were analyzed for genomic profiling using the Oncomine Comprehensive Assay Plus (ThermoFisher Scientific) panel. Cases were also analyzed using a PCR-based global miRNome assay (miRCURY LNA miRNA PCR kit, Quiagen). Potential targets of significantly deregulated microRNA and their biological functions were predicted by STRING and MirDIP softwares. Clinical characteristics including best response to treatment and progression-free survival (PFS) to 1st line TKI were collected. An exploratory analysis of subgroups of short-term responders (STR) and long-term responders (LTR) was also performed.

Results: Genomic profile was performed in 60 samples (44 EGFR+, 16 ALK+), while miRNome analysis in 52 cases (46 in overlap with NGS testing, 36 EGFR+ and 16 ALK+) (table 1). After a median follow-up for PFS of 14 months (range 4-52), univariate analysis of EGFR+ cases showed significantly shorter PFS in those harboring TP53 co-mutations (HR 3.63, 95% CI 1.55-8.49, p=0.0029) and gain in Chr7p (no gain vs gain: HR 0.36, 95% CI 0.15-0.86, p=0.029). In ALK+ cases a significantly shorter PFS was observed in cases with HLA A gene loss (HR 45.26, 95% CI 3.44-545.2, p=0.004) and those without RMS gains (HR 6.97, 95% 1.27-38.11, p=0.025). MicroRNA profiling clustered both EGFR+ and ALK+ cases into 3 main clusters without significant association with treatment responses. However, LTR and STR showed significant deregulation of a set of microRNA. In EGFR+, the most differentially regulated miRNAs were miR-423-3p, miR-744-5p and miR-455-3p, with a main predicted interference of the transforming growth factor-β pathway, whereas in ALK+ cases immune-related chemokine pathway was deregulated through the modulation of miR-135a-5p, miR-331-3p and miR-196a-5p.

Conclusions: The present data suggest the potential role of extended molecular testing to predict benefit of first-line next-generation TKIs in EGFR+ and ALK+ advanced NSCLC. Data from larger populations are warranted to confirm these preliminary findings.

Table 1 Clinical characteristics of patients

	EGFR+ (n: 44)	ALK+ (n:16)
Median age at diagnosis (range)	72 (35-91)	57(43-83)
Sex (male vs female)	15(34.1%) vs 29(65.9%)	9(56.2%) vs 7(43.8%)
Smoking habits (never vs former vs current)	28(63.6%) vs 11(25%) vs 5(11.4%)	7(43.8%) vs 7(43.8%) vs 2(12.4%)
EGFR mutation subtype (ex19 del vs ex21 L858R vs others) / ALK rearrangement partner (EML4 vs others)	22(50%) vs 21(47.7%) vs 1 (2.3%)	14(87.6%) vs 2(12.4%)
TP53 co-mutation (yes vs no)	26(59.1%) vs 18(40.9%)	13(81.2%%) vs 3(18.8%)
Best response to treatment (CR vs PR vs SD vs PD vs NE)	1(2.3%) vs 30(68.1%) vs 11(25%) vs 1(2.3%) vs 1 (2.3%)	0(0%) vs 13(81.2%) vs 2(12.5%) vs 0(0%) vs 1(6.3%)

P2.06.41 Real-World Data and Utility of Newly Proposed Grading System From IASLC for Invasive Lung Adenocarcinoma in Japan

K. Takegahara[1], H. Hoshino[2], A. Hamada[3], N. Haratake[4], S. Katsumata[5], M. Hashimoto[1], S. Funaki[1]
[1]Hyogo Medical University, Nishinomiya/JP ,[2]NHO Okinawa Hospital, Okinawa/JP ,[3]Kindai University Faculty of Medicine, Osaka-Sayama/JP ,[4]Kyushu University, Fukuoka/JP ,[5]Shizuoka Cancer Center, Shizuoka/JP

Introduction: The IASLC has proposed a new pathological grading system for lung adenocarcinoma. In this classification, tumors primarily showing lepidic growth with less than 20% high-grade components are grade 1; tumors predominantly acinar or papillary with less than 20% high-grade components are grade 2; and tumors with ≥20% high-grade components are grade 3. However, limited data are available on its clinical utility.

Methods: To evaluate the utility of the new IASLC grading system in surgically treated lung adenocarcinoma cases in Japan. We retrospectively reviewed 2,266 lung adenocarcinoma cases, surgically resected with complete (R0) resection and EGFR testing from January 2015 to December 2018 across 21 institutions. Tumors were graded into grades 1-3 using both the previous predominant pattern grading system (old classification) and the new IASLC grading system (new classification), and clinicopathological features were compared.

Results: Using the old classification, 686 cases were grade 1, 1,259 grade 2, and 321 grade 3. The new classification identified 678 grade 1, 1,028 grade 2, and 560 grade 3 cases, showing a decreased proportion of grade 2 and increased proportion of grade 3. Survival analysis revealed clear stratification between grade 2 and grade 3 cases, particularly in stage I disease ($p<0.001$). The proportion of EGFR mutations in the new classification decreased with increasing grade, 55.5%/49.3%/27.7% for grade1/2/3, respectively.Among pN0M0 cases, grade 3 tumors classified as pT1mi-1b had survival outcomes comparable to pT1c, while grade 3 tumors classified as pT2 showed survival similar to pT3 tumors.

Conclusions: The new IASLC grading system effectively stratifies tumors previously classified as grade 2 into distinct prognostic groups. Grade 3 tumors identified in early-stage lung adenocarcinoma under the new system may warrant an upgrade in T classification.

P2.06.42 NSD3 Overexpression Predicts Prognosis and Immune Cell Infiltration Patterns in Lung Squamous Cell Carcinoma: A Bioinformatics Analysis

W. Wang, Y. Ying
Taizhou Hospital of Zhejiang Province affiliated to Wenzhou Medical University, Linhai/CN

Introduction: Nuclear receptor-binding SET domain protein 3 (NSD3) is a histone methyltransferase involved in chromatin remodeling and gene transcription regulation, with dysregulated expression reported in various malignancies. This study aimed to investigate the expression of NSD3 in lung squamous cell carcinoma (LUSC) using bioinformatics approaches and to explore its association with clinicopathological features, immune cell infiltration, and patient survival outcomes.

Methods: Expression levels of NSD3 in LUSC and adjacent normal tissues were analyzed using TCGA and GTEx data via the GEPIA2 platform. Kaplan-Meier survival analysis was performed to evaluate the prognostic significance of NSD3 expression. The UALCAN platform was used to assess correlations between NSD3 expression and clinicopathological parameters, including patient age, tumor stage, histological subtype, and TP53 mutation status. Associations between NSD3 expression and chemokines, chemokine receptors, immune subtypes, and molecular subtypes were evaluated using TISIDB. The relationship between NSD3 expression and immune cell infiltration, as well as its prognostic implications, was further explored using TIMER2.0.

Results: NSD3 expression was significantly upregulated in LUSC tumor tissues compared to adjacent normal tissues. High NSD3 expression was associated with favorable survival outcomes, including overall survival (HR = 0.6699, p = 0.007), disease-specific survival (HR = 0.648, p = 0.045), progression-free survival (HR = 0.678, p = 0.004), and progression-free interval (HR = 0.680, p = 0.028). NSD3 expression positively correlated with $CD4^+$ T cell infiltration ($\rho = 0.153$, $p < 0.001$), and negatively with $CD8^+$ T cells ($\rho = -0.108$, $p < 0.05$) and myeloid dendritic cells ($\rho = -0.12$, $p < 0.01$). Notably, NSD3 expression exhibited negative correlations with several chemokines and chemokine receptors, including CCL3, CCL4, CXCL16, CCR1, CCR5, and CCR6 (all $p < 0.001$). Significant variation in NSD3 expression was observed across immune and molecular subtypes ($p < 0.001$).

Conclusions: NSD3 is significantly overexpressed in LUSC and is associated with a favorable prognosis and distinct patterns of immune cell infiltration. These findings suggest that NSD3 may serve as a promising prognostic biomarker, potential therapeutic target, and predictive indicator of treatment response in LUSC.

Introduction: Lung cancer is a complex and heterogeneous disease for which better predictive biomarkers of response are still lacking to guide personalized therapies. A better understanding of the tumor microenvironment (TME) is needed to improve patient outcomes. Here, we propose a novel computational approach that leverages bulk RNA-seq to infer clinically relevant patient-specific cell groups and states, which are normally detectable only with more costly and complex single-cell assays.

Methods: We developed an integrated computational approach based on cell type deconvolution and transcription factor activity estimation combined with an advanced machine learning framework to extract clinically relevant features from bulk RNAseq data. We analyzed a cohort of 62 primary lung adenocarcinoma (LUAD) samples from IUCT patients across disease stages (Hurtado et al. 2024). As validation, we use an independent RNA-seq cohort of early-stage LUAD with 77 RNAseq and 15 scRNA-seq samples collected at Vanderbilt University (Senosain et al. 2023). To assess the potential for this approach in late stage samples, we applied it to a multicenter French cohort with 130 advanced NSCLC patients treated with immunotherapy (IT) (N=90) or chemotherapy (N=40) in first-line setting (E. Gobbini, GFPC and UNICANCER).

Results: Our results identified cell populations associated with immune response and evasion (Hurtado et al. 2024). In early-stage samples, we observed a dual role of natural killer cells, suggesting their involvement in both immune activation and suppression. This dual behavior was linked to patient survival, highlighting natural killer cells as important players (Figure 1AB). In the late stage cohort we identified cell type groups significantly associated with immunotherapy response (p-value = 0.025, F-statistic = 5.188, effect size = 0.051) which predicted response with better performance than several existing approaches (Figure 1C).

Conclusions: Our approach characterizes RNA-seq based TME profiles through immune cell states and interactions, which enhances patient stratification. It identifies immune cell phenotype and interaction biomarkers linked to survival and progression that are validated across independent

cohorts.

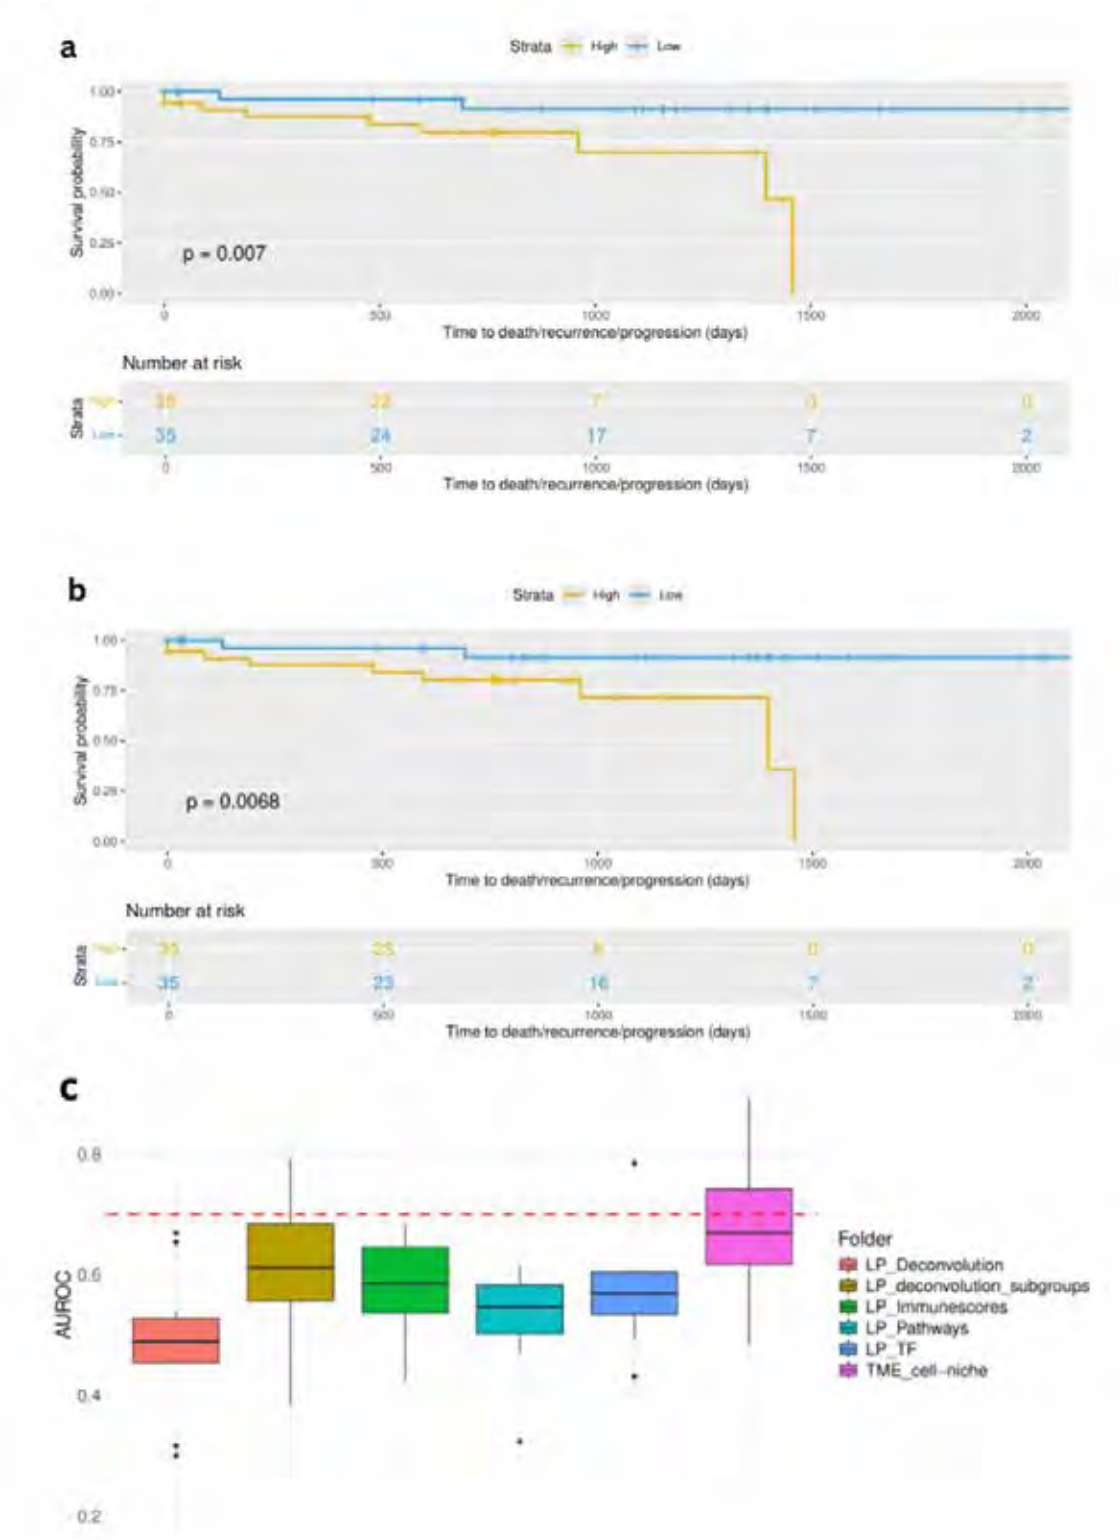

Figure 1. AB. Multivariate cox proportional hazards models across selected TME patient profiles in the early-stage Vanderbilt cohort to evaluate recurrence-free-survival. Survival curves based on high and low risk groups using linear predictors after fitting Cox PH model using cell type groups as covariates (p-value = 0.007, p-value = 0.0068). C. Machine learning models performance (AUC-ROC) to predict immunotherapy response in the late-stage cohort using different approaches to estimate TME features (our approach is named TME_cell-niche, line red = AUC = 0.7).

P2.06.44 More Than a Mutation: Prevalence of HER2 Overexpression, Amplification, and Mutations by Histology in NSCLC

J.A. Marks[1], R. Puentes[2], S.C. Scott[3], J.E. Reuss[4], N. Florez[1], F.J. Scarpa[5], A. Chevalier[6], B. Halmos[7], P.A. Jänne[1], S.V. Liu[4], J.K. Rotow[1]
[1]Dana-Farber Cancer Institute, Boston/MA/USA ,[2]NeoGenomics Laboratories, Inc, San Diego/CA/USA ,[3]Johns Hopkins University, Baltimore/MD/USA ,[4]Georgetown University, Washington/DC/USA ,[5]NeoGenomics Laboratories, Inc, Aliso Viejo/CA/USA ,[6]NeoGenomics Laboratories, Inc, Cambridge/GB ,[7]Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA

Introduction: HER2-directed therapies have gained tumor-agnostic approval and have demonstrated clinical activity in HER2-mutated lung adenocarcinoma with limited data in benefit for HER-2 overexpressing tumors. The prevalence of this therapeutic target in non-small cell lung cancer (NSCLC) remains poorly characterized with evolving and complicated testing guidelines. Here we evaluate the prevalence of HER2 genomic alterations and HER2 overexpression in adenocarcinoma and squamous cell carcinoma (SCC) of the lung.

Methods: We retrospectively analyzed a database of 9,395 NSCLC samples tested at NeoGenomics Laboratories. HER2 protein expression by immunohistochemistry (IHC) was performed using ASCO/CAP breast cancer scoring guidelines (0/1+/ 2+/ 3+). HER2 amplification (amp) was defined by fluorescence in situ hybridization (FISH; HER2/CEP17 ≥ 2.2). Next-generation sequencing (NGS) was used to identify HER2 mutations. Identified genetic variants were annotated according to the American College of Medical Genetics and Genomics standards. Fisher's exact test compared HER2 overexpression, amplification, and mutation rates by histology.

Results: Among 4,875 tissue samples, 3,761 were adenocarcinoma and 941 were SCC. In adenocarcinoma, IHC 2+ was detected in 32.5% (n=1,222) and IHC 3+ in 2.7% (n=100) of cases; whereas in SCC, 15.4% were IHC 2+ (n=145) and 1.3% (n=12) were IHC 3+, confirming the higher prevalence in adenocarcinoma histology (p<0.00001). HER2 amp by FISH occurred in 8.5% of adenocarcinoma (318/3,761) and 3.9% of SCC (37/941) and was more common in adenocarcinoma compared to SCC (p=0.003). Among amplified adenocarcinoma, 41.2% were IHC 2+ (n=131) and 1.9% were IHC 3+ (n=6); in amplified SCC, 43.2% were IHC 2+ (n=16) and none were IHC 3+.

In 7,576 cases assessed by NGS, HER2 mutations were detected in 3.4% of adenocarcinomas (261/7,576) and 3.0% of SCC (55/1,819). Pathogenic HER2 mutations were more common in adenocarcinoma (1.4%, 107/7,576) than SCC (0.3%, 6/1,819; p<0.00001). In adenocarcinoma, 63.6% of pathogenic mutations (68/107) were HER2 exon 20 insertions and 36.4% were other HER2 domain variants (39/107). No exon 20 insertions were identified in SCC. Of cases with HER2 pathogenic mutations in adenocarcinoma (n=107), 1.9% also had IHC 3+ (n=2) and 15.9% had IHC 2+ (n=17), respectively, whereas for SCC, only 1 of 6 had IHC 2+.

Conclusions: HER2 overexpression, amplification, and activating mutations were more prevalent in adenocarcinoma compared to SCC, however within adenocarcinoma, we observed diverse representations of each HER-2 subcategory. These findings emphasize the importance of systematic HER2 testing in NSCLC to identify patients who may benefit from HER2-targeted therapies.

P2.06.45 A Novel Predictive Gene Signature for Liver Metastasis (LM) in NSCLC Using a Comprehensive Linked Clinical-Molecular Database

S. Papillon-Cavanagh[1], J. Snider[2], E. Murphy[1], L. Bouzit[2], C. Cho-Phan[2], K.M. Zimmerman Savill[2]
[1]Caris Life Sciences, Phoenix/AZ/USA ,[2]Flatiron Health, New York/NY/USA

Introduction: Among patients with non-small cell lung cancer (NSCLC), LM is associated with poor prognosis. However, it remains difficult to predict LM and questions remain around the biology underlying LM. We leveraged a real-world (RW) clinical-molecular database to identify a gene expression signature predictive of LM among patients with advanced NSCLC and adenocarcinoma histology (advNSCLC-AC) to inform patient care.

Methods: This study used the US-based deidentified Flatiron Health (FH)-Caris Life Sciences (Caris) NSCLC Clinical-Molecular Database (CMDB), with clinical data from the FH Research Database linked to whole exome sequencing, whole transcriptome sequencing (WTS), and immunohistochemistry data derived from Caris tumor profiling tests (data cutoff, September 30, 2024). Patient characteristics were summarized using descriptive statistics. Among patients with advNSCLC-AC who received first-line (1L) chemoimmunotherapy, a univariate competing-risk Fine-and-Gray model assessed the association between gene expression in lung biopsies collected at advanced diagnosis and time to LM, with death as a competing event. LM-associated genes were selected through cross-validation and aggregated into a composite risk score using single-sample Gene Set Enrichment Analysis. Gene ontology enrichment analysis was conducted to identify biological processes associated with the predictive signature. RW overall survival (rwOS) was estimated using the Kaplan-Meier method.

Results: Among 8697 patients with NSCLC, 1121 met study criteria. Patients had a median age of 67 years at 1L start, 56% were White, 52% were male and the majority had stage IV disease (84%) and a history of smoking (91%). rwOS analysis confirmed that LM at 1L initiation was associated with poorer prognosis (P<.001) (Figure 1A). Leveraging WTS data from 407 patients with no LM at biopsy, we identified genes significantly associated with LM risk (FDR < 0.05). A composite risk score stratified patients into high- and low-risk groups, showing significant separation in cumulative incidence of LM (Gray's P<.01) (Figure 1B). Analysis demonstrated specificity to LM, with no significant association with brain metastases observed (Figure 1C). The signature included 259 genes, enriched for genes involved in organelle fission, cellular division, meiosis, and homologous recombination (Figure 1D).

Conclusions: Analyses of comprehensive and longitudinal multimodal RW data from the CMDB replicated the known association of LM with poor prognosis and identified a composite biomarker for LM risk stratification in the advNSCLC-AC setting. This novel gene signature may inform surveillance and treatment strategies to optimize patient outcomes and elucidate biological mechanisms underlying the development of LM. Further validation in independent cohorts is needed.

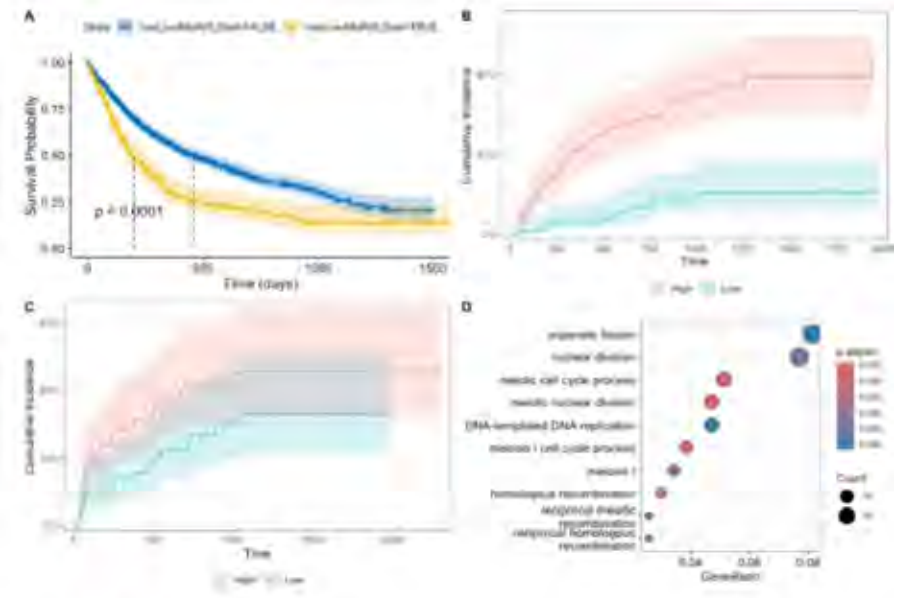

Figure 1. Prognostic value of liver metastasis and characterization of a novel LM predictive signature in NSCLC-AC
A) Kaplan-Meier curve of rwOS on total cohort (N = 1121) stratified by presence of LM at 1L start (true= LM reported at 1L start, false= LM not reported at 1L start)
B) Cumulative incidence function (CIF) of time to first liver metastasis accounting for death as a competing risk stratified by LM composite risk score (high vs. low score)
C) CIF of time to first brain metastasis accounting for death as a competing risk stratified by LM composite risk score (high vs. low score)
D) Gene ontology enrichment analysis of genes included in the LM predictive signature

P2.06.46 Multi-Omics Analysis Reveals Genomic Features Associated With Combination Immunotherapy Benefit in Advanced NSCLC

L. Li[1,2], D. Han[1,2], X. Zhang[1,2], H. Zhou[1,2], J. Li[1,2], T. Tian[1,2], R. Bai[1,2], F. Wang[3], J.C. Yin[3], K. Xu[1,2], Y. Xu[1,2], C. He[1,2], L. Xu[1,2], H. Wang[1,2], H. Tang[1,2], S. Wei[1,2], J. Li[1,2], R. He[4], S. Niu[5], Z. Zhang[1,2]
[1]The First Affiliated Hospital of USTC, Hefei/CN ,[2]University of Science and Technology of China, Hefei/CN ,[3]Nanjing Geneseeq Technology Inc., Nanjing/CN ,[4]Bozhou Traditional Chinese Medicine Hospital Anhui Province, Bozhou/CN ,[5]The Pulmonary Department of Taihe County Traditional Chinese Medicine Hospital, Fuyang/CN

Introduction: Combination immunotherapy has become the standard first-line treatment for patients with untreated advanced non-small cell lung cancer (NSCLC). However, reliable biomarkers predictive of combination immunotherapy outcome remain unclear.

Methods: In this prospective study, we enrolled a total of 54 patients with advanced NSCLC receiving PD-1/PD-L1 blockade plus chemotherapy as first-line treatment. Pretreatment tumor biopsy samples were collected from 45 patients. Blood samples were collected before 1st (C1D1; n=51), 2nd (C2D1; n=45), 3rd (C3D1; n=36), 4th (C4D1; n=29) cycles of combination immunotherapy, as well as at disease progression (n=7). Comprehensive genomic profiling of tissue and circulating tumor DNA (ctDNA) was performed using a 437-gene panel. Transcriptomic profiling on tissue (n=14) was conducted via RNA-seq.

Results: At baseline, patients with STK11 mutations exhibited a trend towards lower PR rate compared to those without (0.0% vs. 60.0%; P=0.085). LRP1B mutations were associated with longer progression-free survival (PFS) (HR=0.35, P = 0.034). In contrast, patients with FBXW7 mutations had shorter PFS than those with wild-type FBXW7 (HR=5.39, P=0.001). Gene set enrichment analysis of the TCGA-NSCLC dataset revealed that FBXW7-mutated NSCLC exhibited upregulation of cell cycle pathway genes, including MYC and E2F, thereby promoting tumor proliferation. In addition, immune pathways related to IFN-α and IFN-γ responses were downregulated, leading to impaired immunity. Analysis of the tumor immune microenvironment indicated that FBXW7 mutations were associated with reduced infiltration of CD4+ memory T cells (p=0.017) and NK cells (p=0.040). Transcriptomic analysis showed that patients with low SPP1 expression, involved in the suppression of CD8+ T cells and tumor evasion of the immune response, has markedly longer PFS (P=0.008). Our longitudinal analysis revealed that at the C2D1, C3D1 and C4D1 time points, patients with detectable ctDNA (ctDNA+) exhibited worse PFS (HR=5.18, P=0.004; HR=17.81, P<0.001; HR=3.91, P=0.018). Patients with early ctDNA clearance, testing negative across C2D1, C3D1 and C4D1, had better PFS compared to those without ctDNA clearance at C4D1 time points (NR vs. 5.6 months, P<0.001).

Conclusions: The multi-omics analysis illuminates the genomic and transcriptomic features of tissue and peripheral blood associated with combination immunotherapy outcomes in patients with advanced NSCLC, highlighting potential predictive biomarkers.

Keywords: non-small cell lung cancer, combination immunotherapy, biomarker

P2.06.47 Axl Receptor Shedding and EMT in Lung Adenocarcinoma: Prognostic Implications Based on STAS

S. Mishima[1], T. Eguchi[1,2], Y. Sato[1], S. Matsuoka[1], Y. Oguchi[1], M. Katsuno[1], D. Nakamura[1], Y. Terada[1], H. Kumeda[1], K. Miura[1], K. Hamanaka[1], M. Iwaya[1], T. Uehara[1], K. Shimizu[1]
[1]Shinshu University Hospital, Matsumoto/JP ,[2]The University of Texas Southwestern Medical Center, Dallas/TX/USA

Introduction: Axl receptor tyrosine kinase promotes epithelial-mesenchymal transition (EMT), facilitating tumor invasion and metastasis. Proteolytic shedding of Axl's extracellular domain (ECD) is not fully understood, especially its role in lung cancer progression. Given the potential relationship between spread through air spaces (STAS) and EMT, we aimed to investigate the prognostic significance of Axl shedding and its association with EMT in lung adenocarcinoma, stratified by STAS status.

Methods: We conduct a retrospective study of 202 patients with surgically resected lung adenocarcinoma. Dual-domain immunohistochemistry (IHC) was utilized to evaluate both ECD and phosphorylated intracellular domain (pICD) of Axl using tissue microarrays. Patients were categorized into shedding and non-shedding groups based on staining intensity (Figure 1). Recurrence-free probability (RFP) was assessed by Kaplan-Meier analysis, stratified by STAS status. A cancer proteogenomic database (LinkedOmicsKB) was used to assess correlations between Axl RNA expression and EMT signatures.

Results: The Shedding pAxl group exhibited significantly worse prognosis than the non-shedding group (5-year RFP: 54% vs. 79%, p<0.001). Notably, when stratified by STAS status, the negative prognostic impact of Axl shedding was significant only in STAS-positive patients (5-year RFP: 38% vs. 73%, p<0.001), but not in STAS-negative patients (Figure 2). Multivariable analysis confirmed shedding Axl (HR=2.28, p=0.008) and pathological stages II/III (HR=2.39, p=0.013) as independent predictors of recurrence. Additionally, significant positive correlation between Axl expression and EMT signature was observed at the RNA level (ρ=0.50, p<0.001).

Conclusions: Our findings demonstrate a significant association between Axl receptor shedding, EMT, and STAS in lung adenocarcinoma, highlighting the prognostic importance of Axl shedding, particularly in STAS-positive tumors. These insights may offer potential pathways for personalized treatment and targeted therapeutic strategies.

P2.06.48 Histology-Specific Genomic and Immune Predictors of Resistance to Neoadjuvant Chemoimmunotherapy in Early-Stage Non-Small Cell Lung Cancer

T.H. Hong[1], C. Lee[1], H. Na[1], G.H. Kwon[1], E.K. Lee[1], J.H. Shin[1], J. Zhu[1], Y.H. Yang[1], H.E. Kim[1], B.J. Park[1], J.G. Lee[1], D.J. Kim[1], S. Hwang[2], S. Lee[2], J.B. Lee[3], C.G. Kim[3], S.M. Lim[3], M.H. Hong[3], B.C. Cho[3], H.R. Kim[3], C.Y. Lee[1], H.S. Shim[1]
[1]Severance Hospital, Yonsei University College of Medicine, Seoul/KR ,[2]Lunit Inc., Seoul/KR ,[3]Yonsei Cancer Center, Yonsei University College of Medicine, Seoul/KR

Introduction: Neoadjuvant chemoimmunotherapy (nCIT) improves outcomes in early-stage NSCLC, yet biomarkers for guiding patient selection prior to treatment remain insufficiently defined. Given the distinct biology of adenocarcinoma (LUAD) and squamous carcinoma (LUSC), we investigated how genomic and immune predictors influence treatment response, with an emphasis on histology-specific resistance mechanisms.

Methods: In this prospective cohort study (NCT06907160), 72 patients with stage IB-III EGFR/ALK wild-type NSCLC (37 LUSC, 34 LUAD, 1 sarcomatoid) received neoadjuvant platinum-doublet chemotherapy plus PD-(L)1 blockade, planned for curative resection. Pre-treatment tumors underwent next-generation sequencing and AI-based tumor-infiltrating lymphocyte (TIL) analysis (Lunit-SCOPE IO) to assess somatic mutations, copy-number variations (CNVs), and the immune microenvironment. Primary endpoints were major pathologic response (MPR), pathologic complete response (pCR), and treatment resistance, defined as (1) no radiologic tumor shrinkage per RECIST 1.1, including progression precluding surgery, or (2) ≥60% residual viable tumor post-surgery.

Results: Twenty-six patients (36%) met resistance criteria—7 due to radiologic progression and 19 due to poor pathologic response. Genome-wide screening identified recurrent copy loss in cytobands 9p24.1 (including CD274) and 19p13.3 (including STK11) associated with treatment response (Fig. 1A-B). Loss of 9p24.1 (23%) correlated with non-inflamed immunophenotype (Fig. 1C), significantly lower MPR/pCR rates ($p<0.001$), and a higher resistance rate across both histologies (Fig. 1D). In LUAD, 16% had 19p13.3 loss and/or STK11 mutations, linked to reduced MPR/pCR rates and increased resistance rate (Fig. 1E); these associations were absent in squamous histology. Integrating genomic features into clinical-immunophenotype variables significantly improved MPR prediction (AUC: 0.87 vs. 0.67, $p=0.007$), with a greater gain observed in adenocarcinoma. (Fig. 2A-C).

Conclusions: This study highlights histology-specific associations between pre-treatment genomic alterations, immune contexture, and pathologic response. CNVs—particularly 9p24.1 and 19p13.3—contributed to resistance in a histology-dependent manner. These findings support pre-treatment molecular stratification to optimize patient selection and identify individuals less likely to benefit from nCIT.

P2.06.49 Spatial Metabolomic Profiling Reveals Dynamic Metabolic Reprogramming During Lung Squamous Cell Carcinoma Evolution

H. Qin[1], X. Liu[2], X. Qin[2], Y. Wang[2], S. Li[2], D. Tang[1], W. Gao[1]
[1]Fudan university, huadong hospital, shanghai/CN ,[2]Tongji university, shanghai pulmonary hospital, shanghai/CN

Introduction: Metabolic reprogramming undergoes dynamic evolution throughout cancer initiation and progression. However, the metabolic landscape underlying the transition from precancerous lesions to invasive lung squamous cell carcinoma (LUSC) remains poorly characterized. To elucidate the spatial distribution and temporal evolution of metabolic alterations during pulmonary carcinogenesis, we performed large-scale spatial metabolomic profiling on surgically resected specimens.

Methods: We conducted large-scale spatial metabolomic profiling of surgically resected specimens spanning precancerous lesions (atypical hyperplasia and carcinoma in situ) to invasive LUSC. This approach enabled the systematic mapping of metabolic pathway dysregulation across distinct stages of pulmonary carcinogenesis.

Results: Our findings reveal that dysregulated metabolic pathways emerge as early as the precancerous stage, with distinct metabolic trajectories observed from atypical hyperplasia through carcinoma in situ to invasive LUSC. Spatial metabolomics demonstrated remarkable metabolic similarity between atypical hyperplasia and carcinoma in situ, which significantly diverged from the metabolic profile of invasive carcinoma. This divergence highlights extensive reprogramming during LUSC invasion. Additionally, retinol metabolic dysregulation correlated with adverse pathological features. Functional validation confirmed that disrupted retinoic acid metabolism promotes cancer cell migration.

Conclusions: The comprehensive characterization of metabolic evolution during LUSC progression uncovers critical insights into early detection and precision therapy. The identification of retinol metabolism as a driver of invasion suggests its dual potential as a therapeutic target and prognostic biomarker. These findings lay a foundation for improving early detection strategies and developing tailored interventions for LUSC patients.

P2.06.50 Transcriptomic Profiling Identifies a Prognostic and Predictive Immune Signature in Patients (Pts) With Lung Squamous Cell Carcinoma (LUSC)

M.K. Hashki[1], N.N. Al-Bzour[1], A.N. Al-Bzour[1], J. AlRawabdeh[2], O.M. Younis[2], F. Abu Rous[3]
[1]Jordan University of Science and Technology, Irbid/JO ,[2]University of Jordan, Amman/JO ,[3]Henry Ford Health, Detroit/MI/USA

Introduction: Intra-tumoral immune infiltration and inflammation have been strongly proposed as promising prognostic and predictive biomarkers in non-small cell lung cancer (NSCLC). However, a transcriptomic approach is not well validated in this setting. Herein, we developed a transcriptome-based score and validated its prognostic and predictive value in LUSC.

Methods: The transcriptomic counts and clinical data were obtained from The Cancer Genome Atlas Lung Squamous Cell Carcinoma (TCGA-LUSC, n = 487). Immune genes were obtained from the molecular signature database and validated genes from the literature. The pts were clustered based on their expression of immune genes into high vs low immune profiles using unsupervised K-means clustering. The Differentially Expressed Genes (DEGs) between the two groups were identified, and then we intersected the DEGs with the immune genes to obtain the immune DEGs. The immune DEGs were fitted into uni- and multi-variate cox regression models to find the independent predictors of survival. An immune score (IS) was calculated using the expression of these genes multiplied by the cox regression coefficients. Pts were split using the median IS into high- and low-IS groups in all datasets. Log-rank tests and Kaplan Meier analysis were used to correlate the score with Overall Survival (OS) and Progression-Free Survival (PFS). Tumor microenvironment using 'CIBERSORT' algorithm, and the proteomic landscape were also analyzed between the two groups. To further validate our findings, we examined the IS on the following GEO cohorts: GSE157009 with 249 LUSC pts and GSE135222 with 27 NSCLC pts treated with immune checkpoint inhibitors (ICI).

Results: We identified 3,616 DEGs, of which 344 immune DEGs were obtained and fitted into the univariate and multivariate Cox regression models. CCL21, CD48, and IL2RB were identified as independent predictors of survival. The high- and low-IS groups included 378 and 375 pts, respectively. The high IS group demonstrated worse outcomes compared to the low IS group in all datasets. In TCGA-LUSC, pts with high IS had worse OS and PFS (P<0.05). Similar results were seen in the external validation dataset, with high IS group showing worse OS in GSE157009-LUSC (P=0.0082). Moreover, high IS predicted for worse PFS in pts treated with ICI in GSE135222-ICI cohort (P=0.018). Notably, these associations remained significant after adjusting for stage, gender, and age, confirming the IS as an independent predictor of survival in all of the cohorts (HR>2, P<0.001). High IS correlated with higher infiltration of M2 macrophages, activated dendritic and mast cells, while low IS correlated with higher M1 macrophages, resting mast cells, cytotoxic T-cells, and activated NK cells infiltration (P<0.05). Low IS correlated with higher protein expression of BCL2, BCL2L11, MSH2, MSH6, PARP1, and LCK, while high IS correlated with higher expression of AKT pathway and mTOR pathway activation proteins (P<0.05).

Conclusions: We developed a transcriptome-based immune score in LUSC that is prognostic and predictive of responses to ICI. The score was based on 3 immune-related genes. Pts with high immune score had worse outcomes, worse PFS after ICI and higher levels of immune inhibitory cells.

P2.06.51 Tumour Tissue Extracellular Vesicle (EV) Biomarkers of Lung Cancer in Patients With or Without Heavy Smoking Histories

E. Stephens[1], C.J. Zahra[1], V. Dharmasena[1], A. Goldsworthy[1,2], G. Olive[1,2], H.M. Marshall[1,2], T.M. Chee[1], K.M. Fong[1,2], I.A. Yang[1,2]
[1]The University of Queensland, Brisbane/AU ,[2]The Prince Charles Hospital, Brisbane/AU

Introduction: Lung cancer in individuals who have never smoked (LCINS) remains an under-recognised and growing phenotype of lung cancer, necessitating the development of innovative early detection methods beyond current screening programs. Extracellular vesicles (EVs) have emerged as leading candidates for early cancer detection for their pro-tumorigenic effects at early disease stages and stability when in circulation, making them prime candidates for liquid biopsy. In order to characterise a tumour EV signature, this study aims to analyse tumour and non-tumour lung tissue-derived EV-RNA from LCINS and lung cancer in individuals who have a heavy smoking history (LCIHS) to: (a) identify tumour EV biomarkers of LCINS and LCIHS, and (b) identify markers expressed in lung tumours irrespective of smoking history.

Methods: Resected tumour and non-tumour specimens of early-stage (I and II) primary adenocarcinoma from LCIHS (n=6) and LCINS (n=3) were analysed. EVs were isolated from tumour and non-tumour lung tissue using a collagenase-dispase digestion buffer and EV samples were purified using differential centrifugation, ultracentrifugation, and size exclusion chromatography. Total EV-RNA was extracted and sequenced (Illumina NovaSeqX) at a target depth of ~40M reads per sample. Gene expression was analysed by tissue type and smoking history, with significance thresholds of an FDR-adjusted p-value<0.01 and a fold change>±10 (HREC/2023/MNHA/89121).

Results: In LCINS, 53 genes were significantly differentially expressed in tumour tissue, compared to non-tumour tissue. The most statistically significant of these was CEACAM5, a protein coding gene which is associated with lung and other cancers. Similarly, in LCIHS, 587 differentially expressed genes were identified in tumour tissue when compared to non-tumour tissue. The most statistically significant of these was XAGE1A, an antigen which has been associated with lung cancer in many studies. Of the genes identified in tumour tissues, 12 were significantly differentially expressed in tumour tissues of both LCINS and LCIHS, when compared to their respective non-tumour tissues (8 upregulated, 4 downregulated). Among these was SPP1, a gene that is well characterised as upregulated in plasma in patients with lung cancer.

Conclusions: Our data indicate the viability of using EVs to detect clinically relevant biomarkers of lung cancer. Differentially expressed genes were identified in tumour-derived EVs in LCINS and LCIHS. Among these genes are known biomarkers of lung and other cancers. Further, our data indicate LCINS tumours are unique to those arising in patients with a heavy smoking history, with the presence of numerous significantly differentially expressed genes between tissues. However, we also observed overlapping differentially expressed genes in tumour tissues. We have identified potential markers unique to LCINS and commonly expressed in tumours from patients with an absent and a heavy smoking history. These findings provide the foundation for the development of a lung cancer biomarker panel, inclusive of people who have never smoked, that can detect early-stage adenocarcinoma. Identifying biomarker candidates in tissue EVs enables translation into blood EVs, potentially offering early cancer detection via blood sampling. These findings are presently being validated in a larger cohort.

P2.06.52 Survival and Mutational Differences of GPER and Estrogen Receptor (ER) in NSCLC

R. Hsu[1], S. Wu[2], N. Kulkarni[2], J. Xiu[2], A. Vanderwalde[2], L. Loo[3], S.L. Park[3], W. Cozen[4], B. Halmos[5], P.C. Ma[6], E.T. Roussos Torres[1], J.J. Nieva[1]
[1]University of Southern California, Los Angeles/CA/USA ,[2]Caris Life Sciences, Phoenix/AZ/USA ,[3]University of Hawaii Cancer Center, Honolulu/HI/USA ,[4]University of California Irvine, Orange/CA/USA ,[5]Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA ,[6]Penn State Cancer Institute, Hershey/PA/USA

Introduction: G-protein coupled estrogen receptor 1 (GPER) is a protein involved in the estrogen signaling pathway and a tumor promoter in non-small cell lung cancer (NSCLC). ER positivity is increased in females and epidermal growth factor receptor (EGFR) mutant (-mt) NSCLC. Here, we evaluated differences based on ER-alpha (ESR1), ER-beta (ESR2), and GPER RNA expression with survival in NSCLC.

Methods: NSCLC samples (n = 52,690) were analyzed by NGS (NextSeq or NovaSeq) andRNA (NovaSeq) (Caris Life Sciences, Phoenix, AZ). Spearman's correlation coefficient (r) was used. GPER, ESR1, and ESR2 expression was split into quartiles (top (-H) and bottom (-L)). Real-world mOS was obtained from insurance claims and calculated from collection to last contact. Hazard ratio (HR) was calculated by Cox proportional hazards model, and P values calculated by log-rank test. Multivariate Cox regression analysis was used.

Results: Females comprised a greater percentage of GPER-H (51.1%) versus (vs) GPER-L (47.7%) ($p < 0.05$). GPER-H had decreased mt in STK11 (10.4% vs 18.6%) and KEAP1 (9.76%vs 16.3%) vs GPER-L but higher in EGFR-mt (14.1% vs 8.68%) ($q < 0.05$). No difference in BRAF, KRAS, HRAS or NRAS-mt was seen. GPER was weakly correlated with ESR1($r = 0.384$) and ESR2 ($r = 0.424$). Longer mOS was seen in ESR1-H and ESR2-H, while, GPER-H had shorter mOS overall and in females and males, separately (Table 1). GPER-H had shorter mOS in females that are ESR1-L and ESR1-H tumors, while males only had shorter mOS in ESR1-L but not ESR1-H tumors. In ESR2-L tumors, GPER-H has shorter mOS in both females and males. In ESR2-H tumors, GPER-H had shorter mOS in females and in males buta smaller Δ mOS (Table 1). GPER-H had shorter mOS in ESR1/2-L tumors adjusting for histology, gender, and EGFR, BRAF, KRAS, HRAS, NRAS, STK11, and KEAP1-mt status (ESR1-L: adjusted HR (aHR): 1.21 (1.03-1.43), $p = 0.02$; ESR2-L: aHR: 1.33 (1.14-1.55),$p = 3.84E-04$).

Conclusions: Our results show unique and biologically meaningful correlations of GPER with ESR1 and ESR2 expression. GPER-H had a greater prevalence of EGFR-mt but decreased STK11-mt and KEAP1-mt. GPER-H was associated with worse mOS in ESR1-H tumors in females but not males. Our results suggest that targeting GPER and ER may help survival in female and EGFR-mt NSCLC patients.

Table 1. Survival by GPER/ESR1/ESR2 Status.

Comparison			mOS	HR (95% CI)	P-value
Overall		ESR1-H/-L	22.2 vs 15	0.77 (74-0.8)	<0.0001
		ESR2-H/-L	23.2 vs 14.5	0.75 (0.72-0.78)	<0.0001
		GPER-H/-L	18.4 vs 19.6	1.06 (1.02-1.1)	4E-03
GPER: -H/-L		Female	22.3 vs 23.9	1.07 (1.01-1.13)	3.1E-02
		Male	15 vs 16.3	1.07 (1.02-1.13)	0.01
ESR1-L	GPER-H/-L	Female	13 vs 20.2	1.27 (1.12-1.44)	3E-04
		Male	10.4 vs 15.2	1.27 (1.14-1.42)	<0.0001
ESR1-H		Female	26.3 vs 32.7	1.2 (1.02-1.41)	0.03
		Male	19 vs 17.5	0.96 (0.82-1.13)	0.563

P2.06.53 TP53 Mutations Drive Therapeutic Resistance in ALK-Rearranged Lung Adenocarcinoma

M-M. Wang, Q. Cui, Y-L. Wu, W-Z. Zhong
Guangdong Provincial People's Hospital, Guangzhou/Guangdong/CN

Introduction: While TP53 mutations and EML4-ALK variants influence ALK inhibitors efficacy. The impact of concurrent genomic alterations on outcomes remains incompletely characterized.

Methods: This retrospective study utilized next-generation sequencing data(NGS) from ALK-mutant lung cancer patients treated at Guangdong Provincial People's Hospital. Clinical data were combined with somatic mutation profiles to investigate associations between TP53, RB1 mutation status, and other genomic characteristics.

Results: Of 219 patients, 4 (1.8%) receiving adjuvant ALK inhibitors after surgery achieved durable responses without requiring first-line therapy, 2 (0.9%) were lost to follow-up. Among 143 treatment-naïve patients with baseline NGS, TP53 alterations (33%) were the most common event associated with decreased first-line progression-free survival and decreased overall survival, along with KEAP1, BRAF, CDKN2A and TYMS 6BP alterations. In addition to pretreatment TP53 alterations, patients with TP53 alterations detected at any time point had shorter PFS (mPFS:17.067m vs 11.833m, HR=1.457, 95% CI: [1.062,1.999], p=0.019) and reduced OS(mPFS: 72.767m vs 43.800m, HR=1.809,95% CI: [1.197,2.734], p=0.004). In patients with primary progressors, TP53-altered tumors showed reduced radiographic responses (CR/PR rate: 31.91% vs 68.09% in wild-type, Fisher's exact test p<0.000), indicating accelerated acquired resistance. Further investigation of the effect of TP53 alterations revealed an association with worse outcomes even in patients with good initial radiographic response (CR/PR) (PFS:HR=1.955,95% CI: [1.193,3.201], p= 0.007; OS:HR=3.008, 95% CI: [1.366, 6.621], p= 0.004). Our analysis revealed that in ALK-rearranged tumors, co-alterations of TP53 and RB1 were not associated with inferior PFS (HR=1.143, 95%CI: [0.951,1.373], p=0.11) but showed a significant trend toward worse OS (HR=1.267, 95% CI: [1.004,1.598], p=0.042), differentiating with known EGFR/TP53/RB1 co-alteration patterns in the past studies.

Conclusions: TP53 mutations drive therapeutic resistance in ALK-rearranged lung adenocarcinoma, with RB1 co-mutation exhibiting context-dependent effects distinct from EGFR-mutant disease. These findings highlight the need for mechanism-tailored combinatorial strategies.

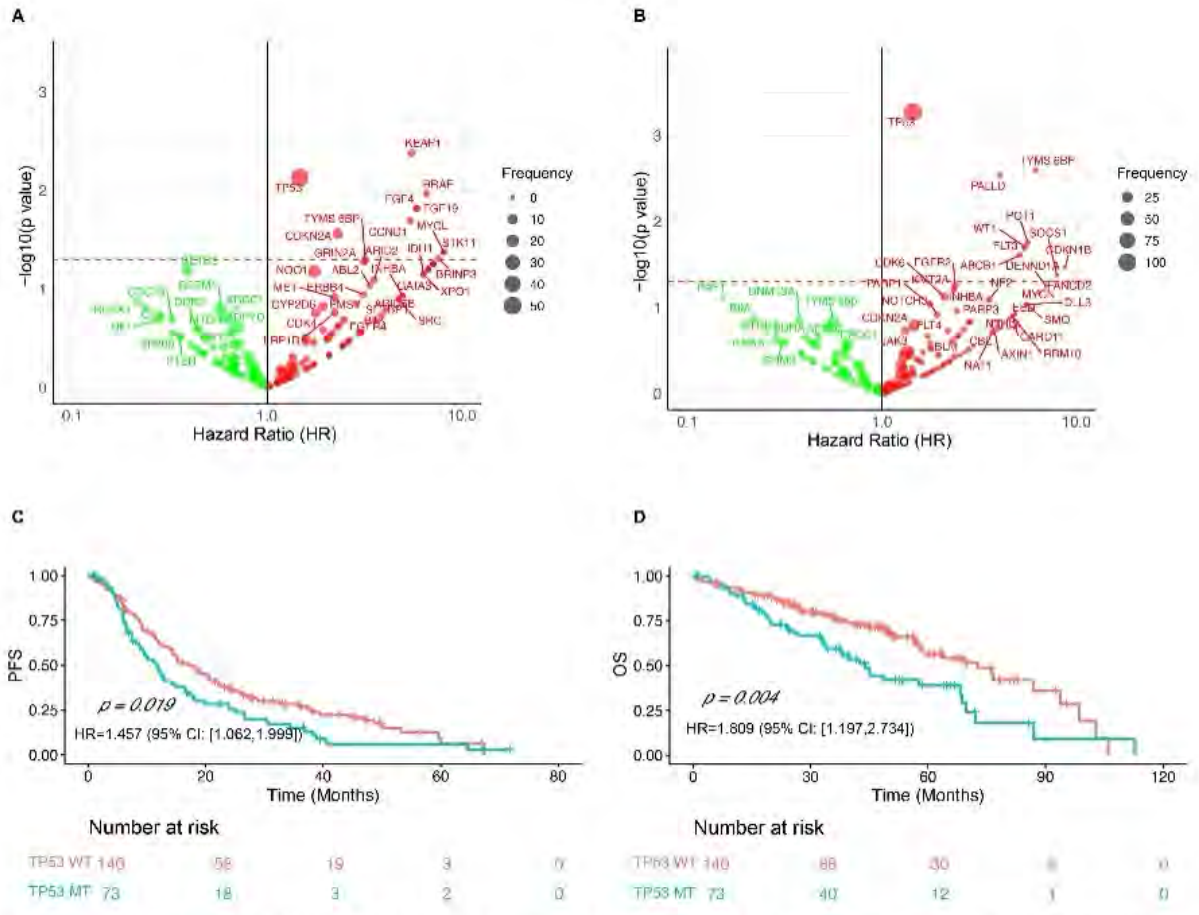

Figure 1. Genomic and clinical correlates of treatment outcomes in ALK-mutant NSCLC. Volcano plots depict associations between co-occurring alterations and (A) PFS (n = 143) or (B) OS (n = 213). Hazard ratios (HRs; x-axis) and −log10-transformed p values (y-axis; univariate Cox model) are shown, with data points color-coded by genetic event. Alterations present in <7 samples were excluded. Association between TP53 alteration detected at any time point and (C) PFS, (D) OS. HR, hazard ratio; CI, confidence interval; PFS, progression-free survival; OS, overall survival.

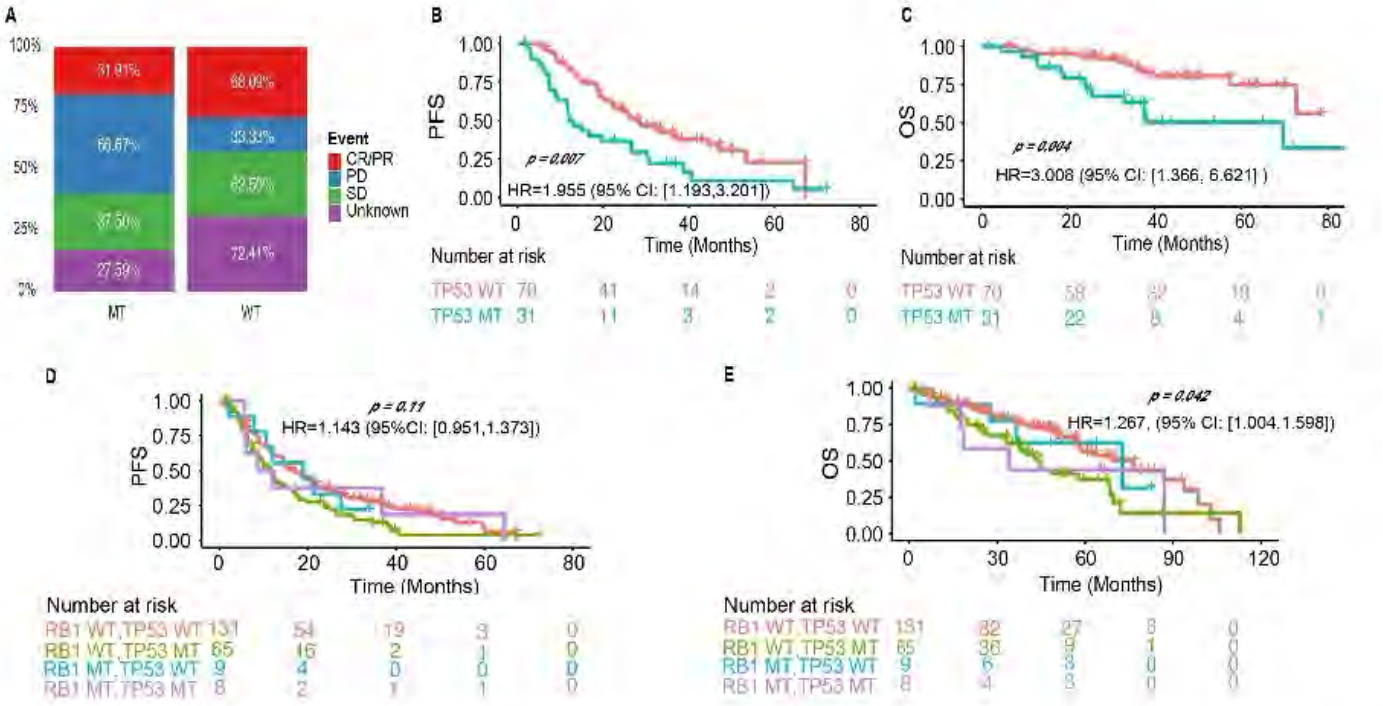

Figure 2. Impact of TP53 alterations on treatment outcomes and resistance mechanisms in ALK-mutant NSCLC. (A) Radiographic response distribution comparing TP53-mutant (MT) versus wild-type (WT) tumors at baseline (Fisher's exact test). (B-C) Kaplan-Meier curves of (B) progression-free survival (PFS) and (C) overall survival (OS) in patients achieving complete/partial response (CR/PR), stratified by TP53 status. (D-E) Survival outcomes in the full cohort (n=213): (D) PFS and (E) OS by combined RB1/TP53 mutation status. WT, wild type; MT, mutant; CR, complete response; PR, partial response; SD, stable disease; PD, progressive disease; HR, hazard ratio; CI, confidence interval; PFS, progression-free

P2.06.54 miR-Roring IFN-Gamma Pathway Activity as a Predictive Tool for Immunotherapy Response in Non-Small Cell Lung Cancer

R. Cuttano[1], K.M. Afanga[1], V. Melocchi[1], E. Dama[1], F. Longo[1], C. Carbonelli[2], P.N.C. Girotti[3], F. Bianchi[1]
[1]Unit of Cancer Biomarkers, Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo/IT ,[2]Pneumology Unit, Department of Medical Sciences, Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo/IT ,[3]General, Visceral and Thoracic Surgery Department, Landeskrankenhaus Feldkirch, Feldkirch/AT

Introduction: Non-small-cell lung cancer (NSCLC) is a leading cause of cancer-related deaths, due to late diagnosis and therapy resistance. Immune checkpoint inhibitors (ICIs), either alone or in combinations with chemotherapy (CT), achieve durable responses in approximately 20% of patients with advanced disease, while the remaining majority fail to respond or acquire resistance. Although several biomarkers have been proposed in literature, PD-L1 expression remains the only widely accepted clinical marker for NSCLC. However, its predictive value is limited by technical variability (different anti-PD-L1 antibodies, inconsistent expression thresholds, and intra-/inter-tumor heterogeneity all undermine its reliability). Consequently, the lack of robust biomarkers for identifying responder patients represent a major challenge to optimizing immunotherapy. MicroRNAs have emerged as promising biomarker candidates due to their exceptional stability in harsh conditions. We recently identified a novel miRNA-based signature that accurately predicts response to neoadjuvant CT in NSCLC. Notably, this miRNA signature hallmarks metastases with an active IFN-γ response pathway, which has emerged as a critical factor in shaping immunotherapy response. Based on these findings, we hypothesized that IFN-γ-related miRNAs could be exploited as predictive biomarkers of response to ICIs/ICIs+CT.

Methods: To identify IFN-γ-related miRNAs, commercially available NSCLC cell line were treated with 100ng/ml for 24 hours and subjected to miRNA-sequencing (Qiaseq). Moreover, we leveraged TCGA dataset to analyze miRNA expression in NSCLC tumors stratified in IFN-γ high and IFN-γ low activity, as determined by CytoSig tool. Finally, spatial transcriptomics (Visium,10x) was carried out in treatment naïve NSCLC samples (n=3) to map the spatial correlation between miRNA activity and IFN-γ signaling within tumor cells versus the surrounding microenvironment. To evaluate whether IFN-γ-related miRNAs could predict response to ICI based therapies, a retrospective cohort (n=34) of stage IV NSCLC patients prior treatment with ICIs/ICIs+CT was collected and subjected to miRNAseq (Qiaseq), digital mRNA-seq and DNA-seq (Oncopanel, Vazyme).

Results: In vitro treatment with IFN-γ significantly altered the miRNome of NSCLC cells, with a total of 67 miRNAs that are differentially expressed (FC>|1,2|; p<0,05). Of these, 7 miRNAs showed an altered expression (FC>|1,2|; p<0,05) in patient-derived samples (TCGA-LUAD, n=507; TCGA-LUSC, n=473) with a predicted different IFN-γ activation status. Moreover, spatial transcriptomics analysis of treatment naïve NSCLC (N=3) confirmed the association between the 7-miRNA signature and IFN-γ activity specifically in tumor cells. Strikingly, the 7-miRNA signature demonstrated higher predictive accuracy for ICIs response than PD-L1 in a cohort of stage IV NSCLC patients (n=34) treated with first-line ICIs-based therapy (AUCmiRNA=0.87 vs AUCPD-L1=0.69). Validation in a second independent cohort of ICIs treated NSCLC patients (N=30) is currently ongoing, together with comprehensive genomic profiling and immunophenotypic characterization, to further refine and validate the predictive power of this signature.

Conclusions: IFN-γ-related miRNAs hold the potential to serve as robust predictive biomarkers for immunotherapy response in NSCLC. If validated in larger cohorts, this miRNA signature could improve patient stratification and the development of more effective therapeutic strategies in NSCLC.

P2.06.55 Association Between Pathologic Necrosis and Postoperative Recurrence in Stage IA Non-Small Cell Lung Cancer

Y. Fan
Shanghai Pulmonary Hospital, Tongji University, Shanghai/CN

Introduction: Currently, there is insufficient evidence to definitively establish pathological necrosis in stage IA non-small cell lung cancer NSCLC) patients as a high-risk factor for postoperative recurrence.

Methods: In this study, clinicopathological data from stage IA NSCLC patients were retrospectively collected, and the association between histopathological necrosis and both overall survival (OS) and recurrence-free survival (RFS) was evaluated using Kaplan-Meier analysis and univariate and multivariate Cox regression models. The tumor microenvironment (TME) characteristics associated with histopathological necrosis in stage IA NSCLC were investigated using a combination of bulk RNA sequencing (RNA-seq), single-cell RNA sequencing (scRNA-seq), and spatial transcriptomics. Additionally, the intersection of necrosis-related genes (NRGs) and recurrence-associated genes (RAGs) was analyzed to explore the transcriptional relationship between pathological necrosis and postoperative recurrence. Experimental validation of key genes was performed to elucidate their functional roles in NSCLC.

Results: Kaplan-Meier analysis of 1,311 stage IA NSCLC patients demonstrated that OS and RFS were significantly worse in histopathological necrosis than in non-pathological necrosis. Univariate and multivariate Cox regression analyses identified histopathological necrosis as an independent risk factor for postoperative recurrence. TME analysis revealed that upregulated NRGs were associated with tumor cell cycle progression, increased proliferation, and hypoxia, while downregulated NRGs were linked to dendritic cell dysfunction. Nine genes were identified as being associated with both histopathological necrosis and postoperative recurrence. Cox proportional hazards regression analysis revealed ANLN as a key gene. In vitro experiments demonstrated that silencing ANLN expression in NSCLC cells suppressed tumor proliferation, invasion, and migration, while inducing apoptosis. In vivo studies further confirmed that ANLN inhibition significantly reduced tumor size.

Conclusions: Our study reveals the genetic link between pathological necrosis and postoperative recurrence in stage IA NSCLC, establishing its role as an independent high-risk factor. These findings support incorporating necrosis into risk stratification and developing targeted strategies to reduce recurrence.

P2.06.56 Enhancing Lung Cancer Diagnosis and Early Recurrence Risk Detection via Bedside Atomic Force Microscopy

J. Alcaraz[1], E. Marin[1], H. Sanz-Fraile[1], M. Querol[2], P. Gausa[2], K. Neal[1], M. Arshakyan[1], M. Rico-Pastó[1], M. Boada[3], D. Sanchez[3], R. Oropesa Nuñez[4], G. Srivastava[4], A. Jizawi[4], C. Ortiz Velez[4], S. Nizzero[4], T. Appenzeller[4], P. Oertle[4], M. Loparic[4], M. Plodinec[4], N. Reguart[2]
[1]Universitat de Barcelona, Barcelona/ES ,[2]Hospital Clinic Barcelona, Barcelona/ES ,[3]Hospital Clinic Barcelona,, Barcelona/ES ,[4]ARTIDIS AG, Basel/CH

Introduction: Lung cancer remains a leading cause of cancer-related mortality; only 16% of cases are diagnosed at a localized stage. Approximately 75% of patients receive treatment, with advances focusing on personalized approaches through mutations like EGFR for targeted therapies or PD-L1 expression for immunotherapy. Treatment decisions rely on molecular profiling, which often takes over two weeks and is complicated by limited tumor sample availability. Beyond genetic markers, tumor physical properties significantly influence cancer progression. Tumor stiffness and extracellular matrix have been proposed as factors affecting treatment penetration and response. The Atomic Force Microscopy (AFM)-based Automated and Reliable Tissue Diagnostics (ARTIDIS) platform offers a rapid, standardized method to evaluate tumor nanomechanical properties. This study demonstrates the feasibility of measuring these properties and explores how nanomechanical signatures (NS) can enhance diagnosis, predict recurrence risk, and improve treatment response assessment.

Methods: This study involved 70 patients diagnosed with non-small cell lung cancer (NSCLC), all indicated for surgical resection at the Hospital Clinic. We procured 140 fresh tumor samples (involved) and paired uninvolved pulmonary tissue samples, meticulously preserved in formalin for subsequent histopathological and molecular analyses. Utilizing the ARTIDIS platform, we evaluated the NS of the collected tissues, employing blinded measurements to minimize bias. Comprehensive clinical and pathological characteristics, treatment responses, and outcomes were documented, with follow-up data available for up to 36 months.

Results: Of the patients analyzed, four had prior neoadjuvant therapy, while 66 were treatment-naïve. Clinical stage distribution: 45.7% stage IA-B, 28.6% stage IIA-B, 22.9% stage IIIA, and 2.9% stage IIIB. Tissue samples included 52 patients (104 samples) with matched tumor-involved and non-involved lung tissue, 17 patients (34 samples) with non-involved tissue only, and one patient (2 samples) classified as tumor-involved. ARTIDIS NS system effectively distinguished malignant tumors from uninvolved pulmonary tissue, achieving 88% sensitivity, 86% specificity, and 87% accuracy (n=52). It identified histological subtypes (adenocarcinoma vs squamous cell carcinoma) with 100% sensitivity and 83% specificity. NS correlated with molecular alterations, showing a higher Young's modulus in KRAS-mutant tumors. In adenocarcinoma cases, high stiffness, marked by increased collagen deposition (Picrosirius red staining), was associated with low CD8+ cell infiltration, suggesting stiffness-driven immune exclusion. Among the 17 patients with recurrence, 47% (8 patients) received first-line treatment (chemotherapy +/- immunotherapy). Twelve patients died (10 due to cancer progression). Notably, ARTIDIS NS predicted tumor progression within 10 months post-surgery, achieving 100% sensitivity and 93% specificity in identifying at-risk patient, even in non-involved tissue, while preserving tissue integrity for further analysis.

Conclusions: The ARTIDIS platform effectively differentiates malignant from non-malignant tissues by measuring tumor physical properties. This tool accurately predicts early recurrence and disease progression, enabling the identification of high-risk patients, including early physical changes in non-involved tissue associated with high-risk recurrence. Notably, high stiffness correlates with specific mutations and immune exclusion, could guide treatment decisions. To validate this, a 200-patient extension study is underway, focusing on neoadjuvant treatment patients to refine strategies for NSCLC and improve patient outcomes.

P2.06.57 TIM-1+ B Cells Promote Immune Suppression and Predict Poor Prognosis in Lung Adenocarcinoma

J. Wen, X. Yin, Y. Chen, X. Meng
Shandong Cancer Hospital and Institute Shandong First Medical University, JINAN/CN

Introduction: T-cell immunoglobulin and mucin domain-containing protein 1 (TIM-1) has been identified as a promoter of tumor cell viability, migration, and invasion. However, the precise role and distribution characteristics of TIM-1 within the tumor microenvironment (TME) remain critical areas of investigation. This study aimed to explore the distribution characteristics of TIM-1 within TME and the prognostic value of TIM-1 Positive immune cells in patients with lung adenocarcinoma (LUAD).

Methods: In this study, multiplex immunofluorescence (mIF) was performed on tissue slides from 126 patients with LUAD to investigate the distribution patterns of TIM-1 and the prognostic significance of three TIM-1 positive immune cell populations in both the primary tumor and tumor-draining lymph nodes (TDLN). Panel 1 (DAPI, CK, CD4, CD8, CD20, TIM-1) assessed TIM-1 distribution, and Panel 2 (DAPI, CD20, CD21, CD23) evaluated tertiary lymphoid structures (TLS).

Results: Compared to the primary tumor, TIM-1+CD8+T cells and TIM-1+B cells exhibited significantly greater infiltration in the TDLN ($p<0.0001$, $p<0.0001$ respectively). In the primary tumor, lower TIM-1+B cell infiltration was associated with longer overall survival (OS) (mOS, 84 vs. 54 months; $p<0.0001$, HR=2.574, 95% CI 1.356 to 4.889) and DFS (mDFS, 53.0 vs. 23.1 months; $p=0.018$, HR=1.721, 95% CI 1.035 to 2.862). In the TDLN, lower TIM-1+B cell infiltration was also correlated with longer OS (mOS, not reached vs. 64.7 months; $p=0.0019$, HR=2.350, 95% CI 1.323 to 4.172) and DFS (mDFS, 68.5 vs. 28.9 months; $p=0.016$, HR=1.707, 95% CI 1.081 to 2.696). Higher TIM-1+B cell infiltration in the TDLN was associated with a lower proportion of mature TLS ($p=0.0009$, $r=-0.3990$, 95% CI -0.5895 to -0.1666) and increased infiltration of TIM-1+B cells in the tumor was linked to reduced CD8+ T cell infiltration ($p=0.016$, $r=-0.2788$, 95% CI -0.3598 to -0.0233).

Conclusions: Our findings confirm the immunosuppressive role of TIM-1+B cells in LUAD and suggest that TIM-1+B cells exert immune suppression by inhibiting TLS maturation and CD8+ T cell infiltration and predict poor prognosis of LUAD patients. These findings highlight TIM-1+ B cells as a potential therapeutic target.

P2.06.58 Predictive Value of Tumor Microenvironment Biomarkers in Neoadjuvant Immunotherapy Combined With Chemotherapy for Locally Advanced NSCLC

X. Guan[1], X. Wang[1], K. Ma[1], C. Sun[1], Y. Xu[1], S. Qiu[1]
[1]The first hospital of Jilin University, Changchun/CN

Introduction: Neoadjuvant immunochemotherapy represents a pivotal treatment strategy for locally advanced non-small cell lung cancer (LA-NSCLC). Pathological response rate serves as a critical prognostic indicator, with emerging evidence suggesting its intimate correlation with the functional dynamics of immune cells within the tumor microenvironment (TME). Despite growing interest, comprehensive insights into TME biomarkers remain limited. This study aims to elucidate the prognostic significance of TME biomarkers through a multidimensional analytical approach.

Methods: This retrospective cohort study investigated 77 patients with stage IIIA-IIIB NSCLC who underwent surgical resection following neoadjuvant immunochemotherapy (2018-2024). The methodological framework comprised four systematic approaches: (1) Immunohistochemical quantification of TME biomarker expressions in pathological specimens; (2) Comprehensive H-score calculation analyzing correlations with pathological response and prognosis; (3) Development of a predictive model for assessing Major Pathological Response (MPR); and (4) Validation of biomarker-response correlations using single-cell sequencing from the GEO database. Statistical analyses were conducted using SPSS 25.0 and R statistical software.

Results: Pretreatment H-scores revealed significant predictive value for CD8+ T cells (P=0.047) and CD20+ B cells (P=0.041) as independent MPR predictors. Single-cell sequencing validation corroborated the correlation between elevated CD8+ T and CD20+ B cell expressions and enhanced MPR rates. Post-neoadjuvant therapy, we observed notable immunological remodeling: significant increases in activating immune cell populations (CD4+ T cells, CD8+ T cells, CD20+ B cells, CD56+ NK cells, and CD86+ M1 macrophages) and concurrent reductions in immunosuppressive cell populations (FOXP3+ Treg cells and CD163+ M2 macrophages). The predictive model integrating CD8+ T and CD20+ B cell immune scores demonstrated superior prognostic accuracy (AUC: 0.761) compared to individual biomarkers.

Conclusions: Pretreatment CD8+ T and CD20+ B cell TME immune scores predict MPR in LA-NSCLC patients receiving neoadjuvant immunochemotherapy. Single-cell RNA sequencing validates the correlation between elevated immune cell expressions and enhanced MPR rates, highlighting biomarkers' predictive potential. The treatment dynamically modulates immune cell functionality, inducing TME immunological remodeling. Our multivariate model integrating immune signatures demonstrates superior prognostic precision compared to single biomarker approaches.

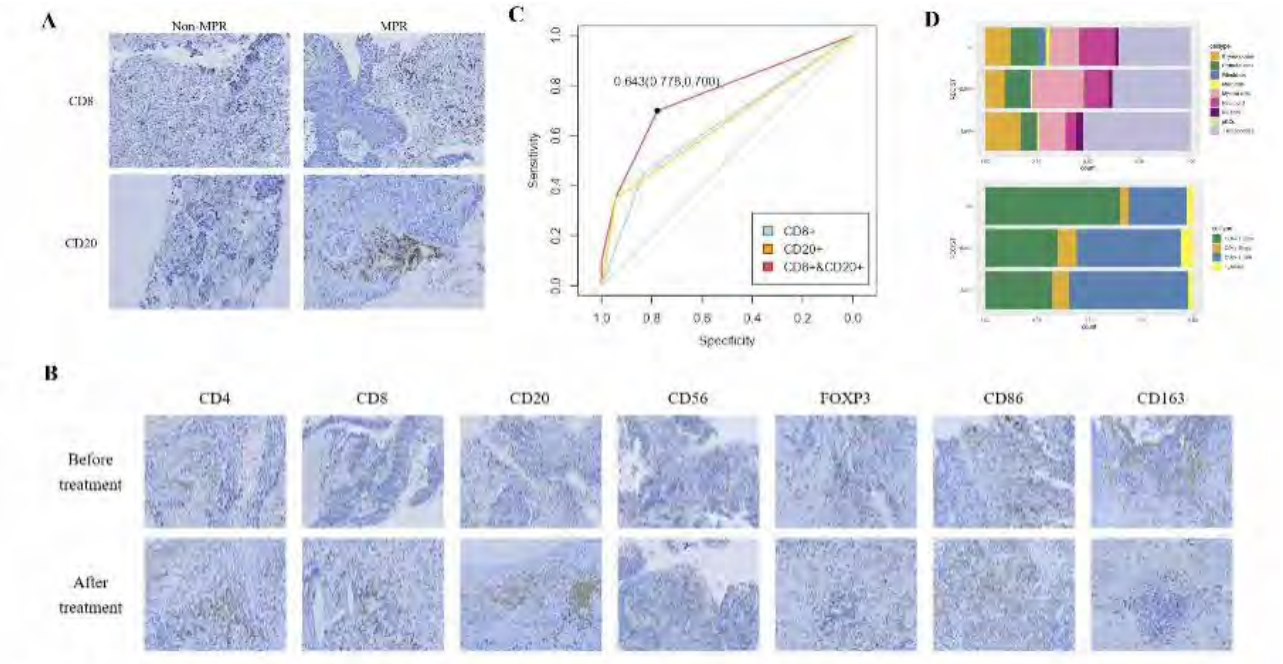

Fig.1 A, Expression of CD8+ T cells and CD20+ B cells in MPR and non-MPR groups before treatment (positive staining manifested as brown granules on cell membrane). **B**, Dynamic H-score changes of immune cells (positive staining of CD4+ T, CD8+ T, CD20+ B, CD56+ NK, CD86+ M1 macrophages, CD163+ M2 macrophages as membrane-distributed brown granules; FOXP3+ Treg positive staining as nuclear brown granules). **C**, ROC curves of CD8+ T cells, CD20+ B cells, and combined prediction model. **D**, Single-cell clustering: Cell type proportions before treatment

P2.06.59 Multi-Level Screening of MET Aberrations in Treatment-Resistant Non-Small Cell Lung Cancer: A Report From LC-SCRUM-TRY

T. Taki[1], H. Izumi[1], S. Matsumoto[1], K. Nishino[2], S. Yano[3], S. Murakami[4], M. Kodani[5], S. Hara[6], K. Chikamori[7], Y. Tanaka[1], T. Sakai[1], H. Udagawa[1], Y. Zenke[1], E. Sugiyama[1], S. Umemura[1], K. Yoh[1], G. Ishii[1], K. Goto[1]
[1]National Cancer Center Hospital East, Kashiwa/JP ,[2]Osaka International Cancer Institute, Osaka/JP ,[3]Kanazawa University Hospital, Ishikawa/JP ,[4]Kanagawa Cancer Center, Yokohama/JP ,[5]Tottori University, Yonago/JP ,[6]Itami City Hospital, Itami/JP ,[7]Yamaguchi Ube Medical Center, Ube/JP

Introduction: MET aberrations are druggable targets in cancer treatment including non-small cell lung cancer (NSCLC) which can occur from both genetic and epigenetic alterations. We have established a nation-wide genomic screening project in treatment-resistant NSCLC (LC-SCRUM-TRY; UMIN000041957) to identify the characteristics of patients with resistant alterations including MET aberrations.

Methods: Tissue/ Plasma samples from patients with NSCLC registered in LC-SCRUM-TRY were analyzed. Tissue samples were subjected to a rapid NGS analysis, Oncomine Precision Assay (tissue OPA). Plasma samples were analyzed by liquid NGS (liquid OPA or Guardant360). MET-FISH was performed for NSCLC resistant to EGFR-TKI or harboring MET amplification by tissue OPA. MET-IHC screening was implemented since Sept. 2024 (Figure 1). MET amplification by NGS was defined as MET copy number ≥4 (tissue OPA), ≥1.2 (liquid OPA), ≥2.12 (Guardant360). MET amplification by FISH was defined as MET/CEP7 ratio ≥2. MET protein staining was graded based on the intensity of the staining in tumor cells (0 to 3+). MET overexpression was defined as ≥25% of tumor cells expressed 3+ staining assessed by two pathologists independently.

Results: As of Mar. 2025, a total of 1868 patients were enrolled, and 1820 treatment-resistant samples were analyzed. Sample type were tissue (89%), and plasma (11%). The median age was 70 (range, 19-90), with 51% male. A total of 1083 (59.5%) were already identified to have oncogenic driver at enrollment, including EGFR mutation (45.0%), and ALK/ ROS1/ RET rearrangement (6.6/1.9/1.5%, respectively). Tissue samples were analyzed by NGS (n= 1620), MET-FISH (n= 721), MET-IHC (n=123), respectively (Figure 1). Any MET aberration was detected in 195/1820 (10.7%). MET amplification was detected in 5.5% by liquid NGS, 5.4% by tissue NGS, and 16.0% by FISH analysis, respectively. MET amplification by tissue NGS was frequently observed in EGFR-mutated NSCLC compared with ALK/ROS1/RET-rearranged and driver-negative NSCLC (7.9% vs 3.8% and 3.4%, p<0.001). MET protein overexpression was detected in 44.7% by IHC. The frequency of MET overexpression was not significantly different between EGFR-mutated, ALK/RET/ROS1-rearranged, and driver-negative NSCLC (47%, 61%, and 38% respectively, p=0.21). Of 195 MET aberration-positive patients, 32 (16.4%) patients were enrolled into clinical trial as 2nd or later line of chemotherapies, including 13 patients into MET-targeted therapies.

Conclusions: MET amplification was predominantly detected in EGFR-mutated NSCLC, while MET protein overexpression was relevantly observed across NSCLC regardless of driver gene status. Multi-level screening of MET aberration in LC-SCRUM-TRY contributed to enrollment into clinical trial of MET-targeted therapies.

Figure 1. Multi-level screening of MET aberration in LC-SCRUM-TRY.

P2.06.60 Multimodal Diagnostic Model for Intraoperative Diagnosis and Surgery Strategy in Stage Ia LUAD (SuRImage V2): A Prospective, Multicentric Study

H. Zhou[1], L. Yao[1], Y. Lu[1], L. Cai[2], C. Cai[1], M. Weng[1], R. Xie[1], J. Li[1]
[1]Department of Thoracic Surgery, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]School of Computer Science and Technology, Harbin Institute of Technology (Shenzhen), Shenzhen/CN

Introduction: Intraoperative frozen section analysis is critical for guiding surgical decisions in stage IA lung adenocarcinoma (LUAD), including resection extent and lymph node dissection. However, its reliance on limited, suboptimal samples and time-consuming protocols risks diagnostic inaccuracy. To address these limitations, we propose an artificial intelligence framework leveraging preoperative chest CT and intraoperative resection images to enable rapid, precise diagnosis and risk stratification. This approach aligned with the diagnostic protocol by thoracic surgeons and aims to reduce reliance on traditional frozen section constraints, enhancing surgical decision-making accuracy and efficiency for early-stage LUAD.

Methods: This study prospective enrolled patients with stage IA lung adenocarcinoma underwent complete resection between June 2020 and September 2023 in Guangdong Provincial People's Hospital (GDPH), Affiliated Hospital of Guangdong Medical University (GDMUAH), Meizhou People's Hospital (MZPH).Preoperative CT within 3 months before surgery were collected and registration with each patient. Surgical resection images of the LUAD were taken by smartphones in operating theaters under natural lighting condition in operating theater. Artificialintelligence models (SuRImage v2) based on preoperative CT, intraoperative surgical resection images and clinical characteristics were established for three tasks. Task1 tend to differentiate invasive lung adenocarcinoma (IAC) from non-IAC lesions. Task2 tend to classify pre-invasive lesion (PIL), minimally invasive adenocarcinoma (MIA) and IAC. Task3 tend to more specifically classify IAC grading according to 2021 IASLC Grading system in LUAD. The study was registered in Chinese Clinical Trial Registry (ChiCTR2300075999).

Results: We prospectively collected 2344 surgical resection images of 1638 lung nodules in 1516 patients from GDPH and 1421 non-enhanced chest CT scans. For each task, we developed three models including CT model, SuRImage and SuRImage v2. In task1 the diagnostic performances were 0.79 for CT model, 0.80 for SuRImage and 0.81 for SuRImage v2. In task2 the diagnostic performances were 0.79 for CT model, 0.82 for SuRImage and 0.84 for SuRImage v2. In task3 the diagnostic performances were 0.77 for CT model, 0.80 for SuRImage and 0.82 for SuRImage v2. Incorporating with CT images, SuRImage v2 could reach better diagnostic performance, demonstrating the critical role of multimodal imaging in optimizing intraoperative decision support.

Conclusions: We developed rapid intraoperative diagnostic models based on preoperative CT, intraoperative surgical resection images and clinical information, which comprehensively combined the macroscopic and radiomic features of lung adenocarcinoma. Compared with frozen section diagnosis, this study could avoid the disturbance of sampling and reach a diagnosis rapidly to assist the decision of surgical strategies.

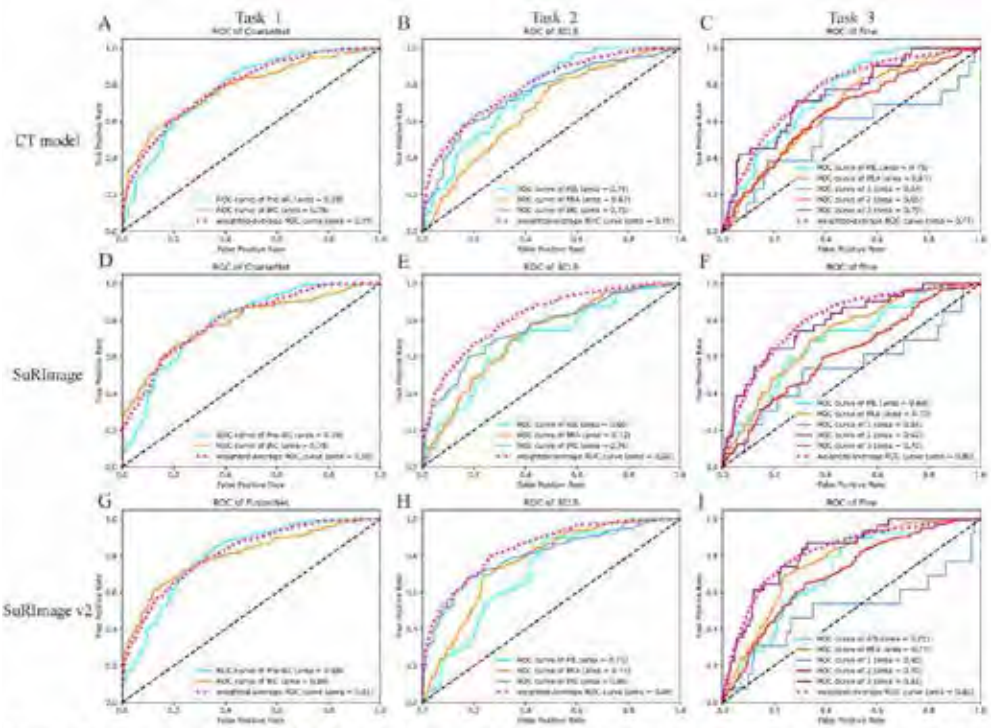

Figure 1. The diagnostic performance of CT model, SuRImage and SuRImage v2. Tasks 1 to 3 refer to different clinical scenarios for IAC identification, diagnosis and grading. CT model (A-C) were established with preoperative chest CT within 3 months, while SuRImage (D-F) were developed with intraoperative surgical resection images. This study enhanced the multimodal intraoperative diagnostic model SuRImage v2 (G-I) by incorporating preoperative CT and intraoperative macroscopic features. Area under the curve (AUC) were calculated for evaluation of model performance.

P2.06.61 ASPiRATION. Australian Nationwide Cohort Study to Assess Impact of Comprehensive Genomic Profiling in Metastatic Lung Cancer

N. Pavlakis[1], C.K. Lee[2,3], M.L. Ballinger[4], C.S.B. Brown[3], J.P. Grady[4], F. Lin[3,5], S. Thavaneswaran[3,5,6], A.J. Mersiades[3], D. Di-Xin Zhou[2,3], J. Lee[3], T. John[7], C.E. Napier[4], M.M. Cummins[3], E. Collignon[4], L. Sebastian[3], O.M.H. Turnbull[4], J. Simes[3], D.M. Thomas[4], B.J. Solomon[7]
[1]Royal North Shore Hospital, University of Sydney, Sydney/AU ,[2]St George Hospital, Sydney/AU ,[3]NHMRC Clinical Trials Centre, University of Sydney, Sydney/AU ,[4]Centre for Molecular Oncology, University of New South Wales, Sydney/AU ,[5]Garvan Institute of Medical Research, Sydney/AU ,[6]Department of Medical Oncology, The Kinghorn Cancer Centre, St Vincent's Hospital, Sydney/AU ,[7]Peter MacCallum Cancer Centre, Melbourne/AU

Introduction: The importance of comprehensive genomic profiling (CGP) for metastatic non-small cell lung cancer (mNSCLC) is well-established but access to testing is not universal. ASPiRATION, an Australian study, investigated the feasibility and clinical impact of upfront CGP testing nationally, alongside standard of care (SoC) testing (i.e. minimum of EGFR, ALK, ROS1), to inform systemic therapy in community settings including regional, rural and remote (RRR) areas via a remote consent/Telehealth model.

Methods: Patients with newly-diagnosed, pathologically-confirmed, non-squamous mNSCLC with adequate tumour tissue for CGP and SoC testing were recruited. CGP was performed prospectively on archival tissue using FoundationOne® CDx or TruSight Oncology 500 panels. Molecular Tumour Boards (MTB) provided treatment recommendations based on genomic driver alterations in the first-line setting, classified as Tier 1 if they had Level 1 or 2 evidence of actionability according to OncoKB or TOPOGRAPH (Australian-developed database). Turnaround time (TAT) was measured from tissue request to MTB report.

Results: Between December 2020-June 2023, 1000 Australians with advanced NSCLC (median age 66yo; 14% Asian, 26% never-smokers, 49% female, 36% ECOG 0) were recruited from 85 hospitals across all states and territories, 27% from RRR areas, reflective of Australia's population distribution (28% RRR per 2023 census). TAT interquartile range was 22-36 days; 23% required additional biopsies within 90 days before CGP results. Twenty-eight (2.8%) participants were ineligible; 779 (80%) had evaluable results by both SoC and CGP. The most common driver alterations were KRAS (G12C, 13%; non-G12C, 18%), EGFR (17%), ERBB2 (5.5%), MET exon 14 skipping mutations (2.6%) and ALK fusions (4.2%). Tier 1 alterations were detected in 293 (38%) by SoC and 385 (49%) by CGP. Tier 1 alterations detected by CGP but not SoC included KRAS G12C (3.9%), MET mutations/amplifications (2.6%), EGFR (1.9%), ALK fusions (1.0%), all but one RET (1.3%) and all NRG1 fusions (0.8%). In 779 participants, 705 were treated with systemic therapy, but 79% commenced prior to receiving CGP results: 52% on chemo/IO and 27% on targeted agents. 16% enrolled in a clinical trial, 12% with targeted agents. Amongst those with Tier 1 alterations, 65% received targeted therapy, including 18% in RRR areas. Ninety-eight (13%) had actionable alterations by CGP but not SoC, of which 45% received targeted therapy. With 27 months follow-up, median overall survival (OS) for participants who received targeted treatment, non-targeted treatment and best supportive care was 34 months (95% CI, 30 - not reached), 16 months (95% CI, 13-20) and 8.1 months (95% CI, 2.7-13), respectively.

Conclusions: Tissue-based CGP testing detects 13% more actionable alterations than SoC testing, demonstrating the value of upfront comprehensive genomic screening in patients with mNSCLC. Considering CGP TAT, a formal utility analysis comparing universal upfront versus reflex testing would inform implementation to guide precision medicine at national scale.

P2.06.62 Integrin-ß6 Modulates the Tumor Microenvironment and Serves as a Prognostic Marker in Lung Squamous Cell Carcinoma

O. Younis[1], J. Al Rawabdeh[1], N. Al Bzour[2], M. Hashki[2], A. Al Bzour[2], F. Abu Rous[3]
[1]University of Jordan, Amman/JO ,[2]Jordanian university of science and technology, Irbid/JO ,[3]Henry Ford Health, Detroit/MI/USA

Introduction: Integrin-β6 (ITGB6) is a member of the integrin family implicated in tumor proliferation and metastasis in non-small cell lung cancer (NSCLC), making it a compelling therapeutic target. Interest in ITGB6 has recently grown with the development of sigvotatug vedotin, an ITGB6-targeted antibody-drug conjugate (ADC) conjugated to monomethyl auristatin E (MMAE), which has shown promising efficacy in heavily pretreated NSCLC. In this analysis, we investigate the prognostic relevance of ITGB6 expression and its impact on the tumor microenvironment (TME) in lung squamous cell carcinoma (LUSC).

Methods: We analyzed bulk RNA sequencing data from the TCGA-LUSC cohort and single-cell RNA-seq data from GSE131907, GSE148071, and GSE162498. ITGB6 RNA and protein expression in tumor vs. normal tissues were evaluated using GEPIA2 and UALCAN, respectively. Differential gene expression between high (top 25%, n =135) and low (bottom 25%, n =135) ITGB6 expressors was performed using DESeq2. Immune cell infiltration was assessed via XCell and EPIC deconvolution algorithms. Gene set enrichment analysis (GSEA) was conducted using Enrichr. Single-cell data were processed in Seurat following standard QC and normalization workflows. Correlation analyses were performed using the CSCORE algorithm. Prognostic value was assessed using a multivariate Cox regression model adjusting for stage, age, and gender.

Results: The TCGA-LUSC cohort included 512 patients with full transcriptomic and survival data. Patients with higher ITGB6 expression, stratified by median expression level, had worse overall survival (OS) compared to those with lower expression (logrank p = 0.0019). Moreover, a multivariate Cox regression for OS confirmed high ITGB6 expression as an independent predictor of poor prognosis (HR = 1.39, P = 0.0201). Bulk RNA and protein analysis revealed no significant difference in ITGB6 expression between tumor and normal samples. However, single-cell analysis demonstrated significantly lower ITGB6 expression in malignant LUSC epithelial cells compared to normal lung epithelium (log2FC = -0.96, P < 0.0001). High ITGB6 expressors showed upregulation of genes involved in epithelial-to-mesenchymal transition (EMT) and cancer-associated fibroblast (CAF) activation, including ANGPTL4, FN1, FAP, VIM, and CAV1. GSEA revealed enrichment in pathways such as EMT, extracellular matrix (ECM) organization, CXCR chemokine receptor binding, and collagen remodeling. Immune deconvolution showed that high ITGB6 expression was associated with increased infiltration of CAFs, dendritic cells, monocytes, M1 and M2 macrophages, T regulatory cells, and higher immune and microenvironment scores. Conversely, infiltration of Th1 and Th2 CD4+ T cells was reduced (all p < 0.01). Single-cell analysis further revealed elevated ITGB6 expression in CAFs from LUSC tumors compared to normal lung fibroblasts (log2FC = 1.97, P < 0.0001).

Conclusions: High ITGB6 expression is an independent poor prognostic marker of OS in LUSC and is associated with an immunosuppressive and fibrotic TME characterized by active CAFs and increased ECM remodeling. These findings suggest that ITGB6 may not only serve as a therapeutic target but also as a biomarker for patient stratification in LUSC, particularly in the context of ADC therapy.

P2.06.63 The Role of the Lower Airway Microbiome in Predicting Treatment Response to Immunotherapy in Patients With Non-Small Cell Lung Cancer

A.E.B. MCLEAN[1], W.A. Cooper[1], S.C. Kao[2], E.T. Lau[1], K.K. Wong[1], X. Jiang[3], H.C. Yim[3], E. El-Omar[3], M.R. Kohonen-Corish[4]
[1]Royal Prince Alfred Hospital, Sydney/AU ,[2]Chris O'Brien Lifehouse, Sydney/AU ,[3]UNSW Microbiome Research Centre, Sydney/AU ,[4]University of Macquarie, Sydney/AU

Introduction: Endobronchial ultrasound guided biopsy(EBUS) is standard of care to diagnose and stage patients with suspected lungmalignancy. Current biomarkers availableto predict treatment response to therapy are imperfect. Recently, the gutmicrobiome has been shown to modulate treatment response to immunotherapy innon-small cell lung cancer (NSCLC). However, despite the lower airwaymicrobiome interacting directly with the tumour microenvironment and multiplestudies suggesting a role for the airway microbiome in tumorigenesis, there arefew studies to date investigating the effect of the airway microbiome ontreatment response in NSCLC.

Methods: Patients attending our tertiary referralcentre for EBUS with suspected lung malignancy from June 2021 to December 2023were consecutively recruited to the study. Clinicopathological and demographicdata as well as information on antibiotic and antacid use were collected.Bronchoalveolar fluid was sampled from the site of the suspected tumour in 74participants. 58 participants were diagnosed with NSCLC and of those, 38patients received systemic therapy, with 24 from this group receivingimmunotherapy. We performed whole genome metagenomic sequencing to obtain the lungmicrobiome profiles from these patients.

Results: Patients treated with immunotherapy were stratifiedinto responders (n = 8; 33%) and non-responders (n= 16; 67%)using Durable Clinical Response criteria. The Simpson index, a measure of alphadiversity was reduced in responders, but this did not reach significance (p =0.06). Compositional differences were also noted. Phylum-001 was significantlyincreased in non-responders (p = 0.004) while Phylum-002 was enriched inresponders (p = 0.003). Multivariate analysis at a species level demonstrated asignificant negative effect on immunotherapy response for two microbial species(p = 0.01-0.02) although this did not remain significant on Benjamini Hochbergcorrection for multiple comparisons.

Conclusions: Few studies have investigated the impact ofthe lower airway microbiome on immunotherapy response in NSCLC. Increasedabundance of firmicutes has previously been associated with the development oflung cancer, as have oral colonisers at the genus levels. Our study is thefirst to suggest that differences in thelocal airway microbiome at the species level may also have a role in modifyingimmunotherapy responses. Larger multicentre studies are needed to furtherexplore its potential as a novel biomarker and therapeutic target. .

P2.06.64 Fusion Transcript Burden Is Associated With Clinical Outcomes in Patients With Resected NSCLC

J.A. Borgia, K. Cagin, A. Khan, S. Shah, W. Naeem, M. Ansari, O.W. Adebayo, H. Moudgalya, A. Sharma, M. Liptay, M.J. Fidler, C.W. Seder
Rush University Medical Center, Chicago/IL/USAty,

Introduction: Disease-free survival (DFS) varies considerably in patients with non-small cell lung cancer (NSCLC) following an anatomic resection, with few validated prognostic biomarkers guiding systemic adjuvant therapy selection. Here, we explore fusion transcript burden (FB), or the total number of unique fusions detected at the RNA level, as a means to prognosticate DFS, based on the premise these events result in increased neoantigen production and heightened immunosurveillance in tumors.

Methods: Paired-end RNAseq was performed by Tempus on 536 FFPE NSCLC tumors, stage IA-IIIB, resected at RUMC between 2010 and 2021, with those receiving neoadjuvant therapy excluded. The overall cohort consisted of patients with resected NSCLC and was 59.1% (317) female and 40.9% (219) male, ranging in age from 41-93 (median 70) yrs. STAR-Fusion was used in parallel to STAR genome alignment, and differential gene expression between groups based on Fusion Burden performed using edgeR with GLM and quasi-likelihood. Kaplan Meier plots were performed using Survival/Survminer. Primary endpoint was DFS, with fusion burden as categorical.

Results: Median follow-up time in the study was 42.4 months. Fusion Burden (FB) followed a right-skewed distribution in the overall cohort, with a range of 5 to 47 (med. value = 14). Wilcoxon rank-sum test showed a difference in FB distribution that was stage-dependent, comparing stage II to III cases ($p = 0.035$), but was independent of histology (Adenocarcinoma vs. Squamous Cell Carcinoma (SCC), $p= 0.25$). However, when a FB threshold of 10 unique transcripts was applied, those with SCC histology had a significant difference ($p=0.037$; $n=100$) in DFS as early as the 2-yr timepoint, versus those with non-squamous histology ($p=0.24$, $n=434$). When we applied this same FB threshold to the full stage II /III sub-cohort, a superior DFS was observed for those with a FB ≥10 at the 1-, 2-, and 5-yr timepoints (all $p \leq 0.05$), relative to those below the threshold. Notably, the prognostic value of FB with respect to benefit from adjuvant therapy was most pronounced for patients with SCC histology, where adjuvant therapy provided a ~20% increase in DFS at the at 5-yr timepoint for those with a FB ≥10 ($p=0.031$, $n = 78$). Finally, when we examined differential gene expression in the full cohort grouped by FB (threshold at 10), there were a total of 2,908 modulated genes with a FDR < 0.05. Among the top 50 results, 22% are implicated in inflammatory/immune response and 20% are implicated in apoptosis.

Conclusions: Our findings support that fusion transcript burden may have value for prognosticating benefit from adjuvant chemotherapy and may hold promise for the improved prognostication of patients with early stage lung cancer and/or guiding selection of immune checkpoint inhibitors as part of their treatment strategy. Efforts are now focused on cohort expansion and contextualizing these findings to the tumor immune microenvironment.

Introduction: Hematoxylin and eosin (H&E) digital pathology slides (DPS) hold valuable information for predicting complex medical tasks, as immune checkpoint inhibitor (ICI) response. While PD-L1, assessed via immunohistochemistry, remains the most reliable clinically-approved biomarker, H&E slides offer a cost-effective, widely-available alternative for computational decision support. We incorporate finer classification of PD-L1 status using single-modality data, adressing a critical gap in the field.

Methods: The I3LUNG (NCT05537922) is a global EU project aiming to predict response to ICIs using artificial intelligence (AI), incorporating data from centers in Italy, Germany, Greece, Spain, US, and Israel. The cohort includes individuals in a non-curative setting who have received first-line treatment for advanced or metastatic NSCLC with ICIs, alone or in combination with chemotherapy or other agents. We used H&E DPS, paired with patient's PD-L1 status. DPS were tiled into squares (224x224px) at 10x magnification. From each tile, we extracted embeddings from UNI foundation model (embedding dimension 1x2024) to be fed as input to an attention-based multiple instance learning (ABMIL) algorithm to predict three-class PD-L1 expression status (<1%, 1-49%, ≥50%). ABMIL treats a DPS as a bag of tiles, using attention mechanisms to identify key tiles influencing the slide-level prediction. We compared multiple model variations, including DP1, using a single ABMIL mode and DP5 and DP15 using an ensemble of 5 and 15 ABMIL, respectively, to assess the impact of ensemble size. We also tested DP5L, a variant replacing the attention mechanism with random sampling and averaging over up to 50 tiles, and a baseline dummy model DM predicting the majority class.

Results: We used 419 pts with available DPS and PD-L1 status (144 pts <1%, 140 pts 1-49%, and 135 ≥50%). The models were evaluated using balanced and per-class accuracy (ACC), precision (PRE), recall (REC), and F1-score (F1). The results are presented in Table 1. All the models outperformed the dummy model DM. Comparing DP5 and DP15, a larger ensemble size appears beneficial for PD-L1 expression classification. Both models significantly outperform DP1, further emphasizing the advantage of the ensemble approach. Additionally, DP5L underperforms compared to DP5 and DP15, highlighting the importance of the attention mechanism in the ABMIL method.

Conclusions: To our knowledge, this is the first AI-based study effectively demonstrating three-class PD-L1 expression classification directly from H&E slides. All models significantly outperformed the baseline model. This approach can assist clinical decision-making without requiring PD-L1 immunohistochemistry, particularly if access to PD-L1 testing is limited.

Table 1. Metrics on the 3-class classification of PD-L1 expression

Metric	DP_5	DP_{15}	DP_1	DP_5L	DM
ACC	0.50	0.43	0.33	0.50	0.33
PRE	0.50	0.43	0.33	0.50	0.12
REC	0.50	0.43	0.33	0.52	0.34
F1	0.50	0.43	0.33	0.49	0.18
PD-L1<1% PRE	0.51	0.43	0.34	0.58	0.34

[1]Queen's University, Kingston/ON/CA ,[2]Johns Hopkins University, Baltimore/MD/USA ,[3]Memorial Sloan Kettering Cancer Center, Middletown/NJ/USA

Introduction: We previously showed that CD8+FoxP3+ cells predict response to anti-PD-1-based therapy in melanoma. Here, we leveraged large-scale mIF analyses (~35M individually mapped cells; 50,000 high power fields) and novel spatial modelling techniques to characterize these cells and their niche as predictive features of a treatment-responsive tumor microenvironment in NSCLC. We benchmark their performance to PD-L1 IHC and tertiary lymphoid structures (TLS).

Methods: A total of 75 pre-treatment biopsy specimens were obtained from 4 cohorts of patients with NSCLC; Cohort 1 (n=25) from the first neoadjuvant clinical trial of anti-PD-1(NCT02259621); Cohort 2 (n=14) from a landmark trial of advanced NSCLC receiving second-line anti-PD-1(NCT01673867); Cohort 3 (n=20) patients received second-line standard of care anti-PD-1; and Cohort 4 (n=16) from a landmark trial of advanced NSCLC receiving second-line chemotherapy (docetaxel) following progression on first-line platinum doublet chemotherapy(NCT01673867). Slides were stained with a previously-validated 6-marker multiplex immunofluorescence (mIF) panel. The AstroPath platform was used to generate comprehensive cellular maps from whole-slide scans. A probabilistic model was trained on the contact neighbours of ~50,000 CD8+FoxP3+ cells in NSCLC resections, and the niche surrounding these cells was defined using CD8, CD163, FoxP3, and cytokeratin. Receiver-operating characteristic curves were used to test the association of patient outcomes with (1) the densities of CD8+FoxP3+ cells and (2) the CD8+FoxP3+ cell niche (i.e. the surrounding ring of cells or "DONUTS").

Results: CD8+FoxP3+ cell densities showed strong predictive value for patient outcomes in all four cohorts. DONUTS defined by using only 4 mIF lineage markers were ~150-fold more abundant than CD8+FoxP3+ cells themselves and met or outperformed the actual cells (Figure 1, AUCs of 0.73-0.86 in all cohorts tested). When benchmarked against other biomarkers, both CD8+FoxP3+ cell densities and the DONUTS were additive to PD-L1 IHC results, and served to further stratify patient outcomes. Additionally, resection specimens were used to show that the density of both CD8+FoxP3+ cells and the DONUTS associated with TLS density (p=0.001), the latter of which are rarely captured on pre-treatment specimens.

Conclusions: Our study identifies CD8+FoxP3+ cells and their immunoactive niche as robust predictive biomarkers of treatment outcome across diverse disease stages and treatment types. Importantly, the DONUTS are more prevalent than the CD8+FoxP3+ cells themselves, reducing concern of sampling error. Further, this biomarker only requires four markers, is additive to PD-L1 and is a surrogate for TLS. Taken together, the DONUTS represent a next-generation predictive biomarker poised for clinical implementation.

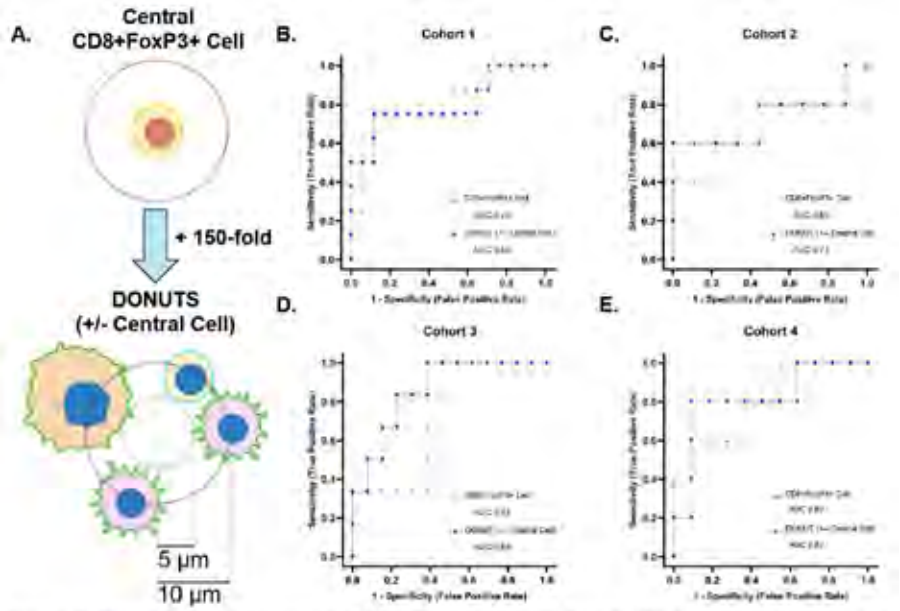

Figure 1. Novel spatial biomarker (DONUTS) validates in four NSCLC cohorts. Densities of CD8+FoxP3+ cells and the CD8+FoxP3+ cellular niches (DONUTS) were used to predict outcome in NSCLC. **A.** The DONUTS (bottom) occur at ~150-fold greater frequency than CD8+FoxP3+ cells themselves (top). **B-E.** Receiver-operator characteristic curves are plotted for four testing cohorts. The DONUTS outperform CD8+FoxP3+ cells in predicting major pathologic response (**B**; AUC=0.80 vs 0.79), overall survival (**C**; AUC=0.73 vs 0.69), radiographic response (**D**; AUC=0.86 vs 0.73), and progression free survival (**E**; AUC=0.82 vs 0.80).

P2.06.67 Retrospective Analysis of 124 LCNEC Tumors With Targeted Expression Profiling of 111 Samples Identifies Candidate Chemo-Sensitivity Biomarker

D.T. Severson, M-B. Joshi, J. Crawford, E. Pavlisko, C. Kelsey, K. Bevers, T. D'Amico, D. Harpole, V. Raman
Duke University, Durham/NC/USA

Introduction: Pulmonary large cell neuroendocrine carcinomas (LCNECs) are high-grade, poorly differentiated lung neuroendocrine neoplasms. LCNECs are rare, representing ~3% of all lung malignancies, but convey poor prognosis, with only 16.7% 5-year survival. Previous genomics profiling of LCNEC has identified prognostic groups: carcinoid- or non-small cell-like (EGFR, STK11, KEAP1 mutations) with improved survival and small cell-like (RB1, TP53 mutations) with worse survival. Despite heterogeneity and poor survival, LCNEC continues to be staged and managed like non-small cell lung cancer (NSCLC). This study aimed to use a single-institution bio-banked LCNEC registry to evaluate clinical and molecular features associated with survival, metastasis, and response to platinum-based chemotherapy.

Methods: A retrospective cohort of 124 cases of LCNEC prospectively consented for RNA profiling were identified in the Duke Biorepository. Diagnosis was reviewed and confirmed by a thoracic pathologist. Patients were included regardless of pathologic stage. Patient- and tumor-related clinical features associated with overall survival (OS) were examined using multivariable Cox proportional hazards including landmark analyses to adjust for time bias experienced by patients who received adjuvant chemotherapy. To identify associated molecular features, 111 of these 124 cases were profiled with a 1,392 immuno-oncogene panel. Differentially gene expression analysis was performed contrasting short and long survivors (separated by median survival: 5.1 years) who received chemotherapy and contrasting pathologic stage I tumors with eventual metastasis vs no metastasis. Significantly differentially expressed genes were identified using a quasi-likelihood F-Test on the relevant coefficient of a generalized linear model (FDR < 0.10).

Results: In our cohort of 124 LCNEC cases with median follow-up of 17.27 years, the median age at time of surgery was 68 (IQR:58-72) and all pathologic stages were represented (I:57, II:36, III:25, IV:6 patients). The incidence of recurrence or metastasis was 31.6% in patients with pathologic stage I disease. Most patients underwent lobectomy. Thirty-seven patients received adjuvant chemotherapy, primarily with a platinum-backbone. We identified age at surgery (HR:1.03, 95%CI:1.01-1.05), ECOG performance status 1 (HR:1.94, 95%CI:1.15-3.30), receipt of platinum-based chemotherapy (HR:0.52, 95%CI:0.29-0.91) and stage III pathology (HR: 2.61, 95%CI 1.39-4.91) as significantly associated with OS. However, chemotherapy was not significantly associated with overall survival (HR: 0.58, 95%CI 0.32-1.05) in a landmark analysis (landmark time: 3 months). We found two significantly differentially expressed genes associated with long survival, BMP7 (log2FC: -1.36, FDR:0.009). and CGREF1 (log2FC: -0.94, FDR=0.057). Median survival after receipt of chemotherapy was 8.43 and 1.79 years for patients with high (above median) and low (below median) BMP7 expression, respectively. No genes were significantly differentially expressed between stage 1 tumors with or without metastasis after multiple hypothesis correction.

Conclusions: In this clinical and immune-oncologic gene expression study of 124 cases of LCNEC, the receipt of platinum-based adjuvant chemotherapy was not associated with OS with adjusted landmark analysis. However, we identified BMP7 and CGREF1 as candidate biomarkers for sensitivity to platinum-based chemotherapy. If validated, these biomarkers could inform clinical decisions regarding perioperative chemotherapy and surgery. Future work will profile candidate biomarkers in banked tissue with immunohistochemistry and aim to validate these findings in an orthogonal cohort.

P2.06.68 Enhancing Precision Medicine in NSCLC - the Importance of Tumor Metabolic Spatial Profiling in Immunotherapy Biomarker Discovery

E. Markovits[1], J. Monkman[2], T.N. Aung[3], S. Bookstein[1], J. Reeves[1], K. O'byrne[4], D. Rimm[3], A. Kulasinghe[2], K. Bloom[1]
[1]Nucleai, Tel Aviv/IL ,[2]The University of Queensland, Brisbane/AU ,[3]Yale University School of Medicine, New Haven/CT/USA ,[4]Princess Alexandra Hospital, Brisbane/AU

Introduction: Immune checkpoint blockade (ICB) therapies provide durable benefits to a subset of patients with non-small cell lung cancer (NSCLC), though the majority do not respond. This study aims to spatially profile the tumor-immune contexture and metabolic activity in ICB-treated patients to gain insights on how spatial organization of cells, activation states and cellular interactions can be utilized predict ICB response and resistance.

Methods: Using a multiplex immunofluorescence (mIF) panel of 44 proteins, encompassing immune and metabolic cell states, we profiled tumor microarrays (TMA) from two large cohorts of NSCLC patients treated with ICB (n=117, 72 with relevant clinical annotations). Employing Nucleai's deep learning (DL)-based analysis pipeline, marker positivity was determined by a DL-classifier for each segmented cell, followed by assignment to 14 cell types by known protein expression profiles. Cell subtypes were established by clustering of positive prediction probabilities of metabolically and immunologically relevant proteins, outputted from the DL-classifier. Spatial features were calculated by integrating cell types, phenotypic states, and spatial context. Welch's T-test identified spatial features linked to clinical outcomes within each metabolic subgroup, distinguishing responders (objective response or prolonged progression-free survival (PFS)) from non-responders. A multivariate model predicting clinical benefit was developed from spatial features within tumor subtypes in a training set (n=53) and validated on an independent test set (n=19).

Results: We identified 5 distinct tumor clusters which differed in their cellular composition, immune and metabolic states, and clinical outcomes following ICB. Key proteins differentiating these clusters included CD44, G6PD, Hexokinase-1, HLA-A, and oxidative phosphorylation (OXPHOS) proteins. All patients in the CD44+ tumor cluster demonstrated clinical benefit, with extended PFS (23.2 months vs. 3.0 and 3.3 months for G6PD+ and HEX1+ clusters, p=0.02) and a trend towards prolonged overall survival (OS). Within the tumor metabolic subtypes, different immune and metabolic states were associated with treatment outcomes - within the G6PD+ and HEX1+ tumor clusters, positivity for OXPHOS proteins was associated with better clinical outcome, while in the HLA+ and OXPHOS- tumor clusters, high expression of immune activation related proteins, such as HLA-A and PD-L1, were more significantly associated with clinical outcome. Thus, the metabolic phenotype of the tumor is critical for accurate ICB response biomarkers identification. A multivariate ICB outcome predictor based on tumor subtypes demonstrated high accuracy (AUC 0.93, p=0.001) in an independent set, with predicted responders showing higher clinical benefit rates (84.6% vs. 16.7%, p=0.01) and prolonged PFS and OS.

Conclusions: In this study we present the analysis results of one of the largest clinically annotated mIF dataset from pre-treatment biopsies of NSCLC patients treated with ICB. Our findings reveal that the clinical relevance of spatial features is intricately linked to the tumor's metabolic phenotype, emphasizing the necessity of integrating metabolic phenotyping into prediction models for improved prediction of ICB outcomes. This research underscores the potential of multiplex imaging and advanced spatial biology tools to significantly advance biomarker discovery and enhance personalized treatment strategies, paving the way for more tailored and effective therapeutic interventions in NSCLC.

P2.06.69 Metabolite Enrichment Patterns Correlate With Race, Gender and BMI in Lung Cancer Patients

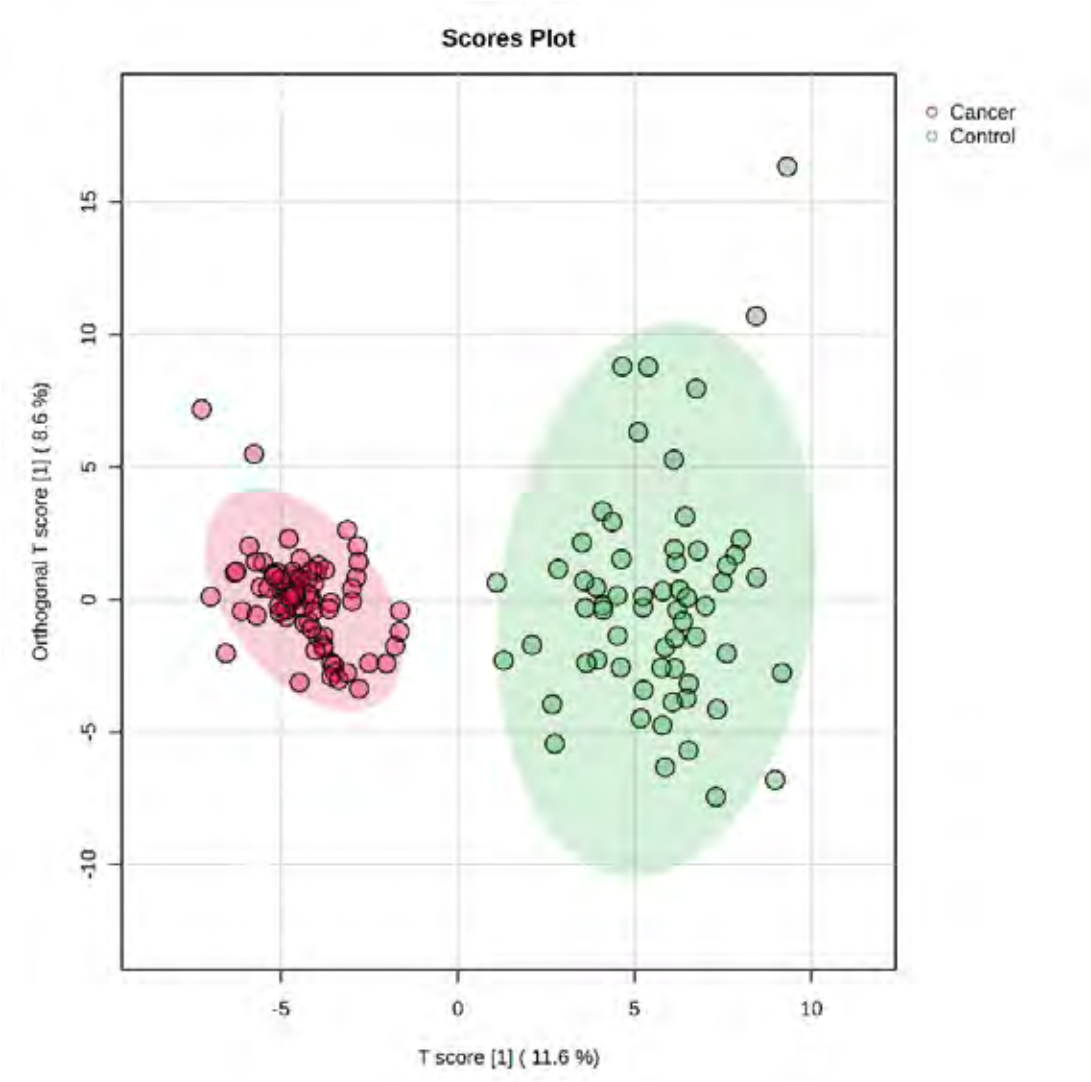
J.J. Pothen[1], M. Pasquinelli[2], A. Mallisetty[2], A. Roy[1], T. Shimamura[2], K. Jiyeon[3], R.H-T. Nguyen[1], A. Hulbert[2], F. Weinberg[1]
[1]University of Illinois College of Medicine, Chicago/IL/USA ,[2]University of Illinois at Chicago, Chicago/IL/USA ,[3]Yale School of Medicine, New Haven/CT/USA

Introduction: Despite the high incidence of lung cancer (LC), the effect of patient demographics on metabolic pathway activity remains poorly understood. Understanding these metabolic differences will provide insight into how patient anthropometric data affects LC development and progression, and could uncover novel therapeutic and preventative strategies, offering the potential for more personalized and effective treatments.

Methods: This retrospective cohort study collected plasma from 62 patients with confirmed LC and 80 control patients without LC. Metabolomic profiling was performed using ultra-high performance liquid chromatography - mass spectrometry (UHPLC-MS). Analysis was conducted using MetaboAnalyst 5.0 to identify distinct metabolite enrichment patterns. Orthogonal partial least squares discriminant analysis (OPLS-DA) was employed to assess significant differences in metabolite levels between LC and control groups. We then determined the most significant metabolite differences, using Variable Importance in Projection (VIP) scores for discrete variables (e.g. race and gender), and a random forest algorithm for continuous variables (e.g. body-mass index (BMI)).

Results:

Figure 1



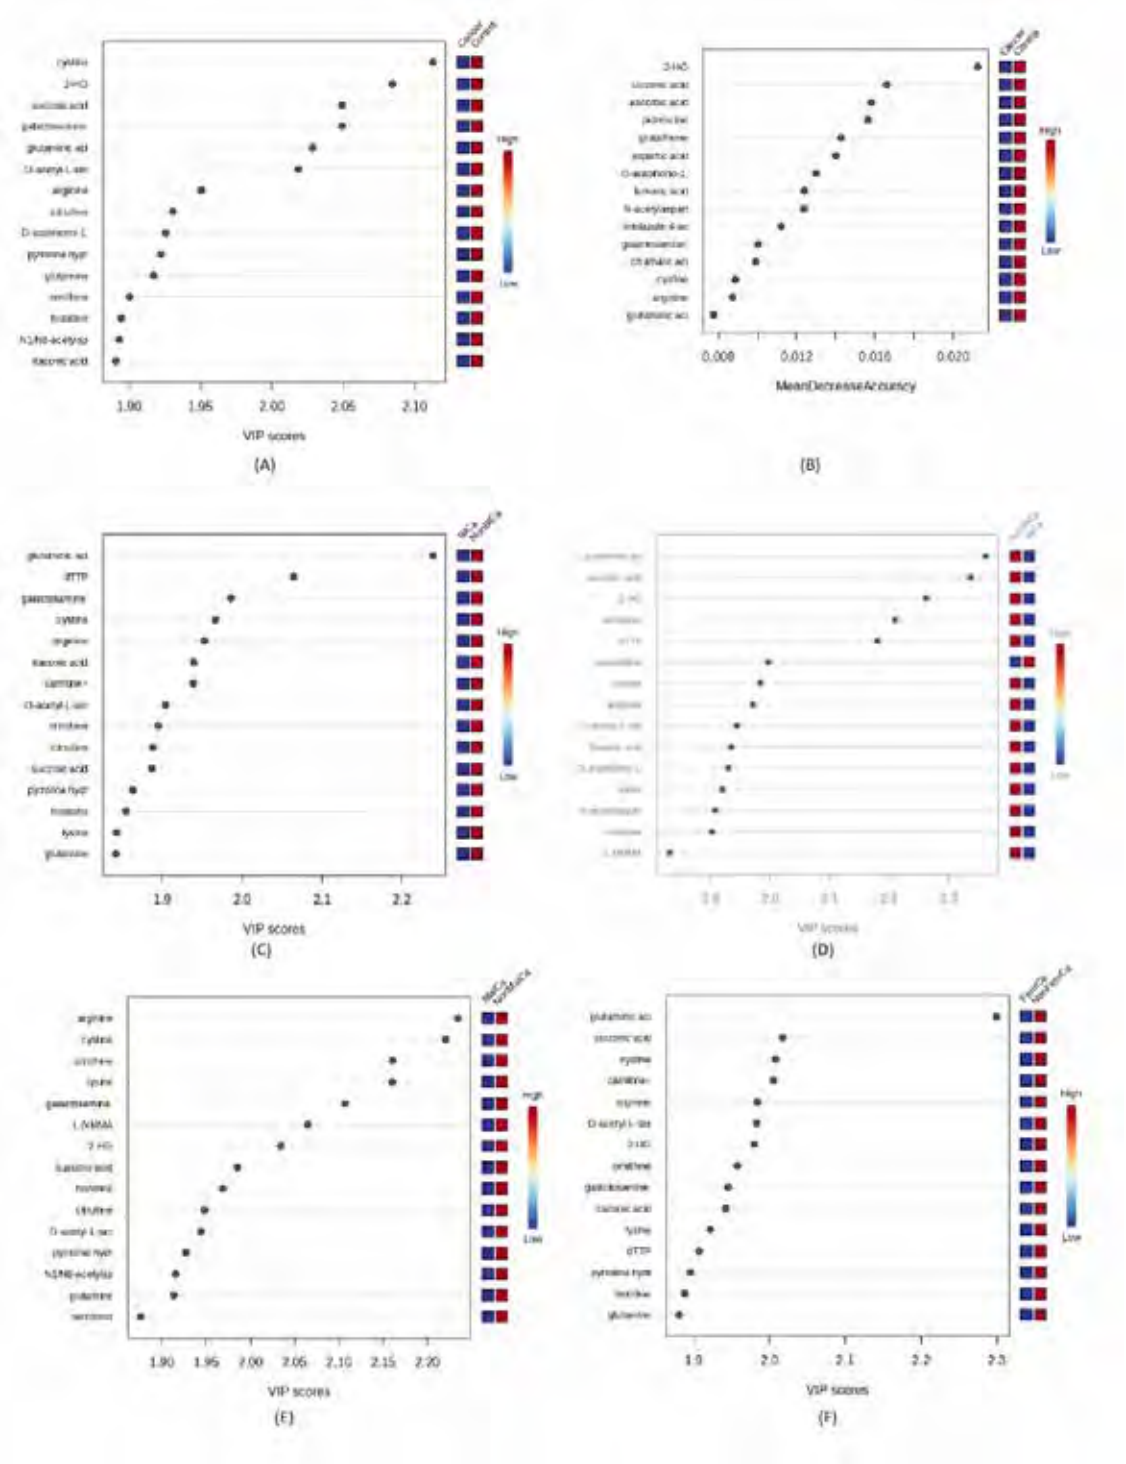


Figure 2

We found significant differences in metabolite expression between cancer and control samples (Figure 1), with decreased metabolite enrichment seen in LC (Figure 2A). We then found the most significant metabolite differences in subgroup analyses for BMI (2B), black race (2C), white race (2D), male gender (2E) and female gender (2F).

Conclusions: Our analysis demonstrates significant differences in metabolite expression between LC and control samples, with most metabolites showing decreased plasma enrichment in LC. This may be attributed to heightened tumor metabolite consumption. Additionally, different patient subsets had different patterns of metabolite enrichment, such as lower plasma levels of 2-hydroxyglutarate in cancer patients with higher BMIs. Future research exploring the relationship between metabolite enrichment and factors such as geospatial location, epigenetic gene expression and social determinants of health will deepen our understanding of how both biological and external factors modulate tumor metabolism.

Introduction: Liquid biopsy (LB) is a valuable tool for detecting actionable molecular alterations in advanced non-small cell lung cancer (aNSCLC), facilitating genotype-matched therapies. While LB is recommended for cases with inadequate/inaccessible tumor tissue, its routine integration into the diagnostic workflow for all newly diagnosed aNSCLC patients remains limited. This study evaluated whether concurrent plasma circulating tumor DNA (ctDNA) next-generation sequencing (NGS) alongside tissue-based NGS improves the time to molecular results and treatment initiation in newly diagnosed aNSCLC patients.

Methods: This single-center, prospective, quality improvement study included two cohorts of patients. The 'ctDNA cohort' underwent plasma ctDNA NGS in addition to standard tissue-based NGS, and the 'reference cohort' received standard tissue-based NGS alone. Both cohorts underwent tissue biopsy and reflex tissue NGS. ctDNA NGS was done on a 31 gene hotspot panel, DNA only, FindIt by Canexia Health. The primary outcome was time from medical oncology consultation to initiation of first-line systemic therapy.

Results: A total of 215 patients were analyzed, 90 in ctDNA cohort and 125 in control cohort. Patient characteristics are shown in table 1. Compared to the reference cohort, the ctDNA cohort had significantly shorter median time to molecular results (14 vs. 35 days; p=0.01); time to molecular results from first respirology/thoracic surgery consultation (22 vs. 48 days; p=0.01); time to treatment initiation from first medical oncology consultation (12 vs. 22 days; p=0.01). Lack of molecular results at the first medical oncology consultation led to treatment delay in 13% (11/86) of patients in the ctDNA cohort, compared to 23% (28/122) in the reference cohort (p=0.06) (Figure 1).

Conclusions: In a publicly funded, single-payer healthcare system, concurrent ctDNA and tissue-based NGS significantly accelerates molecular result acquisition and reduces time to treatment initiation compared to tissue testing alone. These findings support incorporating ctDNA testing early in the diagnostic pathway for aNSCLC.

Table 1: Demographic characteristics of the ctDNA and reference cohorts.

Characteristic	ctDNA cohort (No. (%) of patients, N=90)	Reference cohort (No. (%) of patients, N=125)
Age, years (median)	71	72
Sex		
Male	39 (43)	72 (58)
Female	51 (57)	53 (42)
Histology		
Adenocarcinoma	60 (67)	78 (62)
Squamous cell carcinoma	23 (26)	31 (25)
NSCLC NOS	7 (7)	16 (13)
Clinical stage		
4	65 (72)	125 (100)
3	25 (28)	0 (0)

No., number; NSCLC NOS, non-small cell lung cancer not otherwise specified.

P2.06.71 Clonal Hematopoiesis and Its Association With Lung Cancer Incidence and Immunotherapy Response: A Meta-Analysis

B. Ponvilawan[1], C. Wannaphut[2], M. Tanariyakul[2], S. Subramanian[3], D. Bansal[4]
[1]Northwestern University Feinberg School of Medicine, Chicago/IL/USA ,[2]John A. Burns School of Medicine, University of Hawaii, Honolulu/HI/USA ,[3]Langley High School, McLean/VA/USA ,[4]Endeavor Health, Evanston/IL/USA

Introduction: Clonal hematopoiesis of indeterminate potential (CHIP) is a form of acquired somatic mutation that occurs in the hematopoietic stem cell without detectable hematologic malignancy. It is known to increase the risk of developing solid tumors, including lung cancer, through heightened inflammation and altered antitumor immunity. This may affect the efficacy of immune checkpoint inhibitors (ICI). We performed meta-analyses to evaluate (1) the association between CHIP and the incidence of lung cancer and (2) whether CHIP affects the survival outcome in patients with lung cancer who received ICI.

Methods: Studies indexed in Medline and Embase databases were identified using search terms related to "CHIP" and "lung cancer" from inception to February 2025. We included all observational studies that compared individuals with and without CHIP. For studies evaluating the risk of developing lung cancer, all patients must not have had prior lung cancer diagnoses, then followed for incident lung cancer. For studies evaluating ICI response, all patients with lung cancer must receive ICI, then followed for overall survival (OS). Hazard ratios (HR) or odds ratios (OR), with associated 95% confidence intervals (CI), were pooled using the generic inverse variance method. We conducted subgroup analyses based on smoking status and gene mutations.

Results: In total, eight studies were included in the meta-analysis. The presence of CHIP was associated with an increased incidence of lung cancer (HR 1.40, 95%CI 1.29-1.53; Figure 1A). The elevated risk did not differ between individuals with a history of smoking (HR 1.43, 95%CI 1.29-1.58) and those without (HR 1.42, 95%CI 1.19-1.71) (Figure 1B-C). Among patients with lung cancer who received ICI, CHIP was not associated with an adverse OS (HR 1.04, 95%CI 0.58-1.87; Figure 1D). Based on the involved gene, differential risks were noted, with ASXL1 being associated with the highest risk, followed by DNMT3A and TET2 (HR for ASXL1 1.81, 95%CI 1.35-2.43 vs. HR for DNMT3A 1.66, 95%CI 1.39-1.98 vs. HR for TET2 1.36, 95%CI 1.01-1.83; Figure 1E-G).

Conclusions: CHIP was associated with an elevated risk of incident lung cancer regardless of smoking status. All CHIP genes conferred increased but differential risks, further warranting studies to evaluate risk stratification using CHIP genetic makeup for this at-risk population. Although antecedent CHIP did not worsen overall survival in lung cancer patients treated with ICI, future studies are needed to confirm this finding and identify potential mechanistic vulnerabilities in this patient subgroup, which could potentially guide more individualized screening strategies.

P2.06.72 Impact of Peripheral Electrolyte on Equilibrium Between Immunotherapy Toxicity and Survival in Advanced NSCLC Treated With PD-L1 Blockade

N. Gao[1], Z. Gan[2], Y. Wang[1], S. Wang[1], Z. Lin[3], S. Ai[3], H. Zhang[3], W. Yang[1], C. Cheng[1], S. Ma[1]
[1]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou/CN ,[2]Sun Yat-sen University, Guangzhou/CN ,[3]Southern Medical University, Guangzhou/CN

Introduction: Peripheral electrolyte homeostasis is emerging as a critical regulator of immune cell function and systemic immunologic balance. Understanding how these ions shape the balance between autoimmune versus antitumor response in the context of immune checkpoint blockade may provide novel insights into predicting and managing immune-related adverse events (irAEs).

Methods: Individual participant data of 1,137 patients with non-small cell lung cancer (NSCLC) from two randomized trials (OAK [n=850] and POPLAR [n=287]) treated with atezolizumab versus docetaxel were analyzed. Logistic regression and Cox proportional hazards models were employed to assess the associations between baseline peripheral electrolyte levels (calcium, chloride, magnesium, sodium, phosphorus, and potassium) and the risk of irAEs and survival outcomes (durable clinical response, progression-free survival, and overall survival); significant ions in univariate analyses were further evaluated in multivariate models. Subgroup analyses examined associations with organ-specific (endocrine, neurological, gastrointestinal, cutaneous) and severe (grade ≥3) irAEs. Additionally, parallel analyses in the chemotherapy arm were conducted to examine whether these associations are immunotherapy-specific.

Results: Elevated serum calcium levels at baseline were associated with significantly higher irAE risk while remaining independent of survival and response to immunotherapy, underscoring its toxicity-specific predictive value. Conversely, higher chloride levels predicted both increased irAE incidence and improved clinical efficacy, indicating a dual modulatory role for autoimmune and antitumor response (Figure 1). Organ-specific analyses linked calcium to endocrine irAEs and chloride to neurological and gastrointestinal irAEs. Patients experiencing severe irAEs exhibited higher calcium and chloride levels compared to those without severe irAEs (Figure 2). In contrast, no significant association was observed between these electrolytes and adverse events in the chemotherapy arm, emphasizing their specificity for immunotherapy-induced toxicity.

Conclusions: Baseline electrolyte ions exerted differential impacts on irAE risk and efficacy outcomes in NSCLC immunotherapy. Notably, calcium specifically associates with irAEs, may offering a potential biomarker to guide toxicity mitigation strategies.

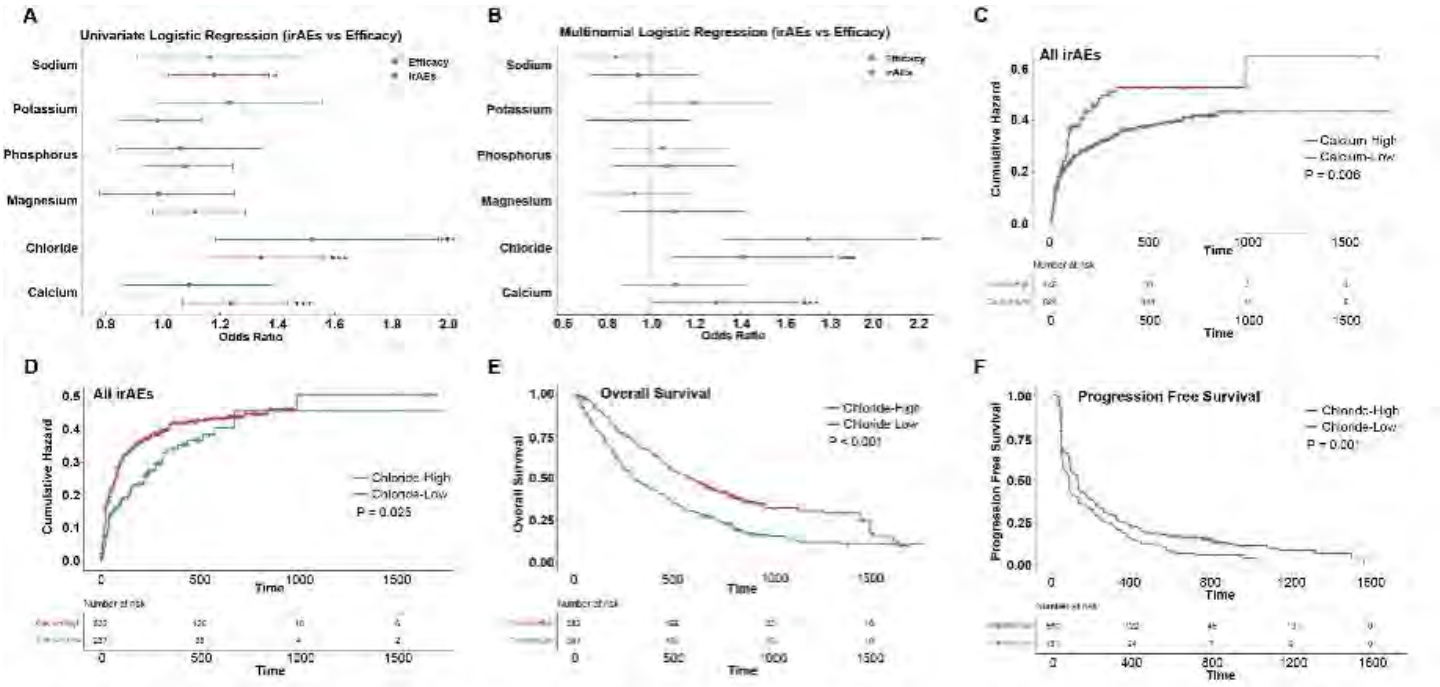

Fig1. Baseline levels of peripheral electrolyte ions captures the predictive value of irAEs and survival outcomes. (A-B)Univariate and multivariate logistic regression analysis of baseline peripheral ions associated with irAEs and immunotherapy response in advanced NSCLC. (C–D) Cumulative hazard curves of irAEs stratified by calcium and chloride levels. (E–F) Survival curves of overall survival and progression-free survival per chloride levels.

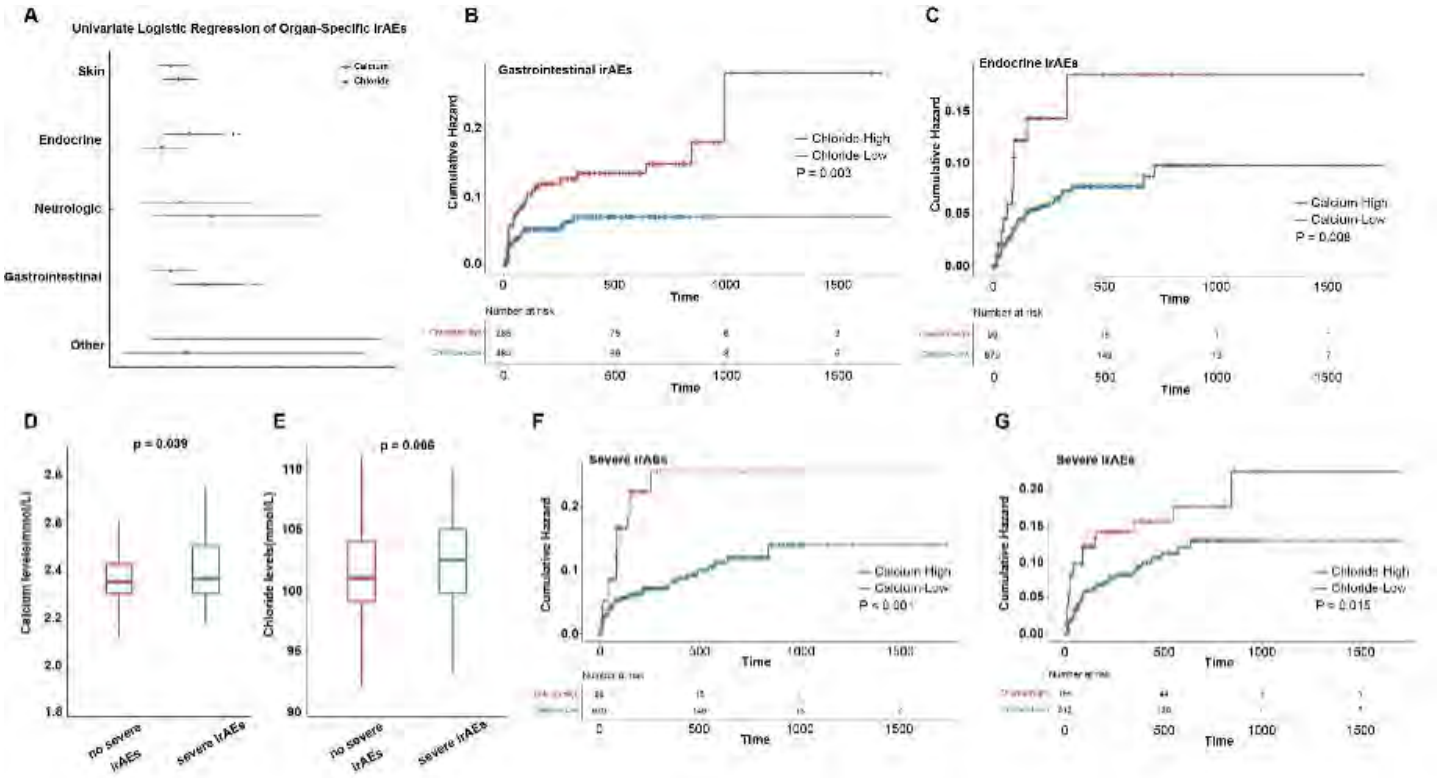

Fig. 2 Stratification of organ-specific and severe irAEs by baseline calcium and chloride levels. (A) Univariate logistic regression of baseline calcium and chloride levels across organ-specific irAEs (skin, endocrine, neurological, gastrointestinal, and others). (B–C) Cumulative hazard curves of gastrointestinal irAEs by chloride levels and endocrine irAEs by calcium levels. (D–E) Severe irAE status–based distribution of calcium and chloride levels. (F–G) Cumulative hazard curves of severe irAEs by calcium and chloride levels.

P2.06.73 Cerebrospinal Fluid Biomarkers in Patients With Leptomeningeal Metastasis of Lung Cancer

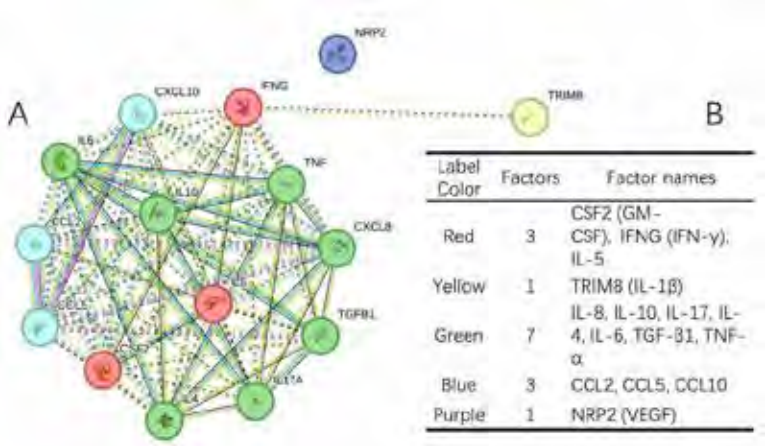
X. Gao, J. Du, S. Fan, Y. Shi, Y. Xu, Y. Li, M. Wang
Peking Union Medical College Hospital, Beijing/CN

Introduction: Lung cancer is a most common malignancy to develop leptomeningeal metastasis (LM). Cerebrospinal fluid (CSF) serves as a unique tumor microenvironment for leptomeningeal metastatic tumor cells to grow. So far, limited research has investigated CSF inflammatory or tumor-related factors in LM patients. Here, we studied the levels of representative cytokines, chemokines, and growth factors in the CSF of patients with LM in lung cancer (LMLC) to identify potential biomarkers for LMLC and explore its unique fluid tumor microenvironment.

Methods: We enrolled 65 cases whose baseline CSF specimens were well-preserved upon diagnosis of LMLC at Peking Union Medical College Hospital between March 2014 and January 2022. Clinical information and long-term survival follow-up were obtained. Meanwhile 53 demographically balanced patients with benign central nervous system diseases were enrolled as a control group. High-throughput detection of factors (including IL-1β, IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12p70, IL-17, TNF-α, IFN-γ, IFN-α, TGF-β1, CCL2, CCL5, CXCL10, VEGF and GM-CSF) in the CSF was performed using magnetic microflow immunofluorescence with the double antibody sandwich method. The LMLC diagnostic value was evaluated using receiver operating characteristic (ROC) curves. Univariate and Cox regression analyses were performed to analyze the prognostic risk factors. Cluster analysis and protein interaction network was used to explore potential interaction characteristics of the identified factors.

Results: 10 factors were identified to show significantly different levels in the CSF of patients with LMLC as with control group. The levels of TGF-β1, VEGF, CCL2, CXCL10, IL-4, IL-6, IL-8, IL-10, and IFN-γ were significantly greater while IFN-α levels were significantly lower ($p<0.05$). TGF-β1 had the greatest area under the ROC curve (AUC=0.856) for diagnosing LMLC. When cutoff value of TGF-β1 was 55.005 pg/mL, the sensitivity and specificity was 0.862 and 0.849,respectively. Patients with high IL-4 levels had a significantly greater mortality risk than those with low levels ($p = 0.0056$). Cluster analysis and protein interaction network(based on public database)revealed potential interaction characteristics of the identified factors.(see Figure 1).

Conclusions: This study provides an insight that LMLC patients demonstrated quite different spectrum of inflammatory and tumor-related factors in CSF than that with benign central nervous system diseases. The CSF levels of TGF-β1 and IL-4 may be used as diagnostic and prognostic biomarker for LMLC, respectively. Mechanism studies are still warranted.



Label Color	Factors	Factor names
Red	3	CSF2 (GM-CSF), IFNG (IFN-γ), IL-5
Yellow	1	TRIM8 (IL-1β)
Green	7	IL-8, IL-10, IL-17, IL-4, IL-6, TGF-β1, TNF-α

P2.06.74 Detection of Actionable Biomarkers in Liquid Biopsy From Non-Small Cell Lung Cancer Patients Using NGS-Based Assays

S. Clavé[1], L. Camacho[1], R. Longarón[1], L. Fernández-Ibarrondo[1], S. Zou[2], Y. Cao[2], A. Conley[2], L. Rishishwar[2], Á. Taus[1], E. Arriola[1], B. Bellosillo[1]
[1]Hospital del Mar, Barcelona/ES ,[2]Pillar Biosciences, Natick/MA/USA

Introduction: Analysis of cell-free DNA (cfDNA) by NGS has emerged as an opportunity for assessing actionable biomarkers in lung cancer patients with limited amount of tumor tissue. However, the availability of in-house liquid biopsy NGS assay options is limited. Many are expensive, require high cfDNA input, or involve complex workflows, limiting their clinical implementation. In this study, we have compared two NGS panels on different sequencing platforms, for the detection of actionable variants using cfDNA from late stage non-small cell lung cancer (NSCLC) patients.

Methods: cfDNA plasma samples from 49 metastatic NSCLC patients were used to prepare NGS libraries with the Oncomine Lung cfTNA Assay (Thermo Fisher, 12 genes), and the oncoReveal Core LBx panel (Pillar Biosciences, 104 genes). Libraries were sequenced with Ion S5 (Thermo Fisher) and NextSeq 550 (Illumina) sequencers, respectively. All lab workflows and sequencing configurations were strictly following the recommended procedure described in the manufacturer's user manuals. Sequencing data were analyzed using Thermo Fisher's Ion Reporter and Pillar's PiVAT softwares. Matched tumoural tissue sample was available in 20 out of the 49 patients.

Results: A total of 53 pathogenic variants were identified in 26 positive samples, detected using the Oncomine panel, of which 47 were also detected by the oncoReveal Core assay (PPA = 88.7%). At sample level, high concordance (47/49; 95.9%) was observed between the two panels (24 positive, 23 negative, and 2 positive samples detected only by oncoReveal Core). A high correlation among the VAFs of detected variants was observed between the two assays (r = 0.96). Further, 256 additional Tier I (drug response) and Tier II (pathogenic) variants were also detected by the oncoReveal Core panel that were not called by Oncomine. In 20 cases, tissue samples that had been previously tested were also available, with a total of 27 pathogenic variants detected in 17 positive tissue samples. 11 out of these 27 variants (40%) were not detected by either panels, 3 of them because they were not covered, and the other 8 likely due to insufficient tumor cfDNA present in the plasma sample. On the other hand, Oncomine and oncoReveal Core also detected 6 and 90 additional Tier I/II variants that were not detected by tissue testing.

Conclusions: Our study shows a high concordance among detected positive variants in NSCLC patient plasma cfDNA between two different liquid biopsy NGS assays. More importantly, the VAF of concordant variants detected were highly correlated, suggesting NGS testing as a dependable, non-invasive, alternative molecular testing for cancer biomarkers. Discrepancies were mainly attributed to low cfDNA levels in liquid biopsy samples and differences in panel coverage, highlighting key factors to consider when integrating NGS plasma testing into clinical practice.

P2.06.75 Liquid Biopsy NGS Accelerating Treatment Decision-Making in Non-Small Cell Lung Cancer

S. Almuinas de Armas[1], S. Atallah[2], K. Brice[3], K. Dumais[3], J. Tsai[4], P.A. Izquierdo[2], L.E. Raez[3]
[1]Memorial Healthcare System, Pembroke Pines/FL/USA ,[2]Memorial Cancer Institute, Pembroke Pines/FL/USA ,[3]Memorial Cancer Institute/ Florida Atlantic University (FAU), Pembroke Pines/FL/USA ,[4]Guardant Health, Redwood/CA/USA

Introduction: Recent breakthroughs in identifying molecular markers have transformed the treatment of non-small cell lung cancer (NSCLC), with therapies targeting specific mutations improving overall survival (OS). The use of Next Generation Sequencing (NGS) in clinical settings enables detailed analysis of tumor genetics to identify potential treatment targets. While traditional tissue biopsies remain the standard for tumor profiling, their invasive nature has made way for plasma-based biopsies, which offer a quicker, less invasive alternative to assess circulating tumor DNA. This advancement has shifted existing treatment approaches and enhanced patient outcomes, especially when used alongside tissue biopsy in a comprehensive testing strategy. This study explored a real-world community cohort of NSCLC patients who underwent both tissue and liquid biopsies to assess how these tests influence treatment decisions, time to start therapy, and overall outcomes.

Methods: This retrospective study analyzed adult patients with advanced NSCLC treated at Memorial Cancer Institute who underwent both tissue and liquid NGS testing between July 1, 2015, and February 25, 2025. We evaluated patient demographics, clinical characteristics, and biopsy-specific factors, including turnaround time (TAT), and time to treatment decision (TtT). Unpaired t-tests were used for statistical analysis of TAT and TtT, while descriptive outcome data were assessed using the Log Rank (Mantel-Cox) test. Treatment decisions were based on the available sample report, affected by insufficient quality or label alterations.

Results: The study analyzed 368 patients with NSCLC, most of whom were white (79.1%), non-Hispanic (63.6%), female (54.6%), and former smokers (63.3%), with adenocarcinoma as the predominant histology (89.7%). Liquid biopsy NGS had a significant reduction in TAT by 12 days compared to tissue biopsy, with median times of 8 days vs. 20 days, respectively ($p<0.0001$). Additionally, while 14.1% of tissue biopsy samples were non-reportable due to insufficient quality, all liquid biopsy samples successfully generated results. Liquid biopsy NGS guided treatment decisions in 81.9% of cases and was associated with a shorter TtT than tissue biopsy, with a median of 10 vs. 14 days for targeted therapy. Among treatment-naive patients, TtT was similar between biopsy methods, differing by only one day overall (13.5 vs. 12.5 days) and by two days for those receiving targeted therapy (7 vs. 9 days). In 190 patients with targetable genetic alterations, concordance between tissue and liquid biopsy ranged from 95.0% to 99.7%. PFS did not significantly differ between biopsy methods ($p\geq0.65$).

Conclusions: This study emphasizes the importance of liquid biopsy NGS in enhancing genomic profiling and supporting diagnostic and therapeutic decisions for advanced NSCLC patients. Liquid biopsy outperformed tissue biopsy in this study, offering faster TAT, reduced TtT, higher sample success rates with high concordance rates. These results demonstrate how liquid biopsy not only complements tissue biopsy but also can be used to decide front line therapy in metastatic NSCLC patients.

P2.06.76 Molecular Profiling of Lung Cancer Brain Metastases: Analysis Between Liquid Biopsy and Brain Metastasis Tissue Results

R. Kotecha[1], E.Y. Akdemir[1], F. Albrecht[1], H. Appel[1], R.H. Press[1], Y. Odia[1], N.T. Eiseler[1], X. Zou[2], L. Bucheit[2], M.S. Ahluwalia[1], M.P. Mehta[1]
[1]Miami Cancer Institute, Miami/FL/USA ,[2]Guardant Health, Inc, Redwood City/CA/USA

Introduction: Molecular profiling is critical to the management of metastatic non-small cell lung cancer (NSCLC) patients in the modern era. While discordant mutational profiles between brain metastasis (BM) and primary tumors have been described, the correlations between peripheral liquid biopsies via circulating tumor (ctDNA) analyses and intracranial tumor tissue have not been well explored.

Methods: De-identified data were queried from metastatic NSCLC patients with both ctDNA and tissue-based assays from BM (Guardant360®, TissueNext). Up to 83 genes were analyzed to assess for differences in actionable genes and variants, defined as those that could be matched to available targeted therapies. Chi-squared tests were used to compare the groups.

Results: 115 patients met inclusion criteria with blood (peripheral) and tissue CNS samples analyzed contemporaneously in most (61% within 30 days). Among these patients, 92 patients demonstrated ≥1 actionable mutation, either on tissue or liquid biopsy analysis, thus constituting the study cohort. At the patient level, tissue analysis revealed alterations in actionable genes in 98% (n=90/92), whereas liquid biopsy identified alterations in actionable genes in only 53% (n=49/92). Therefore, 47% of patients (n=43/92) with altered and actionable genes were identified only by tissue; intriguingly, there were 2% (2/92) of patients identified only by liquid biopsy but not identified by tissue analysis. Of the 47 patients who had actionable genes identified in both tissue and liquid biopsy samples, 16 patients (34%) had concordant, 6 (13%) had partially concordant, and 25 patients (53%) had discordant results. At the variant level (n=1071 variants), 22% of tissue variants (n=162/729) were in actionable genes and 5% (n=36/729) were actionable variants; ctDNA results demonstrated a similar distribution (21% variants in actionable genes [n=73/342], 6% actionable variants [22/342]; p>0.05). Overall, 40 out of 115 patients had a total of 45 actionable variants: 5 were identified by ctDNA only, 22 were identified by tissue only, and all others (n=18) were identified by both ctDNA and tissue. The concordance rate between tissue and liquid biopsy for actionable variants was 37.5% (25 patients were discordant, 15 were concordant).

Conclusions: In this proof-of-concept study, tissue testing from NSCLC brain metastasis showed higher sensitivity than ctDNA for actionable genes and variants compared to blood assessment. This may be due to tumor-shed challenges of ctDNA relative to blood-brain barrier nuances for CNS-related disease. However, each assay identified unique variants. Therefore, integrating both methods may maximize diagnostic yield for brain metastasis patients to manage systemic and intracranial diseases.

P2.06.77 A Perioperative Circulating Tumor DNA Model for Landmark Detection in Non Small Cell Lung Cancer

J-T. Zhang[1], X. Gao[2], C. Huang[1], S. Dong[1], X-N. Yang[1], W-Z. Zhong[1], X. Yi[2], Y-L. Wu[1]
[1]Guangdong Provincial People's Hospital, Guangdong Lung Cancer Institute, Guangzhou/CN ,[2]Geneplus-Beijing Institute, Beijing/CN

Introduction: Evaluation of molecular residual disease status in non-small cell lung cancer (NSCLC) patients after surgery primarily relies on circulating tumor DNA (ctDNA) analysis. However, the false-negative rate of single-timepoint ctDNA detection is approximately 40%, limiting its utility in guiding postoperative de-escalation therapy.

Methods: In this study, we present LAMPAD, an integrated approach that combines preoperative and postoperative ctDNA quantification parameters, capable of predicting disease-free survival (DFS) in patients with postoperative negative ctDNA.

Results: LAMPAD was trained on 163 stage I-III postoperative ctDNA-negative patients, further stratified into low-risk and high-risk groups, with the low-risk group achieving a 2-year DFS rate of 98.0%. The model is applicable to both fixed-panel and personalized ctDNA approaches, with the low-risk group achieving a 2-year DFS rate of 100%. Preoperative blood quantification features significantly contribute to the LAMPAD model, with methylation analysis revealing elevated cell-free DNA from bronchial and alveolar epithelial tissues (p = 0.007) and macrophages (p = 0.015) in the high-risk group.

Conclusions: Overall, the LAMPAD model outperforms single-timepoint postoperative ctDNA detection in predicting DFS, particularly in guiding de-escalation therapy for low-risk patients.

P2.06.78 Using a Personalized, Tumor-Informed Circulating DNA (ctDNA) to Monitor Treatment Outcomes in Lung Cancer Patients

D. Rosas[1], M. Galo[2], J. Valencia-Uribe[2], M. Fernandez-Gomez[2], G. Domingo[1], M. Muminovic[3], L.E. Raez [3]
[1]Memorial Cancer Institute/Memorial Healthcare System, Pembroke Pines/FL/USA ,[2]Memorial Healthcare System, Pembroke Pines/FL/USA ,[3]Memorial Cancer Institute/Florida Atlantic University, doral/FL/USA

Introduction: Lung cancer surveillance traditionally relies on advanced imaging techniques such as MRI brain, CT scans, and PET scans to detect disease progression or response. However, these modalities are associated with limitations including radiation exposure, high costs, and occasional inaccuracies. A personalized, tumor-informed circulating DNA (ctDNA) analysis, has emerged as a promising alternative, offering the potential to detect minimal residual disease (MRD) and early recurrence or response before radiographic evidence becomes apparent. While tumor-informed ctDNA has shown early clinical utility in cancers such as breast and colorectal cancers, its role in the active surveillance of lung cancer remains an area of active investigation. This study aims to evaluate the comparative effectiveness of tumor-informed ctDNA monitoring in lung cancer and explore its potential to complement or replace imaging techniques.

Methods: We did a retrospective study involving 88 patients with lung cancer. We use the Signatera test which is a personalized, tumor-informed assay designed to detect somatic and truncal variants prepared from whole exon sequencing (WES) from tumor and normal tissue. Surveillance results were considered concordant if there was evidence of disease progression (PD) or recurrence on imaging tests corresponding to a positive or increased ctDNA in plasma, while stable disease (SD), responses (CR, PR) or no evidence of disease aligned with a decrease or negative ctDNA result. Patient demographics, tumor characteristics, and genomic analysis were recorded. Concordance between ctDNA and imaging results was calculated to assess the correlation of both methods in detecting disease progression, and statistical analysis via Cohen's Kappa was conducted to determine the strength of the relationship between the two tests.

Results: Among the 88 patients, 52 (59%) were female predominantly White 71 (81%), non-Hispanic 46 (52%). 53 (60.2%) were former smokers, and 33 (37.5%) had never smoked. 85 (97%) patients had non-small cell lung carcinoma (NSCLC), primarily adenocarcinoma (89%). Disease stage at diagnosis: stage I 24 (27%), stage II 5 (6%), stage III 12 (14%), and stage IV 47 (53%). Twenty-six patients (29.5%) were excluded due to unavailable or outdated ctDNA results. CtDNA serum testing showed 94.3% (Cohen kappa (CK): 0.82) concordance with systemic imaging and 75% (CK: 0.25) concordance with brain imaging. Subgroup analysis for stage IV lung cancer revealed 89.7% (CK: 0.79) concordance with systemic imaging in patients treated with chemotherapy or immunotherapy, and 100% (CK: 1.00) in those receiving targeted therapy. In comparison, concordance with brain imaging was lower: 58% (kappa: 0) for chemotherapy/immunotherapy and 78% (kappa: 0.57) for targeted therapy. The patients with positive ctDNA results are significantly more likely to show progression or recurrence.

Conclusions: Personalized, tumor-informed ctDNA was able to accurately correlate with radiologic imaging in most of the NSCLC patients, particularly outside the CNS. There are challenges in making the test based on tissue availability that need to be considered. More and larger studies are needed to validate these results and longer follow up to evaluate survival.

P2.06.79 Deciphering Genomic and Transcriptomic Heterogeneity in Circulating Tumor Cells at Diagnosis in Small Cell Lung Cancer: CTC-CPC Study

L. Callac[1], L. Martinetti[1], U. Jarry[2], C. Pierre[3], P-L. Pinel[3], R. Pedeux[1], C. Ricordel[3]
[1]Univ Rennes, INSERM, OSS (Oncogenesis Stress Signaling), UMR_S [1242], Centre Eugène Marquis/FR ,[2]Univ Rennes, CNRS, INSERM, BIOSIT UAR [3480], US_S [018], Oncotrial, Rennes/FR ,[3]CHU Rennes, RENNES/FR

Introduction: Small cell lung cancer (SCLC) is an aggressive form of lung cancer with a high mortality rate, despite recent advances in therapeutics. Since 2019, a new classification has identified four subtypes based on the expression of transcription factors (ASCL1, NEUROD1, and POU2F3, or triple-negative), which could open new therapeutic opportunities. Solid biopsies are often non-informative in SCLC due to tumor necrosis and limited access to the primary tumor. Therefore, circulating tumor cells (CTCs) represent a valuable biological resource in clinical practice. The goal of the CTC-CPC study is to explore innovative circulating biomarkers in disseminated SCLC.

Methods: The CTC-CPC study is a monocentric, non-interventional study recruiting patients with newly diagnosed, treatment-naïve SCLC since April 2016. The first objective of the CTC-CPC study was to validate an EpCAM-independent CTC isolation method that allows the isolation of viable CTCs from SCLC (Ricordel et al., 2023). We performed whole exome sequencing (WES) on 22 CTC samples, as well as corresponding primary tumor (PT) biopsies from four patients. A Snakemake bioinformatics pipeline was built to perform alignment and variant calling. BioinfoMiner sofware was used to asses pathway enrichment analysis based on WES data from CTC and PT. We also developed a droplet digital PCR-based method to determine the transcriptomic subtype of CTCs.

Results: Among the 80 patients included in the study, WES was performed on CTC for 22 patients at diagnosis. The median age at diagnosis was 62.5 ± 9.5 years. Patients were predominantly male (63%), with disseminated stage SCLC (81%), smoking history (95%) and mainly ECOG PS 0-1. Mean number of CTC at diagnosis was 68.6 ± 136 cells/mL. First-line treatment consisted in platine-doublet plus immunotherapy for 31.8% of patients. Median PFS was 5.2 months and median OS 9 .3 months. CTCs exhibited a high mutational load and wide range of ploidy levels, ranging from tetraploid (4n) to septadecaploid (17n). Pathway enrichment analysis on both the CTC and primary tumor datasets identified specifically altered signaling pathways in CTCs. Filtering of pathways altered in more than 50% of samples revealed that extracellular matrix organization, sensory perception, and signaling by receptor tyrosine kinases were recurrently altered in CTCs but not in primary tumors. Copy number alterations (CNA) revealed two patient clusters: one with more deletions and the other with a more amplified copy number alteration profile. However, no correlation between CNA clusters and clinical characteristics or survival outcomes was found. In an experimental setting, the ASCL1 subtype was successfully detected in SCLC cells contaminating control blood, and we plan to evaluate this novel method on CTCs.

Conclusions: The CTC-CPC study supports the potential of CTCs as non-invasive biomarkers in SCLC. CTCs exhibited a high mutational load and distinct alterations in pathways like extracellular matrix organization and receptor tyrosine kinase signaling, not found in primary tumors. CNA analysis revealed two clusters of CTC with amplification-dominant or deletion-dominant genomic alterations. Additionally, the successful detection of the ASCL1 subtype in experimental settings suggests CTCs could be used to assess tumor subtypes and guide personalized treatment.

P2.06.80 Development of a Proteomics-Based Machine Learning Model for Diagnosing and Predicting Lung Cancer: Insights From the UK Biobank

X. Chen[1], Y. Li[1], W. Yang[1], X. Liu[1], J. Cui[1], X. Chen[1]
[1]The first hospital of Jilin University, Changchun/CN

Introduction: Lung cancer ranks first in morbidity and mortality among malignancies in China. Early identification and treatment of lung cancer are critical for improving patient prognosis and quality of life. In-depth exploration of proteomics offers a foundation for elucidating molecular biological features of lung cancer and identifying novel biomarkers. This study aims to develop and validate a proteomics-based machine learning model for diagnosing lung cancer and evaluate its effectiveness in disease identification.

Methods: Using adult data from the UK Biobank, researchers conducted plasma proteomic analyses (2006-2010) on 2923 proteins from 52,580 healthy individuals and 431 lung cancer patients. Ten differentially expressed proteins between healthy and lung cancer cohorts were screened. Five machine learning models were constructed using protein-level data to predict lung cancer diagnosis, with their predictive performances compared. The SHAP (SHapley Additive exPlanations) framework was applied for interpretability analysis to quantify the contributions of variables to the model's predictions.

Results: Significant proteomic differences were observed between healthy and lung cancer populations. Peripheral blood levels of CD34, ITGAV, NUDT10, and other proteins were markedly elevated in lung cancer patients. Among the five machine learning models developed using the ten screened proteins, the random forest model demonstrated optimal diagnostic efficacy (AUC = 0.771). SHAP feature importance analysis identified CCN3, NUDT10, and APOA1 as the most discriminative proteins, corroborated by maximum SHAP bar plots.

Conclusions: This machine learning model leverages large-scale proteomic data to identify lung cancer patients effectively. The findings provide novel insights into the molecular characteristics of lung cancer and lay a scientific foundation for discovering diagnostic biomarkers and therapeutic targets.

P2.06.81 Circulating Tumour Cells, Spread Through Air Space and Lymph-Nodal Micrometastasis in Surgically Resected Early-Stage NSCLC

P. Bertoglio[1], G. Gallerani[2], F. Ambrosi[3], F. Bianchi[2], J. Brandolini[1], N. Nannini[3], M. Fiorentino[3], P. Solli[4], M. Ferracin[2]
[1]IRCCS Azienda Ospedaliero Universitaria di Bologna, Bologna/IT ,[2]University of Bologna, Bologna, Italy., Bologna/IT ,[3]Pathology Unit, DIAP-Dipartimento Interaziendale Di Anatomia Patologica Di Bologna, Maggiore Hospital-AUSL Bologna, Bologna/IT ,[4]Fondazione IRCCS Istituto Nazionale Tumori, Milan/IT

Introduction: Lung cancer is one of the most lethal malignancies worldwide. In early-stage cases, surgery is considered the cornerstone of therapy; however, recurrence rates after radical resection remain as high as 20% in stage I. While several factors may contribute to treatment failure, many remain unknown.The aim of this project was to analyze the correlation between Circulating Tumor Cells (CTCs), Spread Through Air Spaces (STAS), and lymph node micrometastasis (<2 mm) in patients with clinical stage IA-IIA Non-Small Cell Lung Cancer (NSCLC) who underwent surgical resection.

Methods: This is a monocentric prospective study. From June 2023 patients with clinical stage IA-IIA NSCLC who were candidates for surgery were included. Patients who received neoadjuvant therapy or systemic treatment for other malignancies in the previous three years were excluded, as were those with severe pleural adhesions or who underwent wedge resection. Pathological features, including STAS and lymph node micrometastasis, were assessed on the surgical specimen. CTCs were evaluated through peripheral blood samples collected the day before surgery and 30 days postoperatively.

Results: Fifty-four patients were enrolled in the study; 49 met the inclusion criteria.

Twenty-seven were female (55.1%), with a mean age was 71.2 years (Standard Deviation, SD, ±7.9). Most patients were treated robotically (32, 65.7%) and underwent lobectomy (36, 73.5%). A vein-first approach was used in 32 cases (65.3%). Adenocarcinoma was the most common histology (40 cases, 81.6%). Lymph node micrometastasis was found in only 2 cases (4.0%); conversely, STAS was observed in 24 patients (49.0%). CTCs were detected in 26 patients (53.1%). Both pre- and postoperative CTCs were found in 4 patients (8.2%), while 12 patients (24.5%) had detectable CTCs only after surgery. The mean number of preoperative CTCs was 2.0 (±1.5), while the mean 30-day CTC count was 3.7 (±6.0). CTCs were more frequently found in non-adenocarcinoma histologies (p=0.061) and showed a borderline correlation with STAS (p=0.054); however, STAS was significantly associated with CTC counts >1 (p=0.011). Both CTCs and STAS were significantly more present in patients with a high grade (G3) adenocarcinoma pattern (p=0.003 for both) and in those with vascular invasion (CTCs p=0.002, STAS p=0.049).CTCs, but not STAS, were significantly associated with visceral pleural invasion (p<0.001 vs. p=0.076).Both factors were significantly associated with a higher pathological stage (CTCs p<0.001; STAS p=0.025). No significant correlation was found between lymph node involvement and either CTCs (p=0.288) or STAS (p=0.646). No statistically significant correlations were found between the presence and the number of postoperative CTCs and intraoperative variables, such as surgical technique (VATS versus RATS, p=0.620 and 0.423 respectively) and pulmonary vessel ligation (vein versus artery first, p=0.557 and p=0.188 respectively).

Conclusions: This study is among the first to highlight a significant correlation between CTCs and STAS. Both factors are more frequently associated with aggressive tumor behavior and features and may contribute to an increased risk of local or distant recurrence.Larger studies with longer follow-up are warranted to validate these findings and assess their prognostic impact.

P2.06.82 Cell Free DNA Dynamics in Exhaled Breath Condensate to Predict Outcomes to Immune Checkpoint Inhibition in Advanced NSCLC

D.E. O Reilly[1], J. Dunne[1], G. Dowling[1], S. Marks[1], L. Kirwan[1], S.J. Barry[2], C. Moloney[2], L. Moran[2], C. Cluxton[2], J. Moyle[2], R. Clarke[2], A. Reilly[2], O. Deac[3], C. McNevin[3], R. Dillon[3], C. O'Leary[3], D. Hadi[3], M.P. Barr[4], O. Breathnach[2], P. Forde[3], S. Cuffe[3], S. Toomey[1], B.T. Hennessy[1], J. Naidoo[1]
[1]Royal College of Surgeons of Ireland, Dublin/IE ,[2]Beaumont Hospital, Dublin/IE ,[3]Trinity St. James' Cancer Institute, Dublin/IE ,[4]Trinity Centre for Health Sciences & Trinity St James's Cancer Institute, St. James's Hospital & Trinity College Dublin, Dublin/IE

Introduction: Dynamic changes in cell-free DNA (cfDNA) and/or circulating tumour DNA (ctDNA) may represent a biomarker of response to immune checkpoint inhibitor-based therapy (ICI) in non-small cell lung cancer (NSCLC). Exhaled breath condensate (EBC) is a novel liquid biopsy technique, which we have previously used to detect ctDNA in NSCLC. We sought to explore the hypothesis that dynamic changes in cf/ctDNA EBC may complement plasma ctDNA, in predicting outcomes.

Methods: Baseline EBC, plasma and buffy coat samples were collected from patient's pre-treatment, and 3 and 6 weeks following commencement of treatment. Following DNA extraction, absolute quantification of cfDNA (copies/mL) was performed with digital droplet PCR (ddPCR). Tumour sequencing was conducted as part of standard-of-care molecular testing. Plasma NGS was completed using the 484 gene Novogene PM 2.0 panel and subtraction of variants from buffy coat NGS was conducted using a dedicated bioinformatics pathway. Where variants were identified which could be targeted using ddPCR, custom ddPCR assays were designed based on tumour or plasma NGS and analysed in EBC and plasma using the BioRad QX100 system. The maximal change in cfDNA (Max cfDNA) at 3 and/or 6 weeks was defined as the maximum increase/decrease in cfDNA compared to baseline. Molecular Response (MR) was defined as ≥ 50% reduction in ctDNA variant allele fraction in EBC at 3 and/or 6 weeks following commencement of therapy. In our statistical analysis, we analysed outcomes with consideration of; Durable clinical benefit (DCB): Investigator-assessed radiological and clinical benefit for at least 6 months; Positive predictive value (PPV): Proportion of those with a MR amongst those with a DCB; Negative predictive value (NPV): Proportion of those without a MR amongst those without a DCB.

Results: Amongst 81 patients, the median age was 67 years, and 63% (51/80) of participants were male. The majority of enrolled patients received ICI + platinum doublet (50/81, 64%), as opposed to ICI monotherapy (31/80, 39%). All patient's samples were suitable for EBC cfDNA analysis and 58% (46/80) were suitable for EBC ctDNA analysis. EBC ctDNA MR was associated with a significantly improved PFS (PFS 13.6 mo vs 3.8 mo; HR 0.24, 95% CI 0.1-0.56), OS (OS NR vs 8.8 mo; HR 0.25, 95% CI 0.08 - 0.77; P <0.01) and durable clinical benefit (PPV = 59%; NPV 94%, Chi2 = 12.6, p < 0.01). When those with a MR in either plasma or EBC were combined, this improved the PPV over EBC ctDNA alone (PPV 80%, NPV 66%, Chi2 = 7.68, p < 0.01). Patients with a max cfDNA reduction ≥ 1% had a numerically improved PFS compared to those without with a trend towards significance (PFS 6.4 vs 3.8 mo; HR 0.60, 95% CI 0.36 - 1.01, p =0.06).

Conclusions: EBC-derived cfDNA and ctDNA dynamics are emerging as promising predictors of survival in NSCLC. Our findings suggest that integrating EBC with plasma ctDNA dynamics enhances positive predictive value beyond EBC ctDNA alone. This combined approach has the potential to significantly strengthen plasma-based assays and optimize response-adaptive ctDNA clinical trials in NSCLC.

P2.06.83 Multimethod Circulating Tumor DNA Profiling for Minimal Residual Disease Monitoring in Early-Stage Non-Small Cell Lung Cancer

Q. Cui, J. Zhang, W. Zhong, Q. Zhang
Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Guangzhou/CN

Introduction: Circulating tumor DNA (ctDNA) serves as a valuable biomarker for molecular residual disease (MRD) detection, enabling treatment optimization, recurrence risk assessment, and ultimately improved clinical outcomes. The technical strategies for ctDNA-MRD detection lack standardization, with ongoing debates regarding methodology selection. Tumor tissue samples are unavailable for a subset of cases in real-world practice. While tumor-naive ctDNA assays offer promising applications for MRD detection in tissue-limited NSCLC, their performance data remain scarce.

Methods: We conducted a head-to-head comparison of 417 serial samples from 84 patients using three ctDNA-MRD detection methodologies (tumor-naive, tumor-informed fixed panel and personalized assays) to comparatively assess their detection performance characteristics.

Results: Within our cohort, ctDNA was detected in 20.9% (87/417) of samples, while the remaining 79.1% (330/417) tested negative. Among the 87 ctDNA-positive samples, 74.7% (65/87) showed concordant results across all three methods. Notably, tumor-naive assays identified an additional 11 mutations in 6.9% (6/87) of samples that were not detected by tumor-informed assays. Personalized assays revealed 5 unique mutations in 3.4% (3/87) of samples that were not covered by fixed panel. Furthermore, high-depth personalized sequencing identified 7 low-frequency mutations in 8.0% (7/87) of ctDNA-positive samples that were undetectable by fixed assays. Intriguingly, longitudinal monitoring revealed 5 emerging resistance mutations in 4.6% (4/87) of cases within the 3-month pre-progression window, which were detectable by both tumor-naive and tumor-informed methods but missed by personalized profiling.

Conclusions: This study reveals the limitations and advantages of three ctDNA-MRD detection methodologies and these results serve as a reference for the optimization. Tumor-naive strategy is useful in postoperative MRD testing for NSCLC, and the techniques can be further improved and optimized detection accuracy, coverage, and detection depth, and fully integrated into routine clinical practice.

P2.06.84 Tracking Ctc Phenotypes in SCLC Liquid Biopsies as a Diagnostic and Therapy Response Assessment Tool

M. Bose, C. Ruoff, C.A. Stewart, S. Bhattacharyya, A. Victorian, R. Wang, A. Duarte, S. Ehsan, F.E. Lujan, R. Cardnell, C.M. Gay, L.A. Byers, L.G. Karacosta
MD Anderson Cancer Center, Houston/TX/USA

Introduction: Liquid biopsies present a promising, minimally invasive procedure through which clinicians may be able to assess and monitor disease status by phenotyping circulating tumor cells (CTCs) at the single-cell proteomic level. However, liquid biopsies remain underutilized due to technical difficulties in detecting CTCs and studying their features in great depth. Phenotyping CTCs promises to help stratify patients and predict outcome and therapy response, facilitating treatment decision making. This can be particularly relevant in small-cell lung cancer (SCLC), an extremely aggressive lung cancer type with high CTC counts where tissue biopsies are scarce and targeted therapies are limited. In this study, we utilize CyTOF (Cytometry by Time-of-Flight), to interrogate phenotypic heterogeneity and biomarker expression in CTCs directly in SCLC patient liquid biopsies, providing a potential platform for subtyping and monitoring disease progression and therapeutic resistance at a personalized level.

Methods: We developed a 25-antibody CyTOF panel targeting SCLC markers such as SCLC subtype-specific transcription factors (TFs) NeuroD1, POU2F3, and ASCL1, therapeutic targets (e.g., DLL3), immune regulatory (e.g., PD-L1), and epithelial-mesenchymal transition (EMT) markers. Optimization was performed using SCLC cell lines (subtype controls), and blood samples from healthy donors (negative controls) and SCLC patients. Peripheral blood mononuclear cells (PBMCs) were isolated from whole blood, fixed, and processed for CyTOF. CTCs were initially identified by gating CD45 negative and CD56 positive cells (CD45-CD56+) with further validation based on TTF1 and SCLC subtype-specific TF expression. Whenever feasible, SCLC subtype was validated in matching primary tumor biopsies or CTC-derived xenograft models. Pleural effusions were analyzed in a subset of patients. Computational analysis was performed to assess intra- and inter-patient CTC heterogeneity, phenotypic differences between treatment-naïve and standard-of-care and Tarlatamab treated patients, and CTC dynamic changes in longitudinal specimens.

Results: We performed CyTOF on blood specimens from 12 healthy donors and 28 SCLC patients (treatment naïve, treated/relapsed and longitudinal specimens). Computational analysis revealed 3 clusters of CD45-CD56+ cells that were enriched in SCLC but not in healthy liquid biopsies. These cells were characterized by high expression of SCLC/CTC-associated markers such as CD24, DLL3, EpCAM and ALCAM. Further clustering analysis revealed the four established SCLC subtypes: 1) ASCL1+ (SCLC-A), 2) POU2F3+ (SCLC-P), 3) NeuroD1+ (SCLC-N), and 4) Inflamed (SCLC-I), and found that the most prominent SCLC CTC subtype in liquid biopsies was SCLC-I. We observed substantial CTC subtype and EMT heterogeneity within and across all specimens, with mesenchymal phenotypes increased in the relapsed setting. Notably, DLL3 expression was reduced in CTCs from patients that had undergone standard-of-care therapy compared to treatment-naïve patients. Two patients undergoing DLL3 targeted therapy (Tarlatamab) exhibited significant upregulation in CTC CD24 and MUC1 levels, revealing potential markers of resistance. Longitudinal tracking of CTCs in a subset of patients revealed subtype switching, specifically a gradual decline in NeuroD1 alongside an increase of POU2F3 levels.

Conclusions: Our approach can serve as a potential diagnostic and therapy response assessment tool where by utilizing CyTOF to longitudinally track CTCs directly in SCLC patient liquid biopsies can lead to tailoring SCLC therapy at a personalized level.

P2.06.85 Clinical Utility of a "Plasma 1st Approach" for Molecular Diagnosis Using ctDNA in Advanced Lung Cancer, NHS England Pilot

O. Kennedy[1,2], M-R. Jinga[1], P. Bhatnagar[3], L. Hennah[2], W. Liu[4], N. Murugaesu[4], L. Cheyne[5], A. Qureshi[5], A. Greystoke[1,2]
[1]Newcastle University, Newcastle Upon Tyne/GB ,[2]Newcastle Upon Tyne Hospitals, Newcastle Upon Tyne/GB ,[3]Leeds Teaching Hospitals, Leeds/GB ,[4]Guy's and St Thomas' NHS Foundation Trust, London/GB ,[5]Bradford Teaching Hospitals, Bradford/GB

Introduction: ctDNA can be used for molecular profiling either as a "plasma 1st" before tissue, simultaneous with tissue or salvage on failure of tissue testing. The NHSE pilot has assessed the clinical utility and cost-effectiveness of a Plasma 1st approach in a national programme. We report selected outcomes as to TAT and clinical outcomes in patients enrolled in the pilot.

Methods: Patients within the UK were taken from a list generated by The Royal Marsden GLH who had received liquid biopsy samples through the pilot scheme from 2022 to December 2024. ctDNA testing was conducted using the Royal Marsden360Dx platform (a Tech transfer from Guardant). Patient information was collected from local records including tissue biopsy report date and results. Further information on therapy received and date of last visit or death was assessed from the same source. All data was analysed using R software.

Results: The data from North-East England is presented here with further data collection from other UK sites ongoing and to be presented at the conference. At present 306 patients were analysed. Turnaround time (TAT) was calculated from 223 patients with data available. Median TAT from sample dates for liquid and tissue biopsy were 13 and 15 days respectively (P = 0.01). IQRs respectively were 12 and 4 days. From date of CT scan liquid biopsy median TAT was 28 whilst tissue was 34 days (P = <0.001). IQRs were 23 and 33 days respectively. Tissue biopsy TAT based on histology demonstrated a significant difference (P = <0.001) between adenocarcinoma and squamous subtypes (42 and 31 days) from CT scan date. Survival data was available for 188 patients. Patients stratified to targeted treatment had an improved OS median 16 (CI 13 - NA) compared to 7 months (CI 6 - 10,P = <0.001). Comparing for the effect of biopsy time on survival demonstrated a significant difference between high, medium and low tertiles 15, 9 and 6 months (P = >0.001, HR 0.85 and 0.31).

Conclusions: We have demonstrated a plasma 1st approach decreased the IQR of sample TAT simultaneously decreasing TAT from CT scan leading to a more equitable service. There is space for improvement of TAT with earlier collection of blood samples. As of 1st April 2025, ctDNA will officially be commissioned on the NHS national testing directory.

P2.06.86 Development and Validation of Peripheral Blood 5-Protein Signature Predicting the Efficacy of Immunotherapy in Advanced NSCLC

L. Cheng, C. Zhao, J. Yu, S. Ren, X. Li
Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Immunotherapy has provided clinical benefit for some patients with advanced non-small cell lung cancer (NSCLC), but highly accurate efficacy predictive tools are still lacking in the clinical setting.

Methods: We performed deep proteomics (Proteograph) of plasma samples at baseline from 10 advanced NSCLC patients receiving 1L immunotherapy, and validated the candidate proteins with parallel reaction monitoring targeted proteome (n = 30). An efficacy prediction model was constructed by logistic regression and validated in an independent cohort (n = 30). Response was evaluated using RECIST 1.1 criteria. The PD-L1 tumor proportion score (TPS) was assessed by the PD-L1 immunohistochemistry E1L3N assays. Receiver operating characteristic curve analysis was applied to evaluate the performance of efficacy prediction.

Results: A total of 3216 proteins were detected, with 76% of the proteins identified at low concentrations (< 10 ng/mL) and 'new', and 222 protein levels were significantly different between the Res (CR/PR, n = 5) and non-Res (SD/PD, n = 5) groups ($p < 0.05$). A predictive model consisting of five plasma proteins (PGK1, CHGA, ELN, HNRNPH3, and SERBP1) was constructed with an AUC of 0.88 and treatment response was interpreted as a score >0.3029. Independent cohort validation yielded a specificity of 83.3% and a sensitivity of 88.9%, with a significantly better predictive performance than that of PD-L1 (TPS) ≥50% (AUC, 0.94 (5-protein model) vs. 0.56 (PD-L1)), identifying 83.3% (5/6) of patients with PD-L1 (TPS) <1% treatment response (Figure 1).

Conclusions: We constructed a predictive model of immunotherapy efficacy consisting of five plasma proteins with high accuracy and superior performance to PD-L1 expression.

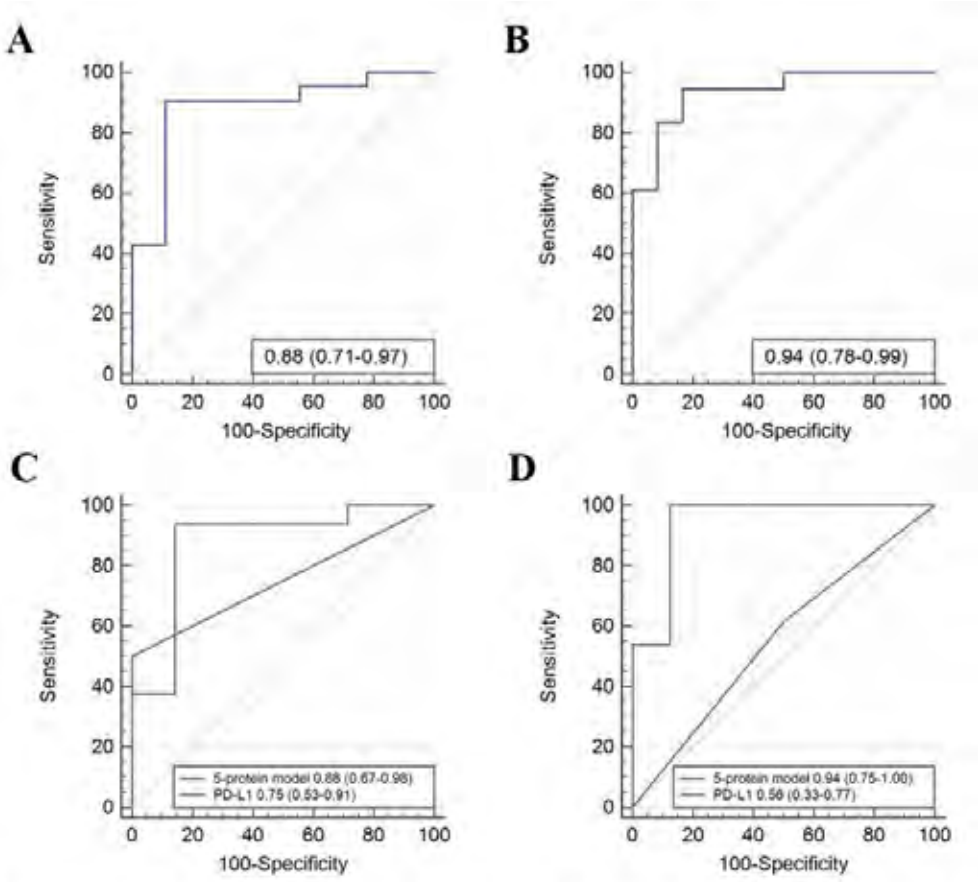

Figure 1. ROC curves and AUCs (95% CIs) for the 5-protein model (A, model development: Res, n=21; non-Res, n=9; B, model validation: Res, n=18; non-Res, n=12) and PD-L1 (C, model development: Res, n=16; non-Res, n=7; D, model validation: Res, n=13; non-Res, n=8). Res, CR/PR; non-Res, SD/PD.

P2.06.87 Reversible Smoking-Dependent Hpg80 Increase, a Path to Identifying NSCLC-Negative Individuals: An Incentive to Quit Smoking?

A. Prieur[1], B. Vire[1], L. Payen[2], C. Vignault[3], V. Hofman[4], C.H. Marquette[4], J-P. Berthet[4], J. Boutros[4], M. Ilie[4], P. Pourquier[1], N. Mimoun[1], D. Joubert[1], P. Hofman[4]
[1]Progastrin Manufacturing, Grabel/FR ,[2]Hospices Civils de Lyon, Pierre-Bénite/FR ,[3]Laboratoire CBM[25]-Biogroup, Besançon/FR ,[4]Centre Hospitalo-Universitaire de Nice, Nice/FR

Introduction: Smoking is a major risk for lung cancer. While LDCT scan is used for early detection, blood-based biomarkers are needed to improve screening. The Wnt target and oncogenic blood biomarker hPG80 is linked to multiple cancers, including lung cancer. This study examines hPG80 in asymptomatic individuals and NSCLC patients, categorized by their smoking status. hPG80 was also evaluated in COPD patients, a comorbidity frequently associated with smoking.

Methods: Plasma hPG80 levels were measured using the ELISA DxPG80.lab kit (Biodena care, France) across five cohorts: 396 NSCLC patients, 200 lung cancer-negative COPD patients, 1199 individuals from the general population, 278 asymptomatic current smokers, and 228 asymptomatic former smokers. The entire cohorts were used for correlation analyses. ROC analyses assessed diagnostic accuracy with area under the curve (AUC) calculation.

Results: In asymptomatic current smokers, hPG80 levels were significantly higher than in the general population (median value 5.51 pM; IQR 3.97-8.00 vs 1.50 pM; IQR 0.32-3.55, respectively; p<0.0001). From 15 pack-years onward, hPG80 levels in asymptomatic current smokers were not statistically different from NSCLC patients whatever the smoking status (7.45 pM; IQR 5.60-10.5 vs 6.59 pM; IQR 4.39-12.08, respectively; p=ns). Similarly, asymptomatic COPD-positive individuals also exhibited significantly higher hPG80 levels than in the general population (6.07 pM; IQR 4.00-11.69; p<0.0001), but not significantly different from COPD-positive cancer patients (6.38 pM; IQR 4.45-13.69; p=ns), whatever the smoking status. In contrast, asymptomatic former smokers had levels of hPG80 similar to those in the general population (2.40 pM; IQR 1.8-3.65; p=ns). Finally, when comparing asymptomatic and cancer-diagnosed non- and former smokers, the AUC were 0.76 (n=37 in each group; 95% CI 0.64-0.88) and 0.85 (n=127 in each group; 95% CI 0.80-0.90) respectively (Figure 1D and 1F; p<0.0001). It was 0.53 (n=113 in each group; 95% CI 0.45-0.0) when compared with current smokers (Figure 1E; p=0.44).

Conclusions: These results show that smoking induces a reversible increase in hPG80 levels, highlighting that hPG80 is not only produced by cancer cells as already documented, but also in a situation increasing the risk of developing cancer, i.e. smoking. Current smokers have levels of hPG80 similar to those of NSCLC patients, whereas the majority of former smokers return to normal levels. Since over 90% of NSCLC in former smokers are hPG80-positive, hPG80 may help identify former smokers likely to be cancer-free, serving as an incentive to quit smoking.

Figure 1: hPG_{80} level in NSCLC patients compared to their respective age-matched controls: non- (**A**), current (**B**) and former smokers (**C**). ROC analyses of the comparison: non- (**D**), current (**E**) and former smokers (**F**).

P2.06.88 CfDNA and WBC DNA Sequencing Through MSK-ACCESS Powered With SOPHiA DDM to Delineate Tumor and Clonal Hematopoiesis TP53 Variants in Lung Cancer

F. Klemm[1], F. Mohammad[1], A.C. Tuck[1], X. Xing[1], G. Morales[1], A. Willig[1], A. Saitta[1], M. Allegra[2], G. Rignol[2], C. Lacoux[2], Z. Xu[1], P. Hofman[2]
[1]SOPHiA GENETICS, Rolle/CH ,[2]Côte d'Azur University, Nice/FR

Introduction: Liquid biopsy (LBx) is a non-invasive approach enabling genomic profiling to identify treatment selection and resistance markers when access to tumor tissue is challenging such as in lung cancer. However, there is a risk of including variants derived from clonal hematopoiesis (CH) which constitute possible confounders in prognostically relevant genes such as TP53. SOPHiA GENETICS has developed a decentralized version of MSK-ACCESS® (Memorial Sloan Kettering Cancer Center - Analysis of Circulating cfDNA to Evaluate Somatic Status). The MSK-ACCESS® powered with SOPHiA DDM™ solution interrogates 147 cancer-associated genes for somatic variants and exhibits a high analytical concordance to the original single-site test. Importantly, through the inclusion of white blood cell (WBC) DNA sequencing, tumor variants are filtered to exclude CH and germline alterations.

Methods: The utility of MSK-ACCESS® powered with SOPHiA DDM™ in patients with lung cancer (small-cell and non-small-cell lung cancer) was investigated in a retrospective observational study. Sequencing libraries were generated from 3.5 - 20 ng of plasma cfDNA and 50 ng WBC DNA using the MSK-ACCESS® powered with SOPHiA DDM™ solution and sequenced on Illumina NovaSeq 6000. Variant detection was performed with the SOPHiA DDM™ Platform and calls without evidence of somatic origin were differentiated into germline and CH origin based on variant allele fraction (VAF). Concordance to orthogonally reported cfDNA variants was measured when available and used to investigate the benefit of matched WBC DNA sequencing.

Results: A total of 48 cfDNA + WBC DNA pairs were included in this study and successfully processed in the participating laboratories. Molecular profiling detected in 40/48 of all samples at least one somatic SNV/INDEL, with a median of 3 per patient (range 1-10). In total 161 variants were detected with a median VAF 0.82% (range 0.08-83%). Putative CH variants were observed at a similar frequency (sum 124, median 2, range 1-8) and distribution (median VAF 1.3%, range 0.07-35%) in cfDNA indicating the importance of matched WBC sequencing for their correct identification. Within all detected 25 TP53 SNV/INDELS, 4 were found at similar VAF in cfDNA and WBC DNA and assigned as CH variants. Importantly, 2/4 were reported by orthogonal liquid biopsy assays as tumor variants. All 4 CH TP53 mutations were classified as either "pathogenic" or "conflicting interpretations of pathogenicity" using the ClinVar catalog.

Conclusions: Combined cfDNA and WBC DNA sequencing by the MSK-ACCESS® powered with SOPHiA DDM™ solution improved the correct assignment of prognostic TP53 mutations in lung cancer by delineating CH from variants of somatic origin.

Introduction: Dynamic ctDNA-profiling in advanced ALK+NSCLC enables personalised treatment. DYNAMALK assesses (1) ctDNA changes relative to prior therapies, PET and tissue biopsy, and (2) resistance patterns to evaluate ctDNA's real-time impact on treatment decisions beyond standard care.

Methods: DYNAMALK-(ACTRN12623000226606p) is a multi-centre, prospective study within AURORA-(ACTRN12625000038493), conducted by the Thoracic Oncology Group of Australasia (TOGA) with consumer co-design. ALK+ patients start first-line lorlatinib (Arm A), or subsequent-line of clinician choice (Arm B). Real-time ctDNA sequencing (Guardant360®USA) is performed baseline, first imaging, and disease progression, with Molecular Tumour Board recommendations. FDG-PET scans accompany ctDNA time-points, with optional tissue. Analysis is conducted after Arm B completed accrual.

Results: DYNAMALK opened August 2023 ,expected to complete enrolment July 2025. In March 2025, N=24/30 are enrolled in Arm A, N=20/20 in Arm B. Median age was 57; 22/44 (50%) Caucasian; 14/44 (32%) had brain metastases. All in Arm A and 4 (20%) in Arm B had a tissue biopsy at entry. In matched cases available, tissue had complete concordance with ctDNA genomic alterations reported in 6/27 (22%), with additional alterations detected in ctDNA in 15/27 (55%). Median turnaround time for results was 11 days (6-30), with 6/77 (8%) samples unanalysable. In Arm B, 15/20 (75%) received Lorlatinib, 5/20 (25%) Neladalkib. Median of prior lines was 1 (1-3). Arm A, 20/23 (87%) had detectable ctDNA at baseline: 1/23 (3%) with ALK-fusion only; 16/23 (70%) ALK-fusion with non-ALK co-mutations and 3/23 (13%) had non-ALK co-mutation(s) only. Arm B, 16/20 (80%) had detectable ctDNA at baseline: 2/20 (10%) with ALK-rearrangement; 7/20 (35%) with ALK-rearrangement and co-mutations (ALK and non-ALK) and 7/20 (35%) non-ALK co-mutations only. In Arm A TP53 was most frequent, followed by loss of tumour suppressors (ATM, PTEN and RB1), EGFR amplification in 2/23 (9%). MYC amplification occurred in both arms. In Arm B, ALK kinase domain mutation in 4/20 (20%). Of cases available, Arm A, 8/19 (42%) had complete plasma clearance at first time point 2-3 months and Arm B, 3/13 (23%). All patients had baseline FDG-PET. 15/18 (83%) Arm A , 13/14 (93%) Arm B had on treatment FDG-PET matched with ctDNA. All had metabolic response in Arm A, and all but one in Arm B. In both arms complete metabolic response did not correlate with ctDNA clearance. At interim analysis, median follow-up was 6 months (range 1-15) for Arm A and 9 months (range 2-17) for Arm B. Median time-on-treatment was not reached, with 90% (18/20) and 87% (13/15) remaining on treatment. In Arm B, 2 (10%) PD, one had co-occurring MYC-amplification and emergent MET-amplification. The second PD, ctDNA reported the ALK-rearrangement only.

Conclusions: DYNAMALK demonstrates the feasibility of a real-world national ctDNA study. This preliminary analysis confirms ctDNA can detect heterogeneous genomics associated with drug resistance. Despite complete metabolic responses on FDG-PET, ctDNA clearance did not directly correlate. Longer term follow up will provided information on molecular evolution of ALK-rearranged NSCLC, receiving next-generation and novel therapeutic sequencing and may help inform treatment personalisation.

P2.06.90 The Role of ctDNA Tumor Fraction in Advanced NSCLC and Its Impact on Patient Treatment Outcomes: A Prospective Real-World Study

A. El Helali[1], B.M.F. Cheung[2], E.Y-L. Ko[1], D.J.H. Shih[3], J.W.H. Wong[3], D.K-C. Leung[2], M.K-L. Chiu[1], I. Ho[2], A.W-M. Lee[4], V.H-F. Lee[1]
[1]Centre of Cancer Medicine, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong/CN ,[2]Queen Mary Hospital, Hospital Authority, Hong Kong/CN ,[3]Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong/CN ,[4]Shenzhen Key Laboratory for Cancer Metastasis and Personalized Therapy, The University of Hong Kong-Shenzhen Hospital, Shenzhen/CN

Introduction: Comprehensive genomic profiling (CGP) using targeted panel next-generation sequencing (TP-NGS) has become pivotal in the clinical management of locally advanced, unresectable, or metastatic NSCLC. Despite the limitations associated with tumor tissue sampling, ctDNA presents a promising alternative. This study aims to assess the prognostic value of ctDNA TF in advanced-stage NSCLC.

Methods: We conducted a multi-center prospective study in Hong Kong. Patients with advanced-stage NSCLC had blood samples collected within 31 days prior to the commencement of treatment, followed by CGP using FoundationOne® Liquid CDx (F1LCDx®).

Results: In our study of 438 patients, we demonstrated that the ctDNA TF serves as a robust prognostic and predictive biomarker. Treatment naïve patients with ctDNA TF high exhibited significantly poorer median progression-free survival (PFS) of 6.9 months and overall survival (OS) of 13.8 months compared to the TF group low ($p < 0.001$). CtDNA TF predicted OS over different time points with AUC ranges from 0.6-0.71 and was remarkable within the EGFR TKI subgroup, with an AUC of 0.77 for OS at 12 months. We validated a 2.3% cutoff for inferior overall survival, as the optimal disease-specific cutoff for ctDNA TF is unclear.

Conclusions: Our findings underscore the potential of ctDNA TF as a robust biomarker for risk stratification and treatment decision-making in advanced-stage NSCLC regardless of metastatic sites, treatment strategy, and lines of treatment, advocating for its incorporation into routine clinical practice.

P2.06.91 Plasma Proteomic Profiling Identifies DHX9 as a Predictive Biomarker for Chemoimmunotherapy Efficacy in Extensive-Stage Small Cell Lung Cancer

L. Chen[1], X-H. Zhang[1], D. Wang[2], H-J. Chen[1], J-J. Yang[1]
[1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Southern Medical University, Guangzhou/CN ,[2]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, South China University of Technology, Guangzhou/CN

Introduction: Although chemoimmunotherapy has improved outcomes in small-cell lung cancer (SCLC), reliable biomarkers for identifying the benefit patients from this treatment remain elusive. This study aims to investigate whether specific plasma protein biomarkers in extensive-stage SCLC (ES-SCLC) can predict the efficacy of chemoimmunotherapy.

Methods: Baseline plasma samples from 46 patients with ES-SCLC who received first-line chemoimmunotherapy at our hospital were analyzed. Patients were stratified into two groups based on their progression-free survival (PFS) following first-line chemoimmunotherapy: those designated as the primary resistance group (PriR; PFS ≤ 6 months) and the secondary resistance group (SecR; PFS > 6 months). A proteomics workflow incorporating liquid chromatography-tandem mass spectrometry (LC-MS/MS)-based data-independent acquisition (DIA) was employed to profile plasma proteomes in the discovery cohort (DC; n=21). Protein biomarkers were screened using differentially expressed proteins (DEPs; defined as $P < 0.05$ with fold change >1.5 or <1/1.5) and elastic net regression. These biomarkers were subsequently validated through targeted parallel reaction monitoring (PRM) in an internal validation cohort (IVC; derived from the DC, n=19) and an external validation cohort (EVC; n=25). A multivariate Cox regression model was used to generate risk scores (RS), and receiver operating characteristic (ROC) analysis evaluated their predictive performance.

Results: A total of 413 DEPs were identified between the PriR and SecR groups. Functional enrichment analyses revealed significant upregulation of the cellular response to tumor necrosis factor ($P = 0.004$) and the chemokine signaling pathway ($P < 0.001$) in the SecR group. Rho GTPase-activating protein 4 (ARHGAP4) and ATP-dependent RNA helicase A (DHX9) were consistently validated in both IVC and EVC. A multivariate Cox regression model was established in the IVC: $RS = 0.21 \times ARHGAP4 - 1.45 \times DHX9$. DHX9 exhibited the highest AUC (0.976) compared to ARHGAP4 and RS in the ROC analysis. The IVC was divided into a DHX9-high (DHX9-H) group and a DHX9-low (DHX9-L) group based on the optimal threshold (0.551), with the DHX9-H group showing a longer mPFS than the DHX9-L group (7.4 months vs. 4.8 months, $P < 0.001$). In the EVC, DHX9 and the RS shared the same AUC (0.799), which was higher than that of ARHGAP4 (0.757). The EVC was also divided into two groups based on the same threshold (0.551) of DHX9 determined in the IVC, and the mPFS of the DHX9-H group was longer than that of the DHX9-L group (10.7 months vs. 2.7 months, $P < 0.001$).

Conclusions: Our study identified DHX9 as a potential biomarker for predicting the efficacy of chemoimmunotherapy in patients with ES-SCLC. Further studies are are required to establish the predictive threshold of DHX9 using ELISA assays and validate its clinical utility.

P2.06.92 Host-Derived Biomarkers of Inflammation and Body Composition Predict Immunotherapy Outcomes in Advanced NSCLC

A. De Giglio[1,2], M. Conte[1], S. De Matteis[2], F. Galuppi[1], F. Lo Bianco[1], M. Naddeo[1], I. Ricciotti[1], A. Di Federico[1], L. Trofarello[1], B. Melotti[2], F. Sperandi[2], F. Gelsomino[2], S. Brocchi[2], C. Mosconi[1,2], M. Bonafè[1], S. Salvioli[1], A. Ardizzoni[1,2]
[1]University of Bologna, Bologna/IT ,[2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna/IT

Introduction: Immune checkpoint inhibitors (ICIs) have improved outcomes in advanced non-small cell lung cancer (NSCLC), yet many patients experience resistance. Treatment selection is currently based on PD-L1 expression, which only partially predicts response. Host factors like body composition and systemic inflammation may also influence ICI efficacy. The prognostic value of circulating inflammatory/metabolic biomarkers, such as sRAGE, FGF21, GDF15, and cPLIN2, and body composition parameters has been scarcely explored in this setting. This integrative analysis was conducted in the framework of the SARC-LUNG study.

Methods: This monocentric prospective study enrolled 40 patients with stage IV NSCLC eligible for first-line ICI monotherapy or chemo-immunotherapy. Blood samples and CT-based body composition analyses were collected at baseline (T0) and after 3 months of treatment (T1). Plasma levels of the above-mentioned biomarkers were measured using ELISA/ELLA. Flow cytometry assessed peripheral leukocyte subsets. Skeletal muscle index (SMI) and fat compartments were measured at the L3 vertebral level from available CTs using semiautomatic segmentation (3D Slicer tool). Inflammation was characterized using derived neutrophil-to-lymphocyte ratio(dNLR), platelet-to-lymphocyte ratio (PLR), LDH, and lung-immune prognostic index (LIPI) as established prognostic indices. Associations with progression-free survival (PFS) and overall survival (OS) were analyzed.

Results: Among the 40 patients, 67.5% were male and 87.5% had ECOG PS 0-1. SMI was below the gender-related threshold in 72.5% of cases. Adenocarcinoma was the predominant histology (82.5%); brain and liver metastases were found in 27.5% and 10% of patients, respectively. 70% received first-line chemo-immunotherapy. No imbalances were found in baseline metabolic biomarkers across clinical characteristics, except for sRAGE, which was higher in patients aged ≥70 years ($p < 0.001$). FGF21 was inversely correlated with muscle area ($r = -0.39$, $p = 0.027$) and SMI ($r = -0.44$, $p < 0.05$). FGF21 also correlated positively with PLR ($r = 0.34$, $p < 0.05$) and negatively with NK cells ($r = -0.59$, $p = 0.023$). Similarly, GDF15 showed a trend toward inverse correlation with muscle area and SMI. cPLIN2 showed a positive correlation with visceral ($r = 0.55$, $p = 0.00018$) and subcutaneous fat ($r = 0.45$, $p < 0.001$), and an inverse correlation with PLR ($r = -0.46$, $p < 0.0001$). sRAGE inversely correlated with LIPI ($r = -0.28$, $p = 0.01$) and dNLR ($r = -0.23$, $p < 0.05$). Patients with high baseline sRAGE (ROC-based cut-off) had longer PFS (10.0 vs 6.2 months, $p = 0.042$) and OS (not reached-NR- vs 16.1 months, $p = 0.024$). sRAGE increased significantly in responders compared to non-responders ($p = 0.04$) from T0 to T1. Low baseline SMI was significantly associated with shorter OS (NR vs 16.1 months,$p < 0.05$) and PFS (10.0 vs 6.1 months,$p < 0.05$). Additionally, an increase in SMI from T0 to T1 was associated with reduced mortality (HR =0.77, $p = 0.012$).

Conclusions: The SARC-LUNG study shows that integrating metabolic, inflammatory, and body composition biomarkers provides meaningful prognostic information in advanced NSCLC under upfront ICI. FGF21 and cPLIN2 reflect catabolic and inflammatory burdens, while sRAGE emerges as a promising early-response biomarker. Muscle loss remains a strong predictor of poor outcomes. These findings support incorporating host-related profiling into immunotherapy decision-making.

P2.06.93 Distinct Clinical and Biological Features of Five SCLC Subtypes Identified by Plasma Proteomic Analysis

D.R. Gandara[1], A.P. Dicker[2], N. Almog[3], Y. Elon[3], M. Harel[3]
[1]UC Davis Medical Center, Sacramento/CA/USA ,[2]Thomas Jefferson University, Philadelphia/PA/USA ,[3]OncoHost, Binyamina/IL

Introduction: Small cell lung cancer (SCLC) is a heterogeneous disease with distinct subtypes defined by molecular profiles and neuroendocrine differentiation. Transcription factor-based classification divides SCLC into four major subtypes - SCLC-A, SCLC-N, SCLC-P, and SCLC-I - each with unique biological features and therapeutic vulnerabilities. The reliance on invasive tissue biopsies limits current SCLC subtyping. Here, we explore the potential of plasma proteomic profiling for SCLC subtyping.

Methods: Pre-treatment plasma samples were collected from 79 patients with extensive-stage SCLC treated with immune checkpoint inhibitors and chemotherapy. Proteomic profiling was performed using an aptamer-based assay that quantifies >7000 proteins per sample. Consensus clustering analysis was used to identify different plasma-proteomics-based subtypes. Bioinformatic analysis was performed to obtain biological and clinical insights per subtype. The study included statistical tests (ANOVA and Fisher exact tests) and examined known transcriptome-based biomarkers and an age predictor model.

Results: Five distinct SCLC subtypes were identified based on pre-treatment plasma proteomic patterns. Patients classified by subtype displayed differential overall survival (OS). The subtype-3 population displayed the lowest median OS (6 months), significantly lower than subtype-1 and subtype-2 populations (p-value 0.015 and 0.044, respectively; hazard ratio 0.417 and 0.438, respectively). The subtype-4 population displayed low median OS (10 months), though not significantly different from other subtype populations. Poor prognostic factors, such as high ECOG performance status and OS events, were significantly enriched among patients classified as subtype-3 (FDR<0.2). There were 469 differentially expressed proteins between the five subtypes, clustered into four main expression groups (ANOVA test, FDR<0.01). Enrichment analysis revealed multiple significantly enriched pathways for each protein cluster (Fisher's exact test, FDR<0.1). Specifically, the protein set associated with subtype-3 was enriched with processes such as cell cycle and splicing and included proteins related to inflammation. Subtype-3 exhibited high expression of multiple neuroendocrine biomarkers, including CHGA, NCAM1, and ENO2, and proteins associated with neuroendocrine-high subtypes, such as LDHA and BCL2. The latter was highly expressed in subtype-4 and VIP, a soluble marker previously suggested for monitoring neuroendocrine tumors. In contrast, subtypes 1 and 2 displayed the highest expression of NOTCH pathway proteins (NOTCH1-3) and HES1, a key transcription factor downstream of NOTCH signaling, both are associated with non-neuroendocrine subtypes. Last, the samples were analyzed using an age-prediction model previously developed on healthy subjects; the subtypes showed a differential age gap between the biological (modeled) age and the chronological age, with subtype-3 displaying the highest median age gap, followed by subtype-5.

Conclusions: Plasma proteomics-based SCLC subtyping represents a minimally invasive approach that overcomes biopsy limitations and enables easy monitoring of subtype shifts that may occur following treatment. The current study reveals novel patient clustering, with 2 subtypes displaying more neuroendocrine-related characteristics and poor prognostic outcomes and 2 subtypes displaying non-NE features. Our findings show an interplay with transcriptome-related subtyping, which can be further studied to develop new potential targets for intervention based on molecular subtyping and soluble markers.

P2.06.94 "Integrating AI-Based Risk Stratification, LDCT, and Liquid Biopsy for Early Detection of Lung Cancer in High-Risk Individuals"

S. Limaye[1], P. Kumar[2], D. Patil[3], C. Madre[4], S. Singh[1], s. dubey[1], A. Parab[1], D. shah[1], P. Kataria[1], A. Raut[1], N. Shah[1], S. Bindroo[1], S. Jha[1]
[1]Sir H. N. Reliance Foundation Hospital and Research Centre, Mumbai/IN ,[2]Datar Cancer genetics, Nashik/IN ,[3]Datar Cancer genetics, Nashik, India, Nashik/IN ,[4]Sir H N Reliance Foundation Hospital, Mumbai/IN

Introduction: Early detection of lung cancer significantly improves patient outcomes, yet existing screening strategies are often limited by low participation and lack of targeted outreach. This study evaluates a layered approach incorporating an AI-based risk stratification tool, low-dose computed tomography (LDCT), and liquid biopsy (ctDNA) for identifying and monitoring early lung malignancies in high-risk populations.

Methods: An AI-driven questionnaire incorporating clinical, behavioural, and environmental risk factors was administered to 1,000 individuals. All participants categorized as high risk underwent LDCT screening. Those with radiological abnormalities (n=200) were further evaluated using plasma-based ctDNA analysis. Key mutations and methylation markers were assessed via targeted sequencing. Individuals with positive ctDNA findings (n=50) were advised structured follow-up with imaging at 3 and 12 months. Invasive diagnostic procedures were reserved for cases with progressive or persistent findings.

Results: Among the 1,000 high-risk individuals screened, 200 (20%) exhibited suspicious nodules on LDCT. Liquid biopsy performed on this subset revealed ctDNA positivity in 50 individuals (25%). These patients were enrolled in longitudinal follow-up, with ongoing monitoring to evaluate disease progression and refine the predictive accuracy of combined radiologic and molecular assessment. Histologic confirmation is currently pending based on follow-up scans and clinical evolution.

Conclusions: This interim analysis supports the feasibility of integrating AI-based risk assessment with imaging and liquid biopsy to enable early surveillance in lung cancer. The ctDNA assay added a valuable layer of specificity in triaging individuals for follow-up, potentially reducing unnecessary invasive procedures. This structured, non-invasive approach may enhance early detection efforts and provide a scalable model for population-level lung cancer screening programs.

P2.06.95 Deep Learning-Based Prediction of Immunotherapy Efficacy in Non-Small Cell Lung Cancer: Automated Tumor and Muscle Evaluation

T. Miyawaki[1], T. Shukuya[1], S. Xu[1], Y. Nakamura[2], K. Suzuki[3], I. Katayama[1], H. Matsuda[1], M. Fujioka[1], M. Torasawa[1], D. Hayakawa[1], R. Kanemaru[1], Y. Mitsuishi[1], R. Shibayama[1], K. Tajima[1], Y. Otsuka[2], K. Takahashi[1]
[1]Juntendo University Faculty of Medicine and Graduate School of Medicine, Tokyo/JP ,[2]Plusman LLC, Tokyo/JP ,[3]Department of Radiology, Juntendo University Faculty of Medicine and Graduate School of Medicine, Tokyo/JP

Introduction: The integration of imaging and clinical information through artificial intelligence (AI) offers a promising approach for accurately predicting the therapeutic efficacy of immune checkpoint inhibitors (ICIs) ± platinum-based chemotherapy in advanced non-small cell lung cancer (NSCLC). Muscle volume has been identified as a key predictor of ICI efficacy, but previous studies have not comprehensively assessed both tumor radiomic features and muscle volume. To enhance the predictive accuracy of treatment efficacy and prognosis, we developed a novel deep learning model for fully automated tumor segmentation and muscle volume quantification.

Methods: This study included patients with advanced NSCLC who received first-line ICI ± platinum-based chemotherapy between March 2017 and August 2023. We developed an ensemble model integrating a logistic regression model for clinical information analysis with a deep learning model for extracting tumor radiomic features and quantifying muscle volume. Tumor segmentation and psoas muscle volume were automatically extracted using a fully automated approach from pre-treatment chest-abdominal CT imaging and brain MRI. Each sub-model was independent, allowing flexibility in adjustments. The models were trained to predict 12-month overall survival (OS), 12-month progression-free survival (PFS), and treatment response using cross-entropy loss. Five-fold cross-validation was employed, with dataset splitting in a 5:3:2 ratio. The area under the curve (AUC) was calculated.

Results: A total of 232 patients were included, with 89 (38%) receiving ICI alone and 143 (62%) receiving ICI + platinum-based chemotherapy. The median OS was 24.5 months (95% confidence interval [CI]: 21.2-30.3), and the median PFS was 7.1 months (95% CI: 5.8-9.1). Our deep learning model demonstrated predictive accuracy with an AUC of 0.77 (95% CI: 0.57-0.97) for 12-month OS and 0.66 (95% CI: 0.53-0.79) for 12-month PFS. Deep learning-based stratification classified test set patients into high-group (N = 67) and low-risk group (N = 69). The high-risk group had a significantly shorter OS (20.3 vs. 30.7 months, $p < 0.05$) and a trend toward shorter PFS (7.2 vs. 8.9 months, $p = 0.06$).

Conclusions: Our deep learning model, integrating fully automated tumor segmentation and muscle evaluation with clinical information, demonstrated favorable predictive performance for survival outcomes in advanced NSCLC patients receiving first-line immunotherapy.

P2.06.96 Exploration the Heterogeneity of HER2 Expression in Potential Candidates for Antibody-Drug Conjugate in Non-Small Cell Lung Cancer

H. Wang, D. Lin
beijing cancer hospital, beijing/CN

Introduction: Recently, T-DXd has been approved in patients with metastatic or unresectable non-small cell lung carcinoma (NSCLC) harboring HER2 mutations. Subsequently, FDA approved T-Dxd for adult patients with unresectable or metastatic HER2 immunohistochemistry (IHC) 3+ solid tumors. Therefore, the clinically more practical and convenient HER2 IHC has drawn increased attention for application in NSCLC. While, currently, there are no standard protocols for the selection of optimal specimen type for HER2 testing in NSCLC. The aim of our study is to investigate the concordance of HER2 status between biopsy and subsequent lobectomy specimens, as well as between primary and metastatic lesions.

Methods: We collected NSCLC cases at Peking University Cancer Hospital spanning the years 2017 to 2024 that underwent HER2 testing, possessed matched specimens, and exhibited at least one lesion with HER2 2+ or higher. All cases were independently re-evaluated by two pathologists.

Results: A total of 129 paired samples were included in our study. Eighty-eight paired surgical and biopsy samples, 102 matched primary and metastatic samples were included in the analysis. The concordance rates between biopsy and paired resection were 51.4% for HER2 2+ and 21.4% for HER2 3+, with significantly higher concordance observed in HER2 2+ compared to HER2 3+ (p=0.040). The concordance rates between primary tumor and metastasis were 39.4% for HER2 2+ and 35.4% for HER2 3+. No significant difference in concordance rates was observed between local regional lymph node metastasis and distant metastasis. Regardless of HER2 2+ or 3+, both biopsy and metastatic samples tended to underestimate HER2 expression. HER2 overexpression was more prevalent in adenocarcinoma (p=0.003), especially for HER2 2+. Additionally, HER2 3+ expression exhibited a significant positive correlation with a positive percentage greater than 30% (p=0.042) and an H-score greater than 65 (p=0.018).

Conclusions: Our results indicate that HER2 exhibits spatiotemporal heterogeneity in NSCLC, suggesting the need for sampling as extensively as possible to optimally identify the potential population that may benefit from T-DXd treatment.

P2.06.97 Monitoring the Risk of Second Primaries Through Blood miRNA Testing: Follow-Up of the BioMILD Lung Cancer Screening Trial

G. Sozzi[1], F. Sabia[2], M. Boeri[3], A. Zanghi[4], U. Pastorino[2]*
[1]Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milan/IT ,[2]Thoracic Surgery Unit Fondazione IRCCS Istituto Nazionale Tumori, milano/IT ,[3]Experimental Oncology Department, Epigenetics and Biomarkers Unit Fondazione IRCCS Istituto Nazionale Tumori, milano/IT ,[4]Experimental Oncology Department, Epigenetics and Biomarkers UnitFondazione IRCCS Istituto Nazionale Tumori, milano/IT

Introduction: The BioMILD study, involving 4,119 participants, combined LDCT with a blood 24-miRNA classifier (MSC) and showed improved prediction of lung cancer incidence and mortality. Here we evaluated the ability of MSC to monitor the disease status in lung cancer patients of the BioMILD cohort after curative surgery. Modulation of MSC risk profile has been assessed to identify second primary tumors and deaths.

Methods: MSC profile has been assessed in plasma samples longitudinally collected after curative surgery for primary LC in 98 Stage I patients of the BioMILD study in over 10 years of follow-up. Overall, 776 MSC tests, 96 at first LC diagnosis and 680 post-surgery (median number of samples 7, IQR 5-11) were analysed by RT-qPCR using a 384-well microfluidic TaqMan cards (ThermoFisher), containing proper controls and probes for the 24 miRNAs of interest in duplicate.

Results: At the time of the first LC diagnosis, 77 patients (80%) had MSC+ and 19 (20%) had MSC- results. A second primary LC was observed in 17 (17%) patients and 11 (11%) died of any cause throughout the 10 years follow-up. Considering all 680 post-surgery MSC tests available, the percentage of MSC+ results decreased from 80% at diagnosis to 53.1% post-surgery. The sensitivity of MSC test for second primary LC was 70% within 6 months before diagnosis and remained high (65.9%, 66.1%, 66.3%) within 1, 2 and 3 years, respectively. Looking at the longitudinal modulation of MSC test over time, percentage of MSC+ gradually decreased in 87 patients who remained disease free (59% at 6mo, 48% at 2yrs, 37% at 5yrs, 33% at 7yrs) while an opposite trend was observed in the 17 who developed a second primary LC (59% at 6mo, 61% at 2yrs, 55% at 5yrs, 80% at 7yrs). When considering the percentage of post-surgery MSC+ test in individual patients, the relative risk was 2.8 (95%CI: 1.1-6.9) to develop a second primary LC in patients with ≥50% MSC+ test (p=0.021).

Conclusions: In BioMILD stage I LC patients, blood microRNA testing showed high sensitivity at pre-surgery and in longitudinal samples post-surgery to predict second primaries and deaths. Such a non-invasive blood test strategy might contribute to optimize the clinical management of LC patients after surgery.

P2.06.98 Deep Learning-Based 18F-FDG PET/CT Radiomics Model for Predicting Pathological Response to Chemoimmunotherapy in NSCLC

a. li[1,2], Z. Mao[3], H. Wang[4], Y. Wang[5], Y. Hu[1], H. Wang[4], L. Jiang[1], B. Jiang[1]
[1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), GuangZhou/CN ,[2]School of Medicine South China University of Technology, GuangZhou/CN ,[3]Peking University, Beijing/CN ,[4]The Frist Affiliated Hospital of Anhui Medical University, Hefei/CN ,[5]The Third People's Hospital of Chengdu, Chengdu/CN

Introduction: In recent years, immune checkpoint inhibitors (ICIs), represented by PD-1/PD-L1, have made breakthrough progress in the treatment of lung cancer. However, the predictive efficacy of current biomarkers for ICIs remains insufficient. This study explores the predictive value of radiomics-based biomarkers for the treatment response to ICIs in NSCLC patients undergoing chemoimmunotherapy.

Methods: We retrospectively collected 18F-FDG PET/CT images from 132 NSCLC patients treated with chemoimmunotherapy between January 2023 and December 2024. A total of 1,834 radiomic features were extracted from CT images and 179 from PET images. A multimodal dataset was constructed by integrating PD-L1 expression, Tumor Mutational Burden (TMB), metabolic tumor characteristics (Metabolic Tumor Volume [MTV] and Total Lesion Glycolysis [TLG]), and peripheral blood biomarkers. The dataset was randomly divided into training and validation cohorts in an 8:2 ratio. We propose a Mask-MLP score model to compute patient-specific scores, which serve as the primary basis for evaluating the study endpoint (Pathological Complete Response, PCR). The model's accuracy was further validated in an external validation cohort consisting of 32 patients from two independent hospitals.

Results: Our study proposes a multi-model deep learning model which was constructed upon LDA feature engineering technique. Our model integrates diverse data sources including 10 clinical characteristics, 3 CT features, and 3 PET features. Our model achieved an AUC of 0.72 (95% CI: 0.39 to 0.8) in the training set. In the external independent validation cohort, the AUC was 0.86 (95% CI: 0.71 to 0.98), sensitivity of 92.86%, specificity of 82.35%. Compared to single-modality models based on clinical features (AUC: 0.53, 95% CI: 0.33 to 0.74) or individual CT (AUC: 0.83, 95% CI: 0.64 to 0.99)/PET features (AUC: 0.82, 95% CI: 0.65 to 0.97), the Mask-MLP score model significantly improved accuracy.

Conclusions: This study developed a deep-learning predictive model that integrates multimodal baseline data to evaluate pathological treatment responses to chemoimmunotherapy in NSCLC. The model allows for the accurate pre-therapeutic identification of potential treatment responders.

P2.06.99 Tumor-Associated Neutrophil Infiltration Predicts Benefit From Combination Chemoimmunotherapy in Non-Small Cell Lung Cancer

C. Norman[1], K. Sachdeva[2], P. Ji[1], S. Grantham[1], N. Leighl[3], M-S. Tsao[3], G. Goss[2], S. Laurie[2], F. Vera-Badillo[1], P.A. Bradbury[3], B. Hughes[4], M. Stockler[5], A. Uriarte[1], M. Olanrewaju[1], M. Fotheringham[1], A. Othman[1], E. Radwan[1], J. Dancey[1], K. Ding[1], T. Cottrell[1]

Introduction: More than half of patients with advanced non-small cell lung carcinoma (NSCLC) do not respond to standard-of-care immune checkpoint blockade (ICB)-based treatment. Tumor-associated neutrophils (TANs) are emerging as potential mediators of resistance to anti-PD1 therapy. Prior studies have sought to indirectly assess TANs by surrogate markers readily accessible in peripheral blood, e.g., neutrophil-to-lymphocyte ratio and serum IL-8. We hypothesized that direct assessment of intratumoral neutrophils on routine H&E slides may improve the sensitivity and specificity of detecting patients unlikely to respond to ICB. The current study leverages data from a previously reported randomized phase 2 clinical trial of durvalumab + tremelimumab +/- platinum-doublet chemotherapy in patients with untreated metastatic NSCLC (CCTG BR34; Leighl et al. JTO 2022). The study aimed to: (1) assess the feasibility of direct scoring of TANs on H&E-stained pretreatment NSCLC biopsies and (2) test the association of intratumoral TANs with survival outcomes in patients receiving combination ICB (CIBC) with or without chemotherapy.

Methods: H&E-stained slides were previously collected from (N=301) patients with treatment-naive, metastatic NSCLC (without sensitizing EGFR or ALK alterations) enrolled in BR34. Inclusion required ≥10 high-power fields (HPFs) of intact, non-necrotic evaluable tumor tissue (at 40x magnification). TAN scoring was performed on n=225 pre-treatment NSCLC specimens from patients treated with chemotherapy + CICB (chemo+CICB, n=114) or CICB alone (n=111). For each slide, a maximum of 20 representative HPFs were visually evaluated for neutrophils by cellular morphology (e.g., segmented nuclei and bright pink cytoplasmic granules). Each HPF with ≥5 TANs located within the tumor epithelium or tumor stroma was scored as a TAN(+)HPF. Neutrophils associated with blood or necrosis were not counted. The proportion of TAN(+)HPFs was calculated. The percentage of necrotic tumor area was estimated. PD-L1 status was evaluated using the tumor proportion score.

Results: Among pre-treatment specimens with ≥1 TAN(+)HPF, the median proportion of TAN(+)HPFs was 5%. The proportion of TAN(+)HPFs did not correlate with percent necrosis (p=0.99) or PD-L1 tumor proportion score (p=0.10). All biopsy specimens with >5% TAN(+)HPFs were designated TAN(high). The prevalence of TAN(high) tumors (18.7%) did not significantly differ by treatment arm (p=0.76). TAN(high) tumors were associated with shortened median overall survival (OS) in the CICB alone arm (7.9 months TAN(high) versus 18.3 months TAN(low), p=0.004; HR: 2.39, 95% C.I.: 1.30-4.39). This association was absent in patients treated with chemo+CICB (HR: 1.00, p=0.99). The median OS for patients with TAN(high) tumors in the CICB alone arm was 7.9 months versus 15.3 months in the chemo+CICB arm (p=0.03). A multivariable adjusted test for interaction confirmed that TAN(high) predicted improved OS for patients receiving chemo+CICB versus CICB alone (HR: 0.39, 95%, C.I.: 0.17-0.93, p=0.03).

Conclusions: Our findings show that H&E-based classification of TAN(high) tumors is feasible and the TAN(high) phenotype is independent of tumor necrosis and PD-L1. TAN(high) NSCLC was associated with reduced OS in patients receiving CICB alone, but predicted OS benefit with the addition of platinum-doublet chemotherapy to CICB. These findings warrant further validation of TAN assessment as a biomarker to guide ICB-based therapy selection in NSCLC.

Introduction: Despite significant progress in the treatment of non-small cell lung cancer (NSCLC) without actionable driver mutations, new therapies along with reliable response biomarkers are required for patients who progress after standard of care treatment. AFM24 is a tetravalent, bispecific innate cell engager (ICE) that binds CD16A on NK cells and macrophages and EGFR on solid tumors, redirecting and enhancing the innate and indirectly the adaptive immune response. This open-label, non-randomized Phase 1/2a study (NCT05109442) is evaluating the combination of AFM24 and atezolizumab for the treatment of EGFR-wildtype (EGFR-WT) NSCLC. The initial clinical and efficacy results of this study were submitted to ASCO 2025; here, we report additional correlative science analyses to identify correlative biomarkers in peripheral blood to complement the efficacy data.

Methods: AFM24 is given weekly at 480 mg intravenously (IV) in combination with 840 mg atezolizumab IV fortnightly, to patients with advanced/metastatic EGFR-WT NSCLC who progressed on ≥1 prior line of therapy, including at least a platinum doublet and a checkpoint inhibitor (CPI). Treatment is given in 28-day cycles until disease progression, intolerable toxicity, investigator discretion, or patient withdrawal of consent. Longitudinal immunophenotyping of various immune cell types was conducted to identify potential biomarkers in peripheral blood and measure pharmacodynamic effects on immune effector cells during the first treatment cycle.

Results: As of 15 January 2025, 43 patients were treated with AFM24 and atezolizumab. All patients had discontinued their previous CPI treatment due to disease progression. As previously reported at ASCO 2025, the combination was well tolerated, with infusion-related reactions being the most common adverse event (AE), and a disease control rate (DCR) of 77% was observed in this study cohort. Immunophenotyping of peripheral blood mononuclear cells (PBMCs) was performed on 12 patients, with 11 patients passing quality thresholds. A correlation between the frequency of NK cells in PBMCs and DCR was observed, with a median NK cell frequency at baseline of 17.5% in patients with disease control (n=8) versus a median frequency of 1.5% in patients without disease control (n=3). After the first AFM24 dose in the safety lead-in phase, a decrease in the NK cell count was measured that remained below baseline levels throughout the first treatment cycle, thus suggesting a potential migration of NK cells to EGFR-expressing tumor cells. Further analysis of activation and exhaustion markers revealed pharmacodynamic effects of AFM24 and atezolizumab on the activation status of various immune cell types, indicating activation of both the innate and adaptive immune systems.

Conclusions: The combination of AFM24 and atezolizumab shows promising clinical efficacy in NSCLC patients who failed prior treatments, including platinum-based chemotherapy and a CPI, with a tolerable and well-managed safety profile. A DCR of 77%, along with some long, sustained responses, correlates with high numbers of NK cells in the peripheral blood, which potentially leave the periphery and migrate to the tumor upon AFM24 treatment. This combination immunotherapy approach could offer a promising chemotherapy-free alternative, with NK cell frequency as a potential minimally invasive predictive biomarker for treatment response.

P2.06.101 Neuroendocrine-Like Subtype or TMB-High Predicts Long-Term Survival Benefit From Sequential Thoracic Radiotherapy and ICI in ES-SCLC

L. Wang[1], D. Chen[1], B. Zou[1], B. Li[1], A. Gao[1], W. Huang[1], Q. Shao[1], X. Meng[1], P. Zhang[1], X. Tang[1], X. Hu[1], Y. Zhang[1], J. Guo[1], Q. Wei[2], x. Li[2], Q. Li[2], C. Zhao[3], C. Zhu[2], J. Yu[1]
[1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan/CN ,[2]Amoy Diagnostics Co Ltd., Xiamen/CN ,[3]Jiangsu Hengrui Pharmaceuticals Co Ltd., jiangsu/CN

Introduction: The efficacy and safety of adebrelimab in combination with first-line chemotherapy followed by sequential thoracic radiotherapy (TRT) in ES-SCLC patients have been reported (NCT04562337). However, biomarkers to select patients who might benefit from TRT remain unidentified. This study integrates real-world data with the original Phase II trial to explore predictive biomarkers for TRT benefit.

Methods: In addition to 30 patients from initial Phase II trial, 27 ES-SCLC patients treated in real world practice were enrolled under similar criteria of phase II trial resulting in a total of 57 patients. 55 and 57 pre-treatment biopsies successfully underwent comprehensive genomic profiling (571-gene panel, AmoyDx master panel) and whole transcriptome sequencing, respectively.

Results: Among 57 patients who received an immunotherapy (with 30 Phase II trial patients treated with adebrelimab) plus etoposide/cisplatin regimen, 34 underwent sequential thoracic radiotherapy (TRT) based on treatment response, while 23 did not (non-TRT group). The TRT group exhibited a significantly longer median progression-free survival (mPFS: 11.3 vs. 6.1 months, p<0.001), although median overall survival (mOS: 22.9 vs. 18.0 months, p=0.68) was similar. Cox analysis revealed that in TMB-high patients (≥10 muts/mb), TRT was associated with a significant PFS benefit (n=27, HR=0.11, p=0.009) and a trend toward OS benefit (n=27, HR=0.12, p=0.095), while no significant differences were observed in the TMB-low group. Using non-negative matrix factorization, transcriptomic data classified patients into three subtypes; notably, in the NEUROD1/ASCL1-enriched NMF3 subgroup (NE-like), TRT conferred a significant PFS benefit (n=17, HR=0.28, p=0.042). Intriguingly, patients with either TMB-high or NE-like subtype features significant improvements in both PFS (n=33, HR=0.18, p=0.001) and OS (n=33, HR=0.12, p=0.017) with TRT.

Conclusions: This study integrates Phase II and real-world data to identify biomarkers predicting long-term survival benefit from TRT and immune checkpoint inhibitors in ES-SCLC patients after treatment of etoposide/cisplatin and immune checkpoint inhibitors.

Introduction: MET protein and genomic alterations are prevalent in NSCLC but the overlap of patients with alterations is not well established in later lines of therapy. Additionally, concordance between genomic alterations in tissue and blood has not been evaluated. Here, we report a centrally-confirmed prevalence analysis of MET overexpression (OE), MET exon 14 skipping (MET ex14) mutation, and MET amplification (Amp) alongside an assessment of the impact of biopsy age on MET OE in patients with advanced NSCLC (aNSCLC). We also present a concordance analysis of multiple MET Amp detection technologies using liquid and tissue matrices.

Methods: Patients with MET-altered aNSCLC (unresectable/metastatic) by local testing received davutamig intravenously Q3W (NCT04077099). MET protein expression was evaluated by immunohistochemistry (IHC) using the SP44 antibody (Roche Tissue Diagnostics). MET Amp and MET ex14 mutation status were performed on baseline tumor biopsies and plasma ctDNA (Guardant Health, Foundation Medicine, Inc.) samples using next generation sequencing (NGS) assays. Fluorescence in situ hybridization (FISH) with MET/CEP7 probes (Abbott Molecular) were used to assess MET Amp. Prevalence analysis was grouped by EGFR and MET ex14 mutation status. Concordance rate between methodologies was calculated by dividing the number of samples identically classified by both methods, by total number of overlapping samples.

Results: As of July 2024, of the enrolled patients (n=82), 70 had MET Amp data, and 59 were evaluable by IHC (54 patients had both results). Association analysis showed a significant relationship between MET OE and MET Amp (IHC 3+ ≥25%: 70% [38/54]; Amp: 48% [26/54]; Pearson's chi-square test: p=0.027). No significant difference in MET OE by IHC was observed between EGFR WT (IHC 3+ ≥25%: 75% [12/16]) and EGFR MUT (IHC 3+ ≥25%: 75% [15/20]) subgroups. Similar levels of MET Amp were reported between EGFR WT (67% [12/18]) and EGFR MUT (61% [14/23]) subgroups. Lower rates of MET OE and MET Amp were observed in patients with MET ex14 mutation (IHC 3+ ≥25%: 62% [8/13]; Amp: 23% [5/22]) compared with patients without MET ex14 mutation (IHC 3+ ≥25%: 75% [27/36]; Amp: 63% [26/41]). There were no significant differences in MET OE between fresh (IHC 3+ ≥25%: 70% [16/23]) and archival biopsies (IHC 3+ ≥25%: 85% [11/13]; p=0.299) and this was not impacted by acquisition timing (100-1000 days prior to enrolment) of archival biopsies (EGFR WT: p=0.87; EGFR MUT: p=0.26). Within tissue-based MET Amp detection technologies, high concordance (78%) was observed between FISH (Gene copy number [GCN] ≥5 or MET/CEP7 ≥1.8) and NGS (GCN ≥6). Liquid-based NGS testing for MET Amp was complementary (74% concordance) to tissue-based genotyping regardless of assay platform.

Conclusions: These findings identified that most patients with aNSCLC exhibited both MET OE and MET Amp, with age of archival tumor biopsy having no impact on MET expression. This supports the use of existing tissue samples and may reduce the need for fresh biopsies. Despite no consensus on technology assessing MET Amp, these results suggest reliable outcomes are achievable with specific cut-offs regardless of assay platform, warranting further sample analysis to validate these findings.

P2.08 .01 Double Lung Transplantation in Patients With Recent History of Malignancy

Y.K. Chae, T. Demir, R. Min, L.I-y. Chung, W. woo, C. Moloney, C. Jung, B. Sanson, R. Dwyer, A. Bharat
Northwestern University, Chicago/IL/USA

Introduction: Recent history of malignancy usually within five years is a contraindication for double lung transplantation (DLT). However, the relationship between a recent history of malignancy and lung transplantation outcomes is unclear.

Methods: Patients with respiratory failure and a history of cancer in the last five years treated with DLT were identified between 09/2021 and 11/2024. All patients had enrolled in the DLT registry aimed for lung-limited malignancies (DREAM) study cohort C (NCT05671887). Standard staging work-up confirmed the absence of any distant metastasis. All patients were followed up with computed tomography every 12 weeks.

Results: 14 consecutive patients who underwent DLT were included (age 58-75, 10 male, 4 female, and 13 former smokers). 10 patients had primary lung (stage IB-IIIB), two had prostate (stage I-IIc), one had bladder, and one had skin cancer. Among lung cancer patients, five patients had adenocarcinoma, four squamous cell carcinoma, and one poorly differentiated non-small cell carcinoma. Prior to DLT, patients received radioimmunotherapy (n=1), chemoradiotherapy (n=2), chemoradiotherapy plus immunotherapy (IO) (n=2), radiotherapy alone (n=2), and chemotherapy alone (n=3). The duration of IO was a median of 2 (2-18) months. The IO-free interval was 11, 27, and 44 months before DLT. All patients had high oxygen requirements before DLT. The indications for DLT were COPD (n=4), IO-related ILD (n=3), IPF (n=2), and COVID-related ILD (n=1). Transplant rejection did not occur, and there was no requirement for oxygen therapy for any patient. The median duration of follow-up for survival after transplant was 9 (7-17) months (Table 1).

Conclusions: 14 patients successfully underwent DLT for non-malignant indications of respiratory failure with less than a 5-year history of cancer without significant complications. Ongoing DREAM study cohort C will continue to investigate the role of DLT in patients with a recent history of malignancy.

Patients (n=10)	Reason for DLT	Smoking Status	Pretransplant cancer diagnosis	Definitive Treatment	Duration ofIO (month)	IO-free interval (month)	Duration of Waitlist (day)	Stage at DLT	OS after transplant (months)	Rejection
Case 1 (61y, White male)	COPD	Former	Stage IIIB (T3N2M0) Lung Mucinous AdenoCA	ImmunoRT	2	11	32	T0N0	12	No

P2.08 .02 Long Term Prognosis Following Wedge Resection in Peripheral = cT1b Non-Small Cell Lung Cancer Patients Without Pulmonary Dysfunction

T. Yun, I.K. Park, J.H. Park, B. Na, K.J. Na, S. Park, H.J. Lee, C.H. Kang, Y.T. Kim
Seoul National University Hospital, Seoul/KR

Introduction: This study is to investigate the long-term prognosis and pulmonary function change after wedge resection in patients with peripheral ≤ cT1b NSCLC and eligible for lobectomy.

Methods: We retrospectively reviewed data of 413 patients who underwent wedge resection for ≤ cT1b NSCLC between 2011 and 2022. Patients with previous history of lung cancer and FEV1 < 60% were excluded. Recurrences were classified as loco-regional recurrence (LRR; recurrences in the index lobe or at ipsilateral hilar/mediastinal nodes) and systemic recurrence (all other recurrences). Overall survival (OS) and freedom-from-recurrence (FFR) rates for all recurrence and LRR were analyzed. Pulmonary function changes at least postoperative 6 months were analyzed also.

Results: Clinical stages were cT1mi in 182 (44.1%), cT1a in 106 (25.7%), and cT1b in 125 (30.3%) patients. Histologic type was adenocarcinoma in 384 (93%) and non-adenocarcinoma in 29 (7%). The mean tumor size was 1.3 ± 0.7 cm and consolidation-to-tumor ratio (CTR) was 0.5 ± 0.5. The mean resection margin distance and margin-tumor ratio (MTR) were 1.2 ± 0.8 cm and was 1.1 ± 1.0, respectively. Lymph node sampling was done in 182 (44.1%) patients. (3.1 ± 5.3 nodes) After a median follow-up of 40 months, recurrences were diagnosed in 26 patients (local - 10; regional - 4; systemic - 12). There was 3 non-cancer-related death, and no patients died from NSCLC. OS rates were significantly different between cT1 stages. (5-year: cT1mi/ cT1a - 100%, cT1b - 97.4%, p = 0.026). FFR rates (5-year: cT1mi - 100%, cT1a - 90.3%, cT1b - 78.9%, p < 0.001) and FFR-LRR rates (5-year: cT1mi - 100%, cT1a - 94.7%, cT1b - 90.6%, p = 0.004) were significantly different between cT stages. In multivariate analysis, risk factors for all recurrence were age (HR=1.07, 95% CI=1.02-1.12, p = 0.003) and smoking (HR= 5.33, 95% CI=1.97-14.45, p = 0.001). However, no other risk factor was significant for LRR in multivariate analysis. After at least 6 months postoperatively, the mean reduction of FVC was -4.5 ± 8.7% and that of FEV1 was -4.5 ± 9.0%.

Conclusions: After wedge resection, overall survival of T1mi, T1a, and T1b were similar and excellent, and pulmonary functions were well preserved. Wedge resection can be an option in peripheral ≤ cT1b NSCLC.

P2.08 .03 Differentgrades of Visceral Pleura Invasion in Lung Adenocarcinomas Correlate With Aggressiveness and Poor Prognosis

S. KORASIDIS[1], D. Bacchin[2], G. Ali[3], V. Aprile[2], M.G. Mastromarino[4], A. Castaldi[2], M.C. Ambrogi[2], M. Lucchi[2]
[1]Thoracic Surgery - University of Pisa, PISA/IT ,[2]University of Pisa, PISA/IT ,[3]University of Pisa, Pathological Anatomy Unit, Department of Surgical,/IT ,[4]University of Pisa, Division of Thoracic Surgery, Cardiac, Thoracic, a/IT

Introduction: Visceral pleura invasion (VPI) in lung adenocarcinoma (LUAD) is a negative prognostic factor. The prognostic impact of different grades of neoplastic VPI; PL1 (beyond the elastic layer but remaining below the pleural surface) and PL2 (emerging on the pleural surface), is still debated. This study evaluates the relationship between PL1/PL2, survival outcomes, and other histology-related risk factors in LUAD patients.

Methods: We retrospectively collected data from patients who underwent radical surgery for LUAD between 2017 and 2020. A multivariable analysis assessed predictors of Overall, Cancer-Specific (OS, CSS), and Disease-Free Survival (DFS). The relationship between VPI grade, other prognostic factors, and the site of recurrence (when it occurred) was also evaluated.

Results: Ninety-seven patients were included (PL1=55, PL2=42). The PL2 group had worse survival outcomes than PL1 ($p \leq 0.001$), independently of the pathologic stage ($p<0.05$). OS and CSS were significantly affected by PL2-VPI and high-grade histological patterns ($p<0.05$). PL2-VPI, with low differentiation grade (G3), also significantly affected DFS ($p<0.05$). Moreover, PL2-VPI was linked to high-grade patterns ($p=0.016$), lower differentiation grade ($p=0.005$), lymphovascular invasion ($p<0.001$), and higher distant recurrence incidence ($p=0.002$) than PL1-VPI.

Conclusions: PL2-LUADs showed worse survival outcomes and more frequent negative prognostic factors than PL1. These findings could help develop a scoring system to predict prognosis and determine the need for adjuvant therapy.

P2.08 .04 Open Versus Thoracoscopic Versus Robotic Sleeve Lobectomy for Central Non-Small Cell Lung Cancer: A Network Meta-Analysis

H. SHEN[1], S. Liu[1], F. Lyu[2], Z. Lin[3], J. Zhu[3], Z. Zhang[1], Z. Chang[1], Y. Xia[1], Y. Zhou[4], X. Cheng[3], J. Fan[1]
[1]The Second Affiliated Hospital Zhejiang University School of Medicine, Hangzhou/CN ,[2]Zhejiang Financial College, Hangzhou/CN ,[3]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN ,[4]Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou/CN

Introduction: Sleeve lobectomy is the preferred surgical approach for central non-small cell lung cancer (NSCLC), but the comparative efficacy of open thoracotomy, video-assisted thoracoscopic surgery (VATS), and robotic-assisted thoracoscopic surgery (RATS) remains unclear. This network meta-analysis (NMA) aims to compare the perioperative and long-term outcomes among these three techniques.

Methods: We systematically searched PubMed, Embase, and Cochrane Library up to December 2024 (PROSPERO ID: CRD42025626437). Included studies compared at least two surgical approaches (thoracotomy, VATS, or RATS) for central NSCLC sleeve lobectomy. Data on perioperative outcomes (operative time, blood loss, lymph node dissection, hospital stay, complications, etc.), and long-term survival (recurrence-free survival [RFS], overall survival [OS]) were extracted. The risk of bias was assessed using the Newcastle-Ottawa Scale (NOS). A random-effects NMA was performed using R and Stata.

Results: Thirteen retrospective cohort studies (1601 patients) were included: thoracotomy (65.3%, n=1045), VATS (27.9%, n=447), and RATS (6.8%, n=109). Eleven studies scored a 7 or 8 in NOS, whereas the other 2 studies scored a 6. As for the perioperative outcomes, RATS demonstrated the significantly reduced blood loss (51.4ml less than thoracotomy, 95% CI: -84.4 to -18.4ml; VATS vs. thoracotomy, -18.4 [-41.6, 4.8]), along with significantly reduced drainage volume (498.8ml less than thoracotomy, 95% CI: -784.3 to -213.3ml; VATS vs. thoracotomy, -381.0 [-512.0, -250.0]) and drainage duration (5.0 days less than thoracotomy, 95% CI: -5.1 to -2.5 days). RATS showed a trend toward shorter operative time (16.6min shorter than thoracotomy, 95% CI: -41.5 to 8.3min; VATS vs. thoracotomy, 40.0 [22.4, 57.7]), and hospital stay (1.1 days shorter than thoracotomy, 95% CI: -2.3 to 0.02 days; VATS vs. thoracotomy, -1.0 [-1.6, -0.4]). While lymph node dissection, positive surgical margins, complications, and mortality were observed comparable between RATS versus thoracotomy (p>0.05), and VATS was associated with the lowest complication rates (OR 0.67 vs thoracotomy, 95% CI: 0.48-0.94). Regarding long-term outcomes, RATS showed favorable trends in overall survival compared to both VATS (HR 0.73, 95% CI: 0.35-1.52) and thoracotomy (HR 0.53, 95% CI: 0.21-1.36), while recurrence-free survival showed no significant differences between approaches (RATS vs. VATS: HR 0.78, 95% CI: 0.36-1.68; VATS vs. thoracotomy: HR 0.83, 95% CI: 0.62-1.10).

Conclusions: Minimally invasive approaches (VATS/RATS) offer superior perioperative outcomes over open thoracotomy for central NSCLC sleeve lobectomy, with comparable long-term survival. RATS may further optimize intraoperative efficiency. Prospective trials are needed to validate these findings.

P2.08 .05 Robotic-Assisted Versus Video-Assisted Sleeve Lobectomy for Central Non-Small Cell Lung Cancer: A Multicenter Cohort Study

H. SHEN[1], Z. Lin[2], F. Lyu[3], S. Liu[1], J. Zhu[2], Z. Zhang[1], Z. Chang[1], Y. Xia[1], Y. Zhou[4], X. Cheng[2], J. Fan[1]
[1]The Second Affiliated Hospital Zhejiang University School of Medicine, Hangzhou/CN ,[2]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN ,[3]Zhejiang Financial College, Hangzhou/CN ,[4]Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou/CN

Introduction: Sleeve lobectomy has emerged as the standard of care for centrally located non-small cell lung cancer (NSCLC), offering superior lung preservation compared to pneumonectomy. While both robotic-assisted (RATS) and video-assisted (VATS) approaches are widely adopted, their comparative efficacy remains uncertain. This multicenter study evaluates perioperative and long-term outcomes between RATS and VATS sleeve lobectomy in a large, propensity-matched cohort.

Methods: This retrospective study analyzed 339 consecutive patients with stage I-III NSCLC undergoing RATS or VATS sleeve lobectomy between January 2015 and September 2024 across three high-volume centers in China. The propensity score matched balanced baseline characteristics. Statistical analyses were performed to evaluate the perioperative outcomes and survival between the two groups (ClinicalTrials.gov ID: NCT06687408).

Results: The entire multicenter cohort enrolled 339 patients with NSCLC undergoing RATS (n=83, 24.5%) or VATS (n=256, 75.5%) sleeve lobectomy comprising predominantly males (n=308, 90.9%), with mean age 62.6±8.0 years and 69.6% smokers. The histological distribution included squamous cell carcinoma (75.2%), adenocarcinoma (9.5%), and others (15.3%), with 34.8% receiving neoadjuvant therapy and 55.5% adjuvant therapy (median follow-up: 30.1 months). The cohort comprised 31.0% in stage I (n=105), 33.9% in stage II (n=115), and 5.1% in stage III (n=119). A total of 154 VATS cases were matched with 76 RATS cases by propensity score. Perioperative outcomes demonstrated significantly shorter operative time for RATS (194.9±61.1 vs. 208.3±65.7 minutes, p<0.0001), less blood loss (123.0±171.5 vs. 163.6±219.1mL, p<0.0001), shorter hospitalization (11.7±6.8 vs. 13.1±6.7 days, p<0.0001), and superior lymph node dissection (stations: 7.7 vs. 7.3, p<0.0001; nodes: 19.4±10.8 vs. 18.0±9.7, p<0.0001). RATS showed similar conversion rates (3.95% vs. 11.04%, p=0.08), comparable R0 resection (88.0% vs. 86.7%, p=0.85), and equivalent complications (22.4% vs. 20.8%, p=0.86). Long-term survival analysis revealed comparable 3-year OS (80.9% vs. 88.4%, HR 1.78, 95%CI 0.67-4.74) and RFS (68.6% vs. 72.9%, HR 1.38, 95%CI 0.73-2.63), with no significant difference in perioperative mortality (5.26% vs. 3.16%, p=0.48).

Conclusions: RATS demonstrated comparable perioperative safety and oncologic outcomes to VATS, with potential advantages in lymph node dissection and postoperative recovery. Preliminary findings support RATS as a viable alternative for central NSCLC resection, warranting further prospective validation.

P2.08 .06 Clinical Significance of Tertiary Lymphoid Structures in Surgically Resected Stage II-III Lung Adenocarcinoma

T. Nakamura, J. Matsubayashi, Y. Kawaguchi, H. Furumoto, Y. Kudo, Y. Kudo, Y. Shimada, M. Hagiwara, M. Kakihana, T. Ohira, N. Ikeda
Tokyo medical university, Tokyo/JP

Introduction: Tertiary lymphoid structure (TLS) is lymphoid follicle-like aggregates observed within or around tumor tissues, playing a critical role in activating antitumor immunity in the tumor microenvironment. In several cancer types, TLS has been reported as prognostic marker and as predictive biomarker for the efficacy of immune checkpoint inhibitors. Although TLS was reported to be a potential prognostic marker in locally advanced non-small cell lung cancer, the subset analysis in terms of histologic type was not performed.. This study aimed to evaluate the association between the presence of TLS and postoperative prognosis in patients with locally advanced lung adenocarcinoma.

Methods: A total of 151 patients who received surgery at Tokyo Medical University Hospital between 2017 and 2020 and were histologically confirmed to be stage II-III adenocarcinoma were retrospectively analyzed. TLS was identified in hematoxylin and eosin stained specimens and defined by the presence of lymphoid follicle-like structures containing tingible body macrophage. The association between TLS and survival outcome was examined.

Results: Lobectomy was performed in 145 patients (96.0%) and segmentectomy in 6 (4.0%) respectively Lymph node metastasis was histologically confirmed in 101 patients (66.9%) and there were 79 stage II cases (52.3%) and 72 stage III cases (47.7%). TLS was detected in 42 patients (27.8%). The median recurrence-free survival (RFS) for the entire cohort was 40.0 months and median RFS was 30.4 months in the TLS-negative group and 47.9 months in the TLS-positive group (hazard ratio [HR]: 0.50; 95% confidence interval [CI]: 0.28-0.89; p = 0.015). The median overall survival (OS) for the entire cohort was 82.5 month and median OS was 65.7 months in the TLS-negative group and not reached in the TLS-positive group (HR: 0.61; 95% CI: 0.29-1.27; p = 0.181). In multivariate analysis for RFS, the presence of TLS (HR: 0.49; 95% CI: 0.280-0.872; p = 0.015) and absence of lymph node metastasis (HR: 0.52; 95% CI: 0.305-0.881; p = 0.015) showed favorable prognosis.

Conclusions: The presence of TLS was favorable prognostic marker in patients with resected stage II-III lung adenocarcinoma.

P2.08 .07 Lymph Node Yield and Survival Among Lung Cancer Patients Treated With Neoadjuvant Systemic Therapy

G. Caturegli, M. Canavan, O.F. Ayoade, B.J. Resio, D.J. Boffa
Yale University School of Medicine, New Haven/CT/USA

Introduction: Lymph node yield during resection of non-small cell lung cancer (NSCLC) has been positively associated with long-term survival, thus a current standard dictates that four nodal stations be sampled in surgically managed lung cancer patients. One rationale for accurate nodal staging has been to identify patients who may benefit from systemic therapy. Our objective was to determine the relationship between lymph node yield and survival among patients receiving pre-operative systemic therapy.

Methods: Adult patients diagnosed with clinical Stage II or III NSCLC between 2010 and 2021 in the National Cancer Database (NCDB) who received chemotherapy, chemoradiotherapy, or chemoimmunotherapy in the 20 weeks leading up to resection were included. Patients were stratified by nodal yield: 0 nodes, 1-3 nodes, 4-9 nodes, or 10 or more nodes. Three-year overall survival was assessed by the Kaplan-Meier method. Propensity-matching for survival curves and Cox proportional hazards models were adjusted for year of diagnosis, age, sex, race, ethnicity, Charlson-Deyo score, insurance, region, facility type, histology, neoadjuvant treatment type, extent of resection, and clinical T and N stage.

Results: Overall, 8631 patients were identified, including 2512 (29.1%) clinical stage II patients and 6119 (70.9%) stage III. The most common neoadjuvant treatment was chemoradiotherapy (4306, 49.9%), and 7228 (83.7%) underwent lobectomy. The median nodal yield was 12 (IQR 7-18), with 329 (3.8%) removing 0 nodes, (7.0%) removing 1-3 nodes, 2273 (26.3%) with 4-9 nodes, and 5422 (62.8%) with 10 or more nodes. Compared to 10 or more nodes in a Cox model, mortality risk was higher for 4-9 nodes (HR 1.09, 95% CI 1.00-1.19, p=0.04) and 1-3 nodes (HR 1.19, 95% CI 1.03-1.36, p=0.02), but similar for 0 nodes (HR 0.87, 95% CI 0.71-1.06, p=0.17, Figure 1A). Among propensity-matched patients, three-year survival following the removal of 10 or more nodes was superior to taking 4-9 nodes (65.7% vs. 62.2%, p=0.02, Figure 1B), but not significantly different to 1-3 nodes (61.9% vs. 58.5%, p=0.18, Figure 1C) or 0 nodes (61.8% vs. 67.4%, p=0.13, Figure 1D).

Conclusions: Lung cancer patients in whom greater than 10 nodes were removed demonstrated a modest survival advantage on multivariable analysis compared to those for whom only 1-3 or 4-9 nodes were removed. Further research is needed to clarify the importance of nodal yield after preoperative systemic therapy.

Figure 1: A) direct adjusted survival curves of Cox proportional hazards model comparing: 0 nodes vs. 1-3 nodes vs. 4-9 nodes vs. 10 or more nodes removed; B) propensity-matched 3-year overall survival curves comparing 10 or more nodes to 4-9 nodes; C) propensity-matched 3-year overall survival curves comparing 10 or more nodes to 1-3 nodes; D) propensity-matched 3-year overall survival curves comparing 10 or more nodes to 0 nodes.

P2.08 .08 Treatment Options and Prognosis for Lung Cancer in Elderly Patients(?80 Years Old)

M. Shinoda, F. Watanabe, K. Adachi, S. Kokawa, D. Morita, S. Iwanaka, Y. Sakakura, T. Nishimura, M. Naito
Nho Mie Chuo Medical Center, Tsu-city/JP

Introduction: According to an official report, the average life expectancy in Japan in 2023 is 81.0 years for men and 87.14 years for women, with the percentage of patients who live to be 90 years old being 26.0% for men and 50.1% for women. Recently, the number of patients undergoing surgical treatment has been increasing; however, once complications occur, they can be serious. Even in the absence of complications, the actual prognosis may be shorter than the predicted life expectancy due to the after-effects of surgery. Other treatment options include cytotoxic chemotherapy, stereotactic radiotherapy, epidermal growth factor receptor-tyrosine kinase inhibitor(EGFR-TKI), and immune checkpoint inhibitors (ICI). Some patients opt for Best Supportive Care (BSC) due to the risk of death from other diseases.

Methods: We retrospectively reviewed the medical records of 244 patients aged 80 years or older, who were pathologically diagnosed with lung cancer between January 2012 and December 2023. We investigated the prognosis of surgical cases, non-operative cases, and BSC cases. For surgical cases, we considered the appropriate age, expected life expectancy, and the type of surgical procedure. Tumor size and lymph node metastasis, as described in the pathology reports, were reclassified according to the UICC 8th edition. We have evaluated EGFR gene mutations since 2014 and programmed cell death ligand-1(PD-L1) expression since 2017.

Results: A total of 244 patients (163 men and 81 women) were enrolled in this study. Of these, 79 underwent pulmonary resection, 80 received non-operative treatment, and 85 chose BSC. Lobectomy (n=51) was the most common surgical procedure, followed by segmentectomy (n=18), wedge resection (n=8), and pneumonectomy (n=2). Postoperative complications in the surgical group included two cases of empyema, one bronchial stump fistula, one cerebral infarction, and one pneumonia, all of which occurred after lobectomy. Non-operative treatments included 45 cases of cytotoxic chemotherapy, 21 cases of radical irradiation, 26 cases of EGFR-TKI, and 1 case of ICI. In stage I lung cancer, the 5-year survival rate was 65% for surgical treatment, 45% for non-operative therapy, and 0% for BSC, with the surgery group having the highest 5-year survival rate. The same trend was observed for stages II and III. Confined to women, the 5-year survival rate was high (>85%) for surgical treatment, regardless of stage. In contrast, for men, the 5-year survival rate was only 55%, even for stage I lung cancer. We further investigated surgical procedures in men and found that the 5-year survival rate was highest for segmentectomy, followed by lobectomy, wedge resection, and pneumonectomy. Lobectomy in elderly men may impose greater surgical stress than survival benefits.

Conclusions: The elderly women who underwent surgery had a high 5-year survival rates similarly to those of patients under 80 years old. In contrast, men who underwent lobectomy had only a 55% 5-year survival rate, suggesting that sublobar resection, rather than lobectomy, should be considered for elderly men based on life expectancy.

P2.08 .09 Surgical Resection After Induction Therapy in Initially Unresectable Driver Mutation-Negative Stage III Non-Small Cell Lung Cancer (NSCLC)

H. Guo[1], X. Yang[1], J. Zhang[1], J. Ding[1], Z. Zhou[2], J. Kang[1], J. Lin[1], R. Liao[1]
[1]Guangdong Provincial People's Hospital, Guang Zhou/CN ,[2]Shenzhen Third People's Hospital, Shenzhen/CN

Introduction: With the significant improvement in the efficacy of drug therapy, some patients initially diagnosed with locally advanced unresectable non-small cell lung cancer (NSCLC) may become eligible for surgical resection after induction therapy. However, the survival benefit of this conversion therapy model (from unresectable to resectable) has not been conclusively established, particularly for patients who do not undergo systematic contralateral mediastinal and supraclavicular lymph node dissection during surgery, where the survival advantage remains controversial.

Methods: This study retrospectively enrolled 39 patients with stage III NSCLC who underwent surgical resection at Guangdong Provincial People's Hospital between January 2018 and April 2023 and met the study criteria. All included patients received at least two cycles of immune checkpoint inhibitor (ICI) monotherapy or combination chemotherapy as induction therapy, followed by surgical resection. The primary surgical approach involved resection of the primary lung lesion combined with ipsilateral systematic mediastinal lymph node dissection.

Results: Among the 39 patients ultimately included in the study, the objective response rate (ORR) to induction therapy was 64.1% (25/39). The major pathological response (MPR) and complete pathological response (pCR) rates in the primary lesion were 42.1% (16/38; 95% CI: 17.5%-48.7%) and 31.6% (12/38; 95% CI: 26.3%-59.2%), respectively. The median follow-up time for the entire cohort was 27.0 months (range: 6.0-80.6 months), with a median PFS of 42.0 months. The 2-year PFS and overall survival (OS) rates were 76.2% (95% CI: 54.9%-89.8%) and 89.3% (95% CI: 72.8%-96.8%), respectively.Patients who achieved a major pathological response (MPR) demonstrated significantly prolonged PFS and OS compared to those without MPR (PFS: Not reached vs. 28.0 months (18.5-35.2); HR: 0.128 (95% CI: 0.037-0.443); P = 0.018; OS: Not reached vs. 37.0 months (28.4-45.6); HR: 0.19 (95% CI: 0.041-0.87); P = 0.032). Additionally, patients who achieved ypN0 status on postoperative pathology demonstrated significantly superior PFS compared to non-ypN0 patients (median PFS: not reached vs. 12.0 months [8.4-15.6]; HR: 0.106 [95% CI: 0.023-0.503]; P<0.0001). Among patients with N3 disease, no statistically significant differences in PFS or OS were observed between those who received postoperative adjuvant radiotherapy and those who did not (median PFS: 30.0 vs. 28.0 months, HR: 0.808 [95% CI: 0.219-2.972], P=0.71; median OS: not reached vs. 59.0 months, HR: 0.728 [95% CI: 0.098-5.426], P=0.76).

Conclusions: The findings of this study suggest potential survival benefits from surgical resection in patients with stage N3 NSCLC who achieve both MPR and ypN0 status following induction therapy.

P2.08 .10 Perioperative Outcomes of Extended Sleeve Resection at Our Institution

C. Kanno
Kanagawa Cancer Center, Kanagawa/JP

Introduction: Following the results of the CheckMate816 and KEYNOTE671 trials, the use of neoadjuvant chemotherapy has increased. The benefits of preoperative treatment include improved surgical safety due to tumor shrinkage, higher rates of complete resection, and the possibility of preserving lung Volume. Given the inclusion of advanced lung cancer, there is an increasing opportunity for extended surgical procedures, leading to a reevaluation of surgical techniques. This study aims to retrospectively examine the perioperative outcomes of patients who underwent Extended Sleeve Resection at our hospital.

Methods: Between January 2010 and December 2024, 39 cases of extended sleeve resection were performed among 4,495 patients who underwent surgery for primary lung cancer. We retrospectively analyzed perioperative outcomes, including the frequency of postoperative complications. The Extended Sleeve Resections were classified as Type A (right upper and middle lobe ± S6 segment), Type B (left upper lobe + S6 segment), Type C (left lower lobe + lingular segment), Type D (right middle and lower lobe), and others based on previous reports.

Results: The study included 29 males (74%), with a median age of 70 years (range 42-85). 12 patients have history of diabetes (30%), and 33 patients (85%) had a smoking history. The clinical stages were as follows: Stage II/III/IV:12(31%) / 25(64%) /2(4%) patients. The median tumor size was 5.2 cm (range 1.2-12). The median %VC and FEV1.0% was 105% (range 67-128), and 68.5% (range 39.2-80.4). Induction chemotherapy was performed 10 cases, and preoperative radiation therapy was 1 case. All surgeries were performed by open thoracotomy and achievement R0 resection. The mean operative time was 261 minutes (range 166-442). The surgical types included Type A (9), Type B (8), Type C (16), and Type D (5) cases. 10 cases were received Pulmonary artery reconstruction at the same time. Pathological diagnoses included adenocarcinoma in 16 cases, squamous cell carcinoma in 17 cases. The pathological stages were Stage I/II/III :5(13%) /15(38%) /19(49%) patients. 14 patients received adjuvant chemotherapy. Common Terminology Criteria for Adverse Events (CTCAE) Grade 3 or higher perioperative complications occurred in 18 cases (46%), while respiratory complication including atelectasis and sputum retention in 8, pneumonia in 3, pneumothorax in 8, bronchial fistula in 1, pulmonary artery thrombosis in 1, chylothorax in 1, postoperative bleeding in 1, empyema in 3 cases. Among the complications, 4 cases required re-operation, of which 2 cases (5.1%) ultimately required completion pneumonectomy. There were 2 cases of postoperative death within 30 days (5.1%).In terms of frequency of complications by surgical technique, there were 4 cases (44%) in A, 5 (63%) in B, 6(38%) in C, and 2(40%) in D, with no statistically significant difference.

Conclusions: We retrospectively analyze the perioperative outcomes of Extended Sleeve Resection at our Hospital. Perioperative results in this study were comparable to previously reported results. While Grade III or higher anastomotic complications were limited to one case. The short-term perioperative outcomes were generally favorable, suggesting that Extended Sleeve Resection is a valuable technique for avoiding pneumonectomy.

P2.08 .11 Management of High-Grade Endobronchial Pre-Invasive Lesion: To Treat or Not to Treat?

I. Smesseim[1], A. Pennycuick[2], R.A. van Boerdonk[3], S. Janes[2], J.M.A. Daniels[3]
[1]Netherlands Cancer Institute, Amsterdam/NL ,[2]University College London, London/GB ,[3]Amsterdam University Medical Center, Amsterdam/NL

Introduction: High-grade pre-invasive endobronchial lesions have the potential to progress to squamous cell carcinoma (SCC), but their natural history varies considerably. As a result, the optimal management of these lesions is controversial, with treatment strategies varying across institutions due to lack of consensus. This study aims to compare the progression free survival (PFS) and overall survival (OS) outcomes between patients who received endobronchial treatment and those who were managed with surveillance alone.

Methods: We conducted a retrospective cohort study across two oncology centers: University College London Hospitals (UCLH, United Kingdom) and Amsterdam University Medical Center (AUMC, The Netherlands). Patients with high-grade pre-invasive lesions detected via autofluorescence bronchoscopy (AFB) underwent surveillance with repeat bronchoscopy and CT scans. At AUMC, patients routinely received endobronchial treatment (primarily diathermy), whereas at UCLH, treatment was reserved for cases that progressed to SCC. The primary outcome was PFS and the secondary outcome was OS. Survival was analyzed using Kaplan-Meier curves and Cox proportional hazards regression, adjusting for potential confounders.

Results: Between 1998 and 2007, a total of 85 patients were included in the study: 34 (40%) received endobronchial treatment, while 51 (60%) did not. There was a significant difference in histological distribution between the two groups: the untreated group had a higher proportion of carcinoma in situ (CIS) compared to the treated group (78.4% vs. 38.2%, p = 0.001). Additionally, patients in the untreated group were significantly younger than those who received treatment (median age: 67.0 vs. 77.0 years, p = 0.001). The overall median follow-up time was 46.2 months (IQR: 21.6-91.5). Endobronchial treatment was associated with a significantly reduced risk of disease progression (HR = 0.39, 95% CI: 0.21-0.73, p = 0.002). Median PFS was 71.0 months (IQR: 55.0-NA) in the treated group, compared to 38.0 months (IQR: 21.0-54.0) in the untreated group (p = 0.002). Treatment was also associated with improved OS, reducing the risk of mortality by 52.8% (HR = 0.47 95% CI 0.26-0.87, p = 0.015).

Conclusions: Our study demonstrated that endobronchial treatment significantly improved PFS and OS in patients with high-grade pre-invasive endobronchial lesions. However, the untreated cohort had a higher proportion of CIS compared to the treated group, raising the possibility that these patients were further along in their disease trajectory, which may have contributed to worse PFS outcomes. A randomized controlled trial is needed to further evaluate whether early intervention in this patient population can lead to improved survival.

Introduction: Patients receiving salvage treatment for thoracic nodal recurrence (tnR) had similar survival to those with de novo stage III disease,so salvage therapy should ideally mimic that for de novo unresectable NSCLC.The objective of this trial was to assess local control (LC) and safety of salvage stereotactic ablative radiotherapy (SAbR) according to the START NEW ERA phase II trial (Clinical trials.gov NCT05291780) in tnR NSCLC patients after initial surgery (1).

Methods: Patients with tnR after previous surgery were enrolled. After PACICIF trial publication neoadjuvant chemotherapy (ChT) was prescribed in PD-L1 fit patients in order to offer immunotherapy (IO) consolidation. The tumor volume included any regionally positive node/s (N) based on PET-CT. Hepilor gel and kariosyte mouthwash were recommended in order to prevent dysphagia and esophagitis.The co-primary study endpoints were LC and safety.

Results: Between 2015 and 2024 32 patients with tnR from NSCLC after surgery were enrolled.Histology was adenocarcinoma and squamous cell carcinoma in 81% and 19%. 8(22%)received neoadjuvant ChT and 4(13%)IO consolidation. The median prescribed dose was 40Gy (35-50) in 5 daily fractions. After a median follow-up of 32 months (4-89), 3(10%) patients had experienced local recurrence (LR). The median LR-free survival (FS) was not reached (95% CI,- to not reached). The 1-,2-,and 3-year LR-FS was 92±5%,82±8%,and 74±11%,respectively. 11(34%)had out-field regional recurrence (outf-tnR) and were submitted to new SAbR on the out-field nodal recurrence site. The median outf-tnR-FS was not reached (95% CI, 28 to not reached). The 1-,2-,and 3-year outf-tnR-FS was 92±5%,82±8%,82±8%. 14(44%) developed distant progression (dP). The median dP-FS was not reached (95% CI,14- to not reached). The 1-,2-,and 3-y dP-FS was 88±6%,61±10%,and 55±11%. The median PFS was 33 months (95%CI,14 to 34). The 1-,2-,and 3-y PFS was 85±7%,54±10%,and 38±11%. At last follow-up, 23(72%) patients were alive. Median overall survival (OS) was 73 months (95% CI, 53-73 months). The 1-,2-,and 3-y OS was 88±6%,78±8%,and 73±9%. No patients experienced ≥ grade (G) 3 toxicity.

Conclusions: Patients with thoracic nodal recurrence from NSCLC after initial surgery and treated with salvage SAbR according to the START NEW ERA phase II trial had optimal LC and promising OS without ≥G3 toxicity. Our outcomes suggest the efficacy and safety of using this approach in thoracic nodal recurrence NSCLC patients in the place of concurrent ChT-RT. Prospective studies are warranted to investigate the association of SAbR with immunotherapy in this setting of patients.

P2.08 .13 Radiation Dose to the Heart and Cardiac Substructures Associated With Adverse Cardiac Events in Locally-Advanced Non-Small Cell Lung Cancer

E. Harris[1], H-I. Yoon[2], Y. Chung[3], D. Neish[1], G. Kim[1], P. Karukonda[1], Y. Cui[1], D. Niedzwiecki[1], J. Christensen[1], D. Labella[1], J. Crawford[1], C. Kelsey[1]
[1]Duke University Medical Center, Durham/NC/USA ,[2]Yonsei Cancer Center, Seoul/KR ,[3]Hanyang University, Seoul/KR

Introduction: Patients with locally-advanced non-small cell lung cancer (NSCLC) are at high risk of developing cardiac complications after concurrent chemoradiotherapy (ChT-RT). While mean heart dose is important, more recent studies have focused on dose to individual cardiac substructures. This study assessed the risk of major adverse cardiac events (MACE- unstable angina, coronary revascularization, myocardial infarction, congestive heart failure, or cardiac death), atrial fibrillation, and all cardiac arrhythmias based on extensive clinical and dosimetric variables.

Methods: All patients completing a course of ChT-RT for stage II-III NSCLC from 2007-2021 at Duke University Medical Center were included. Clinical data including baseline cardiac risk factors (e.g., hypertension [HTN], familial hypercholesterolemia [FH], diabetes mellitus [DM], tobacco use), co-morbid cardiac conditions, and post-treatment cardiac events were extracted. The heart and 15 cardiac substructures were contoured on contrast-enhanced planning CT scans. The cumulative incidence of cardiac events was estimated using the Fine-Gray subdistribution hazard model accounting for the competing risk of non-cardiac mortality. Multivariable Fine-Gray subdistribution hazards regression using a backward stepwise feature selection technique was performed to evaluate the association between clinical and dosimetry metrics and cardiac events. Progression-free (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method.

Results: 320 patients evaluable. Median age: 66 (range, 33-87). M/F: 54%/46%. Baseline incidence of HTN, FH, DM, and tobacco use were 57%, 42%, 24%, and 50%, respectively. Baseline cardiac disease present in 99 patients (31%), most commonly coronary artery disease (n=59, 18%) and atrial fibrillation (n=29, 9%). RT technique: 3D- 47%; IMRT-53%. Median dose: 60 Gy (range, 58-74 Gy). Chemotherapy regimens: carboplatin/paclitaxel (n=143, 45%), cisplatin/etoposide (n=90, 28%), other (n=87, 27%). Adjuvant immunotherapy: 82 (26%). With a median follow-up of 46 months for surviving patients, cardiac events developed in 64 patients after ChT-RT. Accounting for the competing risk of mortality, the 5-year actuarial incidence was 18%. The 5-year risk of MACE, atrial fibrillation, and all cardiac arrhythmias was 8.4%, 6.9%, and 11.7%, respectively. The variables associated with MACE in multivariable regression were 3D RT technique (HR 3.93, 95% CI 1.96-7.90, p<0.001) and adjuvant immunotherapy (HR 2.73, 95% CI 1.39, 5.36, p=0.004). For atrial fibrillation, increasing pulmonary artery V25 (HR 1.02, 95% CI 1.01-1.04, p=0.003) was associated with a higher risk and cisplatin/etoposide (HR 0.25, 95% CI 0.07-0.91, p=0.036) was associated with a lower risk compared with carboplatin/paclitaxel. For all cardiac arrhythmias, increasing pulmonary artery V15 was the only factor associated with a higher risk (HR 1.02, 95% CI 1.01-1.04, p=0.002). PFS and OS at 5 years were 23% and 28%, respectively. All-cause mortality was higher with increasing mean heart dose (HR 1.02, 95% CI 1.01-1.04, p=0.002) and lower with adjuvant immunotherapy (HR 0.56, 95% CI 0.42-0.76, p<0.001).

Conclusions: This study demonstrates that treatment-related variables (chemotherapy regimen, utilization of immunotherapy, and radiation dosimetry to the heart and specific cardiac substructures) were more strongly associated with post-ChT-RT cardiac events than baseline cardiac risk factors in patients with locally-advanced NSCLC. Radiation dose to the pulmonary artery was most strongly associated with cardiac arrhythmias, including atrial fibrillation.

Introduction: Gross tumor volume (GTV) changes during online MR-guided stereotactic body radiotherapy (oMRgSBRT) for lung tumors are poorly characterized. We investigated GTV changes during multifraction oMRgSBRT on a 0.35T MR-Linac.

Methods: GTV changes between simulation (SIM) and first fraction (F1) and all fractions were recorded. Paired Wilcoxon signed-rank tests were used for intra-patient comparisons. Logistic and linear regression models were used for feature-associated variables. The cumulative incidence of local failure (LF) and tumor progression were calculated using cumulative incidence functions (CIF). Area Under the Receiver Operating Characteristic Curve (AUROC) analysis was used to evaluate the performance of a binary classification model.

Results: 53 tumors were treated (215 fractions). The median SIM-F1 interval was 8 days (2 - 42 days). Median GTVs at SIM and F1 were 4.60 cc (range, 0.48 - 49.13 cc), and 4.81 cc (range, 0.70 - 50.57 cc) respectively ($p < 0.05$). Mean GTV ?SF1 (GTV difference between SIM and F1) was +7.25%. In total, 52.83% of GTVs decreased at the last fraction vs F1. Linear regression analysis revealed a significant association between the relative ?SF1 and baseline characteristics, age at initial diagnosis (Pearson correlation coefficient: -0.319, p-value: 0.02), former or current smoker (regression coefficient: -0.09, p-value: 0.012), and the ECOG PS (regression coefficient: -0.11, p-value: 0.047). GTV variations of ? 10%, and ? 20% occurred in 71.11%, and 37.77% between F1 and the final fraction. There was no significant difference in cumulative incidence of LF or progression after oMRgSBRT when stratified by treatment indication (primary lung cancer vs. lung metastases).

Conclusions: Inter-fractional GTV changes are common and may be predicted by baseline characteristics. Daily plan adaptation is pertinent for ensuring adequate target volume coverage and OAR sparing. A mean GTV increase of 7.25% between SIM-F1 indicates that short intervals are desirable.

P2.08 .15 Cardiac Prioritized Planning in Locally Advanced Non-Small Cell Lung Cancer: Comparison of Modern RT Techniques

O. Bascik[1], Y. Arslan[1], I. Kar[1], S. Akyurek[1]
[1]Ankara University, Ankara/TR

Introduction: Our aim in this study is to perform cardiac-prioritized planning using modern radiotherapy (RT) techniques in the treatment of locally advanced non-small cell lung cancer (LA-NSCLC) and to compare these plans in terms of cardiac exposure, doses to other organs at risk, and target doses.

Methods: This retrospective study included 91 patients who received definitive RT for LA-NSCLC between 2022 and 2023. For each patient, three different planning techniques were implemented: IMRT, VMAT, and hybrid (a combination of IMRT and VMAT in a 1:1 ratio). During planning, the following dose constraints were used: heart mean dose (Dmean) <26 Gy, V30<50%; left anterior descending coronary artery (LAD) V15<10%; lung Dmean<20 Gy, V20<35%, V5<60%; esophagus Dmean<34 Gy; spinal cord Dmax<50 Gy.

Results: Tumor, target, and organ volumes are presented in Table 1. For each patient, 19 dosimetric parameters were calculated for IMRT, VMAT, and hybrid plans, and the statistical significance of comparisons among these values is summarized in Table 2. The IMRT technique provided the lowest dose exposure to critical organs such as the heart and LAD, while higher doses were observed with the VMAT technique. In terms of lung doses, IMRT also resulted in the lowest, and VMAT in the highest exposure. Additionally, IMRT and hybrid planning were found to be superior to VMAT in terms of target volume coverage (PTV V95) and plan conformity. All findings were statistically significant.

Conclusions: IMRT planning was found to deliver lower cardiac and lung doses compared to VMAT. In addition to the dose advantage, IMRT plans were also superior in terms of target parameters such as PTV V95 and conformity index. Therefore, we believe that IMRT planning can be prioritized in cardiac-focused planning for LA-NSCLC patients due to its dosimetric advantages.

Table 1. Patients' Tumor, Target, and Organ Volumes (cc)

	Mean±SD	Median (Min-Max)
GTV	135,3±108,8	101,0 (7,1–499,2)
CTV	333,8±190,9	280,0 (54,0-1109,9)
PTV	626,0±298,9	562,0 (136,4-1691,7)
LAD Volume	6,2±2,2	5,6 (3,1-13,8)
Heart Volume	713,2±142,6	701,4 (430,7-1134,6)
Lung Volume	3932,6±943,6	3842,6 (1884,0-6668,4)
(Lung-GTV) Volume	3905,9±944,5	3797,1 (1884,0-6612,2)
Heart and PTV Overlap Volume	19,8±20,9	14,2 (0,0-111,9)

P2.08 .16 National Real-World Data on the Treatment of Locally Advanced NSCLC With Chemoradiotherapy and Adjuvant Durvalumab

M. Vrankar, K. Stanic, S. Jelercic, E. Ciric, D. Casar, M. Peternel, N. Dobnikar, J. Jasna But Hadzic
Institute of Oncology, Ljubljana/SI

Introduction: Adjuvant durvalumab after chemoradiotherapy (ChRT) is the standard treatment for patients with locally advanced non-small cell lung cancer (LA-NSCLC) with PD-L1 positive tumours. We present national results of treatment of patients with LA-NSCLC in Slovenia.

Methods: We retrospectively reviewed the medical records of patients with LA-NSCLC treated with definitive ChRT and adjuvant durvalumab from December 2017 to December 2022 at the Institute of Oncology Ljubljana. We evaluated patient outcomes according to demographic factors and treatment characteristics. The survival outcomes were calculated using Kaplan - Meier actuarial survival methods. Overall survival (OS) was calculated from the start of durvalumab treatment until death from any cause or last follow-up on 13 March 2025.

Results: The majority of the 175 patients included (119 men, 56 women), with a median age of 64 (36-76) years, were current or former smokers (97.1%). Most patients (56%) had a squamous cell carcinoma. Only 7.4% of patients had unknown PD-L1 status and 44% of all patients had PD-L1 expression ≥ 50%. Most patients (68%) were treated with platinum-based induction chemotherapy with gemcitabine followed by concomitant etoposide/cisplatin and 17.1% were treated with pemetrexed/cisplatin. Concurrent chemotherapy was administered in 77.7% of patients and 88% of patients were irradiated with a dose ≥ 60 Gy. The median time from the end of RT to the start of durvalumab treatment was 48 days (range 4 - 130). Treatment with durvalumab completed 45.1% of patients and 25.7% discontinued treatment due to toxicity. Pneumonitis was the most common toxicity in 18.9% of patients. After a median follow-up time of 56 months, the median progression free survival was 23 months (CI 18.3-27.6). The median OS was 52 months, 2-year survival 68.5%, 3-year survival 57.5% and 5-year survival 42.2%. In univariate analysis, there were no differences in median OS according to gender, performance status, TNM stage, histology, PD-L1 expression, type and number of chemotherapy cycles, and radiation dose. Compared to older patients (median age), younger patients had significantly longer median OS, 69 months vs 34 months (p<0.000) and 5-year survival (47.8% vs 29.9%). We observed significantly longer median OS in patients that started durvalumab within 48 days compared to patients starting durvalumab 49 days or later after RT, 57 months vs 34 months (p=0.043), and 5-year survival (46.6% vs 37%).

Conclusions: Our survival data confirmed the results of the Pacific trial and validated the significant survival benefit of durvalumab consolidation treatment in unresectable LA-NSCLC patients,

P2.08 .17 Differential Cardiac Dose Evaluation and the Need of Planning Risk Volume (PRV) Margin for the Heart

K. Raja M, N. Thakur, Y. D, M. Kumar, P. Thakur
All India Institute of Medical Sciences, Bilaspur, Bilaspur/IN

Introduction: The heart, a key organ at risk in thoracic radiotherapy, undergoes motion due to cardiac contractions and respiration. During expiration, it shifts upward, and during inspiration, it moves downward, leading to displacement and volume changes. These movements cause variations between planned and actual cardiac doses. While 4D CT captures respiratory motion, no standardised guidelines exist for measuring cardiac dose on a specific CT phase or dataset. This lack of standardization complicates accurate cardiac dose assessment and management, posing challenges in optimizing radiotherapy planning and minimizing cardiac exposure

Methods: A total of 54 lung cancer patients (all the patients had tumours in the upper lobe and hilar region) who underwent 3D and 4D CT simulation, all treated with VMAT plans, were analyzed using 3D CT, Maximum intensity projection (MIP 4D), inspiratory (INS 4D), and expiratory (EXP 4D) phases of 4D datasets for the heart dose variation and motion. The displacement of the center of the mass (COM) of the heart in all three directions (left-right (LR), superior-inferior (SI) and anterior and posterior (AP)), mean heart dose and cardiac substructure doses were calculated and correlated with tumour location across different lung lobes to understand dose variations.

Results: The atrium and great vessels' motion (in millimetres) in LR, SI, and AP directions were 2(1.2-4.8), 4.5(1.5-6), and 1.4(0.8-4.1) respectively. The ventricular motion was about 2.5(1.1-4.2), 4.5(1.5-6) and 1.4(0.8-4) in the LR, SI, and AP directions. The whole heart motion was about 1.7 (1.1-3.3), 3.8 (1.5-6), and 1 (0.7-1.8) in the LR, SI, and AP directions. For patients who had upper lobe tumour alone (22 patients), the mean heart dose varied (in ratio) between EXP vs 3D CT, EXP 4D vs MIP 4D and EXP 4D vs INS 4D was about 1.1(1.05-1.26), 1.09(1.06-1.13) and 1.26 (1.15-1.39) and the patients with both upper lobe and mediastinal lymphadenopathy (or) hilar tumour (32 patients), it was about 1.09(1-1.22), 1.08(0.97-1.1) and 1.08 (1.02-1.14) respectively. The mean dose differences (in ratio) between atrium and ventricle (in 3D CT) for upper lobe and upper lobe with mediastinal lymphadenopathy (or) hilar tumour patients were 4.15 (3.01-10.93) ($p>0.001$) and 4.16 (1.77-6.52) ($p>0.023$) respectively.

Conclusions: Respiratory motion significantly impacts cardiac dose variation in thoracic radiotherapy. To account for this, applying a planning risk volume (PRV) margin (LR-1.7mm, SI-3.8 mm and AP-1 mm) to the whole heart is essential, as each cardiac substructure contracts at different timings, but the net impact is collective. Additionally, lung lobe-specific heart dose evaluation is crucial. For upper lobe tumours, heart dose measured on expiration (EXP) 4D CT is more accurate, as it shows approximately 10% higher doses compared to conventional 3D CT. Conversely, for lower lobe tumours, inspiration (INS) 4D CT may be more appropriate. Moreover, tumour location greatly influences substructure doses; for example, in the upper lobe and hilar tumours, the atrium receives a significantly higher dose (median dose about 415%($p<0.001$) and 416%($p<0.023$)) as compared to the ventricle. Therefore, cardiac substructure-based dose constraints are likely more reliable than whole-heart volumetric constraints.

P2.08 .18 Evaluation of Target Volume Delineation Variability in NSCLC Radiotherapy

F. Gabrielli[1], L. Faroni[2], M. Nassif[3], G. Reis de Jesus[4], A. Rosa[5], I. Rebouças[6], J. Matiello[7], V. Xavier[8], A. Jacinto[9], I. Veras[10], P. Lazaro de Moraes[11], S. Sala[12], F. Moraes[13]
[1]ICESP - São Paulo Cancer Institute, Sao Paulo/BR ,[2]Oncologia D´Or, Rio De Janeito/BR ,[3]Moinhos de Vento, Porto Alegre/BR ,[4]Oncologia D´Or, São Paulo/BR ,[5]Oncoclínicas, Salvador/BR ,[6]Liga Norte Riograndense contra o Câncer, Natal/BR ,[7]Santa Casa de Porto Alegre, Porto Alegre/BR ,[8]Oncologia D´Or, Brasília/BR ,[9]Hospital do Amor, Barretos/BR ,[10]CRIOS, Fortaleza/BR ,[11]Beneficência Portuguesa, São Paulo/BR ,[12]Hospital Felício Rocho, Belo Horizonte/BR ,[13]Queens University, Kingston/ON/CA

Introduction: To evaluate inter-observer variability in target volume delineation for locally advanced non-small cell lung cancer (NSCLC) radiotherapy and examine the impact of available technological and multidisciplinary resources.

Methods: A combined survey and contouring exercise was performed among radiation oncologists from multiple centers in Brazil. Twenty-five radiation oncologists with expertise in lung cancer from 25 facilities and diverse regions participated in an online survey regarding epidemiology and technological resources and a subsequent contouring session during a conference. Participants received anonymized imaging datasets—including PET-CT, a 10-phase 4DCT study with average and maximum intensity projection reconstructions, and pre-contoured organs at risk—and delineated target volumes using Varian Eclipse v.16 according to their routine clinical practice. Sixteen groups were formed, and data from 12 groups were analyzed due to technical issues, with contour similarity assessed via the Dice similarity coefficient.

Results: Of the 16 groups formed, 4 were excluded because of technical problems, leaving 12 groups for analysis. The original planning target volume (PTV) measured 501 cm^3, while the mean delineated volume was 230.8 ± 88.2 cm^3, indicating a systematic underestimation of target volumes. The overall Dice similarity coefficient averaged 0.58 ± 0.14, with values ranging from 0.28 to 0.75, reflecting moderate agreement among observers. Variability was most pronounced in regions adjacent to organs at risk, suggesting that the proximity of critical structures may complicate accurate delineation. An observable trend indicated that increased clinical experience might be associated with higher contour accuracy, although this was not statistically verified.

Conclusions: The significant inter-observer variability in NSCLC target volume delineation underscores the need for standardized contouring protocols and enhanced training initiatives. Improved access to advanced imaging technologies and a more integrated multidisciplinary approach may mitigate these discrepancies, potentially leading to better treatment planning and patient outcomes. These findings have important implications for clinical practice and suggest that future policies should support the adoption of uniform delineation guidelines.

P2.08 .19 Proton Beam Therapy for Lung Cancer in Patients With Interstitial Lung Disease: Initial Experience From the United Kingdom

C. Maguire[1], P. Nguyen[1], S. Court[1], A. Gosling[1], S. Karis[1], N. Das[1], C. Baker[1], N. Harrold[2], D. Woolfe[2], C. Hiley[1]
[1]University College London Hospitals NHS Foundation Trust, London/GB ,[2]The Christie NHS Foundation Trust, Manchester/GB

Introduction: Managing lung cancer in patients with interstitial lung disease (ILD) can be challenging due to the increased risk of treatment-related toxicities. Photon-based radiotherapy is of particular concern due to reports of severe or even fatal radiation pneumonitis. Due to the unique physical properties of protons, particularly the Bragg Peak, proton beam therapy (PBT) offers a promising alternative treatment option for this patient population. It allows for greater sparing of normal tissues, crucial in minimising lung dose, without compromising coverage of the target volume. This may reduce the risk of life-threatening pulmonary complications in patients with ILD. This study reports on the dosimetric outcomes and acute toxicities in patients with ILD following the initiation of the United Kingdom PBT service.

Methods: The first four patients with ILD treated with PBT were reviewed for this study. Dosimetric parameters, including target coverage, target volumes, doses to organs at risk (OARs) were analysed alongside acute toxicity outcomes. Toxicities were assessed weekly during treatment and one-week post-treatment using the Common Terminology Criteria for Adverse Events (CTCAE) v5.0.

Results: All patients were treated with 60 Gy in 30 fractions. Acceptable target coverage was achieved in all patients. The nominal median dose received by 95% of the clinical target volume (CTV) was 58.5 Gy (Nominal range: 58.2 Gy - 58.9 Gy; worst-case range: 55.7 Gy - 56.9 Gy). The median internal gross target volume (iGTV) was 64.3 cc (range: 30.2 cc - 197.7 cc) and median CTV volume was 162.3 cc (range: 30.2 cc - 197.7 cc). The median lung V20 was 19.8% (12.4% - 29.4%) while the median of the lungs minus iGTV mean dose (dmean) was 9.9 Gy (5.5 Gy - 14.4 Gy). The median dmean for other normal tissues included the heart 7.2 Gy (0.68 Gy -7.29 Gy), contralateral lung 0.1 Gy (0.0 Gy - 0.2 Gy), and the median oesophagus V35% was 12.5% (0.0% - 16.8%). All reported toxicities were grade 1-2, with no occurrences of severe (grade 3 or higher) toxicities.

Conclusions: These early findings are promising, indicating that PBT can be safely delivered to patients with lung cancer and ILD, achieving effective target coverage with no severe acute toxicities reported.

P2.08 .20 VMAT vs IMRT Technique in Locally Advanced Lung Cancer Radiotherapy Treatment -Pulmonary Toxicity and Dosimetric Evaluation

S. Maric[1], P. Banovic[1], D. Trokic[1], A. Mirosavljevic[1], P. Janjic[1], L. Novakovic Lackovic[2], L. Tadic Latinovic[2]
[1]International medical centers-Affidea group, Banja Luka/BA ,[2]University Clinical Center Republic of Srpska, Banja Luka/BA

Introduction: Lung cancer patients on first presentation mostly belong to locally advanced group. Radiotherapy is an important treatment modality in this heterogenous group of patients Sophisticated radiotherapy techniques Intensity modulated radiation therapy- IMRT, Volumetric modulated arc therapy- VMAT have become standard of care in modern radiotherapy centers, still there is no consensus which of these two techniques is more effective. Aim of this study is to analyze and compare dose volume parameters for organ of risk-lungs, and evaluate pulmonary toxicity-acute and late side effects.

Methods: This study included 70 patients diagnosed and verified as locally advanced NSCLC with indication for radical radiotherapy treatment. IMRT treatment with radical dose 60Gy in 30 fraction was planned in first group (35 patients), and VMAT treatment was planned in second study group (35 patients). Dose volume constraints for organ of risk -lungs (V5, V20, MLD -Mean lung dose)were evaluated. Pulmonary toxicity was evaluated by RTOG scale and CTCA V 5.0, acute and late side effects for organ of risks lungs were evaluated.

Results: Based on this results there was statistically significant difference ($p<0.01$) between IMRT and VMAT group based on values V20 and MLD. IMRT group had significantly higher values. Also, based on this results there was no statistically significant difference ($p=0.155$) when comparison of values V5 between IMRT and VMAT group was done. There was no statistically significant difference when comparison of acute ($p=0,867$) and late ($p=0.654$) side effects for organs of risk lungs was done between IMRT and VMAT group.

Conclusions: This study presents dosimetric benefit of VMAT technique in terms of lower values of mean lung dose and V20,but this dosmetric evaluation benefit did not translate into a clinical benefit. There was no statistically significant difference between IMRT and VMAT group in terms of acute and late pulmonary side effect. Smaller number of monitor units, and shorter time for delivery radiation tretament can be factors atributed in favour of VMAT technique.Still, more studies should be done in order to determine optimal radiotherapy technique in tretment of locally advanced lung cancer. Key words- locally advanced,lung cancer. radiotherapy, IMRT, VMAT

Introduction: Chemoradiotherapy followed by immunotherapy is the standard of care for unresectable stage III NSCLC, yet over 50% of patients progress within 24 months. This study analyzes early progression patterns in a real-world setting to guide future treatment strategies.

Methods: We retrospectively analyzed patients with confirmed NSCLC from five tertiary centers who completed CRT (≥54 Gy, platinum-based chemotherapy) and received ≥2 cycles of durvalumab within 2 months. Progression during or after durvalumab by January 31, 2024, was required. Data were analyzed using Python (pandas, scikit-learn, SciPy,plotly), with Gantt and Sankey plots generated for treatment visualization.

Results: Sixty patients were enrolled; 54 received subsequent systemic or local therapy. The median time to next treatment (TNT) and time to next systemic treatment (TNST) were 11.6 and 13.2 months, respectively. The median duration of chemoradiotherapy was 1.1 months, and durvalumab was 6.1 months. The treatment sequence for all patients is illustrated in a combined Gantt chart. A Sankey diagram displays the course of chemoradiotherapy (with/without induction chemotherapy), durvalumab duration, and reasons for durvalumab discontinuation. The most common progression region was lung (n=25), followed by brain (n=12), liver (n=7), lymph nodes (n=5), adrenal (n=4), bone (n=3), contrateral lung (n=2), other (n=2). Patients with local progression had a longer median TNT compared to those with distant or combined progression (17.1 vs. 9.9 months, p = 0.0088). Patients receiving radical local treatment for progression had longer TNST (29.1 vs. 12.6 months, p=0.016), with no similar effect seen for palliative radiotherapy.

Conclusions: The study suggests earlier distant progression than local, underscoring the role of early imaging and the potential benefit of radical local treatment in prolonging TNST.

P2.08 .22 In Field Progression Rates Following Concurrent Chemoradiotherapy for Stage III Non Small Cell Lung Cancer

S. Nesbit, M. Hammonds, T. Oughourlian, J. Goldman, E. Garon, A. Cummings, A. Lisberg, M. Velez, A. Gower, D. Gage, A. Lee, J. Deng, D. Moghanaki
David Geffen School of Medicine at UCLA, Los Angeles/CA/USA

Introduction: A metric for measuring the efficacy of concurrent chemoradiotherapy (cCRT) for stage III non-small cell lung cancer (NSCLC) is in-field tumor control. However, evaluating in-field control rates from published studies is challenging, as many report progression-free survival rates that consider disease progression events occurring outside the RT treatment field. This hampers an understanding of the interactions between RT and consolidation immune checkpoint inhibitor (ICI) therapy, as well measurements of the benefit of surgical resection in lieu of cCRT for locally advanced NSCLC treated with similar systemic therapies. To address this issue, we examined how in-field progression rates are reported in the literature evaluating outcomes for stage III NSCLC treated with cCRT.

Methods: A systematic review was conducted using PubMed, following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. The search included all interventional, observational, prospective, or retrospective studies reporting outcomes in patients with stage III NSCLC who received cCRT ± ICI, published January 2000 to November 2024. Reference lists from retrieved articles were reviewed to identify missed studies. Statistical comparisons between published progression rates were deemed inappropriate for cross-study comparisons.

Results: Sixty articles met inclusion criteria, reporting outcomes from 63% prospective and 37% retrospective studies. Cohort sizes ranged from 10 to 713, totaling 7,350 patients. Median follow-up ranged from 14 to 132 months. Post-cCRT response assessments used criteria established by RECIST (46%), WHO (12%), and ECOG (2%), while 40% did not specify evaluation parameters. Of 60 publications, only 18 had sufficient information to evaluate in-field progression. This included 16 studies evaluating cCRT-alone and 2 studies with cCRT + ICI. Of these 18 studies, four included evaluations of progression within regional lymph nodes or the thorax (see Table). Median in-field progression rates were 30.8% [95% CI 23.1-37.9%] for cCRT, and 17.5% [95% CI 4.0-30.9%] for cCRT + ICI. Only one retrospective study (n=120) reported "in-field only" progression rates at 41% with cCRT and 11% with cCRT + ICI.

Conclusions: Most publications reporting outcomes following cCRT ± ICI do not specify in-field progression rates. Limited data exist to determine whether the benefits of ICI arise from improved tumor control in-field, out-of-field, or both. Future studies will have a greater impact if they clarify what the in-field progression rates are following cCRT ± systemic therapies.

Introduction: Patients with locally advanced non-small cell lung cancer (LA-NSCLC) and high PD-L1 (>50%) expression show improved outcomes with immune checkpoint inhibitors compared to chemotherapy. We hypothesized that concurrent durvalumab and radiotherapy (RT) would be safe and feasible in this population.

Methods: In the phase I study, NRG-LU004 (NCT03801902), stage II-III unresectable LA-NSCLC patients with PD-L1 >50% received durvalumab (1500 mg Q4 weeks) with either accelerated fractionated RT (ACRT, 60 Gy/15 fractions) or standard fractionated RT (SDRT, 60 Gy/30 fractions) for initial and expansion cohorts. Primary objective was safety assessed through dose-limiting toxicities (DLTs). Feasibility was defined as ≥80% of patients receiving ≥80% of planned durvalumab in the first eight weeks. Peripheral blood specimens were collected at baseline and throughout treatment for exploratory immune profiling analyses to evaluate biomarkers related to treatment and/or adverse events.

Results: Among 24 evaluable patients (enrolled 2019-2021), no DLTs occurred in ACRT. One DLT (bronchopulmonary hemorrhage, unrelated) occurred in SDRT. Both initial cohorts advanced to expansion. Most patients received RT per protocol (82.6%). At time of analysis, 24% had completed all durvalumab cycles. In ACRT, adverse events included four grade 3, one grade 4 (lymphopenia), and one grade 5 (lung infection, unrelated). In SDRT, there were eight grade 3 and one grade 5 (respiratory failure, unrelated) events reported. Durvalumab feasibility was 85% in ACRT and 75% in SDRT. Soluble proteomic analysis revealed significant immune changes, with increased Th1 signatures and homing markers in both arms (IFN-γ, IL15, CXCL11). The most extensive changes in circulating immune markers occurred in the durva+SDRT arm, while they were relatively limited in the durva+ACRT arm. Inflammatory and cytotoxicity soluble markers were consistently increased with the prolonged SDRT regimen, up to Day 90 (D90). Soluble markers associated with T-cell activation and cytotoxicity peaking at D90 in plasma were corroborated by CyTOF data where a rebound in T effector memory and TEMRA cell numbers was observed at D90 following an initial decrease. Finally, we also found immune biomarkers differentially associated with the occurrence of AEs, particularly presenting as decreased soluble protein measures at d15 upon durva+SDRT, but not upon durva+ACRT. Several of these markers appear related to tumor or endothelial cell expression (EGF, CAIX, ADA) and to cell death (CASP-8, granzymes A and H, FAS ligand), which implies that SDRT toxicity may reduce the capacity to mobilize effective anti-tumor responses. The most consistent biomarker significantly associated with AE occurrence regardless of arms, when measured either at baseline or early upon treatment (D15), was soluble CD5.

Conclusions: Chemotherapy-free thoracic RT (SDRT or ACRT) with concurrent durvalumab is safe in PD-L1 high LA-NSCLC. In addition, our work establishes the mechanistic basis for combination immunotherapy and radiation on circulating immune biomarkers.

P2.08 .24 Radiation Dose to the Circulating Blood Is Associated With Poor Overall Survival in Patients With Locally Advanced Non-Small Cell Lung Cancer

S. Xing, S. Elguindi, N. Shaverdian, J. Deasy, M. Thor
Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: This study aimed to assess the radiation dose delivered to blood-bearing organs and circulating blood in patients with locally advanced non-small cell lung cancer (LA-NSCLC), and to evaluate their relationships with overall survival (OS).

Methods: The analyzed cohort included 155 LA-NSCLC patients treated with concurrent chemotherapy and intensity-modulated RT. Patients received a median prescription dose of 63 Gy in 1.8-2 Gy fractions. An in-house Artificial Intelligence auto-segmentation algorithm was used to contour 19 blood-bearing organs from planning CTs (Figure 1). Organ dose-volume histograms (DVHs) were generated, which were inputted into the Hematological Dose (HEDOS) framework to estimate blood DVHs for whole-body circulating blood and for blood within major contributing organs (lung, heart, aorta, and superior-vena-cava). Associations with OS were examined for the composite and per-organ mean blood dose. In addition, the mean dose to each organ, and pre-treatment hematologic parameters (lymphocyte, neutrophil, platelet, and hemoglobin, neutrophil-to-lymphocyte (NLR) and platelet-to-lymphocyte ratios) were assessed for their relationship to OS. For each parameter that reached statistical significance ($p<0.05$), the hazard ratio (HR) and its 95% confidence interval (95%CI) were reported.

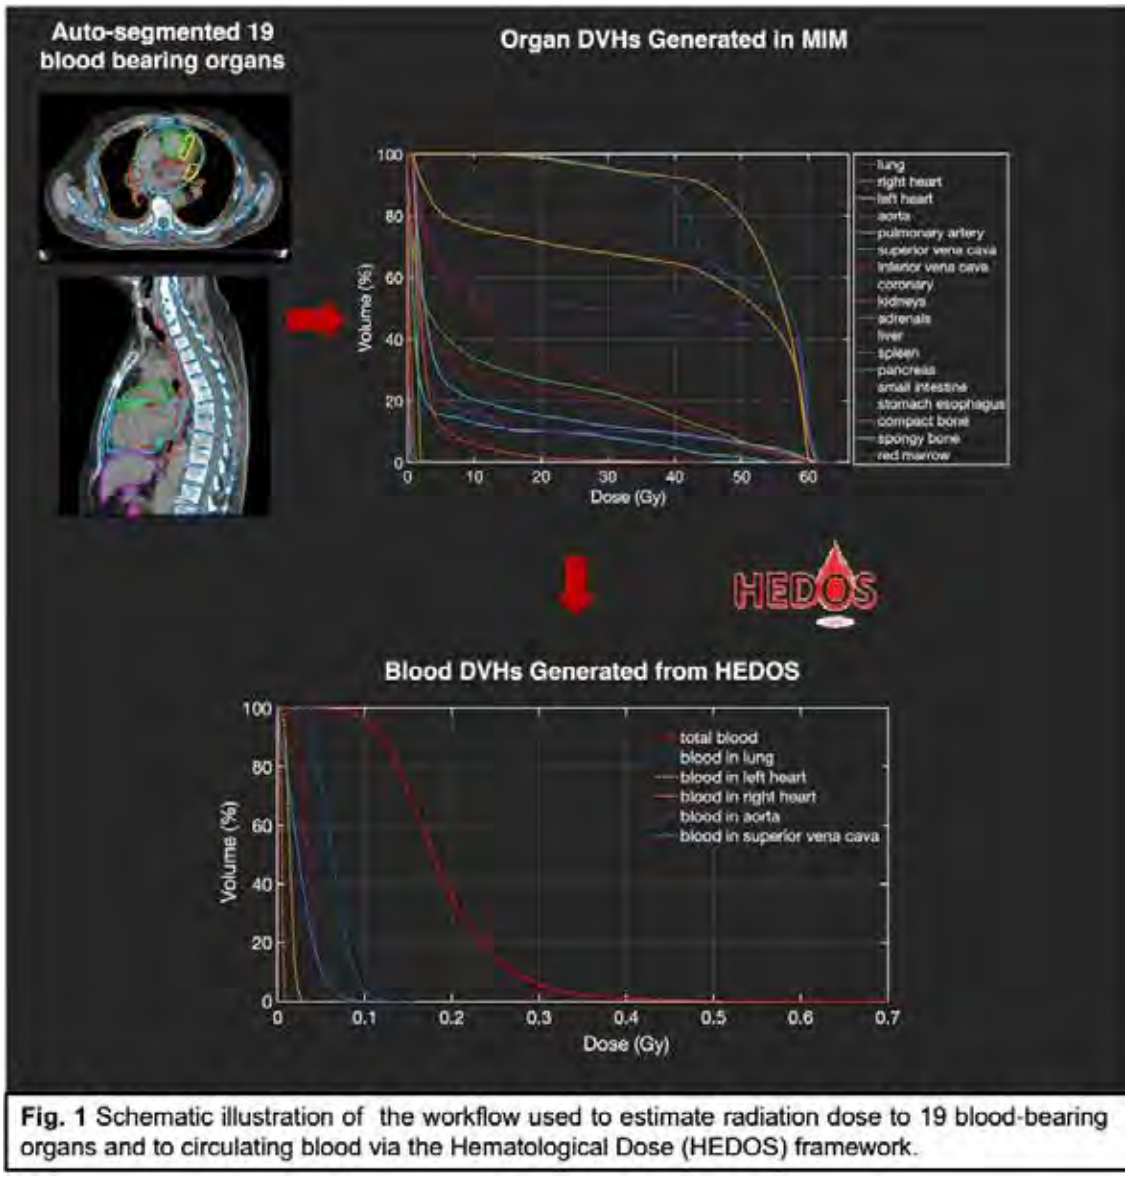

Fig. 1 Schematic illustration of the workflow used to estimate radiation dose to 19 blood-bearing organs and to circulating blood via the Hematological Dose (HEDOS) framework.

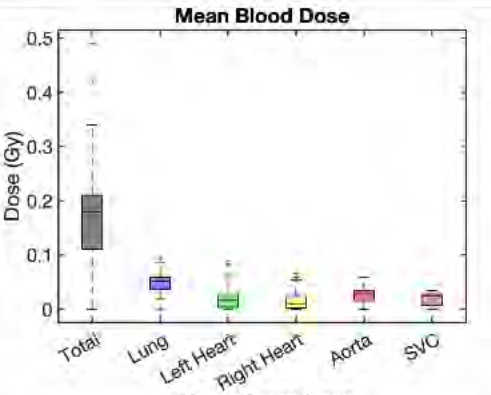
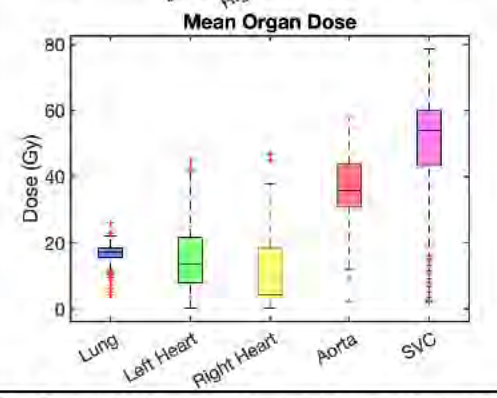
Results: Among the organ DVHs, increased mean dose to the lung, heart, aorta, pulmonary and coronary arteries were significantly predicting worse OS, with the largest HR of 1.2 observed for the mean lung dose (Figure 2). Additionally, higher pre-treatment NLR (HR=1.05 (1.01-1.10)), and lower lymphocytes (HR=0.6 (0.4-0.8)) were correlated with worse OS. Elevated composite blood dose, and the blood dose in lung, aorta, and heart were each correlated with worse OS. Notably, a wider 95% CI was observed for blood DVH metrics, reflecting greater uncertainty driven by the lower magnitude of blood dose.





Mean Dose Metric	HR (95% CI)	P-value
$bDVH_{Lung}$	$6.1x10^{15}$ ($1.3x10^{7}$-$2.2x10^{24}$)	0.0004
Lung	1.2 (1.1-1.3)	0.001
Pre-treatment lymphocytes	0.6 (0.4-0.8)	0.002
$bDVH_{Aorta}$	$1.2x10^{19}$ ($8.5x10^{6}$-$1.0x10^{31}$)	0.002
bDVH	23 (2.5-202)	0.01
$bDVH_{Left\ Heart}$	$1.2x10^{8}$ ($2.0x10^{2}$-$7.0x10^{13}$)	0.01
Left Heart	1.02 (1.00-1.04)	0.02
Pre-treatment NLR	1.05 (1.01-1.1)	0.02
Aorta	1.03 (1.00-1.05)	0.02
Pulmonary Artery	1.02 (1.00-1.04)	0.02
Right Heart	1.02 (1.00-1.04)	0.02
Coronary Artery	1.02 (1.00-1.04)	0.03
$bDVH_{Right\ Heart}$	$2.4x10^{6}$ (4.2-$1.4x10^{12}$)	0.03

Fig. 2. Left: Distribution of mean doses obtained from the total blood DVH (bDVH), the bDVH per organ, and the organ-specific non-bDVHs ; Note the order of magnitude difference in mean dose distributions (y-axis) between the mean blood dose (upper) and the organ dose (lower). Right: All identified significant overall survival associations ($p<0.05$) with mean doses from blood and organ DVHs, and pre-treatment blood analytes. Note: Mean dose metrics are organized in ascending p-value order (lowest p-value on the top).

Conclusions: Our results demonstrated that elevated mean doses to lungs, heart, major vessels, and circulating blood were significantly associated with worse OS, while higher pre-treatment lymphocytes correlated with improved OS.

Ospedali Galliera, Genoa/IT ,[5]Azienda Ospedaliero-Universitaria Careggi, Firenze/IT ,[6]University of Modena and Reggio Emilia and Azienda Ospedaliero-Universitaria di Modena, Modena/IT

Introduction: Postoperative radiotherapy (PORT) in non-small cell lung cancer (NSCLC) with mediastinal involvement has been a therapeutic option for a long time. However, recent randomized phase 3 trials (LungART and PORT-C) have shown no benefit in disease-free survival and increased toxicity with PORT. This randomized phase 2 study aimed to compare sequential and concomitant adjuvant chemoradiotherapy using a modern radiotherapy technique.

Methods: From 2020 to 2023, NSCLC patients were randomized after surgery to receive cisplatin-based chemotherapy for up to 4 cycles and sequential (Arm A) vs concurrent (Arm B) PORT (50 Gy/25 fractions). Intensity-modulated radiation therapy (IMRT) and image-guided radiation therapy (IGRT) were mandatory. The study had 2 co-primary endpoints: G3+ acute esophageal toxicity and locoregional recurrence-free survival (LRFS).

Results: Twenty-four patients were enrolled, 11 in Arm A and 13 in Arm B. The study was closed due to low accrual, mainly due to the COVID-19 pandemic and negative data of LungART and PORT-C trials that discouraged continuation of the study. Patients and disease characteristics are shown in the table. All cases were adenocarcinomas and all patients underwent lobectomy. Nearly 30% of patients had R1 resection due to positive surgical margins or extracapsular nodal extension. In arm B, positive mediastinal nodes were higher and detected ones were lower than in arm A. Sixteen patients completed the planned 4 cycles of chemotherapy, 9 in arm A and 7 in B. One patient in arm A had regional progression after chemotherapy. After a median follow-up of 44 months, 1 local, 2 regional and 15 distant recurrences were recorded, while 17 patients were still alive. The 3-year LRFS was 82% and 91% in arms A and B, respectively. No severe acute esophageal toxicity was ever reported in either arm. Grade 1-2 esophageal toxicity occurred in 2 and 4 patients in arms A and B, respectively. Two patients in arm B reported pneumonitis.

Conclusions: The small sample size does not allow definitive conclusions to be drawn on the usefulness of postoperative concomitant radiochemotherapy. However, the use of modern radiotherapy resulted in a reduction of toxicities and an improvement in locoregional control. Recently, the management of pN2 NSCLC has radically changed with the advent of immunotherapy and targeted therapies, confining PORT to an extremely marginal role. Today, in extremely selected cases (high locoregional risk), PORT could still be proposed to reduce the risk of locoregional recurrence, but only by adopting the highest radiotherapy standards.

P2.08 .27 Impact of CD73 on Immune Evasive Contexture and Clinical Outcomes in Lung Adenocarcinoma in Neoadjuvant Immunotherapy

m. chen[1], W. Zhong[2]
[1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China., Guangzhou/CN ,[2]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China., Guangzhou/CN

Introduction: The study aims to investigate the impact of CD73 expression on neoadjuvant immunotherapy in lung adenocarcinoma. We explored the expression of CD73, its dynamic changes during treatment, impact on the microenvironment, and their relationships with treatment efficacy in lung adenocarcinoma patients treated by neoadjuvant immunotherapy, in order to elucidate the CD73-related tumor microenvironmental changes.

Methods: In the first section, the study included 91 patients with treatment-naïve early-stage lung adenocarcinoma who underwent radical surgery at a provincial tertiary hospital in 2018. A prognostic prediction model was established based on clinical, pathological characteristics, and CD73 H-Score. A nomogram was developed based on the results of the Cox regression analysis. Additionally, 30 patients who underwent surgery after neoadjuvant immunochemotherapy between 2022 and 2023 were included in part 2 study. Multiplex immunofluorescence was done. The impact of CD73+ tumor cells on treatment efficacy and the immune microenvironment was analyzed through quantitative and spatial analysis.

Results: Univariate and multivariate Cox regression analyses revealed that tumor stage, pathological grade, and elevated CD73 H-Score were significant adverse prognostic factors for early-stage lung adenocarcinoma patients after radical surgery. Specimens from 30 lung adenocarcinoma patients were collected before or after neoadjuvant immunochemotherapy treatment. Differences in immune cell density were identified between major pathological response (MPR) and non-MPR patients. No significant correlation was found between CD73 expression on tumor cells and treatment efficacy or immune cell infiltration. In spatial analysis, in non-MPR patients, the distance between CD73+ tumor cells and CD8+ T cells was significantly longer than the distance between CD73- tumor cells and CD8+ T cells, which was not seen in the MPR group. After neoadjuvant treatment, the increase in immune cell density was greater in non-MPR patients than in MPR patients. In postoperative non-MPR patients, the distance between CD73+ tumor cells and CD8+ T cells was significantly longer than the distance between $CD73^-$ tumor cells and CD8+ T cells.

Conclusions: CD73 H-Score is an independent risk factor for poor prognosis in early-stage lung adenocarcinoma patients after radical surgery. In lung adenocarcinoma patients receiving neoadjuvant immunotherapy, the spatial distance between $CD73^+$ tumor cells and $CD8^+$ T cells may serve as a potential predictor for treatment efficacy.

P2.08 .28 Impact of Neoadjuvant Chemoimmunotherapy vs Chemotherapy in Stage III NSCLC: Real-World Analysis From Spanish ReSECT Database

X. Vaíllo[1], C. Gálvez[1], S. Bolufer[1], F. Lirio[1], S. Call[2], U. Jiménez[3], J. Zabaleta[4], M.T. Gómez[5], L. Sánchez[6], L.J. Cerezal[1]
[1]Hospital General Universitario Dr. Balmis, Alicante/ES ,[2]Hospital Universitari MútuaTerrassa, Terrassa/ES ,[3]Hospital Universitario de Cruces, Baracaldo/ES ,[4]Hospital Universitario de Donostia, San Sebastián/ES ,[5]Hospital Clínico Universitario de Salamanca, Salamanca/ES ,[6]Hospital Universitario Marqués de Valdecilla, Santander/ES

Introduction: Stage III non-small cell lung cancer (NSCLC) remains a therapeutic challenge despite multimodal treatment. Neoadjuvant chemoimmunotherapy (CIT) has shown promising results in clinical trials, but its real-world impact on oncologic and surgical outcomes requires further validation. This study compared CIT and chemotherapy (CT) in a multicenter cohort of resected patients. Primary endpoints were pathological complete response (pCR) and T/N downstaging. Secondary endpoints included resection complexity, quality, and perioperative outcomes.

Methods: A retrospective analysis was conducted using the Spanish National ReSECT prospective database. Patients with cIII NSCLC who received neoadjuvant CT or CIT followed by anatomical resection between January 2020 and February 2025 were included. Exclusion criteria comprised Pancoast tumors, N3 disease, alternative regimens, and non-systematic or non-lobe-specific lymphadenectomies. Oncologic variables included ypTNM, pCR, resection status (R0-un/R1-2), and number of resected nodes. Surgical variables included operative time, extended resections, complications, and readmissions. Quantitative variables were expressed as medians and IQRs and compared using the Mann-Whitney U test; categorical variables as frequencies using the chi-squared test.

Results: A total of 112 patients were analyzed (CIT: 73; CT: 39). Baseline characteristics were similar. pCR was significantly higher with CIT (26.0% vs. 7.7%, p=0.020; OR 0.237, 95% CI: 0.065-0.859), with a trend toward greater T downstaging (79.5% vs. 64.1%, p=0.077). Nodal downstaging was comparable (52.1% vs. 48.7%, p=0.736). R0-un resection was achieved in 80.8% (CIT) vs. 82.1% (CT, p=0.874), of which 41.1% and 33.3% were strictly R0 (p=0.421). Pneumonectomy was performed in 6.8% (CIT) and 10.3% (CT) and Minimally invasive approaches in 63.0% (CIT) and 66.7% (CT, p=0.701). Systematic lymphadenectomy was more frequent in CIT (75.3% vs. 59.0%, p=0.073). Dissection of ≥3 mediastinal nodes occurred in 64.0% vs. 66.7%, and ≥3 hilar nodes in 49.3% vs. 64.1%. Extended resections were more common in CIT (20.5% vs. 13.2%, p=0.336), with longer operative time (210 vs. 180 min). CIT showed higher complication (33.3% vs. 20.5%, p=0.155) and readmission rates (10.0% vs. 2.9%, p=0.199).

Conclusions: Neoadjuvant CIT was associated with significantly higher pCR and favorable trends in T downstaging and R0. Surgical complexity and perioperative morbidity were slightly higher without statistical significance. Further real-world studies are needed.

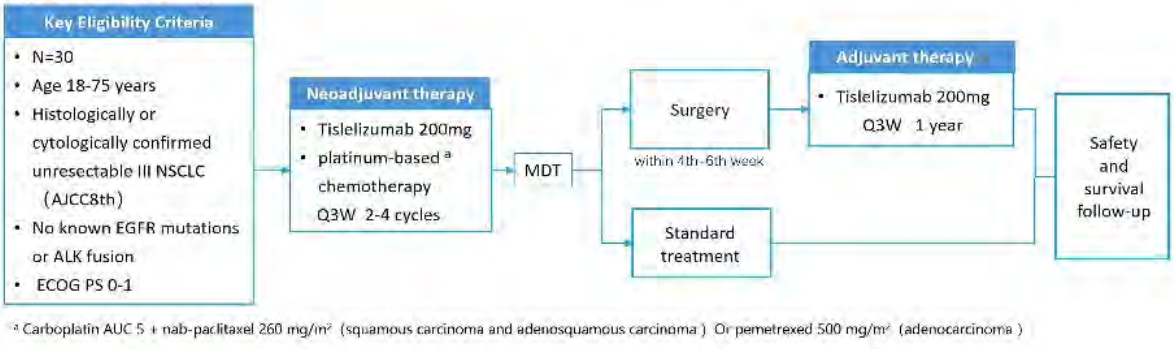
P2.08 .29 Phase 2 Trial of Tislelizumab Plus Chemotherapy Induction Therapy for Newly Diagnosed Stage III Unresectable NSCLC

Z. Wu, W. Jiao, T. Qiu, R. Xu, X. Sun, Y. Wo
the Affiliated Hospital of Qingdao University, Qingdao/CN

Introduction: Patients diagnosed with resectable stage III NSCLC will have a higher rate of pathologic complete response (pCR) and downstaging when treated with neoadjuvant therapy. However, for newly diagnosed unresectable stage III NSCLC, there is insufficient data to support immunotherapy combined with neoadjuvant chemotherapy followed by sequential surgery. Tislelizumab is a humanized IgG4 anti-PD-1 monoclonal antibody specifically designed to minimize binding to FcγR on macrophages. Our study aims to evaluate the efficacy and safety of Tislelizumab combined with chemotherapy in neoadjuvant treatment of newly diagnosed stage III unresectable NSCLC.

Methods: Study design: an open-label, single-arm prospective clinical study. (NCT06357598; Figure 1)The primary endpoint was R0 resection rate.The secondary endpoints included surgery rate, objective response rate (ORR), major pathological response (MPR), pCR, downstaging rate, disease-free survival (DFS), and safety.

Figure 1. Study Design



[a] Carboplatin AUC 5 + nab-paclitaxel 260 mg/m² (squamous carcinoma and adenosquamous carcinoma) Or pemetrexed 500 mg/m² (adenocarcinoma)

Results: As of March 28, 2025, 19 patients were enrolled, 12 patients have completed induction therapy. Among them, 10 patients were successfully converted, 1 patient had cancer progression, and 1 patient was unable to undergo radical resection due to tumor invasion of the aorta. The ORR for all patients was 66.7%. The rates of partial response (PR) and stable disease (SD) and progressive disease (PD) were 66.7 % and 25.0 % and 8.3 %, respectively. The surgical conversion rate was 83.3 %, and the R0 resection rate was 100 %. Among 10 surgically-treated patients, the pathological downstaging rate was 90%, the MPR rate was 50% and the pCR rate was 40%. Surgical details were shown in Table 1. The incidence of Grade ≥3 treatment-related adverse events (TRAEs) was 16.7%, all of which were leukopenia combined with neutropenia. The incidence of immune-related adverse events (irAEs) was 33.3%.

Table 1. Surgical Details

	Patients (n=10)
Interval between the neoadjuvant treatment (Last Dose) and surgery, d, median (range)	36.5 (32-115)
Extent of surgical resection	
Lobectomy	7 (70%)
Sleeve lobectomy	3 (30%)
Completeness of resection	
R0	10 (100%)
R1	0
Surgical approach	
Robotic-assisted surgery	10 (100%)
Thoracotomy	0
Duration of operation, minutes, median (range)	112.5 (70-270)
Intraoperative blood loss (mL) median (range)	20 (20-100)

Conclusions: The findings of this study suggest promising antitumor activity and manageable safety of Tislelizumab combined with chemotherapy in patients with newly diagnosed stage III unresectable NSCLC.

P2.08 .30 Ia-Based Prediction in NSCLC Patients Undergoing Neoadjuvant Radiochemotherapy

c. tacconi[1], C. Greco[2], E. Ippolito[2], A. Iurato[1], M. Miele[1], E. Onorati[1], E. Molfese[1], L. Toppi[1], L.E. Trodella[1], M. Fiore[2], A.N. Caragliano[2], P. Soda[2], V. Guarrasi[2], S. Ramella[2]
[1]Fondazione Policlinico Campus Bio-Medico di Roma, Roma/IT ,[2]Università Campus Bio-Medico di Roma, Roma/IT

Introduction: Despite advances in therapies and diagnostics, the prognosis for patients with advanced-stage NSCLC remains poor, underscoring the importance of timely treatment for early-stage tumors. Therefore, our study proposes a non-invasive artificial intelligence (AI) method for predicting pathological complete response (pCR).

Methods: The features were extracted from simulation CT. Imaging analysis was conducted using two segmentation masks: the lung region of interest (ROI) and the planning target volume (PTV). Two techniques were employed: Gradual Learning (GL) and Explainable AI (XAI), integrated in the Doctor-in-the-Loop approach. The process consists of multiple phases: 1- Data Preprocessing: images were standardized and segmented into three levels. 2- Feature Extraction using CNN, a 3D DenseNet convolutional neural network. 3- XAI and Grad-CAM Heatmap: the model generates Grad-CAM heatmaps to highlight the regions influencing prediction. 4- XAI loss function penalizes the model if it focuses on irrelevant areas. 5- Final Classification: a fully connected layer processes the extracts features and assigns a probability of a positive or negative pathological response.

Results: From 2009 to 2020, 64 patients with a confirmed diagnosis of locally advanced NSCLC undergoing neoadjuvant radiochemotherapy and surgery were enrolled. With a median follow-up of 69.93 months, the median overall survival (OS) and progression-free survival (PFS) were 24.9 months and 20.03 months, respectively. Clinical outcome rates of overall population and the sub-analysis divided by treatment response (pCR/MPR vs. no pCR/MPR) are reported in Table 1. The Doctor-in-the-Loop approach showed progressive improvements throughout its learning phases (Table 1), achieving the best performance at Step 3 (focused on PTV). This step combines GL, which progressively guides network attention through segmentation masks (full CT, lung ROI, and PTV lesion), with XAI loss, which penalizes non-relevant areas identified using the Grad-CAM system, thereby enabling the model to focus on clinically relevant regions for feature extraction. In Step 3, the highest values were achieved for AUC (62.93%) and TPR (46.67%).

Conclusions: This study introduces an innovative approach where XAI models actively influence learning instead of being used only post hoc. Unlike conventional models, Doctor-in-the-Loop not only classifies pCR/no-pCR but also explains predictions, guiding the model toward clinically relevant areas.

P2.08 .31 Clinical and Imaging Characteristics Associated With Pathologic Response After Neoadjuvant Chemoimmunotherapy in Stage II-III NSCLC

D.Y. Jeong, J. Lee, H.Y. Lee, H.K. Kim, J.A. Son, Y.J. Jeon, S-Y. Park, J. Kim, J.H. Cho, Y.S. Choi, S. Park, H.A. Jung, J-M. Sun, S-H. Lee, M-J. Ahn, J.S. Ahn
Samsung Medical Center, Seoul/KR

Introduction: Neoadjuvant chemoimmunotherapy (NICT) has improved resectability and survival in non-small cell lung cancer (NSCLC), however accurate prediction of treatment response remains challenging. This study aimed to identify clinical and imaging biomarkers predictive of pathologic complete response (pCR) and major pathologic response (MPR) in stage II-III NSCLC patients receiving NICT.

Methods: We retrospectively analyzed 82 patients treated with NICT followed by elective surgery. Clinical and imaging data from sequential CT and PET/CT scans were collected. Univariable logistic regression was performed for pCR and MPR, and predictors with $p < 0.1$ in both analyses were advanced to multivariable modeling using backward elimination.

Results: Candidate predictors by univariable analysis included smoking history, histologically non-squamous cell carcinoma (non-SqCC), high PD-L1 expression (≥50%), N2 nodal involvement after chemoIO, tumor cavitation after chemoIO, Δ primary tumor size (representing percent decrease), and Δ SUVmax of primary tumor (also representing percent decrease). For pCR, the final model included N2 nodal involvement after chemoIO (OR, 0.20; 95% CI, 0.04-0.83; p = 0.034), tumor cavitation after chemoIO (OR, 6.96; 95% CI, 1.54-37.55; p = 0.015), and Δ SUVmax (OR, 201.81; 95% CI, 7.19-23,250.10; p = 0.009), with an AUC of 0.882 (95% CI, 0.775-0.989; p < 0.001). For MPR, the final model comprised non-SqCC (OR, 0.32; 95% CI, 0.08-1.18; p = 0.088), tumor cavitation after chemoIO (OR, 8.87; 95% CI, 1.23-134.54; p = 0.054), and Δ SUVmax (OR, 37.01; 95% CI, 4.05-728.01; p = 0.006), achieving an AUC of 0.878 (95% CI, 0.785-0.971; p < 0.001). Common significant predictors across both outcomes were tumor cavitation after chemoIO and Δ SUVmax; models constructed solely with these variables yielded AUCs of 0.856 for CR and 0.872 for MPR.

Conclusions: Our prediction model for NICT response in NSCLC demonstrate individualized risk stratification and guides treatment decisions in clinical practice.

P2.08 .32 Single Cell Transcriptomic Analysis Reveals Tumor Immune Remodeling and Epithelial Cells Gene Signature After Neoadjuvant Immunotherapy

Y. Qian[1], M. Wang[1], W. Wang[1], T. Chen[1], Y. Chen[1], Y. Cao[1], F. Lv[1], Y. Liu[1]
[1]Chinese Academy of Medical Sciences, Beijing/CN,

Introduction: Although more and more phase III randomized clinical trials have confirmed that neoadjuvant immunotherapy and combination therapy can significantly improve the pathological response rate in patients with stage III NSCLC, the in-depth mechanism of benefit is not yet fully elucidated.

Methods: We used scRNA-seq to analyze the transcriptomes of 45,572 individual cells obtained from three lung squamous cell carcinoma (LUSC) patients before and after neoadjuvant immunotherapy, with major pathological response (MPR) in patient P01, and non-MPR in patients P02 and P03 (NCC2023C-892). A least absolute shrinkage and selection operator (LASSO) Cox proportional hazards regression analysis was executed to culminate in the selection of six most predictive genes for the risk prognostic model.

Results: The proportion of adaptive immune cells such as T cells, B cells increased after treatment, and the proportion of T cells in MPR patients increased significantly after treatment. Further, we found a significant increase in the proportion of CD8_CCL5 and CD4_TCF7 T cells in patients with MPR. We identified six genes (CCDC141, SNAL1, MME, CD226, DPP4, and HIGD1B) that distinguish malignant epithelial cells from non-malignant ones. Functional analysis revealed an enrichment of genes related to the EMT and TGF-β signaling pathway in the high-risk group (with highly expression of these six genes). Moreover, the high-risk group correlated with higher immune scores and T-cell receptor repertoire diversity, indicating a positive association with anti-tumor immune activity in the neoadjuvant immunotherapy.

Conclusions: Our study reveals that neoadjuvant immunotherapy remodels the tumor immune microenvironment (TME), and patients with different pathological response are observed with TME changes dissimilarly after treatment. We introduced the innovative risk score, differentiating malignant epithelial cells from non-malignant ones. High-risk groups were associated with the EMT and TGF-β pathway and provided insights into prognosis and immune activities in the neoadjuvant immunotherapy of LUSC.

P2.08 .33 Quantitative Pathological Analysis of the Surgical Specimens of NSCLC After Neoadjuvant Immunochemotherapy

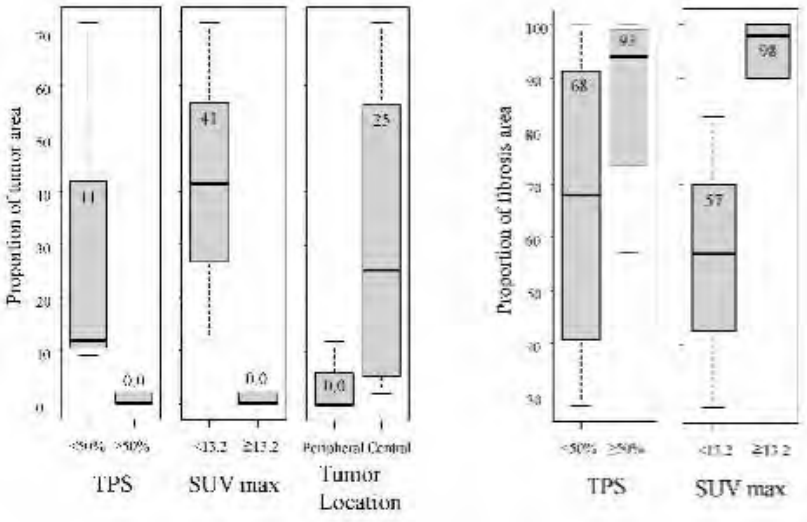
Y. KABURAKI[1], T. Isaka[1], T. Yokose[2], K. Washimi[1], Y. Okubo[1], I. Takada[1], R. Matsuyama[1], C. Kanno[1], T. Nagashima[1], S. Murakami[1], H. Saito[1], H. Ito[1]
[1]Kanagawa Cancer Center, Kanagawa/JP ,[2]Odawara Municipal Hospital, Kanagawa/JP

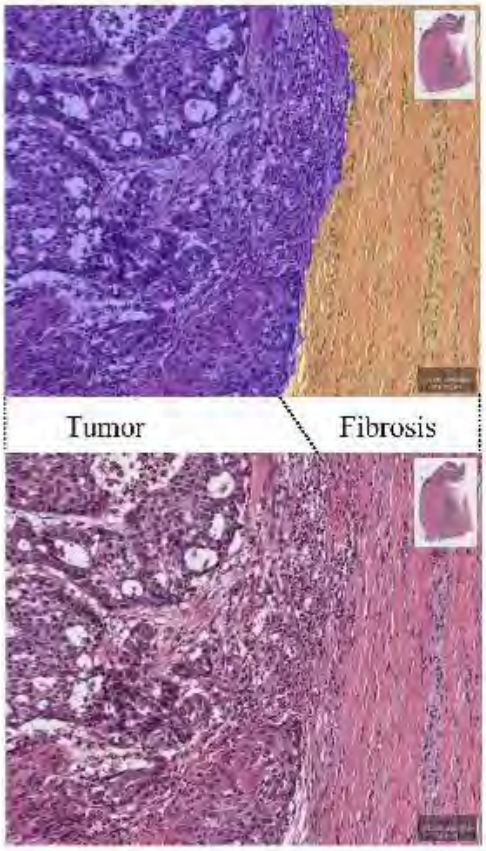
Introduction: Neoadjuvant immunochemotherapy has improved outcomes in non-small-cell lung cancer (NSCLC); however, the relationship between preoperative clinical factors and the histological characteristics of surgical specimens remains poorly understood.

Methods: This study conducted a retrospective analysis of eight patients with NSCLC, treated with curative surgery following neoadjuvant immunochemotherapy with the CheckMate 816 regimen (platinum-based chemotherapy plus nivolumab) between July 2023 and July 2024. For evaluating the distribution of fibrosis, residual tumor, and other components, histological mapping was performed on the largest cross-sectional area of the resected tumors. Quantification of the proportion of fibrosis and residual tumor area was performed using the image analysis software QuPath (Figure). The association between these areas and the following preoperative clinical factors was evaluated: PET SUVmax, tumor proportion score (TPS) from preoperative biopsy specimens, histological subtype, tumor location, and tumor size.

Results: The mean age and PET SUVmax of the eight cases were 64.6 years (47- 79) and 14.1 (5.5-22.7), respectively. The subjects included six males (75%) and three cases with SQ histology. Six patients (75%) had completed three courses of nivolumab + chemotherapy prior to surgery. The proportions of fibrosis, tumor, and other component areas were 76.1%, 17%, and 6.9%, respectively. The higher-SUVmax (≥13.2) group exhibited a lower proportion of tumor area compared with the lower-SUVmax group (median; 0.0% vs 41%). The high-TPS (≥50%) group and peripherally located tumors also exhibited lower proportions of tumor area compared with the lower-TPS group (0.0% vs 11%) and centrally located tumors (0.0% vs 25%). The proportion of fibrosis area was higher in the higher-SUVmax group compared with the lower-SUVmax group (98% vs 57%), and in the higher-TPS group compared with the lower-TPS group (93% vs 68%). No significant differences were observed in the other parameters.

Conclusions: Higher-SUVmax, higher-TPS, and peripherally located tumor were the factors associated with lower proportion of viable tumor cells. Additionally, this quantitative pathological analysis demonstrated an association between higher-TPS and increased fibrosis.





Tumors (Purple), fibrosis (Yellow), and other regions were identified, their areas measured using QuPath, and the percentage of each component within the tumor bed quantified.

P2.08 .34 Serplulimab in Neoadjuvant Therapy for Locally Advanced Non-Small Cell Lung Cancer: A Prospective Single-Arm Study

T. Luo, L. Cai, C. Pan, X. Xu, L. Wang, D. Shen, D. Chen, J. Feng, X. Huang, L. Wu, J. Zeng
Zhejiang Cancer Hospital, Hangzhou/CN

Introduction: Although a series of clinical trials, including CheckMate-816 and KEYNOTE-671, have demonstrated that patients with locally advanced non-small cell lung cancer (NSCLC) can benefit from neoadjuvant chemo-immunotherapy, the role of serplulimab in this setting remains unestablished. This study aims to evaluate the efficacy and safety of serplulimab in combination with chemotherapy as neoadjuvant treatment for locally advanced NSCLC.

Methods: This is a prospective, single-arm clinical study designed to enroll 80 patients with stage II-IIIB (T4N2) NSCLC based on the AJCC 8th edition, whose tumors are assessed as resectable or potentially resectable. Patients will receive 3 cycles of neoadjuvant therapy consisting of serplulimab (300 mg) combined with chemotherapy. Subsequently, patients will undergo curative-intent surgery or definitive chemoradiotherapy if re-assessed as inoperable. The primary endpoint is the major pathologic response (MPR) rate, and the secondary endpoints include pathologic complete response (pCR) rate, objective response rate (ORR), and adverse events (AEs).

Results: From October 1, 2023 to February 28, 2025, a total of 55 patients were enrolled, including 9 cases of adenocarcinoma, 45 cases of squamous cell carcinoma, and 1 case of undifferentiated carcinoma. In terms of clinical stage, 6 patients were stage IIA, 18 were stage IIB, 26 were stage IIIA, and 5 were stage IIIB. Three patients were still undergoing neoadjuvant therapy, and 10 patients withdrew from the study prematurely. Among the remaining 42 patients who completed neoadjuvant therapy and imaging evaluation, radiographic assessment showed complete response (CR) in 2 patients, partial response (PR) in 38, and stable disease (SD) in 2; the ORR was 95.2% (40/42). Except for 2 patients who received definitive radiotherapy due to ineligibility for surgery, 40 patients underwent curative-intent surgery. Among them, 35 (87.5%) underwent thoracopic resection, and the R0 resection rate was 100%. The MPR rate was 67.5% (27/40), and the pCR rate was 37.5% (15/40). During neoadjuvant therapy, 20 patients (36.4%, 20/55) experienced AEs, including 5 patients (9.1%, 5/55) with grade ≥3 AEs. Six patients discontinued treatment due to AEs, but no surgical was delayed due to treatment-related toxicity. One patient developed a serious perioperative complication (bronchopleural fistula), which resolved after stent placement and conservative management.

Conclusions: Interim results suggest that serplulimab in combination with chemotherapy demonstrates promising efficacy and manageable safety as neoadjuvant therapy for patients with locally advanced NSCLC. These findings warrant confirmation with continued patient enrollment and longer follow-up.

P2.08 .35 PD-L1 as a Predictive Biomarker in EGFR-Mutated Non-Small Cell Lung Cancer With Neoadjuvant Immunochemotherapy

Y-F. Qi[1], Z-B. Qiu[1], W-Y. Huang[1], C. Zhang[1], R. Fu[1], G-L. Jie[2], Y-D. Lin[1], H-J. Li[1], Q. Cui[1], J. Su[1], Z. Xie[1], B-Y. Jiang[1], X-C. Zhang[1], X-N. Yang[1], Y-L. Wu[1], W-Z. Zhong[1]
[1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: The role of PD-L1 in the prognosis and the efficacy of immunochemotherapy in perioperative EGFR-mutated (EGFR-M+) non-small cell lung cancer (NSCLC) is still unknown.

Methods: We retrospectively enrolled two cohorts of patients with EGFR-M+ NSCLC: 43 stage IB-IV patients receiving immunotherapy plus chemotherapy followed by surgery (NeoGroup), and 499 stage IB-III patients undergoing surgery without neoadjuvant therapy (AdjGroup). Radiological response, pathological assessment in the NeoGroup and genomic features, and clinicopathological factors in the AdjGroup associated with the PD-L1 tumor proportion score (TPS) were analyzed.

Results: In the NeoGroup, the objective response rate was 44.2%, with a pathological complete response (pCR) rate of 18.6% and a major pathological response (MPR) rate of 41.9%. A frequency of baseline PD-L1 TPS ≥ 1% correlated with better radiological responses (partial response (PR) 78.9% vs. stable disease (SD) 59.1% vs. progressive disease (PD) 0%; P = 0.05). Patients who achieved MPR showed a greater increase in PD-L1 TPS from baseline after therapy than patients without MPR (P = 0.0195). Baseline PD-L1 TPS ≥ 50% was related to more aggressive pathological features (AdjGroup, N = 499, P < 0.05). Patients with PD-L1 ≥ 1% more frequently harbored TP53 mutations, and more regularly appeared in patients achieving MPR than non-MPR(P > 0.05).

Conclusions: PD-L1 is a predictive biomarker for EGFR-M+ NSCLC with neoadjuvant immunochemotherapy. Higher baseline PD-L1 levels and a more significant increase in PD-L1 levels is associated with better efficacy.

P2.08 .36 Survival Outcomes in Locally Advanced NSCLC Patients Converted to Resectable Disease by Neoadjuvant Therapy

E.D. Gulsen, R. Ismayilov, A. Farzaliyeva, M.N. Ramazanoglu, D. Kilic, A. Oguz, Z. Akcali, O. Altundag
Baskent University, Ankara/TR

Introduction: Locally advanced non-small cell lung cancer (NSCLC) poses a significant therapeutic challenge due to its heterogeneity. Neoadjuvant therapy, while increasingly employed to convert inoperable disease to operable status, requires careful patient selection and assessment of response. This study evaluates the survival outcomes of patients with locally advanced NSCLC rendered resectable by neoadjuvant chemotherapy

Methods: We retrospectively reviewed data from adult patients with non-metastatic, initially inoperable locally advanced NSCLC who were treated at our tertiary center between January 2003 and December 2023, and who underwent R0 surgical resection after neoadjuvant therapy. Demographic, clinical, radiological, and pathological characteristics, treatment details, and survival outcomes were collected. Factors associated with event-free survival (EFS) and overall survival (OS) were analyzed.

Results: Thirty-five patients (86% male; mean age 67.6±8.0 years) were included. Staging at diagnosis was IIB (n=1), IIIA (n=11), IIIB (n=19), and IIIC (n=4). Histology was squamous cell carcinoma (80%) and adenocarcinoma (20%). Patients received a median of 3 (range 2-6) neoadjuvant therapy cycles (77% carboplatin and paclitaxel). Postoperative pathology revealed mediastinal lymph node involvement (37%), pleural contact/invasion (34.3%), angiolymphatic invasion (25.7%), and cartilage invasion (5.7%). Adjuvant treatment (56% carboplatin and paclitaxel) was administered to 51.4% of patients, with no factor significantly associated with this decision. During a median follow-up of 40.6 months (95% CI: 29-52.2), 13 (37.1%) patients experienced recurrence and 14 (40%) died. The 2-year EFS and OS rates were 53.9±8.9% and 66.3±8.4%, respectively. Median EFS was 15.7 months (95% CI: 0-56.1); median OS was not reached. Conversion to operable status after ≥3 neoadjuvant cycles, postoperative mediastinal lymph node involvement, and angiolymphatic invasion were associated with worse EFS and OS.

Conclusions: Neoadjuvant therapy offers long-term survival potential for select patients with locally advanced NSCLC. However, requiring ≥3 cycles for resectability, as well as the presence of postoperative mediastinal lymph node involvement and angiolymphatic invasion, are associated with poorer outcomes. These factors may help identify patients who could benefit from more aggressive treatment strategies or closer surveillance

Table 1. Factors associated with event-free and overall survival

Factors	2-year EFS	p	2-year OS	p
Neoadjuvant therapy cycles <3 *vs.* ≥3	85,7±13,2 *vs.* 43,8±10,2	**0,012**	100,0±0,0 *vs.* 55,7±10,1	**0,041**
Postoperative mediastinal lymph node involvement absent *vs.* present	67,6±10,1 *vs.* 27,1±14,8	**0,013**	81,6±8,3 *vs.* 36,3±15,4	**0,017**
Angiolymphatic invasion absent *vs.* present	65,4±9,3 *vs.* 15,6±14,2	**0,015**	76,7±8,3 *vs.* 31,1±17,9	0,071

* Survival rates are expressed as percentages with corresponding standard errors, and the P values were calculated using the Log-rank test.

[1]Hospital Universitario Nuestra Señora de Candelaria, Tenerife/ES ,[2]UOMi Cancer Center, Clínica Mi Tres Torres, Barcelona/ES ,[3]HM CIOCC, Facultad HM de Ciencias de la Salud de Universidad Camilo José Cela, Instituto de Investigación Sanitaria HM Hospitales, Madrid/ES ,[4]Hospital de la Sant Creu i Sant Pau, Barcelona/ES ,[5]Hospital de Jerez de la Frontera, Jerez de la Frontera/ES ,[6]Fundación Jiménez Díaz, Madrid/ES ,[7]Instituto Valenciano de Oncologia, Valencia/ES ,[8]Hospital Universitario de Jaén, Jaén/ES ,[9]Hospital Virgen de la Victoria, Instituto Biomedico de Investigación (IBIMA plataforma BioNAND), Málaga/ES

Introduction: Neoadjuvant chemoimmunotherapy (N-CT-IO) has become a standard approach for resectable non-small cell lung cancer (rNSCLC), showing significant improvements in pathological response and survival. The CheckMate 816 trial demonstrated that adding nivolumab to chemotherapy significantly improved pathological complete response (pCR) and event-free survival (EFS) over chemotherapy alone. NADIM I and II confirmed efficacy in stage IIIA NSCLC in the Spanish setting. More recently, KEYNOTE-671 supported perioperative pembrolizumab in stage II-IIIB rNSCLC. However, real-world (RW) data on clinical and molecular characteristics, treatment patterns, and outcomes remain limited.

Methods: We conducted a multicenter retrospective study of 82 patients with stage IB-IIIC rNSCLC treated with N-CT-IO across 9 Spanish centers. Clinical, pathological, and molecular features, including PD-L1 status and KRAS mutations, were collected. Pathological response and survival outcomes were assessed. EFS and overall survival (OS) were estimated using Kaplan-Meier curves, with subgroup analyses based on PD-L1 expression, molecular alterations, and baseline LIPI score.

Results: Median age was 64.7 years; 67% were male; 97.6% had ECOG 0-1. Most patients had stage IIIA (62.2%), with adenocarcinoma (54.9%) and squamous histology (41.5%). PD-L1 expression was <1% in 23.4%, 1-49% in 40.3%, and ≥50% in 36.4%. KRAS mutations were found in 45% of tested cases. The most common neoadjuvant regimen was carboplatin-paclitaxel-nivolumab (61%). Grade ≥3 toxicity occurred in one patient (1.2%). Surgery was performed in 85.4% (N=70), with a pCR rate of 32.9% (N=27). Among 42 patients with N2 disease, 83% underwent resection. pCR rates were similar across PD-L1 groups (<1%: 35.3%; 1-49%: 38.5%; ≥50%: 43.5%; p=0.865) and KRAS status (mutant vs wild-type: 33.3% vs 31.2%). pCR was 38.5% in patients with any molecular alteration vs 25% in those without. Favorable LIPI score was associated with higher pCR (41.3%) compared to intermediate/poor scores. No statistically significant differences in pCR were found across biomarker subgroups. At a median follow-up of 14.3 months, 1-year EFS and OS rates were 85.4% and 89.0%, respectively. Among resected patients, 7/70 relapsed. Median EFS was 12.9 months; median OS was not reached. Patients with PD-L1 ≥50% had the longest OS (42.1 months) with no deaths, while those with PD-L1 <1% had median OS of 28.3 months. Poor LIPI score was associated with shorter OS (19.3 months) compared to intermediate (43.9 months) or good (not reached) scores. There was a trend toward longer OS in patients without molecular alterations compared to those with at least one (p=0.23). None of these differences were statistically significant.

Conclusions: This multicenter RW analysis confirms the feasibility and efficacy of N-CT-IO in rNSCLC in routine clinical practice. Pathological and survival outcomes align with clinical trials, supporting its implementation as standard of care.

P2.08 .38 Identifying Risk Factors for Recurrence in Non-Small Cell Lung Cancer Patients With Pcr After Neoadjuvant Immunochemotherapy

W. Sun, D. Lin
Beijing cancer hospital, Beijing/CN

Introduction: In non-small cell lung cancer (NSCLC), achieving a pathologic complete response (pCR) following neoadjuvant immunochemotherapy is typically associated with a favorable prognosis. However, even patients with pCR remain at risk of recurrence after surgery. The factors contributing to recurrence in these patients have not yet been extensively investigated.

Methods: A retrospective analysis was conducted on 116 patients with NSCLC who achieved pCR after neoadjuvant chemoimmunotherapy. Among them, bulk RNA sequencing was performed on preoperative specimens, and multiplex immunofluorescence was conducted on postoperative specimens. Preoperative PET-CT scans and PD-L1 expression were also evaluated. The presence of treatment response in postoperative lymph nodes suggested lymph node metastasis before treatment.

Results: During the follow-up period, 12 patients experienced recurrence or died from tumor-related causes, while 1 patient died from a second primary cancer. RNA sequencing of preoperative specimens revealed that downregulation of ITGA8, NRG1, PLEKHG6, and PLA2G4C was significantly associated with recurrence (figure 1A). This association was further confirmed through univariate survival analysis (figure 1B). Although immune-related gene expression profile (GEP) scores were not related to recurrence (figure 1C), cancer-associated fibroblasts, neutrophils, and epithelial-mesenchymal transition were found to be significantly associated with recurrence (figure 1D). Higher standard uptake values (SUV) on preoperative PET-CT scans (cutoff = 12.9) (figure 2A) were associated with poorer survival ($p = 0.036$) (figure 2B). The presence of lymph node metastases before treatment was also significantly related to recurrence ($p < 0.001$). In contrast, PD-L1 expression levels were not associated with recurrence ($p = 0.704$). The immune microenvironment in postoperative specimens, including tertiary lymphoid structures, was not associated with prognosis.

Conclusions: Patients with high preoperative SUV values and lymph node metastasis, despite achieving pCR following neoadjuvant immunochemotherapy, remain at a significantly higher risk of recurrence.

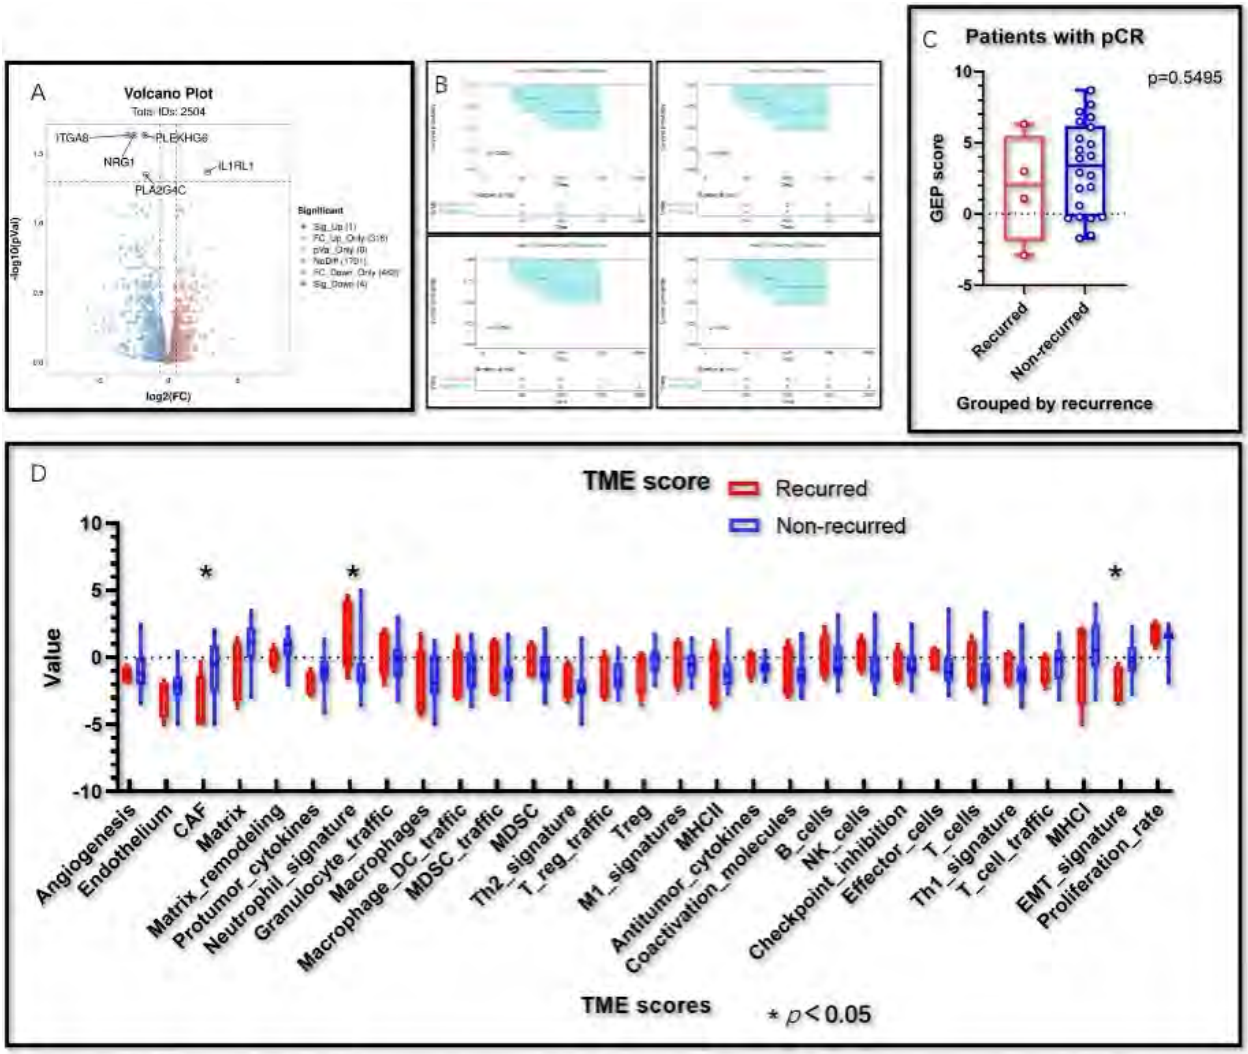

Figure 1. (A) Volcano plot of RNA sequencing revealed 5 differentially expressed genes between patients with recurrence and those without recurrence; (B) Four genes, namely ITGA8, NRG1, PLEKHG6, and PLA2G4C, were significantly associated with prognosis (univariate survival analysis); (C) Immune-related gene expression profile (GEP) scores were not associated with recurrence; (D) Tumor microenvironment (TME) scores indicated that cancer-associated fibroblasts, neutrophils, and epithelial-mesenchymal transition (EMT) were significantly associated with recurrence.

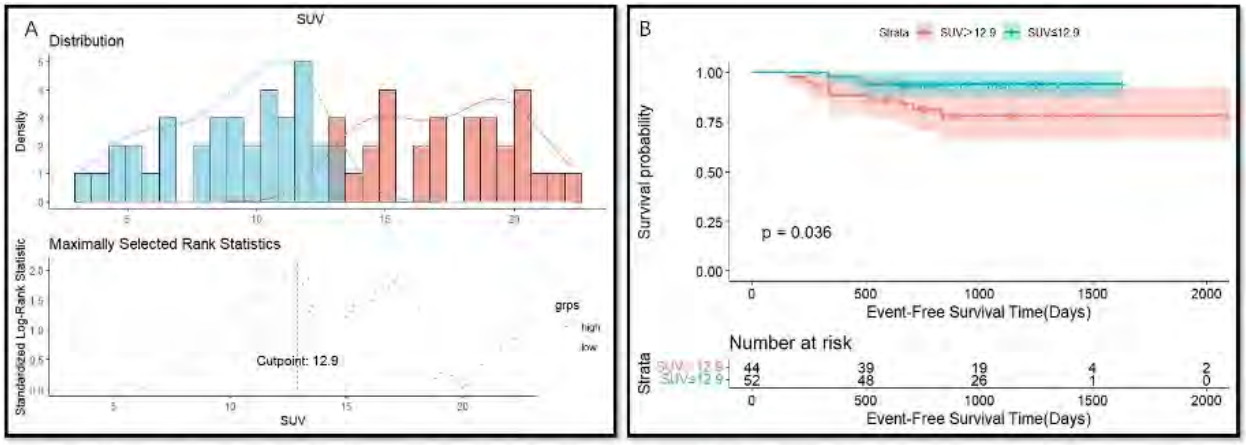

Figure 2. (A) The optimal cut-off value for survival analysis based on SUV from PET-CT scans, with the highest peak indicating the optimal cut-off point; (B) Kaplan–Meier survival curves stratified by the SUV cut-off value, demonstrating a significant difference between the two groups.

P2.08 .39 Targeting CHCHD3-cGAS to Remodel Immunosuppressive Microenvironment in Lung Adenocarcinoma: Mechanism and Clinical Translation

M. Zhang
Tianjin Medical University Cancer Institute and Hospital, Tianjin/CN

Introduction: A significant proportion of treatment-naive lung adenocarcinoma (LUAD) patients exhibit intrinsic resistance to neoadjuvant chemoimmunotherapy (N=816 trial cohort), underscoring an unmet need for mechanism-driven therapeutic strategies.

Methods: We conducted multi-omics profiling of 64 multicentric LUAD specimens from the CheckMate 816 trial cohort using single-cell RNA sequencing (scRNA-seq) and Visium spatial transcriptomics, enabling systematic identification of therapy-resistant subclones and spatially resolved immune-microenvironment dynamics. Experimental validation was performed through three complementary platforms:

1. Tet-op-hEGFR-TD/CC10rtTA bitransgenic mice for lineage tracing of EGFR-driven LUAD progression;
2. Humanized NSG mice (NOD.Cg-Prkdcscid IL2rgtm1Wjl/SzJ) with reconstituted human immune systems to model immunotherapy responses;
3. Patient-derived organoids (n=18) maintaining original tumor-stroma interactions for high-throughput drug screening.

Key techniques included: quantitative multiplex immunohistochemistry, luminescence-based cGAS-STING activity assays, high-content drug screening platforms integrating, CRISPR-Cas9 knockout validation, and PET-CT-guided pharmacodynamic monitoring with [18F]FDG to assess tumor metabolic response in real-time.

Results: Multi-omics profiling of 64 LUAD specimens (scRNA-seq, N=64; spatial transcriptomics, N=12) from CheckMate 816 clinical trials identified Coiled-Coil-Helix-Coiled-Coil-Helix Domain Containing 3 (CHCHD3) as the top resistance driver. CHCHD3 overexpression induced immunosuppression in PDOs and EC mice ($p<0.01$). Mechanistically, the CHCHD3-S2 domain directly binds to the catalytic core of cGAS, reducing cytosolic cGAS by 68±5% ($p<0.001$) and inhibiting downstream chemokines production. CHCHD3 knockout upregulated CXCL5/CXCL10, enhancing CD8+T cells and macrophages infiltration, which sensitized immunotherapy. Drug screening identified TN4510 as a dual-target inhibitor binding CHCHD3-S2 and cGAS-S3 domains. Combining TN4510 with anti-PD-1 and chemotherapy synergistically inhibited tumor growth in humanized NSG mice (65% reduction vs. control, $p<0.001$).

Conclusions: CHCHD3 drives immunotherapy resistance by mitochondrial sequestration of cGAS and suppression of the cGAS-STING axis. Targeting CHCHD3 with TN4510 restores antitumor immunity and enhances neoadjuvant therapy efficacy in LUAD, providing a clinical strategy for treatment-refractory patients.

P2.08 .41 The Influence of Perioperative Chemoimmunotherapy on Surgery for Resectable Non-Small Cell Lung Cancer:A Systematic Review and Meta-Analysis

S. Chen, F. Yang, M. Qiu
Peking University People's Hospital, Beijing/CN

Introduction: Perioperative chemoimmunotherapy has demonstrated significant improvements in event-free survival (EFS) and pathological complete response (pCR) rates compared to chemotherapy in patients with early-stage or locally advanced resectable non-small cell lung cancer (NSCLC). However, its impact on surgical procedures and perioperative outcomes remains to be fully elucidated.

Methods: We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) to assess the comprehensive effects of perioperative chemoimmunotherapy on surgical outcomes. A systematic search was performed across PubMed, Web of Science, Cochrane Library, and Embase to identify published phase 2/3 RCTs investigating perioperative immunotherapy combined with chemotherapy (chemoimmunotherapy) versus chemotherapy alone in resectable NSCLC. Study outcomes included: rate of undergoing surgery, R0 resection rate, pathological downstaging, surgical approach and type, surgery cancellation or delay rate, operative duration, postoperative hospitalization duration, and surgical complications. Random-effects model were used for meta-analysis.

Results: Eight RCTs involving 3387 patients were included, two trials evaluated neoadjuvant therapy and six assessed neoadjuvant plus adjuvant regimens. Compared to chemotherapy, chemoimmunotherapy significantly improved the rate of undergoing surgery (RR = 1.05, 95% CI 1.01-1.10, P = 0.015) and R0 resection rate (RR = 1.04, 95% CI 1.02-1.07, P = 0.001), with no significant differences in R1 or R2 resection rate. Perioperative chemoimmunotherapy promoted pathological downstaging (RR = 1.37, 95% CI 1.10-1.69, P = 0.004), facilitating more definitive surgical interventions. Patients receiving chemoimmunotherapy were more likely to undergo minimally invasive procedures and limited resections (Table). No significant intergroup differences were observed in surgery cancellation/delay rates, operative time, or postoperative hospitalization duration (Table). Importantly, perioperative chemoimmunotherapy did not increase the risk of surgical complications, neither any grade nor grade ≥ 3 surgery-related adverse events (Table).

Conclusions: This meta-analysis demonstrates that integrating immunotherapy into perioperative treatment does not compromise surgical safety but enhances surgical feasibility through improved resection completeness and pathological downstaging. These findings support the dual role of perioperative immunotherapy in optimizing both efficacy and surgical outcomes for resectable NSCLC.

Table: Pooled results of meta-analysis

Outcomes	Pooled effect (95% CI)	*P* value
Rate of undergoing surgery	RR = 1.05 (1.01-1.10)	0.015
R0 resection rate	RR = 1.04 (1.02-1.07	0.001

P2.08 .42 Impact of Delayed Initiation of Adjuvant Chemotherapy on Overall Survival Among Patients With Non-Small Cell Lung Cancer

E.C. Namoglu, E. Cain, R. Nicolae, O. Yaghi, J. Vera, E. Knox, K. Mortman, P. Ashok Kumar, S. Ely
George Washington University, Washington/DC/USA

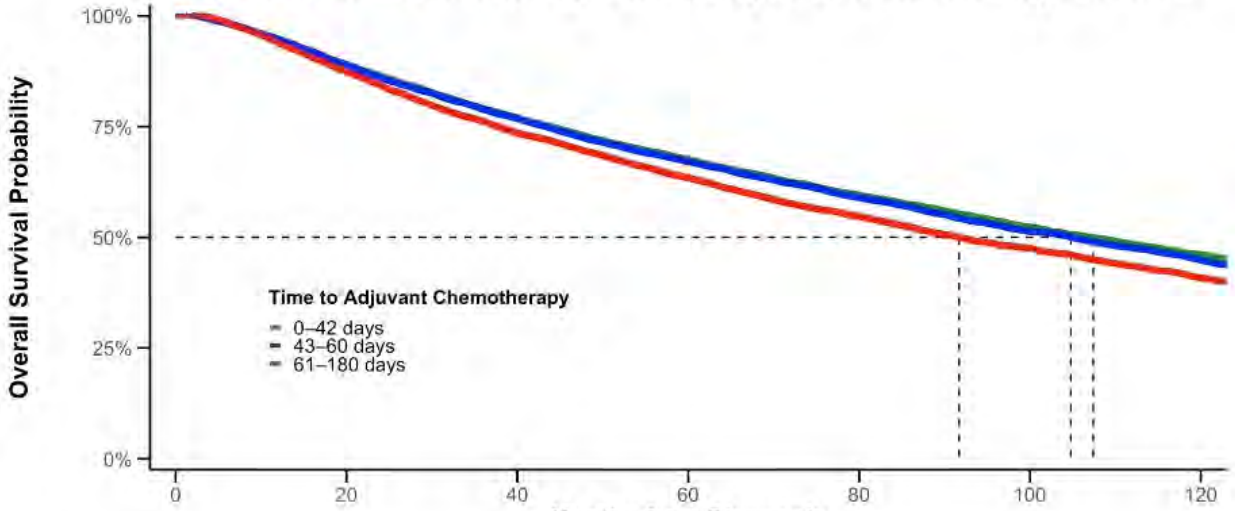
Introduction: Clinical trials included in the landmark LACE Bio analysis mandated adjuvant chemotherapy (AC) initiation 6-8 weeks after complete resection of non-small cell lung cancer (NSCLC); however, there are no data defining optimal AC timing in this population. This study aimed to evaluate whether delayed AC (initiation >60 days[d] after surgery) impacts overall survival in NSCLC.

Methods: We conducted a retrospective analysis of patients diagnosed with NSCLC between 2010-2021 in the National Cancer Database (NCDB). Inclusion criteria required complete resection by lobectomy or greater and receipt of AC 0-180d after surgery. Overall survival (OS) was evaluated using Kaplan-Meier (KM) method. Multivariate logistic regression was used to evaluate odds of 5-year mortality for patients with adequate follow up (diagnosed 2010-2017), adjusted for key sociodemographic and clinical characteristics.

Results: Of 28,581 patients who met inclusion criteria, 9,473 (33.0%) initiated AC 0-42d after surgery, 10,343 (36.0%) 43-60d, 8,765 (30.7%) 61-180d. KM curves for the entire cohort (n=28,581) showed significantly different survival among these groups (log-rank p<0.001); median OS for 0-42d was 107.4mo (95%CI:102.5-111.8), 43-60d was 104.8mo (95%CI:100.8-108.3), and 61-180d was 91.7mo (95%CI:88.3-95.6). Among patients with adequate 5 year follow up data (n=17,680) the adjusted odds of mortality at 5 years with delayed AC (60-180d) was 1.17 (95%CI:1.09-1.26, p<0.001). Higher stage, increasing Charlson comorbidity score, and treatment at a community center were also associated with higher 5-year mortality while female sex, Asian race and squamous cell histology associated with lower adjusted odds of mortality (Table 1).

Conclusions: Delayed AC >60d after NSCLC resection is associated with inferior OS and 17% higher odds of 5-year mortality. While some literature suggests that patients may still benefit from delayed AC compared to none, our data indicate that timely initiation of AC (≤60d postoperatively) is associated with improved OS.

Figure 1. Overall Survival by Time to Adjuvant Chemotherapy Initiation



at risk

P2.08 .43 Perioperative Adebrelimab Plus Chemotherapy in Patients With Resectable Stage II-III NSCLC: 4-Year Update From a Phase 1b/3 Trial

Y-L. Wu[1], W. Yan[2], W-Z. Zhong[1], Y-H. Liu[1], Q. Chen[3], W. Xing[4], Q. Zhang[5], L. Liu[6], D. Ge[7], K. Chen[2], F. Yang[8], X. Lin[9], Y. Huang[9], L. Song[9], W. Shi[9]
[1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Beijing Cancer Hospital, Beijing/CN ,[3]Zhejiang Cancer Hospital, Hangzhou/CN ,[4]The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou/CN ,[5]Jiangsu Cancer Hospital, Nanjing/CN ,[6]West China Hospital of Sichuan University, Chengdu/CN ,[7]Zhongshan Hospital Fudan University, Shanghai/CN ,[8]Peking University People's Hospital, Beijing/CN ,[9]Jiangsu Hengrui Pharmaceuticals Co., Ltd, Shanghai/CN

Introduction: In the phase 1b part of a phase 1b/3 trial (NCT04316364), neoadjuvant adebrelimab, a novel humanized IgG4 anti-PD-L1 monoclonal antibody, combined with chemotherapy has demonstrated favorable surgical outcomes, with high rates of major pathological response (55.9%) and pathological complete response (29.7%) in patients with resectable NSCLC. Here, we report 4-year updated outcomes following perioperative adebrelimab and chemotherapy.

Methods: In the phase 1b part, patients with previously untreated, resectable stage II and III (IIIA and T3N2M0 IIIB) NSCLC per AJCC 8th edition and without EGFR/ALK alterations, were enrolled. Patients received neoadjuvant treatment with 3 cycles of intravenous adebrelimab (20 mg/kg; day 1, Q3W), nab-paclitaxel (100 mg/m2; days 1, 8, and 15, Q3W), and carboplatin (area under the curve 5 mg/mL per min; day 1, Q3W), followed by surgical resection and 16 additional cycles of adjuvant adebrelimab (20 mg/kg; day 1, Q3W). Survival outcomes, including event-free survival (EFS), disease-free survival (DFS) and overall survival (OS), were secondary endpoints.

Results: 37 patients were enrolled and initiated study treatment; among them, 34 underwent surgery and 31 received adjuvant therapy. As of data cutoff (Jan.11, 2025), median follow-up was 47.0 mo (range 4.4-53.0). Sustained clinical benefits were observed overtime (Table 1), with 4-year EFS rate of 71.4% (95% CI 52.0-84.1), DFS rate of 72.1% (95% CI 53.0-84.5), and OS rate of 81.1% (95% CI 64.4-90.5). Across all treatment phases, 29 (78.4%) patients had grade ≥3 treatment-related adverse events (TRAEs) and 10 (27.0%) had treatment-related serious AEs. All grade ≥3 TRAEs occurring in ≥10% of patients were hematological toxicities. There were no treatment-related deaths.

Conclusions: With extended follow-up, perioperative adebrelimab and chemotherapy led to clinically meaningful survival benefits in patients with resectable stage II-III NSCLC. The safety profile remained consistent with previous reports, with no new safety signals identified. The randomized, double-blind, placebo-controlled phase 3 part of the trial is ongoing, with primary results expected soon.

Table 1. Survival outcomes

	Patients (n=37)

P2.08 .44 Adverse Cardiovascular Events Related to Immune Checkpoint Inhibitors in Staging IB-IIIb Non-Small Cell Lung Cancer: A Real-World Study

J. Kang[1], L. Jiang[2], J. Chen[2], H-H. Ma[2], W-Z. Zhong[3]
[1]Guangdong lung cancer institute, Guangzhou/CN ,[2]Guangdong Cardiovascular Institute, Guangdong Provincial People's Hospital, Guangzhou/CN ,[3]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Guangzhou/CN

Introduction: The development of novel immune checkpoint inhibitors (ICIs) has improved early-stage or local-regional non-small cell lung cancer (NSCLC) outcomes but may result in cardiovascular toxicities. Traditional approaches to clinical trial safety evaluation have limitations in their ability to detect signals of cardiovascular risk. This study aims to evaluate immune-related adverse cardiovascular events in a real-world study.

Methods: This is a retrospective study of staging IB-IIIB NSCLC patients who were treated with immunotherapy as perioperative treatment or induction therapy or consolidation therapy at the Guangdong Provincial People's Hospital from 2018 to 2023. Cardiotoxicity was assessed using the CTCAE V5.0 criteria. We also explore the association between temporal elevations of cardiac biomarkers with disease trajectory and outcomes.

Results: In total, 1160 patients were included (85.7% male and 14.3% female), with a mean age of 61 years [23-92]. The percentage of patients with any grade cardiotoxicity was 16.5%; 87.5% of patients with previous heart disease (N=40) were diagnosed with cardiotoxicity, and 13.9% of those without previous heart disease (N=1120) were diagnosed with cardiotoxicity. Cardiac arrest and cardiac failure led to death in 45 cases. The median time from the initiation of treatment until the cardiac event was 45 days [14-96]. The most frequent toxicity was arrhythmias in 18.7% of patients, followed by coronary atherosclerotic heart disease in 15.9% of patients. The percentage of patients with myocarditis was 1.5%. Within 72 hours of admission, the increased cTnT, cTnI, and CK values compared with upper reference limits were associated with ICI myocarditis. Overall, ICI treatment increased the risk of cardiotoxicity compared with control groups (p-value<0.0001). Patients without adverse cardiovascular events had better event-free survival and overall survival.

Conclusions: These findings highlight that ICI-associated cardiovascular adverse events, particularly in patients with pre-existing heart disease, substantially impact NSCLC prognosis. Our results emphasize the critical need for enhanced cardiovascular monitoring protocols during ICI therapy. The identification of early biomarker signatures, as demonstrated in this study, may enable timely detection and intervention for cardiotoxicity. Future research should focus on validating sensitive predictive biomarkers and developing risk-stratified surveillance strategies.

P2.08 .45 Immune Gene Guided Multi-Scale Pathomic Signature in H&E-Wsi Predict Neoadjuvant Immunotherapy Response in NSCLC

S. Wu[1], L. Kong[2], C. Cai[1], C. Li[1], L. Huang[3], M. Li[1], Y. Lei[1], M. Weng[1], L.W-C. Chan[2], H. Zhou[1]
[1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangdong, China, Guangzhou/CN ,[2]The Hong Kong Polytechnic University, Hong Kong, China, HongKong/CN ,[3]Competence Center of Thoracic Surgery, Charité Universitätsmedizin Berlin, Berlin, Germany, Berlin/DE

Introduction: Neoadjuvant immune-chemo therapy (NICT) has revolutionized resectable non-small cell lung cancer (NSCLC) treatment, yet heterogeneous pathological responses (18-83% MPR rates) and unresponsiveness in 30% of patients necessitate precise predictive tools. This study aims to develop a multi-scale deep learning model integrating H&E whole-slide image (WSI) features and immune-related gene expression profiles to predict pathological response to NICT.

Methods: A retrospective cohort of 260 stage I-III NSCLC patients (2019-2024) receiving NICT followed by resection and 465 patients from TCGA-LUAD was analyzed. The multi-scale fusion model (MSF-DS) combined: 1) WSI-derived morphological features via a Swin Transformer-based encoder pretrained on 15 million image tiles, 2) predicted expression of 135 immune dysfunction/exhaustion-related genes using ResNet50-autoencoder with attention mechanisms. Features were fused through a lightweight Transformer classifier. Model performance was evaluated using AUC, sensitivity, specificity, calibration curves, and decision curve analysis (DCA).

Results: The MSF-DS model achieved superior performance in the independent test set (n=65), with an AUC of 0.882 (95% CI:0.803-0.947), significantly outperforming MSF-only (AUC=0.776, P<0.001) and DS-only (AUC=0.629, P<0.001) models. Calibration curves demonstrated excellent agreement between predicted probabilities and observed frequencies (Brier score=0.177), outperforming single-modality models (MSF:0.241; DS:0.329). Key metrics included sensitivity=60.5%, specificity=96.7%, and PPV=92.0%. The model maintained robust prediction in PD-L1-negative subgroups (AUC=0.897). Saliency maps revealed decision-critical regions aligned with tumor nuclei atypia and lymphocyte infiltration patterns. Gene expression predictions correlated with T-cell activation markers (CXCL10, CD8B; Spearman ρ=0.41-0.58). DCA demonstrated clinical net benefit across 15-85% threshold probabilities.

Conclusions: This study establishes the first interpretable immune gene guided multi-scale model leveraging histomorphological patterns from pretreatment biopsies to predict NICT response in NSCLC. By bridging tissue architecture with transcriptic information, MSF-DS provides clinically actionable predictions (AUC>0.88) and visualizes biologically plausible decision drivers, offering a transformative tool for personalized neoadjuvant therapy stratification.

P2.08 .46 COPD Reshape the Tumor Microenvironments of NSCLC and Potentiate Antitumor Efficacy of Anti-PD-1 Therapy

J. Fan[1], Y. Xia[1], F. Qiu[1], G. Guo[2], X. Chen[2]
[1]The Second Affiliated Hospital Zhejiang University School of Medicine, Hangzhou/CN ,[2]Zhejiang University, Hangzhou/CN

Introduction: Non-small cell lung cancer (NSCLC) patients with chronic obstructive pulmonary disease (COPD) have been reported to exhibit enhanced responses to anti-PD-1 therapy. However, the clinical association between COPD comorbidity and immunotherapy outcomes in NSCLC remains controversial, largely due to limitations in accurate COPD data collection. Furthermore, the underlying mechanisms driving these observations have not been fully elucidated.

Methods: We analyzed two independent cohorts of NSCLC patients receiving anti-PD-1 therapy. Cohort 1 consisted of 90 advanced NSCLC patients, rigorously stratified by COPD status based on comprehensive clinical evaluations including pulmonary function tests and imaging. Statistical analyses were performed to determine the impact of COPD on treatment response. In Cohort 2, we conducted integrated single-cell RNA sequencing and spatial transcriptomics on freshly resected tumor samples from 18 NSCLC patients with and without COPD to characterize the tumor microenvironment (TME) and identify key cellular drivers of immunotherapy efficacy.

Results: Our analysis of Cohort 1 demonstrated that NSCLC patients with COPD experienced significantly enhanced therapeutic responses to anti-PD-1 therapy, with COPD comorbidity emerging as a significant factor influencing treatment outcomes. In Cohort 2, multi-transcriptomic analyses revealed a distinct accumulation of CXCL14 basal-like tumor cells in NSCLC patients with COPD. These cells exhibited notable tumorigenic potential and were associated with the recruitment of CXCL9 macrophages within the TME. The presence of CXCL9 macrophages, known to enhance cytotoxic T cell activity, likely contributes to the improved response to anti-PD-1 therapy observed in this patient population.

Conclusions: Our findings identify the CXCL14-CXCL9 axis as a central mechanism driving the remodeling of the TME and enhancing the efficacy of anti-PD-1 therapy in NSCLC patients with COPD. These results underscore the critical need for accurate COPD data collection in cancer research and suggest that targeting this axis may provide novel therapeutic strategies to further optimize immunotherapy outcomes in this unique patient group.

P2.08 .47 Lymphocyte Recovery and Risk for Immune Pneumonitis After Chemoradiation in Locally Advanced NSCLC

M. Satoskar, S. Zhao, K. Chian, N. Johns, A. Rudich, A. Khorasanchi, L. Wei, J. Gheeya, L. Roof, A. Alahmadi, R. Memmott, J. Kaufman, C. Presley, K. He, P. Shields, D. Carbone, M. Li, D. Owen
The Ohio State University, Columbus/OH/USA

Introduction: Consolidation durvalumab has played a pivotal role in the treatment of locally advanced non-small cell lung cancer (NSCLC) following concurrent chemoradiotherapy (CRT). Pneumonitis is a potentially severe adverse outcome of immunotherapy. In the landmark PACIFIC trial, one-third of patients who received durvalumab developed pneumonitis of any grade/etiology. There is limited evidence on biomarkers associated with pneumonitis risk especially after CRT. Lymphocytes play a role in the development of pneumonitis, and we hypothesized that fluctuations in absolute lymphocyte count (ALC) during CRT may be associated with immune checkpoint inhibitor (ICI) pneumonitis. In this study, we investigate the post-CRT lymphocyte recovery and its association with pneumonitis risk among patients receiving adjuvant durvalumab therapy.

Methods: This retrospective study included consecutive patients with unresectable Stage III NSCLC who underwent CRT followed by at least one dose of durvalumab at a single tertiary cancer center. Clinical data was extracted through review of electronic medical records. ALC was collected at nadir during CRT and approximately 30 days post-CRT. Lymphocytopenia was classified using the Common Terminology Criteria for Adverse Events V5. The diagnosis of pneumonitis was determined from review of radiology reports and medical oncology notes. Pneumonitis cases were further characterized as either certain ICI pneumonitis, or combined etiology of radiation and possible ICI pneumonitis. A competing risk model was used to evaluate the associations of post-CRT ALC, as well as the absolute change in ALC from nadir to post-CRT (absolute ALC recovery) with pneumonitis risk. Association between the presence of pneumonitis and overall survival (OS), calculated from durvalumab initiation to date of death or loss to follow-up, was also assessed using Cox proportional hazards model.

Results: This study included 117 patients with a mean age of 64.1 years, who received durvalumab within 12 weeks of completing CRT. The median ALC at nadir during CRT was 300 cells/uL (IQR: 200-450), increasing to 760 cells/uL (IQR: 510-1040) post-CRT. Among the 117 patients, 43 (37%) developed pneumonitis, including 13 cases of certain ICI pneumonitis (30%) and 30 cases of probable ICI pneumonitis (70%). Among the 43 patients with pneumonitis, the median time to onset of pneumonitis was 10.8 months. Post-CRT ALC was not associated with pneumonitis risk, however the absolute ALC recovery from nadir to post-CRT did show a positive trend towards significance. Every 10-unit increase in ALC was associated with a 0.8% higher risk of pneumonitis (HR=1.008; 95% CI: 1.000-1.017; p=0.05) after adjusting for age, ECOG performance status, histology, and PD-L1 expression. Median OS among patients with pneumonitis was 56.97 months and those without pneumonitis was 27.63 months; pneumonitis of any grade and cause was significantly associated with longer OS (p=0.018).

Conclusions: Absolute recovery in ALC from nadir during CRT to post-CRT (before durvalumab initiation) may be a predictor for pneumonitis risk in patients with advanced NSCLC receiving adjuvant durvalumab. The presence of pneumonitis was associated with longer OS. This may be related to lymphocyte count recovery resulting in improved immunotherapy response, although studies are warranted to understand the underlying mechanisms.

Keywords: pneumonitis, immunotherapy, lymphocyte recovery

P2.08 .48 Pacific Real-World Experience at Hospital Doce De Octubre

M. Temes, D. Pelegrina Sánchez, F. García Luque, F.J. Calleja Holgado, P. Alcaide Cordoba, J. Valin Barajas, L. Rodríguez Nogueira, G.M. Guardia López, C. Fernández Pedrero, S. Pedraza Fernández, N. Gascón Costoso, H. Bote, M. Zurera, J. Zugazagoitia, L. Fernández Banda, M. Pérez Escutia
Hospital doce de Octubre, Madrid/ES

Introduction: Historically, chemoradiotherapy (CRT) was the standard for treating unresectable stage III NSCLC, though outcomes were limited (median OS of 21.9 months). The PACIFIC trial significantly improved survival and progression-free survival (PFS), establishing a new standard of care. These findings have since been validated in real-world settings by the PACIFIC-R study. In line with this, a study was conducted to assess the experience with the PACIFIC regimen at our center.

Methods: This is a retrospective descriptive study that analyzed 24 patients with unresectable stage III NSCLC treated at Hospital 12 de Octubre between June 2018 and September 2024. All patients had ECOG 0-2 and any level of PD-L1 expression, receiving either concurrent or sequential chemoradiotherapy followed by durvalumab (10 mg/kg-every-2 weeks). The study evaluated treatment response (based on RECIST criteria), toxicity, progression patterns, and dosimetric variables such as V20 and mean lung dose. Statistical analysis was conducted using STATA version 18.

Results: Among the 24 patients analyzed (characteristics shown in Table 1), 67% received cCRT and 33% sCRT, with a median of 7.5 cycles of durvalumab (range: 1-26). The objective response rate was 54.2%. Median overall survival (OS) was 31.3 months (range: 3.1-66.5), and median progression-free survival (PFS) was 29.3 months (range: 2.2-66.5). Disease progression occurred in 11% of patients. At 5 years, OS and PFS rates were 45% and 29%, respectively. Pneumonitis was observed in 25% of patients—66% of which were grade 3—without correlation to lung dosimetric parameters. All patients received a mean lung dose below 20 Gy and a V20 <35%.

Conclusions: Our center's findings support the PACIFIC trial results, endorsing chemoradiotherapy followed by Durvalumab for unresectable NSCLC. Although OS was similar between concurrent and sequential CRT, the latter sowed poorer PSF (graph1). A high incidence of pneumonitis was observed, underscoring the importance of close patient monitoring.

Introduction: Some studies, including a meta-analysis, observed that the circadian rhythm of immune cell's proliferation and destruction may influence progression-free and overall survival in metastatic cancer treated with immunotherapy (IO). This study aims to assess whether such differences persist in patients with locally advanced non-small-cell lung cancer (NSCLC) undergoing radical concurrent chemo/radiotherapy (CRT) and IO consolidation depending on the time of day of IO administration.

Methods: For this retrospective study, all the patients with histologically confirmed unresectable NSCLC PDL1 ≥1% treated with radical concurrent CRT and at least 1 cycle of IO consolidation (PACIFIC protocol) from 2018 to 2023 at three hospitals of the Institut Català d'Oncologia (ICO) were included. These patients were categorized depending on the most frequently time of IO administration in two groups: morning (receiving 50% or more doses before 3pm) or afternoon group (receiving less than 50% doses before 3 pm). Survival outcomes were estimated using Kaplan-Meier analysis and compared with the log-rank test. Progresion Free Surrvival (PFS) and Overall Survival (OS) were defined by RECIST criteria, and median follow-up was calculated using the Kaplan-Meier method.

Results: A total of 212 patients were identified. Median follow up 24 months. The mean age was 66.3 years (range 42-89) of which 165 (77.8%) were males, 113 (53.3%) were currently smokers and 116 (54.7%) presented squamous cell carcinoma histology. The morning group included 153 patients (72.2%), while the afternoon group included 59 patients (27.8%). Patients received a mean of 7.31 months (range 1-14) of consolidation IO after radical concurrent CRT wih a median follow up of 23 months. Progression-free survival (PFS) was significantly better in the morning group compared to the afternoon group. Median PFS was of 31 vs 19 months, Hazard Ratio 0.6294 (95% CI 0.4212-0.9404, p=0.0238). The 1-year and 3-year PFS rates were 70.2% vs. 60.2% and 48.7% vs. 32.8% respectively. Overall survival (OS) favoured the morning group but did not reach statistical significance. Median OS was 50 vs. 29 months, Hazard Ratio 0.6875 (95% CI 0.4585-1.031, p=0.070). The 1-year and 3-year OS rates were 80.4% vs. 72.9% and 57.6% vs. 33.0% respectively.

Conclusions: This is the first retrospective analysis in which has been observed that patients treated preferentially before 3pm exhibit a better disease control than those treated onwards in radical treatment with immunotherapy. Preferential treatment in the morning may enhance disease control and improve OS. These findings support the need for prospective clinical trials to further explore the impact of circadian timing on treatment outcomes.

P2.08 .50 Tislelizumab With Chemotherapy as Neoadjuvant Therapy for Unresectable Stage III Lung Cancer: A Single-Arm, Phase II Trial

x. hou, F. Yang, W. Zhu, J. Cao, T. Zhou, Z. Zhang, D. Chen
Beijing Tsinghua Changgung Hospital, Beijing/CN

Introduction: Non-small cell lung cancer (NSCLC) remains one of the leading causes of cancer-related mortality worldwide. For patients with unresectable stage III NSCLC, traditional treatment methods have limited efficacy. Recently, the combination of immunotherapy and chemotherapy has shown potential benefits in conversion therapy of initial unresectable NSCLC. Tislelizumab has been approved for perioperative indications in resectable NSCLC in China, further highlighting its potential in conversion therapy. This study aims to evaluate the efficacy and safety of tislelizumab combined with chemotherapy as neoadjuvant therapy in patients with initial unresectable stage III NSCLC.

Methods: This prospective, single-arm, single-center clinical trial plans to enroll 30 patients with initial unresectable stage III NSCLC. Pts received neoadjuvant therapy of tislelizumab plus double platinum-based chemotherapy for 2-3 cycles (Q3W) followed by surgical resection. The primary endpoint was resectability rate. Secondary endpoints included pathology complete response (pCR), major pathological response rate (MPR), R0 resection rate and safety.

Results: As of February 28, 2025, eight pts with initial unresectable stage III NSCLC were enrolled. The median follow-up time was 19.2 months (range: 7.4-23.7). Among the 8 pts, 87.5% (7/8) completed 3 cycles of neoadjuvant therapy, and 12.5% (1/8) completed 2 cycles. All patients underwent surgery, achieving a surgical conversion rate of 100%. Preoperative imaging assessments revealed an objective response rate (ORR) of 75% and a disease control rate (DCR) of 100%. Postoperatively, three patients (37.5%) achieved complete pathological response (pCR), and all patients achieved major pathological response (MPR, 100%). 7 pts received sequential therapy with tislelizumab combined with chemotherapy following tislelizumab monotherapy, while 1 patient did not receive postoperative treatment. Three patients experienced recurrence or metastasis, and one of them died.

Conclusions: Tislelizumab combined with chemotherapy demonstrated significant efficacy and acceptable safety in patients with initial unresectable stage III NSCLC. This treatment regimen significantly improved surgical resection rates and pathological response rates, warranting further research and clinical application.

P2.08 .51 Outcomes From a Phase II Study of Hypofractionated Chemoradiation and Consolidation Immunotherapy in Locally-Advanced NSCLC

G.R. Vlacich[1], S. Waqar[1], C. Robinson[1], A. Chaudhuri[2], C. Bergom[1], S. Wu[1], J. Liu[1], K. Stavroulaki[1], R. Govindan[1], D. Morgensztern[1], P. Samson[1]
[1]Washington University in St Louis, St Louis/MO/USA ,[2]Mayo Clinic, Rochester/MN/USA

Introduction: Concurrent chemoradiation followed by immunotherapy for unresectable locally advanced non-small cell lung cancer (LA-NSCLC) results in suboptimal locoregional control (LRC) which is independently associated with worse overall survival. Standard radiation dose escalation has proven unsuccessful in improving outcomes and hypofractionation has been limited by increased toxicity risk. In this study, we use intermittent online adaptive Magnetic Resonance (MR)-guided radiotherapy to improve the therapeutic index of hypofractionated radiation with concurrent chemotherapy with the goal of improving LRC.

Methods: A single-institution, single arm prospective Phase II clinical trial with safety lead-in (NCT03916419) was conducted in individuals with inoperable AJCC 8th Ed. Stage IIB, IIIA, and select IIIB and IIIC NSCLC. Participants received 6000 cGy in 15 fractions with weekly carboplatin/paclitaxel and consolidation durvalumab for up to 12 months. Adaptive treatments occurred at fractions 6, 9, and 12. The primary endpoint was LRC with secondary endpoints including overall survival (OS), progression-free survival (PFS), and distant metastasis-free survival (DMFS). Acute and late toxicities were characterized per CTCAE v5 and dose limiting toxicity (DLT) defined as persistent non-hematologic grade 3 or any grade 4 toxicity within 6 months of chemoradiation. Survival outcomes were assessed with Kaplan-Meier analysis.

Results: Twenty-six individuals were enrolled (6 safety lead-in, 20 Phase II) between 8/2019 and 9/2023 with a median follow up of 20.7 months. Median age was 69 (range 58-81) with a majority male (54%), white (77%), ECOG performance status 0-1 (92%), clinical stage IIIA (54%) and adenocarcinoma histology (54%). All patients completed radiation and 25 patients (96%) received all 3 cycles of chemotherapy. Twelve months of consolidation durvalumab was completed in 6 patients (23%) with early discontinuation in the remaining from progression (42%) or immunotherapy toxicity (27%). No DLTs were observed in the safety lead-in. Grade 3 acute and late non-hematologic toxicity developed in 2 and 5 patients respectively including esophagitis (n=1), pneumonitis (n=2), and esophageal stricture (n=1). In addition to the grade 3 pneumonitis already noted, toxicities leading to durvalumab discontinuation included grade 1 (n=2) or 2 (n=1) pneumonitis, grade 2 arthralgia (n=1), or grade 2 colitis (n=1). No grade 4/5 toxicity was observed. Two deaths (respiratory failure and fatal hemoptysis) occurred 2-3 months after chemoradiation and were attributed to comorbidities or disease progression. Intermittent adaptation failed to consistently improve tumor coverage or organ-at-risk ideal constraint violation. Overall LRC was 77% (95% CI: 58-89%) with a median locoregional PFS of 38.8 months. Median OS and PFS were 29.6 months and 8.8 months respectively with a 3 yr OS of 44% (95% CI: 27-73%) and 3 yr PFS of 31% (95% CI: 16-60%). Overall distant control rate was 62% (95% CI: 43-78%) with a median DMFS of 23.6 months.

Conclusions: Hypofractionated chemoradiation and consolidation durvalumab is feasible with acceptable and anticipated toxicity and results in excellent LRC with OS comparable to other contemporary studies. With intermittent adaptation demonstrating no additional toxicity benefit, this hypofractionated regimen may effectively substitute for conventional chemoradiation and be more broadly applicable to non-MR and non-adaptive radiotherapy platforms.

P2.08 .52 Optimizing Lung Cancer Radiation Therapy: Integrating Immunotherapy and Targeted Therapy for Enhanced Clinical Outcomes

T.R. Dias[1], M.L.T. Bento[1], J.S. Pavão[1], L.B. Assunção[1], R.A.B. Aguiar[1], G.L.F. Cunha[1], R. Ferrari[2], G.B. Freire[2], E. Fuks[2], L. Franco[2], P. Cannary[2], C.E. Almeida[2], J.V.d. Melo[3], D. Przybysz[2]
[1]Petropolis Medical School - FMP, Petrópolis/BR ,[2]RadioSerra Radiation Therapy, Petrópolis/BR ,[3]Centro de Terapia Oncológica, Petrópolis/BR

Introduction: Lung cancer remains a leading cause of cancer-related mortality worldwide. Recent advancements suggest that integrating radiotherapy (RT) with immunotherapy (IO) and targeted therapy (TT) may enhance clinical outcomes. This study evaluates the impact of these combined modalities on overall survival (OS) in lung cancer patients, based on a comprehensive retrospective analysis of patient data and contextualized within recent findings from Europe and the USA.

Methods: A retrospective cohort study analyzed 198 lung cancer patients treated from 2020 to 2025, stratified into three groups: RT alone (45%), RT combined with IO (30%), and RT combined with TT (25%). The median age was 65.4 years (range: 29-90 years). Dosimetric parameters assessed included mean lung dose (MLD), lung volume receiving 5% (V5%), 20% (V20%), and 60% (V60%) of the prescribed dose. Kaplan-Meier survival analysis and Cox proportional hazards models were used to assess overall survival (OS), with significance set at $p<0.05$.

Results: The combination of radiation therapy (RT) with immunotherapy (IO) significantly improved overall survival (OS) compared to RT alone, with a median OS of 15.2 months versus 9.8 months ($p<0.05$). Although RT combined with targeted therapy (TT) showed a trend toward improved survival, the difference did not reach statistical significance. Dosimetric analysis confirmed that pulmonary toxicity remained within acceptable thresholds across all treatment groups. The mean lung dose (MLD) was 11.8 Gy (range: 8.5-15.2 Gy), remaining below established limits for radiation-induced lung injury. The lung volume receiving at least 5 Gy (V5%) had a mean value of 53.91%, aligning with international safety benchmarks to minimize pneumonitis risk. The lung volume receiving at least 20 Gy (V20%) averaged 21.5%, staying below the 30-35% threshold associated with symptomatic radiation pneumonitis. Additionally, the lung volume receiving at least 60 Gy (V60%) had a mean of 0.88%, indicating minimal exposure of lung tissue to high radiation doses. No significant increase in severe late toxicities, including long-term pulmonary fibrosis, was noted across the treatment groups. Furthermore, there was no significant rise in costal fractures among patients receiving combined therapies, reinforcing the feasibility and safety of integrating IO and TT with RT.

Conclusions: Our findings strongly support the integration of immunotherapy (IO) and targeted therapy (TT) with radiation therapy (RT) in lung cancer management, demonstrating significant improvements in survival and local control without increasing severe toxicity. The comprehensive dosimetric analysis confirms the safety of this multimodal approach, ensuring adherence to established pulmonary dose constraints. These results align with recent high-impact studies from Europe and the United States, reinforcing the growing consensus on the efficacy of combined modality treatments. Further prospective clinical trials are essential to refine patient selection criteria, optimize treatment sequencing, and maximize therapeutic benefit in clinical practice.

Introduction: The PACIFIC trial has established the standard of care for unresectable, stage III non-small cell lung cancer (NSCLC). The DEDALUS trial is a phase 2, single-arm, multicenter study aimed at patients who are not eligible for concurrent chemoradiotherapy (CRT) and are candidates for sequential CRT. This study evaluates safety and efficacy of an induction chemo-immunotherapy regimen followed by de-intensified, hypo-fractionated radiotherapy (RT) delivered concurrently with durvalumab, followed by durvalumab maintenance. This report presents the final safety analysis (primary endpoint).

Methods: Patients with unresectable stage IIIA-C NSCLC, regardless of PD-L1 expression levels and EGFR/ALK wild type, who were deemed unsuitable for standard concurrent CRT by a multidisciplinary evaluation, were considered eligible for this study. After three cycles of CT-durvalumab, responders received hypo-fractionated thoracic RT (45 Gy over three weeks) alongside durvalumab, followed by durvalumab maintenance for up to 12 months or until disease progression. The primary endpoint was safety, defined as the incidence of Grade 3 and Grade 4 possibly related adverse events (PRAEs) within the first six months from the initial durvalumab dose. Secondary endpoints were efficacy in terms of progression-free survival (PFS), overall survival (OS), and quality of life, using the EORTC QLQ-C30 and LC13 questionnaires administered at baseline, after chemo-immunotherapy, post-CRT and at the end of the study.Benchmark comparisons were conducted using the safety and efficacy data from the PACIFIC-6 study, applying identical inclusion and exclusion criteria. An estimated proportion of PRAEs within six months not exceeding 35% was considered acceptable; based on this estimate, the sample size was calculated to include 45 patients, with an expected rate of 20% for PRAEs, corresponding to an upper confidence interval (CI) limit of 34.6%. All data obtained from this study were recorded using an Electronic Data Capture system based on the RedCap platform with electronic case report forms.

Results: Between February 2022 and August 2024, 28 patients were screened, and 25 were enrolled across three Italian sites. Enrollment was halted earlier than anticipated due to a low accrual rate. The median age of participants was 70.4 years (ranging 51-84). Out of the 25 patients, 18 (72.0%) did not experience disease progression after induction chemo-durvalumab and received subsequent RT; 16 patients (64.0%) received at least one dose of durvalumab after RT.Adverse events (AEs) were distributed as follows: 79% Grade 1, 40% Grade 2, 15% Grade 3, and 1% Grade 4 toxicity. Twenty-four AEs were related to durvalumab, 46 to chemotherapy, and 5 to RT. The incidence of Grade 3-4 PRAEs was 11 (8.1%). The number of patients experiencing at least one Grade 3-4 PRAE was 7 (28.0%, 95% CI: 10.4-45.6, p = 0.35), with three patients experiencing more than one. Only one Grade 3-4 PRAE was immune-related, while 10 were related to chemotherapy and none to RT. No statistically significant changes were observed during the study treatment regarding quality of life.

Conclusions: Despite the reduction in the planned sample size, DEDALUS met its primary endpoint, showing acceptable safety and tolerability. Data concerning PFS and OS will be presented.

P2.08 .54 Contemporary Treatment Patterns and Outcomes in Stage III NSCLC in the Immunotherapy Era

Q.N.J. Nguyen[1], N. Blais[2], M. Liberman[2], A. Desilets[2], E. Filion[2], M. Florescu[2], M-P. Campeau[2], M. Tehfe[2], J. Martin[2], L. Masucci[2], P. Ferraro[2], T. Vu[2], B. Routy[2], H. Bahig[3]
[1]CHUM, Mont/QC/CA ,[2]CHUM, Montreal/QC/CA ,[3]Centre Hospitalier de l'Université de Montréal, Montreal/QC/CA

Introduction: Background: Stage III non-small cell lung cancer (NSCLC) is a heterogeneous disease that requires complex, multimodal management. While recent advances—including neoadjuvant chemoimmunotherapy and consolidation immunotherapy post-chemoradiation—are gaining traction, real-world outcome data from leading academic centers remain limited. This study aims to describe contemporary treatment patterns and clinical outcomes in a cohort treated at a high-volume tertiary care institution.

Methods: This retrospective cohort included 213 patients with clinical stage III NSCLC treated between 2019 and 2023, all of whom received immunotherapy as part of their treatment. Immunotherapy (IO) indication included neoadjuvant IO followed by surgery (33%), adjuvant IO (15%), consolidation IO following definitive chemoradiation (31%), and palliative IO as part of a systemic treatment with or without a chemotherapy backbone (21%). Locoregional control (LRC), progression-free survival (PFS), and overall survival (OS) were estimated using Kaplan-Meier estimates.

Results: Median follow-up was 23.2 months (range, 1.2-65.5) and was similar across treatment groups. The median age was 64 years (range 38-86), with 59% of patients being male. Adenocarcinoma (65%) and squamous cell carcinoma (33%) were the predominant histologies. Actionable driver alterations were identified in 24% of patients, specifically KRAS (15.7%), EGFR (3.3%), BRAF (2.4%), and ROS1 (1.0%). PD-L1 tumor proportion score (TPS) was <1% in 37%, 1-49% in 31%, and ≥50% in 32% of patients, respectively. High PD-L1 expression (TPS ≥50%) was observed in 35% of patients receiving neoadjuvant therapy, 32% in the chemoradiation group, 29% in the upfront surgery group, and 30% among those treated with systemic palliative treatment. Stage distribution was 59% IIIA, 33% IIIB, and 8% IIIC. Notably, patients undergoing neoadjuvant therapy were primarily resectable stage IIIA (71.8%) and IIIB (23.9%), while those receiving chemoradiation included a higher proportion of stage IIIB (46.2%) and IIIC (12.3%). At 2 years, LRC was 66% in the neoadjuvant group, 60% in chemoradiation, 61% in surgery, and 34% in the palliative group. OS at 2 years was 71%, 73%, 58%, and 46%, respectively. PFS at 2 years was 48% in both the neoadjuvant and chemoradiation groups, compared to 23% in the palliative systemic therapy group.

Conclusions: In this real-world cohort, neoadjuvant immunotherapy followed by surgery and definitive chemoradiation yielded excellent outcomes, particularly in stage IIIA and IIIB disease. These findings highlight the importance of multidisciplinary management and appropriate patient selection in achieving high rates of cancer control.

P2.08 .55 Comprehensive Analysis of Baseline Genomic Features and Plasma ctDNA Dynamics in Unresectable Locally Advanced NSCLC

Y. Xu[1], H. Guan[1], Y. Wu[2], H. Huang[1], S. Yu[1], X. Yin[2], M. Wang[1], X. Gao[1]
[1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN ,[2]Precision Medicine & Biosamples, Oncology R&D, AstraZeneca, Shanghai/CN

Introduction: Locally advanced NSCLC (LA-NSCLC) is a highly heterogeneous group of tumors. With the continuous advancement of immune checkpoint inhibitors in clinical research, the treatment strategies for patients with unresectable LA-NSCLC have undergone significant changes. This study aims to characterize baseline tissue mutations, plasma circulating tumor DNA (ctDNA) dynamics, and their association with progression-free survival (PFS) in LA-NSCLC patients undergoing combined radiotherapy, chemotherapy or/and immunotherapy.

Methods: A total of 26 patients with unresectable LA-NSCLC were enrolled. Baseline tumor tissue mutations were identified using next-generation sequencing (NGS), and plasma ctDNA was longitudinally monitored through treatment and follow-up. Clinical outcomes, including PFS, were correlated with genomic alterations and ctDNA status.

Results: Baseline tissue analysis revealed frequent mutations in TTN, TP53, CSMD3, and MUC16, and frequent copy number variations in BDH1, MECOM, and PIK3CA. Significant associations were observed between specific mutations and PFS: SYNE1 (HR = -1.880, p = 0.001) and OTOP1 (HR = -2.030, p = 0.001) were associated with improved PFS, while KMT2D (HR = 2.118, p = 0.001) and NCOA1 (HR = 1.96, p = 0.006) were linked to worse PFS. DCHS1 copy number variation was associated with PFS (p = 0.039). Plasma ctDNA analysis showed that pre-radiotherapy ctDNA positivity was influenced by chemoimmunotherapy, with lower positivity rates in patients receiving induction chemoimmunotherapy (p < 0.05). Longitudinal ctDNA monitoring revealed that ctDNA-positive status at TP1 (at a radiation dose of 30Gy) and persistent ctDNA positivity were associated with worse PFS (p < 0.05). Furthermore, ctDNA dynamics demonstrated distinct patterns between treatment responders and non-responders, with early ctDNA clearance correlating with improved PFS. The ctDNA positivity rate at pre-radiotherapy baseline was 42%, decreasing to 23% at TP1 and 15% at TP2 (at a radiation dose of 60Gy). Patients with sustained ctDNA negativity after treatment had a median PFS of 18 months, compared to 8 months in those with persistent positivity.

Conclusions: This study highlights the prognostic value of baseline genomic mutations and ctDNA dynamics in LA-NSCLC. Specific mutations and ctDNA status can serve as biomarkers to guide personalized treatment strategies and predict patient outcomes. ctDNA monitoring provides real-time insights into treatment response and disease progression, offering a non-invasive approach to inform therapeutic decisions.

P2.08 .56 Sequencing of Chemoimmunotherapy in Resectable Locally Advanced NSCLC: Single Center Experience

P. Adavelly[1], H. Gandler[1], A. Meeter[1], P.A. Desai[2]
[1]Temple University Hospital, Philadelphia/PA/USA ,[2]Fox Chase Cancer Center, Philadelphia/PA/USA

Introduction: Chemoimmunotherapy (chemo-IO) has become a standard treatment for resectable, locally advanced non-small cell lung cancer (NSCLC). Neoadjuvant chemo-IO (NCI) is gaining traction due to its biological rationale—exposing an intact tumor to immune checkpoint inhibitors (ICI) potentially triggering a more robust and lasting antitumor immune response. While this strategy has shown superiority over adjuvant chemo-IO (ACI) in melanoma, no prospective randomized comparison exists in NSCLC.

Methods: We conducted a retrospective review of patients with surgically resected stage II or higher NSCLC treated with either NCI or ACI from January 2018 to December 2023. Tumors were staged per AJCC 8th edition. Demographic, clinical, and survival data were collected and analyzed.

Results: Among 24 eligible patients, 79% were over 65, 50% male, and 75% European American. Alcohol and tobacco use were prevalent (83% and 100%, respectively). Most had government insurance (75%) and stage II disease (58%). Squamous histology was seen in 33%, and 46% had PD-L1 >50%. Carboplatin-based doublet therapy was used in 71% of regimens, with only one patient receiving concurrent radiation. Lobectomy was the primary surgical approach (92%). Of the cohort, 29% (7/24) received NCI and 71% (17/24) received ACI. More NCI patients presented with stage III disease (57%) compared to ACI (35%), but other baseline characteristics were similar. There was no significant difference in overall survival (OS) between NCI and ACI groups (median OS: undefined in both; HR 0.87, 95% CI 0.18-4.07; p = 0.86). Median follow-up among survivors was comparable: 32 months (NCI) vs 30 months (ACI; p = 0.41). Median progression-free survival (PFS) was 24 months in the NCI group and undefined in the ACI group (p = 0.25). Two-year OS rates were 71% (NCI) and 79% (ACI), while 3-year OS was higher in the NCI group (71% vs 53%). However, 2- and 3-year PFS rates favored ACI (62% and 51%) over NCI (44% and 0%).

Conclusions: In this small retrospective study, no survival differences were observed between NCI and ACI. A trend towards improved 3-year OS with NCI was noted, though ACI was associated with better PFS. Larger studies, including the ongoing PROSPECT-Lung trial (NCT06632327), are needed to clarify optimal sequencing of chemo-IO in resectable NSCLC.

Figure 1. Comparing neoadjuvant chemoimmunotherapy (NCI) versus adjuvant chemoimmunotherapy (ACI) in resectable, locally advanced non small cell lung cancer (LA-NSCLC) in terms of (A) overall survival and (B) progression free survival.

P2.08 .57 Small Volume Segmental Lung Autotransplantation for Treatment of Central Lung Cancer:One Case Report

J. Xie, B. Liu, M. Qiu, J. Xiao, X. Li
The First Affiliated Hospital, Fujian Medical University, Fuzhou/CN

Introduction: Lung cancer, predominantly NSCLC, remains a global mortality leader, with central tumors posing unique surgical challenges due to proximity to critical bronchovascular structures. While sleeve resections preserve lung function, 15-20% of advanced central lesions still require pneumonectomy—a high-risk intervention with 6-8% 30-day mortality. Small-volume segmental autotransplantation addresses these limitations through precision resection of bronchovascular units (<30% lung volume), combining radical tumor excision with functional preservation. Our technique achieves 1.5cm resection margins—surpassing conventional sleeve limits (0.5-1cm)—via vascular anastomosis while mitigating ischemia-reperfusion risks. This innovation resolves two critical challenges: 1) balancing oncologic radicality and lung preservation in compromised patients, and 2) standardizing anastomotic techniques for broader applicability.

Methods: A 67-year-old male with a 30-pack-year smoking history and a family history of lung cancer (father) presented with paroxysmal cough and short of breathe for 6 months. PET/CT scan showed: (I) a hypermetabolic left hilar mass (12*10*9cm) invading left bronchus and left pulmonary artery trunk; hypermetabolic 3A lymph node (II) enlarged left hilar, carinal, and other mediastinal lymphnodes; (III) no sign of distant metastasis .Bronchoscopic biopsy confirmed squamous cell lung cancer. Endobronchial Ultrasound (EBUS) confirmed negative 7 and 4R lymph nodes (cT4N2M0,IIIB). PET/CT scan after 6 cycles of neo-adjuvant chemoimmunotherapy (cisplatin+paclitaxel+nivolumab) showed both the mass and mediastinal lymph nodes were slightly smaller and less hypermetabolic (Fig 1). Small volume lung autotransplantation was consideredto preserve the left 9+10 segments. After general anesthesia, the patient was placed on right lateral decubitus position. A 25 cm incision was made in the 5th left intercostal space. Left upper lobectomy with S6+7+8segmentectomy was performed. Frozen section of resection margins showed negative results. Wetherefore decided to perform left S9+10 segment autotransplantation in situ. After systemic heparinization (1 mg/kg), venous anastomosis was firstly completed between the pulmonary vein of the segmental graft and left upper pulmonary vein with 5-0 Prolene. Left A9+10 was anastomosed to left pulmonary artery stump with 5-0 Prolene. The anastomosis between B 9+10and left main bronchus was end to end style with 3-0 Prolene. The vessels and airway reconstruction procedures were diagrammatically demonstrated in Fig 2.

Results: Patient was extubated immediately after operation transferred to normal wards. Prophylactic antibiotic and analgesics were administered. Bronchoscopy was performed daily to evaluate the anastomosis and remove secretion. Chest tubes were removed on POD 5, and he was discharged on POD 12. CXR before discharge showed no pleural effusion or pneumothorax. Bronchoscopybefore discharge show no anastomotic ischemia or leakage. Tumor showed a 10.5 cm × 9.3cm×8.1 cm mass with hard texture, grey-white appearance. The Pathological diagnosis was bronchial squamous cell carcinoma. Patient underwent chest CT scan every 2 months and bronchoscopy every 3 months. Bronchoscopy showed no anastomotic stenosis or tumor recurrenceat 9-month follow-up.

Conclusions: While Di Rienzo's end-to-side tracheal anastomosis addresses diameter mismatches, our cases achieved tension-free bronchial reconnections via conventional end-to-end techniques. This simplification reduced operative complexity without compromising airway patency, as evidenced by absent anastomotic stenosis at 9-month follow-up.

P2.08 .58 Advancing Care in NSCLC: Evaluating the Impact of New Treatment Modalities on Patient Outcome at the LTZ of the Comprehensive Cancer Center Zurich

J. Pikelis[1], K. Chiffi[1], C. Britschgi[2], I. Schmitt-Opitz[1]
[1]University Hospital Zurich, Zurich/CH ,[2]Cantonal Hospital Winterthur, Winterthur/CH

Introduction: Lung cancer remains one of the most diagnosed cancers worldwide and the leading cause of cancer-related deaths in Switzerland. Breakthroughs in detecting actionable genomic alterations (AGAs) permitting matched targeted therapies, immune checkpoint inhibitors (ICIs) and advanced locally ablative therapy (LAT) techniques have revolutionized cancer treatment for non-small cell lung cancer (NSCLC). The Lung and Thoracic Oncology Center (LTZ) at the Comprehensive Cancer Center Zürich (CCCZ) is at the forefront of these achievements, ensuring patients benefit from cutting-edge therapies. This study aimed to characterize treatment modalities and assess their impact on outcomes across all NSCLC stages, managed at the LTZ over the past decade.

Methods: Outcomes of patients with NSCLC of all stages diagnosed in 2018 ('modern cohort') were compared with patients treated before 2016 ('historic cohort') in a real-world setting. Patient and tumor characteristics, including age at diagnosis, gender, histological subtype, AGAs, PDL1 expression status, data on treatment types (e.g. locally ablative techniques for oligo-metastatic or oligo-progressive disease), and treatment lines. Patients were grouped into two cohorts by diagnosis date. Chi-square Test analyzed characteristics. Kaplan-Meier analysis was performed to assess overall survival, using capped survival data, with a maximum follow-up of 50 months. Log-rank test and Fisher's exact test evaluated survivor functions equality.

Results: 885 NSCLC cases were analyzed, with 698 cases assigned to the historic cohort and 187 cases to the modern cohort. In the historic cohort, 30.3%, 13.9%, 24.1% and 31.6% of patients were UICC Stage I, II, II and IV, respectively. This distribution was not significantly different from the modern cohort (P=0.98; 29.4%, 13.4%, 24.6%, 32.6%, respectively).There was a significantly higher 1-year survival rate in the modern cohort (84% versus 73%; p = 0.008), as well as a significantly higher 3-year survival rate (60% versus 49%; p = 0.015). In the stage-by-stage analysis, the 1-year- and 3-year survival rates were not different in Stage I. In Stage II, the 1-year survival rate was not different, but the 3-year survival rate showed a trend towards improved survival in the modern cohort (84.0% versus 59.8%; p=0.09). In Stage III, both the 1- and 3-year survival rates were significantly higher in the modern cohort (1y: 95.7% versus 74.1%; p=0.003. 3y: 67.4% versus 45.4%; p=0.02). Stage IV survival rates showed improvement trends in the modern cohort (1y: 62.3% versus 49.4%; p=0.08. 3y: 31.1% versus 23.9%; p=0.25). Overall survival trended higher in the modern cohort but was not significant, likely attributable to follow-up variations (p=0.027). In the stage-by-stage analysis, the survival was not different for Stage I, showed a trend towards improvement in Stages II and IV, as was significantly different for Stage III (p=0.019).

Conclusions: We observed improved survival rates and long-term survival in patients who were treated in 2018 compared to patients treated two or more years earlier. This might be attributed to increased use of new treatment modalities in patients with metastatic disease or relapses. We are expanding our database with retrospective data from 2019 onward and will present it at the meeting.

P2.08 .59 SCGB1A1 Enhances Radioimmunotherapy Efficacy and Mitigates Pulmonary Toxicity via Dendritic Cell Functional Reprogramming

Y-P. Zhang[1], K. Zhuang[2], Z. Guo[2], X. Cai[2], Z. Rong[2], Z-Y. Dong[2]
[1]Shunde Hospital, Foshan/CN ,[2]Nanfang Hospital, Guangzhou/CN

Introduction: Although radioimmunotherapy confers survival advantages in locally advanced NSCLC, tumor recurrence persists, with real-world data demonstrating elevated rates of grade 3-5 pneumonitis. Notably, attempts to enhance antitumor efficacy by including additional therapeutics have been largely discouraged due to concerns of exacerbating fatal pulmonary toxicity. Consequently, there remains a desperate need to develop effective strategies that concurrently optimize antitumor benefits and mitigate pneumonitis risks in radioimmunotherapy regimens.

Methods: Integrated transcriptomic-clinical analysis identified dual efficacy-pneumonitis regulatory molecules, validated through a radioimmunotherapy cohort and transgenic knockout murine models. Single-cell RNA sequencing of tumor-bearing Scgb1a1 KO mice characterized immune niche dynamics and critical cellular subpopulations, complemented by pathway enrichment studies elucidating mechanistic networks.

Results: Comparative transcriptomic profiling of efficacy versus pneumonitis in a lung cancer radioimmunotherapy cohort identified SCGB1A1 as a potential dual-regulatory molecule. SCGB1A1, which is specifically expressed in pulmonary club cells, encodes the secretory protein CC10. Increased expression of CC10 was associated with improved clinical outcomes and reduced pulmonary toxicity. In orthotopic lung tumor models, knockout of Scgb1a1 significantly diminished the efficacy of radioimmunotherapy and exacerbated pneumonitis. Single-cell analysis revealed enhanced neutrophil infiltration in tumors lacking Scgb1a1. Importantly, dendritic cell subsets demonstrated dual enrichment for both immune checkpoint inhibitor (ICI) efficacy and toxicity signatures, with wild-type groups exhibiting upregulation of ICI-efficacy markers, whereas knockout groups showed elevated ICI-toxicity markers. Mechanistically, the ablation of Scgb1a1 led to increased IL-1β signaling and suppression of DNA damage response pathways in dendritic cells.

Conclusions: SCGB1A1 enhances radioimmunotherapy efficacy while mitigating pulmonary toxicity through dendritic cell functional reprogramming. Intratracheal delivery of SCGB1A1 protein might be a promising strategy to improve patient survival and quality of life during radioimmunotherapy.

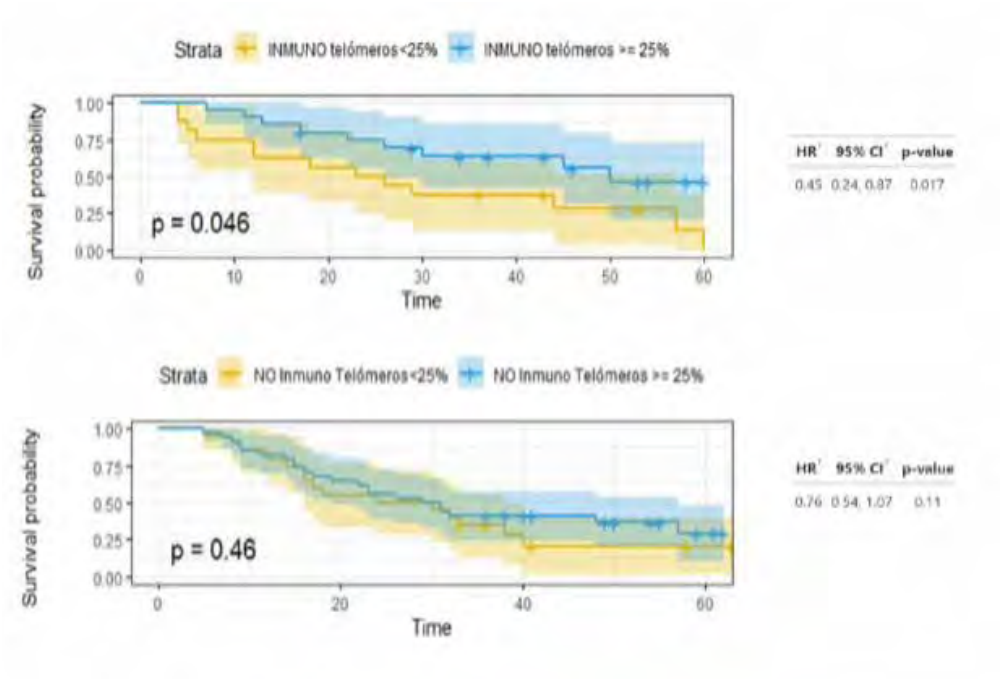
P2.08 .60 Telomere Length and Survival in Patients With Locally Advanced Unresectable Lung Cancer: Is There a Relationship?

A. Marín-Muñiz, S. Aso-González
Bellvitge University Hospital - IDIBELL. University of Barcelona, L'Hospitalet de Llobregat/ES

Introduction: Telomerase is overexpressed in 80-90% of tumors, preventing telomereshortening and providing "cellular immortality". Immunotherapy (IT) after concurrent chemoradiotherapy (CCRT) has demonstrated a benefit in overall survival (OS) in patients with non-small cell lung cancer (NSCLC) PDL-1 positive. The objective of this study is to analyze the relationship between telomere length (TL) and OS in patients with NSCLC PD-L1 positive treatedwith CCRT and IT.

Methods: Unicenter prospective study conducted between 2018-2021. Clinical, analyticaldata, tumor and treatments characteristics were collected. TL was obtained by buccal swab. Patients were classified into two groups based on z-score percentile used to measure TL: percentile <25 and >25. OS was analyzed during follow up until death/last visit using the Kaplan-Meier method

Results: Results: A total of 90 patients were included; 90% were men, mean age of 72 years (SD 6.3). 54% were squamous cells and 40% received IT. Regarding TL, 83% of patients showed lower length than the healthy population. No significant differences in OS were observed between the two study groups (HR 0.98, p=0.9). However, in subgroup analyisis, patients who received ITtreatment with TL percentile <25 had better OS than dose with TL percentile >25 (p=0.046). No differences on OS were observed in patients without IT treatment (Figure 1).



Conclusions: NSCLC patients have lower LT than healthy individuals. Those patients treatedwith IT with LT above the 25th percentile showed better OS. Further studies to validate these findings are required.

Keywords: Oncology, Pneumonitis, Telomere

P2.10.01 Maintenance Pemetrexed/Pembrolizumab vs Maintenance Pembrolizumab Alone in Advanced Non-Squamous Non-Small Cell Lung Cancer

G.W. Strohbehn[1], M. Tokaz[2], D.S. Shin[3], S. Jalal[4], H. Tavalire[5], D. Gyori[6], J. Moeller[6], B. Bazzell[6], M. Kelley[7], L. Fraley[1], A.M. Fendrick[1], E. Kerr[1], D. Elliott[1], N. Ramnath[1], T. Hofer[1], A. Bryant[1]
[1]University of Michigan, Ann Arbor/MI/USA ,[2]VA Puget Sound, Seattle/WA/USA ,[3]VA Houston, Houston/TX/USA ,[4]Richard L Roudebush VA Medical Center, Indianapolis/IN/USA ,[5]West Haven VA Cooperative Studies Coordinating Center, West Haven/CT/USA ,[6]VA Ann Arbor, Ann Arbor/MI/USA ,[7]VA National Oncology Program, Durham/NC/U

Introduction: KEYNOTE-189 demonstrated that adding pembrolizumab to both induction and maintenance chemotherapy improved progression-free and overall survival (OS) in patients with advanced/metastatic non-squamous NSCLC. Trial design limitations, however, leave unclear whether maintenance pemetrexed adds benefit to maintenance pembrolizumab alone. Maintenance pemetrexed remains a guideline-recommended standard of care in the immunotherapy era despite this ambiguity.

Methods: We identified Veterans with NSCLC who completed 4 cycles of carboplatin/pemetrexed/pembrolizumab (n=62) and then either maintenance pemetrexed/pembrolizumab ('pem/pembro', n=473) or pembrolizumab alone ('pembro', n=149). Survival estimates were generated by the Kaplan-Meier method. We performed propensity weighting to account for differences in baseline characteristics, including histology, PDL1, age, race, comorbidities, CNS disease, and response to induction chemoimmunotherapy. The primary outcome of the study was OS. Key secondary outcomes included time-to-next treatment (TTNT) and incidence of grade ≥ 3 adverse events of special interest. We estimated spending on the pemetrexed component of maintenance pemetrexed/pembrolizumab by US federal government payers (VA, Medicare Part B, and Medicaid) from 2017 to 2022.

Results: Baseline characteristics were well balanced. Unadjusted median OS was 18.1 months (95% CI 13.9-28.6) for pembro and 17.7 months (95% CI 16.4-19.9) for pem/pembro. After adjusting for baseline factors, treatment group was not associated with OS (adjusted hazard ratio [aHR] 1.06 for pem/pembro vs pembro, 95% CI 0.83-1.36, p=0.62) or TTNT (aHR 1.17 for pem/pembro vs pembro, 95% CI 0.93-1.48, p=0.19). Pem/pembro was associated with higher incidence of grade ≥ 3 neutropenia (aHR 2.86, 95% CI 1.44-3.05, p=0.004). Estimated cumulative US federal government payer spending on pemetrexed in the context of maintenance pembrolizumab from 2017 to 2022 amounted to $1.4 billion ($1.6 billion in 2024 USD).

Conclusions: In this retrospective cohort study, maintenance pemetrexed/pembrolizumab did not improve survival compared with pembrolizumab alone but was associated with increased toxicity and potentially unnecessary spending. Reassessment of legacy therapies in modern combination regimens and consideration of component contributions at the time of regulatory approval may be warranted.

Introduction: The developments in the treatment of non-small cell lung cancer have rapidly emerged in the last decade by adding different targeted agents to the chemotherapy regimens we have been applying for the last 50 years. It seems important for our oncology practice to quickly transfer these treatment options, which have positive effects on quality of life and survival in the treatment of non-small cell lung cancer, to our daily practice and to ensure that our patients benefit from these treatment options. In this study, we investigated the reflections of newly developed treatments in our daily practice.

Methods: In our country, within the scope of the Registurk-Lung observational study (NCT05254119), a total of 5382 patients without driver mutation, metastatic non-small cell lung cancer were recorded between December 2021 and April 2024 in 41 centers representing the whole country. The demographic, histopathological, molecular and clinical data of the patients were recorded. The relationship between progression-free survival (PFS) time and overall survival (OS) time with these characteristics was investigated.

Results: 5382 patients were evaluated. The median age was 65 (25-91) years and 15.1% of the patients were female. The proportion of patients who never smoked was 9,6 %. Histopathologically, 39,7 % of the patients were diagnosed with squamous cell carcinoma. Unfortunately, subgroup determination could not be provided in 10,2 % of our patients. The other patients had non-squamous histology. 12,3 percent of patients received single agent immunotherapy or chemoimmunotherapy. Other patients had received only a combination of doublet chemotherapy. The PFS was 6.6, 7,7 and 9,6 months in only chemotherapy, chemoimmunotherapy and only immunotherapy groups respectively. Compared to the group that received chemotherapy alone, PFS and overall survival were longer in the group that received chemoimmunotherapy. This difference between the two groups was found to be statistically significant (p:0,001 for PFS and 0,041 for OS).

Conclusions: In clinical studies, the addition of immunotherapy to chemotherapy provides improvements in PFS and OS data. When we also consider the quality of life data, immunotherapy appears to be a development that increases both the quality of life and survival for patients in non-small cell lung cancer, as in other types of cancer.

MONDAY, SEPTEMBER 8, 2025 - 10:30 - 12:00

P2.10.03 Long-Term Pemetrexed Administration Poses Risk of Renal Function Decline

T. Tamura, M. Yamashita, T. Koyanagi, T. Nishi, T. Umeno, S. Kuyama
NHO Iwakuni Clinical Center, Iwakuni/JP

Introduction: Pemetrexed is a standard cytotoxic anticancer drug used for non-small cell non-squamous cell lung cancer and malignant pleural mesothelioma, and is increasingly administered long-term for non-small cell lung cancer in combination with immune checkpoint inhibitors or molecular targeted therapy. However, pemetrexed is a nephrotoxic drug, and there are reports that the cumulative dose correlates with nephrotoxicity.

Methods: Among patients treated with pemetrexed at our institution between November 2009 and March 2024, we conducted a retrospective study of patients who received at least 2 cycles of pemetrexed therapy.

Results: 461 pemetrexed-treated patients, 351 were included in the analysis, excluding patients who had received their first dose of pemetrexed outside of our hospital, patients who received pemetrexed again, patients who were started with an estimated creatinine clearance (eCCr) <45 mL/min, and patients in whom pemetrexed was discontinued after one course. Median age was 70 (36-90) years, 259 (73.8%) were male, 318 (90.6%) had non-small cell non-squamous lung cancer, 31 (8.8%) had malignant pleural mesothelioma, 2 (0.6%) had thymic carcinoma, median number of doses was 6 (2-83), median estimated eCCr at start was 72.3 (45.3-140 .2) mL/min. Concomitant medications included cisplatin in 152 patients (43.3%), carboplatin in 78 patients (22.2%), bevacizumab in 72 patients (20.5%), immune checkpoint inhibitors in 59 patients (16.8%), and EGFR-TKI in 4 patients (1.1%). Patients who had an eCCr <45 mL/min at pemetrexed discontinuation tended to have an older starting age, a smaller body surface area, and a lower starting eCCr. The results of propensity score matching using these background factors in 60 patients in each group showed that a higher frequency of administration was significantly correlated with a decrease in eCCr < 45 mL/min.

Conclusions: Long-term pemetrexed administration is associated with risk of renal failure.

P2.10.04 Real-World Evidence on the Efficacy of TS1 in Patients With Advanced Non-Small Cell Lung Cancer

C-Y. Yeh[1,2], H-C. Huang[1,2], C-L. Chiang[1,2], C-I. Shen[1,2], Y-T. Liao[1,2], Y-H. Tseng[1,2], Y-M. Chen[1,2], Y-H. Luo[1,2]
[1]Taipei Veterans General Hospital, Taipei/TW ,[2]National Yang Ming Chiao Tung University, Taipei/TW

Introduction: TS-1, an oral fluoropyrimidine derivative, has been used to treat advanced non-small cell lung cancer (NSCLC) following standard therapies. However, its real-world effectiveness across different lines of treatment, combination regimens, and clinically or molecularly defined subgroups remains inadequately characterized.

Methods: This retrospective study included 363 patients with advanced NSCLC who received TS-1 between 2012 and 2024. Primary endpoint was overall survival (OS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), and time to treatment failure (TTF). Subgroup analyses were based on treatment line, dose, regimen, histology, metastatic sites, EGFR mutation status, and PD-L1 expression.

Results: TS-1-based regimens yielded an ORR of 19.0% and DCR of 86.2%, with median PFS, TTF, and OS of 2.4, 2.8, and 9.3 months, respectively. In multivariate analysis, patients who received TS-1 as first- or second-line therapy had significantly longer OS (p=0.028), PFS (p<0.001), and TTF (p=0.004) than later line use. Higher TS-1 dose (>40 mg) was associated with longer PFS (p=0.025), TTF (p=0.035), and higher response rate (p=0.029). Compared to TS-1 monotherapy, TS-1-based combination therapy was associated with improved OS (p=0.045). TS-1 combined with second-/third-generation EGFR-TKIs improved OS (p=0.019) and TTF (p=0.014), with additional TTF benefit observed in those receiving TS-1 combined with third-generation EGFR-TKIs (p=0.027). TS-1 combined with platinum-based chemotherapy significantly reduced progression risk (p=0.03) and improved ORR (44.4%) and DCR (88.9%) over monotherapy (ORR 17.7%, DCR 84.1%), although lower response rates were observed in patients with driver (p=0.023) and EGFR mutations (p=0.028) compared to TS-1 monotherapy. Absence of brain metastases was associated with higher odds of treatment response (p=0.048). Poorer OS was associated with non-adenocarcinoma histology (p=0.006), squamous subtype (p=0.002), ECOG PS of 2-4 (p=0.002), smoking (p=0.032), and the presence of bone (p=0.048), abdominal (p=0.033), or liver metastases (p=0.007). Additionally, abdominal (p=0.004) and liver metastases (p=0.007) were associated with shorter TTF. In patients with EGFR mutations, TS-1 combined with targeted therapy improved OS in univariate analysis (p=0.036), particularly when combined with second-/third-generation EGFR-TKIs (p=0.036) compared to TS-1 monotherapy, but not in multivariate analysis. Mutation status significantly impacted OS (p=0.04), with inferior outcomes in patients harboring ALK, ERBB2, or BRAF mutations compared to patients without identifiable driver mutations (p=0.005). Among patients tested for PD-L1, expression levels of 50-60% had worse OS than PD-L1-negative patients (p=0.004). Improved OS (p=0.01) was observed in patients with 30% PD-L1 expression; however, this association was not observed in neighboring PD-L1 expression ranges. In patients with PD-L1 ≥1%, TS-1 combined with either targeted (p=0.008) or immunotherapy-based therapies (p=0.012) improved treatment response, with both remaining significant in PD-L1 ≥30% subgroups (p<0.001 for both).

Conclusions: Earlier-line use of TS-1, higher dosing, and combination therapy, particularly with second-/third-generation EGFR-TKIs, were associated with improved OS. Better response rates were observed in PD-L1-positive patients receiving TS-1 in combination with targeted or immunotherapy-based regimens. Conversely, poorer OS was related to non-adenocarcinoma histology, ECOG PS of 2-4, smoking, and specific distant metastases. These findings underscore the potential value of developing biomarker- and phenotype-guided strategies to optimize TS-1-based treatment in NSCLC.

Introduction: Osimertinib is the current standard of care as first-line (1L) treatment for patients with EGFR-mutant advanced non-small cell lung cancer (aNSCLC). Recently, the FLAURA-2 trial showed a longer progression-free survival (PFS) with 1L platinum-pemetrexed plus osimertinib vs osimertinib alone. These results raise questions about the optimal treatment strategy, osimertinib followed by chemotherapy or the combination upfront. Real-world (RW) evidence on the efficacy of second-line (2L) chemotherapy after osimertinib is scarce. Therefore, RW data could be very informative in the context of a changing landscape, with intensification regimens moved to the front-line.

Methods: We retrospectively identified patients with EGFR-mutant aNSCLC who received 2L carboplatin plus pemetrexed after 1L osimertinib between May 2018 and June 2023 in 11 European centres. Demographics and clinical data were collected and analysed. The primary endpoint was the overall response rate (ORR), while secondary endpoints included PFS and overall survival (OS) from the start of chemotherapy, as well as toxicity.

Results: We identified a total of 91 patients. Median age was 62.5 years (range 40 - 81), 56 patients (61.5%) were males, 58 patients (63.7%) were never smokers. Most patients (n = 81, 89.0%) had a common mutation, either exon 19 deletion (n = 48) or L858R (n = 33). The TP53 mutational status was available in 51 patients, among them a mutation was present in 19 patients (37.3%). ECOG performance status was ≥ 2 in 31 patients (35.3%). Baseline liver and brain metastases were present in 32 (35.2%) and 26 (28.6%) patients, respectively. Among 72 patients evaluable for response, the ORR was 33.3%. Median follow-up in right-censored patients was 20.5 months (95% CI 13.7 - 27.2). Median PFS was 5.3 months (95% CI 4.4 - 6.1) and median OS was 9.2 months (95% CI 7.5 - 10.8). In the multivariate Cox regression analysis, EGFR mutation subtype was not significantly associated with differences in PFS or OS (Table 1). Twenty-four (24.4%) patients experienced grade 3-4 chemotherapy-related adverse events. Dose reductions were required in 21 patients (23.1%), while treatment was stopped due to toxicity in 13 patients (14.3%).

Conclusions: This RW cohort of patients treated with carboplatin and pemetrexed after osimertinib showed an ORR and PFS comparable to previously published evidence, while the OS was notably shorter, reflecting the inclusion of patients with poorer PS in our cohort. Overall, outcomes with 2L carboplatin plus pemetrexed post-osimertinib remain poor and confirms the need to find more effective strategies.

Table 1. Multivariate Cox regression model of OS and PFS in EGFR-mutant NSCLC patients treated with second-line carboplatin plus pemetrexed after receiving first-line osimertinib.

P2.10.06 Docetaxel in NSCLC: A Multi-Centre Real World Evidence Analysis in the Immunotherapy Era

C. Theriau[1], H. Shah[1], S. Moore[1], Y. Li[2], D. Akurang[1], R. Juergens[3], N. Leighl[4], P. Wheatley-Price[1]
[1]University of Ottawa, Ottawa/ON/CA ,[2]Queen's University, Kingston/ON/CA ,[3]McMaster University, Hamilton/ON/CA ,[4]Princess Margaret Cancer Centre, Toronto

Introduction: Lung cancer screening (LCS) rates in the U.S. remain low despite endorsements from professional organizations and broad insurance coverage with no co-pay. Family physicians play an essential role in LCS, in having long-term relationships with their patients that emphasize preventive care, established screening protocols for other cancers, routinely screening for tobacco use, and providing cessation resources to their patients who smoke. Understanding what family physicians know about LCS, how they are implementing it their practices and their preferences for doing so, is critical to increasing the uptake of this life saving screening test.

Introduction: Docetaxel has been a standard of care in advanced non-small cell lung cancer (NSCLC) for over 2 decades, and numerous attempts to develop more efficacious options have failed. Docetaxel remains the 'final' line of approved therapy in most putative algorithms, but real-world evidence (RWE) outcomes have not been recently reported, particularly in the era of immune checkpoint inhibition (ICI).

Methods: With ethics board approval, we reviewed patients with advanced NSCLC who received docetaxel monotherapy over 10 years (January 2011 - December 2020) across 3 academic cancer centres in Ontario, Canada. We hypothesized that treatment outcomes in the RWE setting would be similar to those reported in clinical trials. RECIST response was not available. Eligibility included adult patients; histological confirmation of NSCLC; treatment with docetaxel monotherapy in the second line setting or beyond; and stage 3B or 4 at the time of treatment initiation.

Results: In total, 285 patients were included. Median age 62 years (17-85); 43% female; 68/22/9% ECOG PS 0-1/2-3/unknown; 65/27/7% adenocarcinoma/squamous cell/other. Metastatic sites: brain (28%), adrenal (16%), liver (35%), bone (63%), contralateral lung (52%) and pleura (57%). 16% had EGFR mutations. KRAS status was available in 64%, of whom 15% were mutation positive. PDL1 status was available in 66% (13% ≥50%, 17% 1-49%, 36% <1%). 48/35/17% were treated in 2nd / 3rd / 4th+ line with docetaxel. 112 (39%) of patients had received ICI therapy prior to docetaxel in previous curative and palliative intent. The median number of cycles received was 3 (range 2-9). Median OS in the whole population was 6.5 months (95% CI 5.9 - 7.3 months). OS in different populations is reported in the Table 1. In univariate analysis, factors associated with shorter survival included ECOG 2 vs 0 (HR 2.41, 95% CI 1.55-3.76, p<0.0001), ECOG 1 vs 0 (HR 1.82, 95% CI 1.23-2.69, p=0.0026), duration of prior line of therapy to docetaxel >6 months (HR 1.40, 95% CI 1.03-1.90, p=0.0311) and factors associated with a prolonged survival included KRAS mutation (HR 0.53, 95% CI 0.34-0.83, p=0.0054). In multi-variate analysis, KRAS (p=0.0268) and ECOG 2 vs 0 (p=0.0091)/ 1 vs 0 (p=0.0181) remained predictors of OS.

Conclusions: Docetaxel RWE OS is similar to early clinical trials, regardless of immunotherapy use. KRAS mutation, good ECOG PS (0/1) and a shorter duration of prior line of therapy to docetaxel were all associated with prolonged survival.

Table 1: Overall survival (OS) in different treatment populations

Patient group	Number	Median OS (months, 95% CI)	p-value
Overall	285	6.5 (5.9-7.3)	------
Prior ICI	112	6.6 (5.8-8.4)	0.58
No prior ICI	173	6.3 (5.4-7.3)	
2nd line	138	6.4 (5.3-7.6)	0.84
3rd line	99	6.3 (4.3-7.8)	
4th line +	48	7.2 (5.4-9.9)	
EGFR mutation	47	6.1 (3.7-7.5)	0.12
KRAS mutation	28	10.2 (3.8-17.2)	0.0047
ECOG PS 0	43	8.5 (5.8-14.0)	0.0012
ECOG PS 1	151	6.8 (6.0-7.9)	
ECOG PS 2	58	4.3 (3.1-6.2)

P2.10.07 Combined Immunoscore for Predictive Stratification of Unresectable Non-Small Cell Lung Cancer

O. Aazzane[1,2,3], S. Fathi[1,2], A. MELLOUKI[2], R. ALLALI[2], M. CHARKAOUI[4], A. Acharki[5], N. BENCHAKROUN[1,4], S. Sahraoui[4], H. Fellah[1,3], M. Karkouri[1,2]
[1]Laboratory of Cellular and Molecular Pathology, Faculty of Medicine and Pharmacy, Hassan II University of Casablanca, Morocco, Casablanca/MA ,[2]Laboratory of Pathology, Ibn Rochd University Hospital, Casablanca, Morocco., Casablanca/MA ,[3]Laboratory of Immunology, Faculty of Medicine and Pharmacy, Hassan II University of Casablanca, Morocco., Casablanca/MA ,[4]Mohammed VI Cancer Treatment Center, Ibn Rochd University Hospital, Casablanca, Morocco., Casablanca/MA ,[5]Ryad Oncology Clinic, Casablanca, Morocco, Casablanca/MA

Introduction: The identification of an immunoscore combining multiple components of the tumor microenvironment such as PD-L1 expression by tumor cells, CD8 and CD4 T lymphocyte infiltration, the presence of tumor-associated macrophages and neutrophils (TAMs and TANs), and the derived neutrophil-to-lymphocyte ratio (dNLR) appears highly promising in non-small cell lung cancer (NSCLC).

The primary objective of this study is to evaluate the predictive value of these biomarkers, particularly tumor PD-L1 expression, CD8 and CD4 T-cell infiltration, TAMs, TANs, and dNLR, in patients with unresectable NSCLC treated with a chemotherapy doublet.

In parallel, the secondary objective is to develop a combined immunoscore to optimize predictive stratification in these patients, thereby enabling better personalization of therapeutic approaches.

Methods: Between 2019 and 2023, we conducted a study on 56 patients with unresectable NSCLC. All patients were treated with a chemotherapy doublet at the Mohamed VI Cancer Treatment Center of Ibn Rochd University Hospital in Casablanca.

Immunohistochemistry was used to assess PD-L1 status (clone 22C3) and the density of CD8 (clone C8/144B), CD4 (clone 4B12), and TAMs (clone KP1). Additionally, the density of TANs was determined using H&E staining. Statistical analysis was performed using SPSS V21 software.

Results: The median age of the patients (N=56) was 67 years (range: 38-92 years), with a sex ratio of 5.22. A total of 80.35% of patients had a history of smoking, 80.14% were diagnosed at stage IV, and 33.93% had a performance status of 0.

Analysis of PD-L1 expression, as well as the density of CD8, CD4, TAMs, TANs, and dNLR, alongside chemotherapy response, revealed that patients with tumors poorly infiltrated by CD8 T lymphocytes had significantly better progression-free survival (PFS) and overall survival (OS) compared to those with highly CD8-infiltrated tumors (PFS: 6.63 vs. 3.01 months, p=0.012; OS: 14.07 vs. 5.06 months, p=0.005).

Furthermore, a low TAN density was associated with prolonged PFS (PFS: 7.04 vs. 3.26 months, p=0.020). Additionally, a dNLR < 0.12 was linked to improved PFS and OS compared to a dNLR ≥ 0.12 (PFS: 6.72 vs. 2.73 months, p=0.002; OS: 15.79 vs. 5.10 months, p=0.002).

Regarding the immunoscore, a combined score <9 was associated with significantly better PFS and OS compared to an immunoscore ≥9 (PFS: 6.60 vs. 3.13 months, p=0.002; OS: 12.26 vs. 7.05 months, p=0.009).

Multivariate analysis revealed that the presence of bone metastases and high-density CD8 infiltration were significantly associated with reduced PFS (p=0.004, p=0.005, respectively). Meanwhile, a performance status (PS 1-2) was significantly linked to poorer OS (p=0.043).

Conclusions: Our results suggest that tumor infiltration by CD8 T lymphocytes, TANs, and dNLR plays a significant role in predicting chemotherapy response. Additionally, the combined immunoscore appears to be a promising tool for stratifying patients based on their likelihood of responding to chemotherapy.

Schulich School of Medicine & Dentistry, Western University, London, ON N6A 3K7, Canada; [2]. Verspeeten Family Cancer Centre, London Health Sciences Centre, London, ON N6A 5W9, Canada., London/ON/CA

Introduction: Docetaxel following progression on immunotherapy and platinum-based chemotherapy remains the standard of care for advanced non-small cell lung cancer (NSCLC), but offers limited efficacy. Antibody-drug conjugates (ADCs) may improve outcomes in this population. This meta-analysis evaluates the efficacy and safety of ADCs versus docetaxel in previously treated advanced NSCLC through a systematic review and meta-analysis of randomized controlled trials (RCTs).

Methods: Databases [PubMed (MEDLINE), EMBASE and Cochrane Library], clinical trial registries, and proceedings of global oncology conferences from January 2015 to November 2024 were screened for phase II/III RCTs comparing ADC (e.g., sacituzumab govitecan, datopotamab deruxtecan, and tusamitamab ravtansine) versus docetaxel. Two researchers independently completed data retrieval and screening work using Covidence. The primary outcomes include progression-free survival (PFS) and overall survival (OS), while the secondary outcomes include objective response rate (ORR), disease control rate (DCR), and adverse events (AEs). The pooled hazard ratios (HR) and odds ratios (OR) were meta-analyzed using the generic variance and Mantel-Haenszel methods as appropriate. Random-effect models were used to compute pooled estimates.

Results: Of the 212 records screened, 3 RCTs involving 1597 patients were included (Figure 1). ADCs did not significantly improve PFS (pooled HR: 0.91, 95% CI: 0.73-1.13). For OS, the pooled HR was 0.88 (95% CI: 0.78-1.00, p = 0.06), reflecting a borderline significant trend favoring ADCs, with negligible heterogeneity (I^2 = 0%). Furthermore, subgroup analysis demonstrated a significant OS benefit in the non-squamous cohort (HR: 0.85, 95% CI: 0.74-0.98, p = 0.03). Additionally, no difference was observed in terms of ORR (OR: 1.16, 95% CI: 0.54-2.51) and DCR (OR: 1.39, 95% CI: 0.75-2.57). Grade ≥ 3 treatment-related AEs were significantly lower (pooled OR: 0.49, 95% CI: 0.26-0.90, p = 0.02) with ADCs despite high heterogeneity (I^2 = 87%).

Conclusions: Our findings report a significant survival benefit in patients with non-squamous NSCLC treated with ADCs compared to docetaxel with a manageable safety profile. However, further research is needed to address heterogeneity, refine patient selection and obtain more mature survival data with predictive biomarkers.

P2.10.09 Single-Cell RNA Sequencing Reveals Subtype-Specific Resistance Mechanisms to TROP2-Targeted ADCs in Non-Small Cell Lung Cancer

O. Younis[1], A. Al Bzour[2], N. Al Bzour[2], M. Hashki[2], J. Al Rawabdeh[1], B. Ricciuti[3], F. Abu Rous[4]
[1]University of Jordan, Amman/JO ,[2]Jordanian university of science and technology, Irbid/JO ,[3]Dana Farber Cancer Institute, Boston/MA/USA ,[4]Henry Ford Health, Detroit/MI/USA

Introduction: Antibody-drug conjugates (ADCs) targeting TROP2 have demonstrated variable efficacy across non-small cell lung cancer (NSCLC) subtypes. The currently available TROP2-targeted ADCs, sacituzumab govitecan and datopotamab deruxtecan, have shown limited benefit in NSCLC overall, with relatively greater efficacy in lung adenocarcinoma (LUAD) compared to lung squamous cell carcinoma (LUSC), as seen in the TROPION-1 trial. In this study, we investigated the molecular basis underlying this differential response between LUAD and LUSC.

Methods: Single-cell RNA-seq datasets GSE131907, GSE148071, and GSE162498 were obtained from TISCH2.0, comprising a total of 361,000 cells from 97 patients after quality control. Data preprocessing involved merging datasets, normalization, scaling, and principal component analysis, followed by batch effect correction using Harmony. TROP2 expression was assessed across cell types and NSCLC subtypes using Seurat's FindMarkers function and pseudobulk differential expression analysis. Correlation analyses between TROP2 and markers of sensitivity or resistance to topoisomerase I (TOP1) inhibitors were conducted using the CSCORE algorithm.

Results: TROP2 was highly expressed on malignant epithelial cells in both LUAD and LUSC, with significantly higher levels in LUAD (fold change [FC] = 1.66, $P < 0.0001$). However, expression was not significantly different from that in normal lung epithelial cells in either subtype. In LUAD, TROP2 expression correlated positively with TOP1 ($r = 0.46$, $P < 0.0001$), suggesting potential sensitivity to TOP1 inhibitors. No such correlation was observed in LUSC. Instead, TROP2 expression in LUSC showed strong positive correlations with GCLM ($r = 0.85$), GCLC ($r = 0.40$), and GSR ($r = 0.33$), enzymes involved in glutathione metabolism and known mediators of resistance to TOP1 inhibitors. TROP2 in LUSC also correlated with ABCC2 ($r = 0.19$), a drug efflux transporter implicated in resistance to TOP1 inhibitors (all $P < 0.001$). Conversely, SLFN11, a gene associated with TOP1 inhibitor sensitivity, was negatively correlated with TROP2 in both LUAD ($r = -0.38$) and LUSC ($r = -0.36$) ($P < 0.0001$ for both).

Conclusions: Our study provides insight into the limited efficacy of TROP2-targeted ADCs in NSCLC, particularly in LUSC. While TROP2 remains a viable target, its expression in LUSC is associated with molecular signatures of resistance to TOP1 inhibitors, including upregulation of glutathione-related enzymes and drug efflux transporters. In LUAD, the correlation between TROP2 and both sensitivity and resistance markers suggest a more heterogeneous response. These findings highlight the need to optimize ADC payload selection for improved efficacy in NSCLC, especially in LUSC. Further translational studies are warranted to validate these findings.

P2.10.10 Soluble Ceacam5 Resistant ADC for Effective Tumor Targeted Delivery With Clinically Validated Tumor Selective Linker Payl

N. Choi[1], H. Oh[1], C. Park[1], S. Park[2], M.R. Yun[3,4], D. Kim[3,4], B.C. Cho[3,4], C-W. Chung[1]
[1]LigaChem Biosciences Inc., Daejeon/KR ,[2]DAAN Biotherapeutics, Seoul/KR ,[3]Yonsei University College of Medicine, Seoul/KR ,[4]Yonsei University College of Medicine, Seoul/KR

Introduction: Carcinoembryonic antigen cell adhesion molecule 5 (CEACAM5) is a cell surface glycoprotein prominently expressed in various cancers, particularly non-small cell lung cancer (NSCLC) and colorectal cancer (CRC). LCB58A, a set of novel antibody-drug conjugate (ADC) targeting CEACAM5, utilizes a novel IgG1 antibody clone conjugated to LCB's proprietary ConjuAll technology. Key improvements over prior CEACAM5 ADCs include resistance to soluble CEACAM5 and use of LCB's clinically validated β-Glu cleavable linker with various payloads offering a promising therapeutic strategy.

Methods: The α-CEACAM5 monoclonal antibody was tested for binding affinity and internalization into cancer cells, in the presence of soluble CEACAM5 positive patient sera, using FACS and Incucyte systems. ADCs with various linker-toxin combinations were produced, and their cytotoxicity was evaluated across multiple cancer cell lines. For in vivo analysis, both cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models were employed alongside toxicity studies in human CEACAM5 transgenic (TG) mice. Toxicokinetic studies were also analyzed in TG mice using LC-MS/MS bioanalysis.

Results: The novel α-CEACAM5 antibody demonstrated efficient internalization, surpassing that of comparator antibody Tusamitamab in the presence of soluble CEACAM5. Binding specificity to CEACAM5 was validated via Retrogenix screening at therapeutically relevant doses. LCB58A ADCs exhibited significant cytotoxic effects in vitro and showed remarkable anti-tumor efficacy in CDX and PDX models tested. Toxicity studies showed that LCB58A ADC was well tolerated at efficacy dose with favorable toxicokinetic profile in TG mice.

Conclusions: LCB58A ADCs, leveraging the soluble CEACAM5-resistant antibody H81E6, demonstrate robust efficacy at tolerable doses. The ADCs' ability to specifically bind and efficiently internalize offers a significant therapeutic advantage, particularly in tumor environments with high levels of soluble CEACAM5. These findings highlight LCB58As' potential as highly effective treatment options for patients with CEACAM5-expressing solid tumors, representing a promising avenue in cancer therapy.

Introduction: Antibody-drug conjugates (ADCs) combine the specificity of monoclonal antibodies with the cytotoxic potency of chemotherapeutic agents and have emerged as a promising treatment strategy in oncology. In non-small cell lung cancer (NSCLC), several ADCs have been investigated and showed better responses in lung adenocarcinoma (LUAD) compared to squamous cell carcinoma (LUSC). In this analysis, we leverage single-cell RNA sequencing to identify optimal targets and payloads for ADC development in LUSC.

Methods: The raw cell expression matrix, cellular annotations, and metadata for GSE131907, GSE148071, and GSE162498 were downloaded from TISCH2.0. Cells with less than 500 genes, 1000 counts, or more than 10 percent mitochondrial genes were excluded. A total of 361,000 cells from 97 patients were utilized. Preprocessing included merging the datasets, normalizing, scaling, and running principal component analysis. Integration of the datasets was then carried out using harmony, adjusting for batch effects. Differential expression of ADC targets between cell types and tissue subtypes was performed using the FindMarkers function in Seurat and a limma-based pseudobulk approach. Correlation analysis between ADC targets and sensitivity/resistance markers to topoisomerase 1 and microtubule inhibitors was conducted using the CSCORE algorithm.

Results: Transmembrane glycoprotein NMB (GPNMB) was significantly overexpressed in LUSC malignant cells versus normal epithelial cells (log2FC = 1.10, P = 0.012), while Activated leukocyte cell adhesion molecule (ALCAM) did not reach statistical significance. Both targets were also elevated in multiple cell types in the LUSC tumor microenvironment as compared to LUAD, including fibroblasts, macrophages, alveolar cells, and CD8+ T cells ($p < 0.0001$). In LUSC malignant epithelial cells, ALCAM negatively correlated with ABCC2 ($r = -0.41$, $P < 0.0001$) and ABCB1 ($r = -0.17$, $P < 0.0001$), two efflux transporters linked to resistance to maytansinoids and emtansine. ALCAM also positively correlated with CLTC ($r = 0.96$, $P < 0.0001$), which mediates clathrin-dependent ADC internalization. In contrast, GPNMB showed strong positive correlations with ABCG2, ABCC2, ABCB1, and SLC47A2 (all $p <0.0001$), which confer resistance to MMAE and camptothecins via drug efflux. Lastly, GPNMB ($r = -1$, $p < 0.0001$) and ALCAM ($r = -0.79$, $p < 0.0001$) were negatively correlated with NANS expression which can lead to increased ADC internalization and sensitivity by depleting sialic acid from the cell surface.

Conclusions: Our analysis highlights ALCAM and GPNMB as potential ADC targets in LUSC, with broad expression across malignant and stromal compartments. ALCAM's expression profile suggests susceptibility to maytansinoid-based ADCs such as Praluzatamab Ravtansine, due to its association with endocytosis and absence of efflux resistance signals. GPNMB, while a promising target, is associated with expression of multiple efflux transporters, raising concerns about resistance to ADCs like Glembatumumab Vedotin. These findings support a tailored approach to ADC design based on tumor subtype and resistance landscape.

Introduction: In October 2024, trastuzumab deruxtecan (T-DXd) became the first HER2-directed therapy to receive conditional approval in China for previously treated HER2-mutant (ERBB2; HER2m) unresectable/metastatic NSCLC. Approval was supported by primary results from both DESTINY-Lung02 (confirmed objective response rate [ORR], 49%; median progression-free survival [PFS], 9.9 months; median overall survival [OS], 19.5 months) and DESTINY-Lung05 (confirmed ORR, 58.3%; median PFS by independent central review [ICR], not evaluable [NE]). Here, we report the DESTINY-Lung05 (NCT05246514) final analysis.

Methods: This open-label, single-arm, Phase 2 study evaluated T-DXd (5.4 mg/kg intravenously every 3 weeks) in patients from China with HER2m (locally or centrally confirmed activating HER2 exon 19/20 mutation) metastatic NSCLC with disease progression on or after ≥1 prior anticancer therapy. Confirmed ORRs by ICR (primary endpoint) and by investigator (secondary endpoint) were per RECIST 1.1. Other secondary endpoints included duration of response (DOR), disease control rate (DCR), and PFS by both ICR and investigator per RECIST 1.1; OS, and safety.

Results: At data cutoff (November 4, 2024), 72 patients with HER2m NSCLC had received T-DXd 5.4 mg/kg; median age was 57.0 years (range 34-76), 56.9% were female, and 69.4% were non-smokers. Patients had received a median of 2.0 (range 1-7) prior systemic therapies. Median T-DXd treatment duration was 8.6 months (range 0.7-26.9), and median duration of follow up was 20.2 months (range 2-27). Confirmed ORR was 56.9% by ICR (95% confidence interval [CI] 44.7, 68.6), and 59.7% by investigator (95% CI 47.5, 71.1). By ICR, median DOR was 11.6 months (95% CI 5.8, NE), DCR was 91.7% (95% CI 82.7, 96.9), and median PFS was 9.9 months (95% CI 7.1, 16.5). Median OS was 21.0 months (95% CI 17.5, NE). Additional efficacy data are reported in the table. Grade ≥3 drug-related adverse events (AEs), drug-related serious AEs, and drug-related AEs leading to discontinuation occurred in 40 (55.6%), 23 (31.9%), and four (5.6%) patients, respectively. Overall, the most common drug-related AEs were platelet count decreased (66.7%) and white blood cell count decreased (66.7%). No drug-related deaths occurred. Adjudicated drug-related interstitial lung disease / pneumonitis occurred in nine (12.5%) patients (n=1 Grade 1; n=7 Grade 2; n=1 Grade 3).

Conclusions: Building on the primary DESTINY-Lung05 data, these results with longer follow up further demonstrate that T-DXd 5.4 mg/kg provides durable responses and survival benefit in patients from China with pretreated HER2m metastatic NSCLC. No new safety signals were reported.

Introduction: Sunvozertinib is a rationally designed, oral, and potent epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI). A pivotal clinical study (NCT05712902) has demonstrated the significant antitumor efficacy of sunvozertinib monotherapy for previously treated advanced non-small cell lung cancer (NSCLC) with EGFR exon 20 insertion mutations (exon20ins), leading to its conditional approval in China in this disease indication. With the positive results of EGFR TKI combined with bevacizumab in NSCLC with EGFR sensitizing mutations (ARTEMIS-CTONG1509), it is hypothesized that sunvozertinib combined with bevacizumab could further enhance the antitumor effect in NSCLC with EGFR exon20ins. Here we report the preclinical and clinical data on this combination therapy.

Methods: The preclinical effect of sunvozertinib with bevacizumab was tested in patient-derived xenograft (PDX) animal models carrying EGFR exon20ins, and potential mechanism-related biomarkers were evaluated before and after treatment by immunohistochemistry. WU-KONG29 (NCT06276283) is an ongoing phase 2 multicenter dose escalation and expansion study to investigate the safety and efficacy of this combination therapy in patients with EGFR mutant (EGFRm) NSCLC, with a focus on EGFR exon20ins. In the dose escalation part, previously treated patients with EGFRm NSCLC received sunvozertinib 200 mg or 300 mg once daily (QD) with bevacizumab 15 mg/kg once every 3 weeks. In the dose expansion part, previously treated patients with EGFR exon20ins received sunvozertinib 300 mg QD with bevacizumab. Safety and efficacy were assessed by investigators per CTCAE5.0 and RECIST1.1, respectively.

Results: Sunvozertinib with bevacizumab led to greater tumor shrinkage in PDX models, as well as a greater decrease in tumor microvessel density and downstream signaling (pS6) than single drugs. As of January 3, 2025, a total of 19 previously treated patients were enrolled in the WU-KONG29 study, and 14 patients who had EGFR exon20ins were treated with sunvozertinib 300 mg QD and bevacizumab. The median age was 56 years, and 92.9% had an ECOG score of 1. All patients had metastatic disease, and 42.9% had baseline brain metastasis. All patients received prior chemotherapy. Per investigator assessment, 8 out of 14 patients achieved partial response, with an objective response rate (ORR) of 57.1% (50% confirmed) and a disease control rate of 100%. With a median follow-up of 9.8 months, the median duration of response (DoR) was not reached, and the 12-month durable response rate was 71.4%. With a median follow-up of 12.4 months, the estimated median progression free survival (PFS) was 16.4 months. In patients with baseline brain metastasis, the confirmed ORR was 50%, and the median PFS was 11.0 months. Treatment-related adverse events of grade ≥3 and serious adverse events were reported in 52.6% and 10.5% of patients, respectively. No new safety risks were noted compared to individual drugs.

Conclusions: Our results demonstrated notable combination effect of sunvozertinib with bevacizumab in pretreated NSCLC with EGFR exon20ins.

P2.10.14 Individualized Neoantigen Therapy With Unusual Radiotherapy Enhancement (iNATURE) a Phase II Randomized Study

Y. Zhang[1], Y-F. Hu[2], R. Li[3], W. Dai[2], Q. Wang[1], W. Chen[1], J. Huang[1], Y. Han[1], J. Zhang[1], F. Zhang[1], T. Cao[1], L. Ma[1], J. Zhang[1], X. Chen[1], X. Su[4], G. Yang[5], P. Fu[6], J. Huag[2], J. Wang[7], K. Cheung[2], W.S. POON[2], F-M. Kong[1,2]
[1]University of Hong Kong-Shenzhen Hospital, Shenzhen/CN ,[2]University of Hong Kong, Hong Kong/CN ,[3]P&PMed Biotechnology Co., Shanghai/CN ,[4]The Second Afliated Hospital of Wenzhou Medical University, Wenzhou/CN ,[5]Peking University, Beijing/CN ,[6]Case Western Reserve University, Cleveland/OH/USA ,[7]YuceBio Technology Co., Shenzhen/CN

Introduction: Personalized neoantigen-based vaccines targeting tumor-specific neoantigens are emerging as a promising immunotherapy, with recent publication in Nature reporting 9 cases showing no relapse 40 months after surgery. However, in refractory solid tumors, the effect is limited due to significant tumor burden. We hypothesized that neoantigen peptide vaccines combined with immune modulating precision Critical Lesion Radiotherapy (CLERT) can improve local and distant tumor control. This study aimed to evaluate the safety, feasibility, and early efficacy of this approach in metastatic cancer patients who failed systemic therapy.

Methods: This is a phase II randomized study (NCT06314087) focusing on refractory metastatic cancers. Eligibilities included metastatic solid tumors with progression after systemic therapy and “targetable” lesions for CLERT. Neoantigens were selected using an AI-powered immunogenicity prediction platform based on whole exosome sequencing by three independent teams. There were two arms: the control arm with placebo, and the vaccine arm receiving fully personalized peptides, BXP-001. All patients received CLERT one week before vaccine injection, with 5 prime immunizations and four monthly boosters. Control patients crossed over to the vaccine arm upon disease progression. Immune responses were assessed through T cell and antibody testing.

Results: This is a pre-planned interim report. A total of 46 patients have been screened with WES genomic testing of over 20000 genes. On average, 2.626 (95% CI: 2.111-3.142) tumor mutation burden were tested. All patients had immunogenic mutations, with tumor neoantigen burden ranged from 0.756-1.099 (median 0.928), 60% patients were found to have 5+ high-ranking immunogentic neoantigens, confirmed by all 3 teams. Upto March 31, 2025, 11 of these NSCLC patients were enrolled and successfully randomized. Two patients died from tumor progression accociated complication before protocol treatment start. Seven patients are currently undergoing treatment or have already completed it, while others are awaiting treatment initiation. Among the 7 treated patients treated per protocol, 3 and 4 patients were assigned to the neoantigen and control arms, respectively. 3 of 4 control patients had disease progression on placebo arm and were subsequently crossed over to the vaccine arm. All 7 patients received vaccine had disease controlled with a median follow-up of 2.73 months (95% CI 1.16-6.39). The median PFS for the placebo group was 1.4 months (95% CI 1.13-NR), while the median PFS for the neoantigen group has not yet been reached. Immunogenicity analysis of PBMC and plasma samples revealed neoantigen-specific immune response in T cell and antibody in all tested patients. There was no grade 2 above toxicity in either of the arms, 14.3% received vaccine had grade 1 injection site bruise and 14.3% fatigue.

Conclusions: This study at the first time demonstrated iRT of fully personalized neoantigen peptide vaccine (BXP-001) and CLERT was feasible, safe, and capable of eliciting neoantigen-specific immune responses in all analyzed patients with refractory solid tumors. The preliminary results in PFS between vaccine and placebo groups appears to be promising. Further study with larger sample size in multicenter setting is beining kicked off to confirm this promising strategy.

P2.10.15 Mechanistic Study of Osimertinib Combined With Sitravatinibto Overcome Acquired Osimertinib Resistance in Non-Small Cell Lung Cancer

X.Q. Wang[1], R.P. Li[2], Y.J. Wang[2], C. Chen[3], D.H. Luo[4], M. Meng[1], Y.P. Chen[4], S.S. He[1]
[1]Affiliated Second Hospital of Zunyi Medical University, Zunyi/CN ,[2]Jiangsu Normal University, Xuzhou/CN ,[3]Affiliated Hospital of Zunyi Medical University, ,Zunyi/CN ,[4]The Third Affiliated Hospital of Zunyi Medical University, Zunyi/CN

Introduction: Osimertinib,a third-generation EGFR inhibitor, has become the standard treatment for EGFR-mutant non-small cell lung cancer (NSCLC). However, acquired resistance remains a major challenge for most patients after prolonged therapy.Sitravatinib a multi-target tyrosine kinase inhibitor, has shown promise in overcoming immune resistance and chemotherapy resistance in the treatment of various solid tumors. Its potential to overcome targeted therapy resistance in NSCLC, however, remains unclear.

Methods: A NSCLC osimertinib-resistant cell line (PC-9/OR) was established to mimic clinical resistance. In vitro experiments were then conducted to evaluate the effects of combining osimertinib with sitravatinib on cell proliferation, migration, and invasion, while also investigating the underlying molecular mechanisms. Furthermore, a NSCLC osimertinib-resistant mouse model was developed to assess the in vivo anti-tumor activity of the combined therapy.

Results: Compared with osimertinib monotherapy, the combination of osimertinib and sitravatinib significantly inhibited the proliferation, migration, and invasion of drug-resistant cells. However, this combinational treatment did not exhibit a markedly enhanced inhibitory effect on the parental cells. Moreover, in a mouse model of osimertinib-resistant non-small cell lung cancer (NSCLC), the combination therapy significantly suppressed subcutaneous tumor growth compared to osimertinib alone.Transcriptomic and proteomic analyses revealed that in the osimertinib-resistant cell line, several differentially expressed genes were identified, among which the anti-apoptotic protein TRAF1 and mesenchymal markers associated with epithelial-mesenchymal transition (EMT), including Vimentin and N-cadherin, were markedly upregulated. Upon treatment with varying concentrations of sitravatinib, the expression levels of TRAF1, Vimentin, N-cadherin, and proteins related to the TGF-β signaling pathway, which regulates EMT, were reduced in a dose-dependent manner. In contrast, the expression of the epithelial marker β-catenin increased in a dose-dependent fashion. Additionally, the expression of the pyroptosis-associated protein NLRP3 was elevated in a dose-dependent manner.

Conclusions: This study found that the combination of sitravatinib and osimertinib significantly inhibits the proliferation, migration, and invasion of osimertinib-resistant non-small cell lung cancer (NSCLC) cells, and markedly suppresses tumor growth in vivo. Mechanistic investigations revealed that TRAF1 and EMT-related signaling pathways are notably activated in osimertinib-resistant cells. The combined therapy may overcome resistance by simultaneously inhibiting anti-apoptotic mechanisms, inducing pyroptosis, and targeting the TGF-β/SMAD/SNAIL axis to suppress the EMT process. These findings provide novel insights and potential therapeutic strategies for the treatment of NSCLC after the development of resistance to osimertinib.

P2.10.16 Paclitaxel Liposome Combined With Immunotherapy in the First-Line Treatment of Advanced NSCLC: Updated Results of a Real-World Study

L. Jiang[1], D. Zheng[2], J. Ni[2], H. Ding[3], Y. Zhao[1], y. shang[4], W. Heng[5], X. Cai[1], J. Yan[6], J. Wang[2], J. Guo[1], Y. Du[7], X. Hong[8]
[1]Shanghai Chest Hospital, Shanghai/CN ,[2]Shanghai Pulmonary Hospital, Shanghai/CN ,[3]Zhenjiang First People's Hospital, zhenjiang/CN ,[4]Affiliated Hospital of Hebei University, Baoding/CN ,[5]The First Affiliated Hospital of Soochow University, Suzhou/CN ,[6]Hebei Petro China Center Hospital, Langfang/CN ,[7]The First Affiliated Hospital of Anhui Medical University, Hefei/CN ,[8]Harbin medical university cancer hospital, Harbin/CN

Introduction: Paclitaxel liposome is a formulation in which paclitaxel is encapsulated within liposomes composed of lecithin and cholesterol. Unlike conventional solvent-based paclitaxel, this formulation eliminates the need for polyethoxylated castor oil, thereby reducing the incidence of drug-induced toxicity, particularly hypersensitivity reactions. This study aimed to evaluate the real-world effectiveness and safety of paclitaxel liposome-based chemotherapy plus immunotherapy as first-line treatment among Chinese patients with advanced non-small cell lung cancer (NSCLC).

Methods: Data were extracted from the "Efficacy and Safety of Immunotherapy in NSCLC Patients: A Multi-Center Observational Study" project ,part of a real-world lung cancer database initiative launched by the Lung Cancer Special Committee of the China Medical Education Association.This analysis specifically focused on paclitaxel liposome plus immunotherapy regimens. Patient records were obtained from an online hospital platform. Non-laboratory adverse events were based on analyses of patient-reported outcome(PRO) data.The study evaluated advanced NSCLC patients who underwent first-line treatment with paclitaxel liposome-based chemotherapy and immunotherapy in eight Chinese hospitals between April 2020 and January 2025. The primary outcome was progression-free survival (PFS), while secondary outcomes included objective response rate (ORR), overall survival(OS) and safety.

Results: Among 336 eligible patients, 320 were male, with a median age of 68.5 years (range: 61.0 -73.0). 240 (71.4%) were squamous cell carcinoma, 27(8.0%) were adenocarcinoma. 31.0% of the patients were at stages IIIB-IIIC, and 69.0% were at stage IV. The median treatment cycles for first-line paclitaxel liposome-based chemotherapy and immunotherapy were 4. Immunotherapy agents included tislelizumab (n=192), pembrolizumab (n=51), sintilimab (n=38) and others. All patients were co-administered platinum with 91.1% receiving carboplatin. As of March 2025,the median duration of follow-up was 14.9 months. The median PFS was 13.07 months (95% CI: 11.4-14.0),with 1-year and 2-year PFS rates were 53.1% (95% CI: 46.3-58.5) and 28.6%(95%CI:20.4-35.0),respectively. The 1-year and 2-year OS rates were 90.7% (95% CI: 86.6-93.6) and 73.7%(95%CI:65.4-79.1),respectively. Multivariate analysis identified treatment cycles (>3) of paclitaxel liposome and achieved ORR as independent predictors of prolonged PFS(P<0.05) Among all patients,24 achieved a complete response, 188 demonstrated a partial response, 106 had stable disease, and 18 experienced progressive disease. The overall ORR was 63.1%, and the DCR was 94.6%. Adverse events of all grades were recorded in 94.6% of the patients,with 63.4% were of grade 3 or higher. All observed adverse events were consistent with those described in the product prescribing information. The most common adverse events included bone marrow suppression, gastrointestinal reactions, and liver function abnormalities. The adverse events observed in >20% of the patients were anaemia, leucopenia, neutropenia, increased r-glutamyltransferase, increased alanine aminotransferase, thrombocytopenia, hypoproteinemia, increased alkaline phosphatase and increased aspartate aminotransferase.

Conclusions: In this real-world study, paclitaxel liposome-based chemotherapy plus immunotherapy demonstrated robust efficacy and a manageable safety profile in advanced NSCLC, without an increased risk of unexpected toxicity. These findings support its use as a viable first-line treatment option in this population.

P2.10.17 Dual PARG-TOP1 Inhibition Exacerbates Dna-Protein Crosslinks and Replication Stress: A Promising Strategy for Enhancing Top1i-ADC Efficacy

R. Maskey, P.X. Lim, M. Conway, V. Nagarajan, Z. Roland, A.A. Rao, I. Shabalin, K. Trego, J. Ryan, R.M. Choy, P. Teriete, C. Frey, Y. Bai, P.A. Barsanti, C. Neilan, J. Sachdev, M.A. White, D.M. Delgado
Ideaya Biosciences, South San Francisco/CA/USA

Introduction: Antibody-drug conjugates with topoisomerase I inhibitor payloads (TOP1i-ADCs) are having a significant impact as cancer therapies in select tumor types. However, a persistent challenge facing broad development of TOP1i-ADCs across solid tumors is optimization of tumor-specific payload delivery required for meaningful anti-tumor activity given low or heterogeneous tumor-selective antigen expression. Recent findings indicate an essential role for the poly ADP-ribose glycohydrolase, PARG, in the repair of TOP1-DNA cleavage complexes (Top1ccs), a type of enzymatic DNA-protein crosslink (DPC) that can promote lethal DNA damage when sufficiently induced by TOP1i. Here we evaluated the potential for PARG inhibition to selectively amplify TOP1i-induced DNA damage and to promote the therapeutic effects of TOP1i-ADCs in multiple preclinical models. We find that the clinical-stage PARG inhibitor, IDE161, significantly enhances TOP1i-dependent accumulation of Top1ccs and associated replication fork failure in cell line models. Notably, IDE161 promotes the efficacy of multiple TOP1i-ADCs in lung cancer models, establishing IDE161 as a promising partner for TOP1i-based ADC therapies to enhance efficacy and durability and improve patient outcomes.

Methods: Mechanistic PARGi sensitivity and PARG gene dependency associations were assessed by multiomic profiling across cancer cell line panels. Single-agent and combination effects of PARG and TOP1 inhibitors on cell viability were evaluated via high-throughput multiplexed screens and synergistic effects were validated in select cell lines. Mechanism of action was established by quantifying drug effects on replication stress markers including replication fork progression (DNA fiber assay), PAR chain accumulation (MSD), and Top1cc/γH2AX levels (immunofluorescence). In vivo tumor growth inhibition was measured in tumor cell-derived xenografts (CDX) treated with IDE161 and TOP1i-ADCs.

Results: Evaluation of IDE161 antiproliferative activity across a panel of molecularly characterized cancer cell lines highlighted significant associations of PARG sensitivity with molecular signatures of chronic replication stress. Consistent with this, IDE161 induced PAR chain accumulation, extensive replication fork stalling, increased transcription-replication conflicts, activation of the ATR-mediated cell cycle checkpoint, and γH2AX signatures associated with pan-genomic replication fork collapse. Notably, pan-cancer drug assessments indicated a strong correlation between PARGi and several TOP1 inhibitors. Multiplexed viability screens with combination treatment of IDE161 and topotecan revealed enhanced cellular proliferation defects in multiple tumor models compared to single agent treatment. Mechanistically, the combination of TOP1 and PARG inhibition showed increased Top1cc levels and enhanced replication fork slowing, suggesting that the IDE161/TOP1i combination induces DNA lesions that interfere with DNA replication. In addition, TOP1 inhibition synergistically increased the accumulation of cellular PAR levels and γH2AX caused by IDE161 treatment, suggesting hyper-PARylation of Top1ccs and failure of DPC resolution, demonstrating that IDE161 amplifies TOP1 inhibitor-induced DNA damage and replication catastrophe. Importantly, deep, durable, and complete responses were observed with IDE161 in combination with multiple TOP1i-ADCs in lung cancer CDX models, that were not achievable with monotherapy.

Conclusions: These findings deliver a strong mechanistic rationale for the use of systemic PARG inhibition to enhance the efficacy and durability of TOP1i-ADC therapies in solid tumors, particularly in the setting of lung cancer.

P2.15 .01 Expedited Diagnostics Coordination Leads to Expedited Care in Advanced Stage Lung Cancer

R. ANDERSON, E. Ihrke
Mayo Clinic, Rochester/MN/USA

Introduction: To design a patient-centric treatment plan for advanced stage non-small cell lung cancer, evaluation of actionable genetic variants is essential. Genetic mutations can be evaluated via tissue analysis and serum analysis. Such tests typically take time to process which can lead to delayed initiation of systemic treatment if there is not a symptomatic presentation necessitating urgent initiation of chemotherapy. These delays not only burden oncology practices but are also a source of significant anxiety for patients awaiting a conclusive treatment proposal and subsequent initiation of therapy.

Methods: The purpose of this work was to expedite genetic variant analysis and to reduce testing delay-related anxiety for newly diagnosed patients with advanced stage NSCLC. The intervention was two pronged: First, serum genetic variant testing was ordered at the time of diagnosis/staging by the lung nodule clinic within the pulmonary department as part of the preparation for upcoming oncology consultation. If the patient is local, the testing was obtained at the treatment facility. If the patient lived a distance from the treatment facility, a draw local to the patient was coordinated in collaboration with the serum genetic variant testing vendor; there was no additional charge to the patient for this service. Standard practice was to have such testing obtained at the time of oncology consult. Second, within 48 hours of the pulmonary provider delivering the diagnosis to the patient, the lung cancer nurse navigator conducted a virtual visit with the patient to provide an overview of the oncology process at the treatment facility. A discussion of consultation visit expectations, processing time of genetic variant testing and the necessity of those results prior to treatment planning, and general overview of management of advanced stage NSCLC was provided. The patient was provided an opportunity to ask questions of the nurse navigator.

Results: Over a period of 6 months, data abstraction from the patient record comparing the intervention group (patients sent from pulmonary department) versus the control group (patients triaged direct to oncology from non-pulmonary provider) was completed. At the time of oncology consult, 51% of intervention patients had serum genetic variant analysis resulted while only 11% had resulted in the control group. Therefore, treatment decisions were finalized in 71% of intervention patients as compared to 26% from the control group. Patients who were referred from pulmonary medicine who received the post-diagnosis oncology introductory phone call expressed appreciation in timely contact, education, and resource access when applicable.

Conclusions: Coordination of genetic variant analysis serum testing at the time of diagnosis increases the likelihood that test results will be available at the time of oncology consult to therefore allow for treatment decisions at the first consult visit. Additionally, by drawing variant testing earlier systemic treatment can be initiated earlier. This in combination with a nurse navigator-initiated oncology introduction call can reduce patient anxiety, set clear patient expectations, and illustrate to the patient that the team is actively working on their case all leading to an improved patient experience.

P2.15 .02 Communication Needs of Patients With Advanced Lung Cancer Receiving Immunotherapy: Results of a Qualitative Study

M. Villalobos[1,2], P. Ullrich[2], H. Voß[2], M.T. Leimbach[2], L. Unsöld[2], M. Thomas[2]
[1]Heidelberg University Hospital, Heidelberg/DE ,[2]Dept. of Thoracic Oncology, Thoraxklinik, Heidelberg University Hospital and National Center for Tumor Diseases (NCT), NCT Heidelberg, Translational Lung Research Center Heidelberg (TLRC-H), Member of the German Center for Lung Research (DZL), Heidelberg/DE

Introduction: The demand for information and participation in decision-making among cancer patients is steadily increasing but often remains unmet. The rapid advancements in lung cancer treatments over recent years have resulted in greater complexity, which can be overwhelming for patients. For a predominantly elderly and frail population, shared decision-making is particularly challenging. Recent studies indicate that lung cancer patients receiving immunotherapy frequently have an inadequate understanding of treatment goals and prognosis hazarding the timely integration of palliative care. Our study aims to explore patients' knowledge about immunotherapy, the information and decision-making process, and their awareness of palliative care topics in order to inform the development of a digital decision-support tool.

Methods: Semi-structured, in-depth interviews were conducted with 20 patients with advanced lung cancer receiving immunotherapy at the Department of Thoracic Oncology (Heidelberg University Hospital), Germany. Qualitative content analysis was performed using MAXQDA.

Results: We identified the following themes: decision-making preferences, information provision and processing, prognostic awareness, perceptions of palliative care, and utilization of digital tools. Overall, patients showed limited and often inaccurate knowledge about immunotherapy. They recalled the informed consent process, but participation in decision-making with physicians was minimal, leading in most cases to uncritical acceptance of the medical treatment recommendations. The primary information source was the medical staff, while web-based information and digital sources were generally viewed negatively. Although patients were mostly aware of the goals of palliative care in general, there was significant variability in their prognostic awareness and perceptions of personal palliative care needs.

Conclusions: The substantial gaps in knowledge regarding the effects and risks of immunotherapy, along with limited awareness of opportunities to integrate personal preferences into decision-making, highlight the need for enhanced patient empowerment strategies. The rapid pace and complexity of advancements in cancer treatment options require flexible approaches to information delivery and decision-making. Digital solutions could play a key role in supporting this process. The negative attitude towards the use of digital devices in our study may be age-related, underscoring the importance of involving elderly patients in the development of digital tools. These tools should be designed to empower patients in a way that addresses their unique information needs and decision-making strategies.

Keywords: communication, decision-making, immunotherapy

P2.15 .03 Predictive Value of LIPI Score in the Response to Immunotherapy in Very Elderly Patients With Advanced Non-Small Cell Cancer

A. Olivares Hernández, A. Albarrán Gómez, L. Corvo-Félix, L. Posado-Domínguez, J.C. Redondo-González, L. Bellido Hernández, E. Fonseca-Sánchez, S. Jiménez Cabrera, E. del Barco Morillo
Salamanca University Hospital, Salamanca/ES

Introduction: The Lung Immune Prognostic Index (LIPI) score is a tool for predicting response to immunotherapy in non-small-cell lung cancer (NSCLC). However, its use in very elderly populations is unknown, although the use of immunotherapy is increasing in this group. In addition, there is an increasing incidence of NSCLC in very elderly (≥80 years, geriatric guidelines definition). Objective: study the value of LIPI in predicting response to immunotherapy in very elderly patients "pts" with advanced NSCLC.

Methods: Prospective study of pts over 80 years with a diagnosis of advanced NSCLC who had received immunotherapy. The LIPI score was calculated using LDH and dNLR values collected 30 days prior to the start of treatment (dNLR>3, LDH >ULN). Molecular study (TruSight Panel) and PD-L1 were performed in all pts. SPSS software and Kaplan-Meier test were used to compare survival in months "m" (statistical significance p<0.05) between prognostic groups according the LIPI score.

Results: Thirty pts with a median age of 83 years [80-95] were studied. Males were 80% and females 20%. The most frequent histology was adenocarcinoma (18 pts, 60%) followed by squamous (10 pts, 33.3%). The PD-L1 was ≥50% in 13 pts (43.3%) and <50% in 17 pts (56.7%). 26.7% of pts had driver mutations, the most frequent were KRAS G12C (10%), METex14 skipping (10%) and ERRB2 (Ex20Ins 3.3% and G660D 3.3%). The most frequently altered gene was KRAS (20%). 80% (24 pts) received first-line treatment (62.5% monotherapy 'ICI' and 9 chemo-immunotherapy 'CT-ICI') and 20% in second-line (100% monotherapy). According to LIPI score, 7 pts (23.3%) belonged to the good prognostic group, 15 pts to the intermediate group (50%) and 8 pts to the poor prognostic group (26.7%). Median overall survival (OS) was 14m in good prognosis group, 6m in intermediate and 1m in poor prognosis group (p=0.062). Median progression-free survival (PFS) was not reached 'NR' in the good prognosis group, 5m in intermediate group and 1m in poor prognosis group (p=0.035). The disease control rate was 85.7% in good prognosis group, 60% in intermediate and 25% in poor prognosis group (p=0.057). Statistically significant differences were maintained in OS and PFS irrespective of the use of chemo-immunotherapy or immunotherapy and the use in first-line treatment. In the CT-ICI group OS was 8m versus 7m versus 1m (p=0.18) and PFS was 6m versus 7m versus 1m (p=0.018). In the ICI group the OS was 14m versus 5m versus 1m (p=0.133) and the PFS was NR versus 2m versus 1m (p=0.110). In first-line treatment the OS was NR versus 6m versus 1m (p=0.038) and PFS was NR versus 5m versus 1m (p=0.007). In second-line treatment was not possible calculate differences due to the sample size.

Conclusions: The prognostic groups established according to the LIPI score correlated with efficacy to immunotherapy in very elderly pts with advanced NSCLC. The LIPI score is a valid tool that may allow personalisation and individualisation of the treatment of NSCLC in very elderly pts that present an increasing incidence.

P2.15 .04 End-Of-Life Systemic Therapy and Survival in Metastatic Lung Cancer: A Territory-Wide Real-World Studyof 24,608 Patients

S. Wang[1], H. Zhou[2], T.L.T. Lee[1], Z. Ye[1], C. Fang[3], J. Liu[4], P. Fu[5], F-M.S. Kong[1]
[1]The University of Hong Kong, Hong Kong/CN ,[2]The University of Hong Kong-Shenzhen Hospital, Shenzhen/CN ,[3]The Chinese University of Hong Kong, Hong Kong/CN ,[4]Peking University Shenzhen Hospital, shenzhen/CN ,[5]Case Western Reserve University, Cleveland/OH/USA

Introduction: The role of systemic anticancer therapy (SACT) at the end of life (EOL) remains controversial. While concerns exist regarding overtreatment and diminished quality of life, recent advances in targeted therapies and immunotherapies may provide clinical benefits even in the terminal phase of lung cancer patients. However, limited real-world evidence exists on the impact of EOL SACT, particularly in Asian populations.

Methods: This cohort study with prospective follow-up utilized a territory-wide electronic healthcare database covering over 90% of Hong Kong's population. Patients diagnosed with metastatic lung cancer with minimum follow-up of 2 years were eligible. Hospitals were stratified into quartiles based on the National Quality Forum 0210 measures (NQF 0210) which was designed to evaluate the proportion of cancer patients receiving SACT within 14 days of death, aiming to reduce potential overtreatment at the end of life. The primary outcome was overall survival (OS), while SACT and hospice care utilization were tested as independent variables. Overlap weighting was applied to balance covariates, and survival analyses were performed across NQF 0210 quartiles.

Results: A total of 24,608 patients with stage IV lung cancer were enrolled between January 1, 2010, and December 31, 2022. The median survival was 8.3 months (95% confidence interval (CI), 8.1-8.4) in all patients, and 12.7 months (95% CI, 12.5-12.9) in 16.544 patients (67%) received SACT 67.2%.. The median survival was 7.1 months (95% CI, 6.9-7.3) in 4,067 patients (57.1%) received hospice care. In 8050 patients (32.7% received both SACT and hospice care, the median OS was 12.0 months (95% CI, 11.7-12.4). Interestingly, higher NQF 0210 rates were associated with significantly longer OS (Q4 versus Q1: hazard ratio (HR), 0.620; 95% CI, 0.570-0.674; P < 0.001). Median OS was 4.2 months in Q1 versus 10.4 months in Q4. Improved OS in higher NQF 0210 quartiles persisted across subgroup analyses by diagnosis year and hospice use. Notably, hospice care alone in patients without SACT showed no significant survival improvement (2.7 vs. 2.5 months; HR, 0.894; 95% CI, 0.778-1.028; P = 0.115), whereas combining hospice with aggressive SACT was associated with significant survival gains (Q4 versus Q1, HR, 0.575; 95%CI, 0.514-0.643).

Conclusions: Higher hospital-level SACT use at EOL is associated with improved OS in advanced lung cancer patients, either alone or with use of hospice service. Medial survival difference is remarkable for these patients with end stage of life. Value of EOL SACT deserves further study. Refinement of EOL quality measures is needed to balance minimizing ineffective treatment while preserving survival benefits.

P2.15 .05 A Shared Decision Aid for First-Line Treatments of ALK+ Advanced Non-Small Cell Lung Cancer: A Patient-Centered Approach

T.E. Stinchcombe[1], T.W. Leblanc[1], K. Culver[2], M. Reiss[3], J. Coulter[4], H.L. Peay[5], C. Poulos[5], R. Moultrie[5], S. Potter[5], C. Bussberg[5], C. Vass[5], N. Rifi[6], S. Krulewicz[4], L. Brown[4], H. Le[4]
[1]Duke Cancer Institute, Duke University School of Medicine, Durham/NC/USA ,[2]ALK Positive, Atlanta/GA/USA ,[3]Go[2] for Lung Cancer, Washington DC/DC/USA ,[4]Pfizer Inc, New York/NY/USA ,[5]RTI International, Durham/NC/USA ,[6]Pfizer Inc, Paris/FR

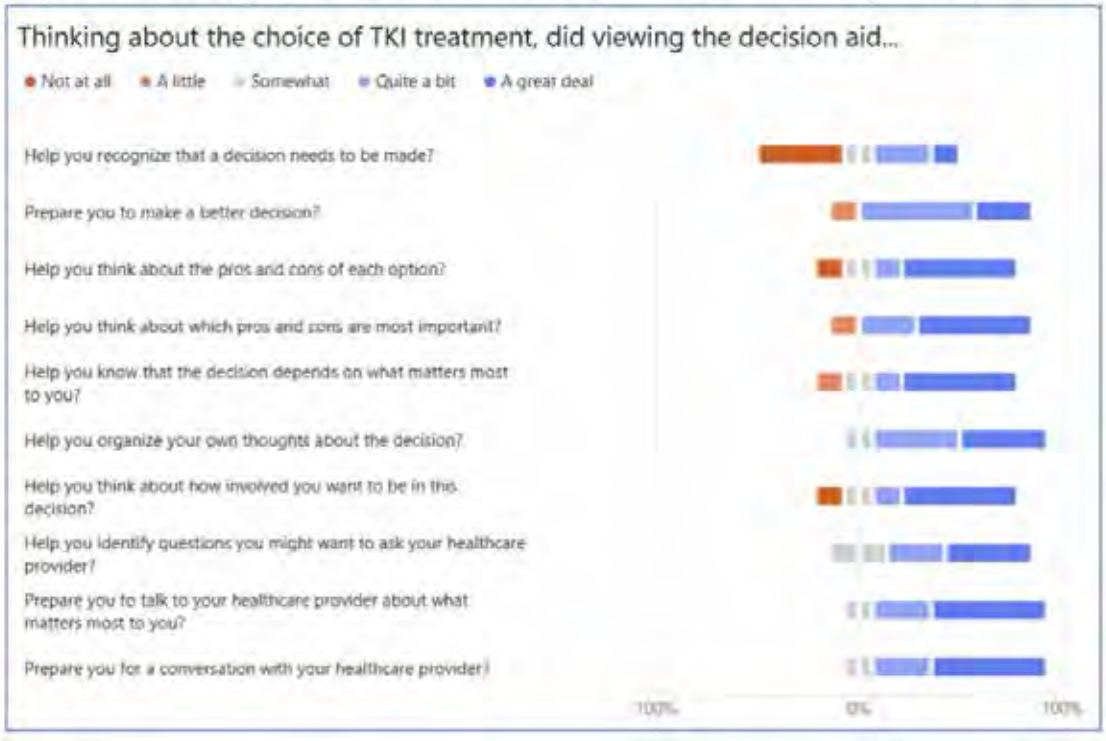
Introduction: Choosing first-line (1L) anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitors (TKIs) for ALK+ advanced non-small cell lung cancer (aNSCLC) is challenging due to varied treatment risk/benefit profiles, lack of head-to-head trials, and patient preferences. Patient decision aids (DAs) can improve knowledge, reduce decisional conflict, and support values-concordant decisions. A team of oncologists, patient advocacy group (PAG) representatives, DA and preference experts, industry scientists, and web developers created the first digital DA with a values clarification activity (VCA) for newly diagnosed ALK+ aNSCLC patients to support shared decision-making with oncologists.

Methods: The study included 25 participants. Concept interviews with 11 patients informed content and user interface development, followed by 3 oncologist interviews and beta testing with 7 patients (interviews and surveys) to refine the DA. Transcripts were analyzed using an Excel-based matrix. Four patient advisors provided feedback throughout development. The DA comprises: Introduction/patient journey, TKI education, resources, a quantitative VCA (Best Worst Scaling [BWS]), an individualized report with a treatment attribute priority list, and other features.

Results: Patients (n=18, age range: 33-76; time since diagnosis: 2-20 months; all using 1L TKIs) expressed the value of the DA for newly diagnosed patients seeking information about treatment options. Many indicated that having this DA upon diagnosis would have been informative and empowered them to engage in shared decision-making with their providers. Patients endorsed the teaching approach, aggregating treatment "similarities" and "differences" to highlight differentiators and reduce information overload. Findings indicated balanced treatment presentation, attention to cognitively/psychologically challenging concepts, question features, and use of the VCA. Patients confirmed the importance of individualized reports and pre-generated questions. Beta testing demonstrated the desired deliberation during the VCA; participants discussed multiple attributes as important, and selecting the most and least important features was challenging yet meaningful in determining their priorities. Beta participants demonstrated positive responses on the preparation of the decision-making measure (Figure 1). Oncologists (n=3; 1 community health and 2 academic centers; currently caring for patients with ALK+aNSCLC; range: 2-10) supported the DA's value in helping patients understand treatment options and identify preferences. Suggestions were made to refine content further (e.g., addition of a new similarity item).

Conclusions: The DA was well received. Participants discussed the value of centralized, patient-friendly information about 1L TKIs that helps patients understand their priorities and supports shared decision-making. The DA will be disseminated by ALK Positive (United States) and Go2Lung PAGs via their websites in the second half of 2025.

Figure 1. Results from preparation of the decision-making measure (beta user testing interview)



Keywords: ALK+ aNSCLC, shared decision making, first line

P2.15 .06 Best Practices and Process Variations of Lung Cancer Multi-Disciplinary Teams: Insights From Europe and Israel

Introduction: Multidisciplinary teams (MDTs) are key in the Lung Cancer care pathway. They leverage diverse disciplines involved in patient treatment decisions to achieve better patient outcomes than single-discipline decisions. MDTs drive earlier treatment initiation and improved guideline-concordant care, positively impacting survival outcomes. Although they share a common goal, there are significant differences in how Lung Cancer MDTs operate across hospitals in Europe and Israel, with each hospital employing varied best practices to achieve high-performing MDTs.

Methods: Over 150 semi-structured interviews were conducted with MDT members from 28 hospitals across 20 countries in Europe and 3 hospitals in Israel. MDT members also completed an MDT self-assessment to demonstrate MDT maturity and a questionnaire to assess perceived impact of Lung Cancer MDTs on: MDT status quo (team composition, process), patient pathway (scale, time), and qualitative impact (patient outcomes, cost). Best practices and process variations were then pressure tested with 31 working groups within respective hospitals.

Results: We obtained 3 sets of results: First, a clear overview of the existing MDT organisational processes within Europe and Israel, including variations, advantages, and disadvantages in processes, as well as the maturity level of participating MDTs. The MDT self-assessment results demonstrate a high MDT maturity across participating hospitals, especially in domains of MDT process (average score 3.2/4.0) and culture (average score 3.3/4.0); conversely, a lower score in Technology (average score 2.2/4.0). The lower score in technology likely reflects a lack of integrated systems, digital tools to aid MDT preparation and decision making, and a few hospitals still using a paper-based system. Second, 50+ best practices encompassing patient access, MDT operations, technology utilisation, medical practice quality, and team capabilities were identified. Third, insights on common gaps and challenges across European countries and Israel requiring process organisation, institutional, or policy-level action were identified. Examples mentioned by participating hospitals range from a lack of structure to registering patients for MDT discussion, to the need for an MDT coordinator or Nurse Navigator role to follow patient journeys, as well as the MDT preparation, discussion, and follow-ups. Although 40% of participating centres indicated a Nurse Navigator or MDT coordinator present, this was usually in the form of a secretary providing strictly administrative support. Another common insight was the lack of funding from national health services or hospitals on resources, time and effort required by all disciplines to participate in MDTs. Organisational and institutional level gaps were identified and matched to actionable best practices, including quick-wins ready for implementation (e.g., creation of a standardised patient registration template and reporting structure) and long-term initiatives requiring further efforts.

Conclusions: This study provides insights into specific Lung Cancer MDTs' ways of working, process variations, best practices, and recommended actions for improvement. This can improve how MDTs are organized and managed Europe-wide, ultimately improving patient outcomes. The description of typical challenges and gaps encountered by MDTs throughout Europe and Israel can serve as a guide for hospitals on the essential collaboration needed to effect change on both national and global scales.

Keywords: Multi-disciplinary Team, MDT, Lung Cancer

P2.15 .07 Effect of Message Framing in a Digital Lung Cancer Screening Decision Navigation Intervention: A Three-Arm Randomized Controlled Trial

F. HUANG, X.j. Lin
Fujian Medical University, Fuzhou/CN

Introduction: The risks and benefits of low-dose CT (LDCT) screening necessitate informed decision-making among high-risk individuals. Patient decision aids (PDAs) help align screening choices with personal values. Research suggests message framing influences health decisions, but its impact on lung cancer screening (LCS) uptake remains unclear. To address this, we developed China's first LCS PDA, the LCS Loss-Gain Balance (LCS-LG-B), integrating gain-framed (emphasizing benefits) and loss-framed (highlighting consequences) messaging. This study aims to develop a digital decision navigation intervention tailored for high-risk individuals in China and evaluates its effectiveness in promoting LCS uptake by leveraging gain-framed and loss-framed messaging through the LCS-LG-B.

Methods: Using a systematic review, qualitative interviews, and expert consultation, we developed a digital LCS decision navigation intervention incorporating shared decision-making, patient navigation, and framing effects. From March 2024 to March 2025, participants were recruited and randomly assigned (1:1:1) into three groups (63 per group). Details of the intervention are shown in Figure 1. Primary and secondary outcomes—including LDCT uptake, decision conflict, self-efficacy, decision preparation, LCS knowledge, and health beliefs—were assessed at baseline (T1), post-intervention (T2), and at 1-month (T3), 3-month (T4), and 6-month (T5) follow-ups, with data analyzed using generalized linear mixed models and Chi-square tests.

Results: A total of 53, 54, and 56 participants remained in the loss-framed, gain-framed, and control groups, respectively. Both intervention groups showed significant improvements over the control group in decision conflict (F=4.232, p=0.015), decision self-efficacy (F=8.392, p<0.001), decision preparation (F=7.430, p<0.001), and health beliefs-perceived risk (F=4.347, p<0.001). Decision preparation was higher in the gain-framed group at T2 (D=3.757, p=0.005), T3 (D=2.814, p=0.016), and T4 (D=3.300, p=0.004). Health beliefs-perceived barrier was higher in the loss-framed group at T3 (D=3.157, p=0.009). Health beliefs (D=6.700, p=0.001), perceived benefit (D=1.286, p=0.031), and self-efficacy (D=2.743, p=0.001) were higher in the loss-framed group at T2. About 29 (53.7%) in the loss-framed, 23 (42.6%) in the gain-framed, and 9 (16.1%) in the control group underwent LDCT ($\chi 2$=14.60, p=0.001).

Conclusions: This study preliminarily applies cognitive framing in LCS decision-making using China's first LCS PDA. Both gain- and loss-framed interventions significantly improved LCS knowledge, health beliefs, decision quality, and LDCT uptake. Message framing effectively motivates high-risk individuals to undergo screening, supporting early lung cancer detection and improved outcomes. This structured, personalized approach to secondary prevention offers a new strategy for increasing voluntary LCS participation and reducing lung cancer mortality. Future research should explore long-term effects and scalability across diverse populations.

P2.15 .08 Effects of a Decision Support Intervention for Patients With Advanced Lung Cancer: RCT-Results and Document Analysis

M. Villalobos[1,2], L. Unsöld[1], N. Deis[1], A. Siegle[3], M. Thomas[1]
[1]Heidelberg University Hospital, Heidelberg/DE ,[2]Dept. of Thoracic Oncology, Thoraxklinik, Heidelberg University Hospital and National Center for Tumor Diseases (NCT), NCT Heidelberg, Translational Lung Research Center Heidelberg (TLRC-H), Member of the German Center for Lung Research (DZL), Heidelberg/DE ,[3]Faculty of Business and Health, Department of Health Sciences and Management, Baden-Wuerttemberg Cooperative State University Stuttgart (DHBW), Stuttgart/DE

Introduction: The therapeutic algorithms in lung cancer are rapidly evolving due to the continuous approval of new drugs, resulting in steadily improving survival rates. However, recent studies show that the increasing complexity has had a negative impact on prognostic awareness and patient-physician communication. In a population primarily composed of elderly and frail patients, this uncertainty threatens goal-concordant care. As a result, the importance of guideline recommendations emphasizing patient-empowerment and shared decision-making has never been greater. Yet, there is still al lack of evidence-based tools that are comprehensively implemented to support these practices.

Methods: Randomized controlled, open, mono-center trial (n=138) with two arms: A) use of a decision aid incl. clarification of personal values accompanied by a decision-coaching session vs. B) usual care; primary endpoint: clarity of personal values (Value Clarity Subscale of the Decisional Conflict Scale). Secondary outcomes: patients' self-efficacy (DSES), decisional conflict (DCS), perceived preparation for and involvement in decision-making (PDMS and PICS), general health and emotional state (EQ-5D-5L and HADS). We performed an additional document analysis for information needs, participation preferences, and personal values (decision aids and decision coaching; n=40).

Results: The evaluation showed high values for decisional conflict in both groups (total mean score arm A 41,25 and arm B 38,65), exposing relevant conflict in 57,6% of patients, highest in the subscale for information (64,4%) and uncertainty (58,9%). PDMS showed that most patients considered the intervention helpful. All other outcomes showed no significant differences with equally high DCS scores in both arms' follow-up. The document analysis showed the highest information needs in regard to treatment options (67,5%), general information about the disease (65%), its course/prognosis (60%), supportive care (52,5%), and side-effects (50%). For participation preferences 27,5% wished the physician to decide, 55% shared decision-making and 17,5% to decide alone. The most important personal values patients indicated were quality of life (65%), honesty (47,5%), hope (40%), and trust (35%).

Conclusions: Patients with advanced lung cancer experience significant decisional conflict. While the intervention successfully enhanced their perceived preparation for decision-making, it was not sufficient to substantially reduce the measured conflict. Given the considerable uncertainty faced by these patients, it is crucial to identify their specific information needs, personal values, and preferences for participation. These factors should guide the development of future decision support interventions and go together with a pro-active attitude by physicians in addressing them. In a landscape of rapidly evolving oncological information and increasing prognostic uncertainty, there is an urgent need for tailored support that can adapt flexibly to the individual needs of patients in their decision-making process.

P2.15 .09 Long-Term Survival in Malignant Pleural Effusion: Validation of the LENT and PROMISE Scores

S.Y. Kim, Y.S. Park
Seoul National University Hospital, Seoul/KR

Introduction: Malignant pleural effusion (MPE) is a common manifestation of advanced cancer, associated with poor prognosis. The LENT and PROMISE scores are prognostic scoring systems for MPE, developed to predict short-term mortality and aid in clinical management decisions. This study aims to identify long-term survivors (LTS) among patients with MPE and to evaluate whether the LENT and PROMISE scores are useful in predicting LTS.

Methods: We conducted a retrospective cohort study of adults with cytologically confirmed MPE at a tertiary academic center in South Korea between January 2003 and December 2023. The prognostic performance of the LENT and PROMISE scores was assessed using Kaplan-Meier survival analysis. LTS were defined as patients who survived ≥5 years after MPE diagnosis. Clinical characteristics and independent predictors of LTS were evaluated using multivariable logistic regression.

Results: Among 2,614 patients with MPE, the mean age was 61.4±13.0 years, and 58.5% were female. The most common primary malignancies were lung (50.5%), gastrointestinal (18.2%), and breast cancers (17.9%). Both the LENT and PROMISE scores effectively stratified survival (log-rank $p<0.01$). A total of 166 patients (6.4%) were LTS. Lung cancer was more common among LTS (63.9%), while gastrointestinal cancers were less frequent (7.8%). In multivariable analysis, both the LENT and PROMISE scores were independently associated with LTS. The use of tyrosine kinase inhibitors (TKIs) and immune checkpoint inhibitors (ICIs) also showed significant associations with long-term survival.

Conclusions: Among patients with MPE, 6.4% survived for more than five years. Both the LENT and PROMISE scores were validated as independent predictors of LTS, and the use of TKIs or ICIs was also significantly associated with LTS.

Keywords: malignant pleural effusion, LENT score, PROMISE score

P2.15 .10 Improving Patient-Reported Outcome Symptom Monitoring Using Bayesian Networks

C. Verberkt[1], L. Gennissen[1], N. Billingy[1], C. van den Hurk[2], A. Becker-Commissaris[3], J. Kwisthout[4], I. Walraven[1]
[1]Radboudumc, Nijmegen/NL ,[2]Catharina Ziekenhuis, Eindhoven/NL ,[3]Amsterdam UMC, Amsterdam/NL ,[4]Radboud University, Nijmegen/NL

Introduction: The SYMPRO-Lung study showed that patient-reported outcome (PRO) symptom monitoring linked to an alert system significantly improves health-related quality of life in patients with lung cancer. However, to implement PRO-symptom monitoring on a larger scale, it is critical to decrease the number of unnecessary alerts. We aimed to optimize the SYMPRO-Lung alert algorithm using Bayesian networks to 1) lower the number of unnecessary alerts and 2) explain determinants of reported symptoms.

Methods: Within the SYMPRO-Lung study, patients with lung cancer starting new treatment reported their symptoms weekly during one year via an online questionnaire (based on the PRO-CTCAE). When symptoms reached a pre-defined threshold, an alert was triggered indicating contact with a healthcare professional was necessary. Patients could indicate if they felt contact was unnecessary. To decrease these unnecessary alerts, we used a Noisy-OR network, a causal independency model in which each cause-node influences the effect-node independent of other cause-nodes. Subsequently, a Bayesian network was created to explore determinants of alarming situations (triggering a necessary alert) compared to non-alarming situations (triggering an alert labeled as unnecessary or triggering no alert), corrected for baseline characteristics (age, treatment and cancer stage and histology). Determinants included receiving treatment, progression of disease, emotional functioning, comorbidities and other reasons.

Results: We included 7185 symptom reports from 244 patients. 1325 (18%) symptoms triggered an alert, of which 799 (60%) were classified as necessary alerts. The Noisy-OR model predicted 979 necessary alerts (74%), of which 628 (64%) were correctly predicted as a necessary alert. None of the alerts missed by the Noisy-OR model concerned severe symptoms. The Bayesian network indicated that undergoing treatment was the most apparent determinant of reported symptoms (probability 0.68), followed by impaired emotional functioning (probability 0.42). Patients who reported alarming situations were more likely to have comorbidities, disease progression, or impaired emotional functioning compared to patients reporting non-alarming situations (Table 1).

Conclusions: The Noisy-OR network for alert prediction was able to reduce the number of alerts with 26% by better predicting if contact with healthcare is necessary compared to the original SYMPRO-Lung algorithm, without missing severe symptoms. Based on the Bayesian network we gained insights in the relation between symptoms and their determinants. This optimized alert algorithm will advance the further implementation of PRO-symptom monitoring on a larger scale.

Table 1. Mean probability (standard deviation) of underlying reasons in alarming and non-alarming situations, given the symptoms and patient characteristics.

Underlying reason	Alarming situation	Non-alarming situation
Receiving treatment	0.89 (0.31)	0.78 (0.42)
Progression of disease	0.07 (0.16)	0.06 (0.14)
Impaired emotional functioning	0.57 (0.36)	0.29 (0.29)
Two or more comorbidities	0.37 (0.37)	0.17 (0.25)
Other reasons	0.03 (0.14)	0.13 (0.31)

Alarming situation: a situation triggering an alert that is indicated as necessary. Non-alarming situation: a situation triggering an alert that is indicated as unnecessary or a situation not triggering an alert.

Keywords: non-small cell lung cancer, symptom monitoring, Bayesian Network

P2.15 .11 Non-Cancer-Related Mortality in Lung Cancer Patients: The Role of Comorbidities in a 7-Year Retrospective Case-Control Study

E. Cantor[1], J. Segovia[1], H. Vargas[1], B. Wills[1], C. Triana[1], Z.F. Gomez Giraldo[1], L. Niño Mora[2], M.V. Garcia[2], A.F. Mendivelso Botello[2], S. Dueñas-Hernandez[2]
[1]Fundacion Santa Fe de Bogota, Bogota/CO ,[2]Universidad de los Andes, Bogota/CO

Introduction: Lung cancer remains one of the leading causes of mortality worldwide, prompting continuous efforts to develop therapies that improve survival outcomes. However, these patients frequently present with multiple comorbidities, whose exacerbations may negatively influence prognosis and, in some cases, constitute the direct cause of death.

Methods: We conducted a retrospective, observational, and analytical case-control study including patients diagnosed with lung cancer and treated at Fundación Santa Fe de Bogotá between 2016 and 2023. The primary objective was to evaluate the association between comorbidities and all-cause mortality. We collected sociodemographic and clinical variables, comorbid conditions, and causes of death (cancer-related or not). The main outcome was all-cause mortality at two years of follow-up. A descriptive analysis of the population was conducted, followed by bivariate analysis using the Chi-squared test, and subsequently a multivariate analysis to adjust for potential confounding variables.

Results: A total of 503 patients were included, of whom 53.7% were women. The mean age was 69 years (range: 28-97). The most prevalent comorbidities were smoking history (55%), arterial hypertension (45.5%), chronic obstructive pulmonary disease (COPD) (17.2%), and diabetes mellitus (15.6%). Overall mortality was 59.4% (n = 299), with non-oncologic, comorbidity-related deaths accounting for 24% of all deaths. The most frequent non-oncologic causes of death were septic shock (32%), heart failure (10%), and chronic kidney disease (7.5%). Bivariate analysis revealed statistically significant associations between mortality and tumor stage, history of COPD, and pulmonary embolism (PE). Detailed findings are presented in Table 1. In the multivariate analysis, adjusted for tumor stage, age, sex, and treatment type, COPD (OR: 2.43; 95% CI: 1.31-4.55; p = 0.00) and PE (OR: 2.12; 95% CI: 1.01-4.79; p = 0.04) were associated with increased risk of death. Interestingly, heart failure was associated with lower mortality risk (OR: 0.43; 95% CI: 0.21-0.92; p = 0.02); however, 92% of these patients had a left ventricular ejection fraction (LVEF) >40%, with a mean LVEF of 56%.

Conclusions: Comorbidity exacerbations significantly contribute to mortality in lung cancer patients. Notably, COPD and PE were associated with increased risk of death, highlighting the importance of early identification and management of these conditions to potentially improve patient outcomes.

Table 1. Bivariate Analysis of Clinical and Comorbidity Variables Associated with All-Cause Mortality in Lung Cancer Patients

Characteristic	Category	Alive (n = 204)	Deceased (n = 299)	p-value (Chi²)
Stage	I (n=80)	75%	25%	<0.001
	II (n=31)	71%	29%	
	III (n=58)	45%	55%

P2.15 .12 Non-Pharmacological Dermatologic Care for the Prevention and Management of Immune-Related Skin Toxicities in Patients With Lung Cancer

J. Serra López[1,2], C. Pujol Besora[2], M. Malaret Verge[2], A. Barba Joaquin[2], S. Martínez Recio[2], M. Pastor[3], J. Pérez Fierro[4], E. Hernández Martínez-Esparza[1], M.A. Martínez-Momblan[5], M. Majem[2]
[1]Escola Universitària d'Infermeria Sant Pau, Barcelona/ES ,[2]Hospital de la Santa Creu i Sant Pau, Barcelona/ES ,[3]Datexbio, Barcelona/ES ,[4]Responsable del Departamento de Oncología de La Roche-Posay, Barcelona/ES ,[5]Fundamental and Clinical Nursing Department. Nursing Faculty. University of Barcelona (UB), Barcelona/ES

Introduction: Checkpoints are one of the main pillars of cancer treatment. However, despite their overall favorable profile, their use has been associated with specific toxicities called immune-related adverse events (irAEs). Dermatologic irAEs are among the most common (40%), especially pruritus and dryness.Although these skin toxicities are usually mild, diagnosis and early management are crucial for maintaining an acceptable quality of life for patientsThis is an analysis of the subgroup of lung cancer patients included in this study in patients with different types of cancer receiving immunotherapy. The aim of the study was to determine whether Niacinamide and Shea Butter provide better control of immune-related skin toxicities.

Methods: This is a single-center, phase IV 2-arms single-blinded, randomized trial. In the intervention arm, participants received cleansing and moisturizing products containing the active ingredients niacinamide and shea butter, and in the active control arm, cleansing and moisturizing products containing the active ingredients argan oil and coconut butter.For data collection, an initial (baseline) visit was conducted, followed by three additional visits every 8 weeks. The data collection instruments included two validated scales: the itching intensity scale and the Dermatology Life Quality Index questionnaire.Additionally, participants answered a questionnaire about soap and cream use frequency, sunscreen application, skin changes, and the need for medication due to skin toxicity.

Results: From May 30th, 2022, to December 21st, 2023, 130 patients with different tumor types were enrolled. This analysis includes data from 58 patients with lung cancer, 27 control and 31 intervention group, with similar baseline characteristics baseline characteristicsThe intervention reduced the probability of pruritus in lung cancer patients. In the control group, pruritus increased from nearly 0% at baseline to ~80% by visit III. In contrast, the intervention group started slightly above 10% and never exceeded ~25%. The gap between the intervention's actual effect and the expected 'no intervention' scenario suggests that the treatment prevented the worsening of pruritus over time (Figure 1). This plot is based on R models using a Mixed-Effects Logistic Regression schema.

Conclusions: The intervention arm effectively reduced pruritus in lung cancer patients, preventing its worsening over time. These findings highlight its potential in managing immune-related skin toxicity.

P2.15 .13 Patient Self Management Education and Cancer Treatment Adherence in Low Middle Income Africa a Systematic Scoping Review

D. Tsegaye[1,2], D. Currow[3], P. Davidson[4], V. Brunelli[1]
[1]University of Wollongong, Wollongong/AU ,[2]Debre Markos University, Debre Markos/ET ,[3]University of Technology Sydne, Sydney/AU ,[4]University of New South Wales, Sydney/AU

Introduction: Cancer mortality is disproportionately higher in low-middle-income Africa than in high-income countries. Lung cancer is the leading cause of cancer death worldwide and, in Africa, lung cancer related morbidity is concerning as mortality rates continue to steadily increase. Currently, lung cancer is one of the top three leading cancers, ranked by deaths, in Africa. High mortality is, in part, due to poor cancer treatment adherence. Patient self-management is a critical driver of treatment adherence, but the most appropriate self-management education for the African population is unclear. To improve cancer treatment adherence in countries like Ethiopia, it is imperative to first understand the evidence base on factors that influence treatment adherence at the local level and, in so doing, gain an understanding of what might constitute appropriate and effective patient self-management education. This presentation showcases phase 1 of a 3-phase PhD co-design research program that aims to reduce unnecessary premature disability and death with improved cancer treatment adherence in Ethiopia. The paper aimed to systematically review the literature on patient self-management education and cancer treatment adherence discrete to low-middle income countries in Africa.

Methods: MethodsUtilising Joanna Briggs methodology, CINAHL, MEDLINE (PubMed), HINARI, Web of Science, the Cochrane Register of Controlled Trials, and Google Scholar databases were searched, with no date limits. Peer-reviewed, primary studies focusing on patient self-management education and cancer treatment adherence in adults (≥18 years) in low- or middle-income countries in Africa were included. No limits were set on cancer type and stage, clinical or education setting; education type or delivery mode; health professional role that delivered the education. Qualitative and quantitative studies could be included. Synthesis took a narrative analytical approach using the Template for Intervention Description and Replication (TIDieR) checklist.

Results:

ResultsAn initial 3,785 studies were identified. After duplicate removal and title and abstract screening, 251 studies underwent full text review, with 12 studies included. Three key themes were generated to describe mediators of cancer treatment adherence and, in turn, inform patient self-management education and delivery mode (phase 2 of the PhD program): 1. Safe, “meaningful” education, 2. Challenge of social structures, and 3. The power of interpersonal interactions between nurse, patient and family. Financical implications, health care access, cultural and religious beliefs, and health literacy affect cancer treatment adherence. Attitudes of health professionals towards cancer treatment also affect patient adherence to treatment. Quality interactions among nurses, patients, and caregivers represent a crucial role in influencing adherence.

Conclusions: ConclusionAppropriate self-management education delivered by knowledgeable, skilled health care clinicians has the potential to facilitate cancer patient treatment adherence in low-middle income Africa. However, empiric high quality evidence on strategies to address mediators of adherence is limited, heterogenous and often not evaluated with validated approaches. Notwithstanding that this gap in knowledge represents immediacy in terms of poor health outcomes in real world low-middle income Africa, it emphasises the urgent need for this grassroots, cross-border collaborative research between Ethiopia and Australia.

P2.15 .14 Improving Access and Recruitment to Clinical Trials for Lung Cancer Using the Lung I-Act Tool: A Mixed Methods Uk Wide Pilot Study

C.J. Dodd[1], B. Lond[1], Z. Davey[1], L. Darlison[2], J. McPhelim[3], J. Rawlinson[4], I.R. Williamson[5], C. Henshall[1]
[1]Oxford Brookes University, Oxford/GB ,[2]University Hospitals of Leicester, Leicester/GB ,[3]University Hospital Hairmyres, East Kilbride/GB ,[4]European Lung Foundation, Sheffield/GB ,[5]De Montfort University, Leicester/GB

Introduction: Globally, lung cancer is the leading cause of cancer related death. Clinical trial participation can lead to better patient outcomes by providing access to new and innovative treatments and making a contribution to the development of treatments for future generations. Despite reported widespread enthusiasm for clinical trial participation, less than 10% of cancer patients take part. Reasons for this include sub-optimal communication, with less than half of lung cancer patients stating that clinical trial opportunities were discussed between themselves and a healthcare professional. Lung cancer nurses often feel ill-equipped to talk about clinical trial opportunities with patients. Lung I-ACT is a tool that has been developed to support lung cancer nurses to talk to patients about clinical trial opportunities. It has been piloted across the UK to test its acceptability to lung cancer nurses and patients in practice-based settings. The pilot study findings can inform approaches to effectively improving discussions about clinical trials between nurses and patients.

Methods: The development of Lung I-ACT was informed by findings from a systematic literature review and qualitative focus groups exploring barriers and facilitators to clinical trial participation for lung cancer patients. A subsequent co-production workshop conducted with lung cancer nurses and patients helped researchers shape tool development further. Lung I-ACT comprises a complementary patient-facing leaflet with a nurse-facing poster, each designed to promote a drip feed approach to discussions about trials so that patients can make informed choices about participation. A six-month pilot, consisting of longitudinal surveys for nurses and interviews with nurses and patients was conducted at seven UK-wide NHS Trusts. Four intervention and three control sites were selected to compare differences in clinical trial knowledge, confidence and awareness between nurses using the Lung I-ACT tool and nurses who were not.

Results: Interview findings identified that specific elements of the Lung I-AT tool acted to encourage nurses to discuss clinical trials with more patients, increasing their perceived knowledge, confidence and awareness of trials. Benefits of the tool in terms of its content, presentation and utility in practice were highlighted, with the tool's content cited as facilitating effective discussions about trial participation. The survey data (n=29) demonstrated no significant differences in knowledge, confidence and awareness between intervention and control sites, but participant numbers were small.

Conclusions: Our findings demonstrate that with effective, targeted support, lung cancer nurses can be empowered to have more conversations about clinical trial opportunities with patients. This has the potential to lead to more patients being able to make informed choices about enrolment. The findings have international applicability across a range of healthcare settings.

P2.15 .15 Impact of Palliative Care in Patients With Non-Small Cell Lung Cancer and Brain Metastases: A Retrospective Quality Analysis

K. Zhu[1], T. Khodadad[1], S.R. Schuetz[2], A. Chang[1], H.T. Rehman[1], C.E. Fadul[3], A.A. Thomas[1], R. Singh[1]
[1]University of Vermont Medical Center, Burlington/VT/USA ,[2]Beth Israel Deaconess Medical Center, Boston/MA/USA ,[3]University of Virginia, Charlottesville/VA/USA

Introduction: Brain metastases (BMETs) represent a common and devastating complication of non-small-cell lung cancer (NSCLC). Several factors, including functional status and extracranial disease presence, significantly affect prognosis in these patients. The updated Recursive Partitioning Analysis (U-RPA) classification can aid in guiding prognosis, with U-RPA classes 2b and 3 indicating survival of likely less than 1 year. Early utilization of palliative care (PC) is recommended in the multidisciplinary care of patients with BMETs. This study assessed PC utilization and its relationship with survival, hospice referrals, emergency care, and advance care planning in this population.

Methods: We conducted a retrospective review of NSCLC patients diagnosed with BMETs at the University of Vermont between January 1, 2017, and December 31, 2022. Inclusion criteria were age ≥18 years, diagnosis of NSCLC with BMETs, and follow-up ≥ 3 months. Patients were stratified into U-RPA Class 1/2a (> 1-year survival) vs. Class 2b/3 (< 1-year survival). Outcomes were compared between those who received PC and those who did not. Kaplan-Meier analysis assessed survival, while chi-squared and regression analyses evaluated associations between PC involvement and hospice use, emergency visits/readmissions, and completion of advance directives (ADs).

Results: Among 222 patients, 114 (51%) received PC consultations. PC utilization was higher in patients with poor prognosis (U-RPA 2b/3: 74% of PC group). Median survival was shorter in the PC group (114 vs. 432 days, p = 0.00007); however, among U-RPA 2b/3 patients, survival did not differ significantly (146 vs. 160 days, p = 0.07). PC involvement was associated with higher hospice enrollment in both U-RPA groups, particularly in U-RPA 2b/3 (71% vs. 49%, p = 0.012). AD completion was more frequent among PC patients overall (82% vs. 63%, p = 0.003), although not statistically significant in the U-RPA 2b/3 subgroup (82% vs. 70%, p = 0.14). Emergency visits/readmissions were more common in PC patients with poor performance status (33% vs. 11%, p = 0.01). Adjusted analyses showed that PC was not independently associated with survival (p = 0.39) but correlated with greater hospice and AD uptake.

Conclusions: Palliative care remains underutilized in NSCLC patients with BMETs, particularly among those with poor performance status and despite guidelines recommending early integration. Although PC did not confer a survival advantage, its association with improved hospice utilization and advance care planning highlights its value in enhancing quality care at end-of-life care. Increased systemic efforts are needed to promote early PC referral for this population.

Measure		Palliative Care	No Palliative Care	P-value

P2.15 .16 ECMO as a Procedural Bridge for Malignant Airway Obstruction in Lung Cancer

H.J. Cho[1], J. Lee[2], S.J. Kim[1]
[1]Seoul ST. Mary's Hospital., Seoul/KR ,[2]Seoul ST. Mary's Hospital., Seoul/QC/CA

Introduction: Malignant central airway obstruction (MCAO) is a potentially fatal complication in advanced lung cancer requiring urgent airway intervention. Rigid bronchoscopy remains the standard approach forrestoring airway patency, but the procedure necessitates advanced anesthetic support, which may not be readily available in low-volume centers. In such settings, extracorporeal membrane oxygenation (ECMO) may serve as a physiologic bridge to maintain oxygenation and procedural stability, especially when anesthesiology teams lack experience with complex airway management. We report a case series of patients with lung cancer-related MCAO who underwent ECMO-assisted rigid bronchoscopy at a center performing fewer than eight such procedures annually.

Methods: We retrospectively reviewed four patients with lung cancer and MCAO who underwent rigid bronchoscopy under veno-venous ECMO support at our centre . All patients were assessed by a multidisciplinary team. ECMO cannulation was performed in the operating room immediately prior to the intervention, and ECMO decannulation was performed on postoperative day (POD) 1. Clinical variables including histologic subtype, ECOG performance status, tumor stage, procedural time, and stent placement were analyzed.

Results: Four patients (2 males, 2 females; median age 65.5 years) with lung cancer-related MCAO underwent ECMO-assisted rigid bronchoscopy. Histologic subtypes included adenocarcinoma (n=1), squamous cell carcinoma (n=2), and adenoid cystic carcinoma (n=1); stages ranged from IIIB to IV. ECOG performance status was 2 in three patients and 3 in one. All procedures were completed successfully under VV-ECMO support. Airway stents were placed in three patients (2 Song's, 1 Dumon); one patient underwent tumor debulking without stenting. Mean procedure time was 2 hours 14 minutes (ECMO insertion time 13-25 minutes). Oxygenation was stable throughout, and all patients were weaned from ECMO on postoperative day 1 without complications.

Conclusions: ECMO-assisted rigid bronchoscopy was safe and feasible for managing lung cancer-related MCAO, even in a low-volume center. ECMO support facilitated procedural stability, particularly where anesthetic experience was limited.

P2.15 .17 Preliminary Results on Feasibility of Virtual Delivery of Exercise Therapy for Mitigation of Lung Cancer Decline

L. Curry[1], K. Zadravec[2], C. Yin[2], P. Camp[2], K. MacKenzie[2], S.A. Stelling[2], J. Laskin[1], K. Campbell[2], Y. Wang[1]
[1]BC Cancer Agency Vancouver, Vancouver/BC/CA ,[2]University of British Columbia, Vancouver/BC/CA

Introduction: Exercise may mitigate declines in physical and psychosocial function in patients living with advanced lung cancer. However, low patient recruitment and retention limit the development and uptake of evidence-based exercise programs. To overcome these potential barriers, MoVE Phase 2 is a virtual exercise program for patients living with advanced lung cancer in British Columbia, Canada, that builds upon patient feedback that Phase 1 did not reach all people who could benefit due to the travel requirements. Our primary objective is to assess the feasibility of a virtual 12-week exercise intervention amongst patients with advanced lung cancer. Our secondary objective is to assess the efficacy of resistance training delivered virtually to mitigate declines in physical and psychosocial function associated with lung cancer treatment.

Methods: This prospective, single-arm study is currently ongoing with a planned recruitment of 4 consecutive cohorts of 12 patients each. Eligible participants are patients on systemic therapy for advanced lung cancer willing to participate in a twice weekly, one-hour, supervised virtual group exercise program for 12 weeks. Feasibility measures include uptake (attendance and retention ≥80%), adherence (meeting self-reported target exercise intensity over 24 sessions, ≥80%), and safety. Efficacy measures, including patient-reported outcomes and physical function, will be reported with availability of additional data from subsequent cohorts.

Results: Preliminary feasibility data from cohort 1 are presented in Table 1. Twelve of 15 participants screened were enrolled (80% recruitment). Eleven participants completed baseline assessments (one withdrew prior due to symptom burden) and 10 participants completed the supervised exercise program (83% retention). One participant withdrew during the program due to an unrelated adverse event. Average attendance was 75%, with treatment-related symptoms (39%) and conflicting appointments (37%) accounting for most missed sessions. One participant missed 15 of 24 sessions (38% attendance) due to high symptom burden; attendance excluding this individual was 81%. Exercise adherence was 99%. There were no related safety events.

Conclusions: Our preliminary results show that a virtual exercise program for patients being treated for advanced lung cancer is mostly feasible to deliver; however, intervention attendance did not meet the target for cohort 1 (<80%) due to one participant's poor attendance of 38%. With this outlier removed, attendance met feasibility at 81%. An exercise intervention that leverages the emerging acceptance of virtual healthcare delivery may address a critical gap in health equity in older adults with lung cancer in British Columbia.

Table 1

Participant Characteristics at Baseline	n=11
Age (average, range, in years)	65 (51-77)
Gender (F:M)	6 (55%): 5 (45%)

P2.15 .18 Quality of Life for Lung Cancer Survivors

J.E. Dobbs[1], A. Kodan[2], M.Z. Guo[1], Y. Wang[2], C. Burley[2], C. Eaton[2], M. Hsu[3], J. Feliciano[1]
[1]Johns Hopkins Hospital, Baltimore/MD/USA ,[2]Johns Hopkins Bayview Medical Center, Baltimore/MD/USA ,[3]University Hospitals, Case Western Reserve University, Cleveland/OH/USA

Introduction: Lung cancer is the leading cause of cancer-related deaths in the United States, with 87% of diagnoses being non-small cell lung cancer (NSCLC).1 Medical innovations have contributed significantly to improved outcomes for lung cancer survivors (LCS). However, more research is needed to understand the quality of life (QOL) for patients as they live longer with this diagnosis.

Methods: Patients who were alive at least one year after diagnosis with NSCLC were designated as survivors. Survivors who were treated at Johns Hopkins between 2020-2024 completed the European Organisation for Research and Treatment of Cancer (EORTC) QLQ-C30 as part of a larger survey battery. Demographic information, types of therapy, and the intent of therapy (curative or palliative) were gathered via chart review. Clinical and sociodemographic factors associated with the EORTC QLQ-C30 Global health status/QoL scale were examined using Wilcoxon rank sum and Kruskal Wallis tests. This analysis focused on patients who were ever versus never on OTT. Additionally, a subgroup analysis excluded curative intent patients, and another analysis examined demographic and clinical characteristics associated with QOL among ever OTT patients only. The results of this abstract focused on QOL overall and did not differentiate between ever versus never on OTT.

Results: Of the 428 patients invited to complete the survey, 307 were included in this analysis. The median age of the cohort was 68, and predominantly female (59.9%) and Caucasian (73.9%). 38.4% of patients had Stage I-II NSCLC, 18.6% had Stage III and 43% had Stage IV; yet 60% received palliative-intent therapy. LCS who had received 3 or more lines of therapy reported higher QOL (83 vs. 66.7 for 1-2 and 66.7 for 0, p=0.006). Retired LCS reported the highest QOL at 75, compared to 58.33 for employed patients and 66.67 for those who were unemployed or did not respond (p= 0.015). Notably, household income, level of education, and living arrangements did not meet statistical significance.

Conclusions: As the LCS population grows, it is important to understand their needs and QOL in the survivorship period. Our study shows that retirement and more lines of therapy were significantly associated with higher QOL. Further evaluation of targeted interventions towards LCS at high risk of impaired QOL related to sociodemographic factors is warranted. References 1. American Cancer Society. P2.15 .19 Assessment of NSCLC Treatments and Correlation With Hypogonadism in Male Patients With NSCLC

R. Chahine[1,2], J. Perez[1], S. Zhong[1], E. Harper[1], L. Chiec[1,2], Q. Wang[1,2], A. Dowlati[1,2], M.L. Hsu[1,2]
[1]University Hospitals, Cleveland/OH/USA ,[2]Case Western Reserve University, Cleveland/OH/USA

Introduction: Non-small cell lung cancer (NSCLC) is the most prevalent subtype of lung cancer, with treatment advancements significantly improving patient survival. However, systemic therapies including chemotherapy, immunotherapy, and targeted therapy may contribute to endocrine dysfunction, including hypogonadism, which remains an underexplored aspect of NSCLC management. This study evaluates the prevalence of hypogonadism in male patients with NSCLC and assesses its correlation with different treatment modalities.

Methods: A retrospective analysis was conducted on 4,428 male patients with NSCLC, stratified by baseline hypogonadism status utilizing the TriNetX database. Patient characteristics, treatment types, and testosterone levels pre- and post-therapy initiation were analyzed. Paired t-tests assessed changes in testosterone levels, and logistic regression models evaluated associations between therapy types and hypogonadism outcomes.

Results: At baseline, 1,507 patients (34.1%) had hypogonadism, with affected individuals being older (mean age: 67.3 vs. 64.1 years, $p < 0.001$) and having a higher BMI (28.5 vs. 26.6, $p < 0.001$) compared to those without baseline hypogonadism. Comorbidities, including diabetes ($p < 0.001$) and hyperlipidemia ($p < 0.001$), were more prevalent in the hypogonadal group. Post-treatment testosterone levels of the whole cohort significantly declined from baseline assessment (mean difference: -67.32 ng/dL, $p < 0.001$) over a mean of 338 days from cancer treatment initiation. For patients without baseline hypogonadism, logistic regression indicated that targeted therapy was significantly associated with increased odds of developing hypogonadism (OR=1.62, 95%CI: 1.32-1.99, p<0.001), while chemotherapy was also significantly associated with increased odds of developing hypogonadism, but to a lesser degree (OR=1.24, 95 CI: 1.03-1.50, p=0.025). Immunotherapy did not show a statistically significant correlation with developing hypogonadism. For patients with baseline hypogonadism, only targeted therapy was significantly associated with odds of worsening hypogonadal status (OR=1.47, 95%CI: 1.05-2.03, p=0.022).

Conclusions: Hypogonadism is prevalent in male NSCLC patients and is worsened by systemic therapies, particularly targeted treatments. These findings underscore the need for routine endocrine evaluation and potential testosterone monitoring in NSCLC management. Future research should explore the risk of hypogonadism with individual targeted therapies and strategies to mitigate treatment-induced hypogonadism and its impact on patient quality of life.

P2.15 .20 Influence of Preoperative Mental Health on the Postoperative Outcome and Quality of Life After Anatomic Lung Resection

U-T. Le, P. Leber, A. Kornyeva, B. Passlick, S. Schmid
Medical Center-University of Freiburg, Freiburg/DE

Introduction: In addition to functional and technical aspects, mental health plays a crucial role in the recovery and quality of life after surgical procedures. Systematic analysis on the influence of factors such as anxiety, stress, and depression on the postoperative outcome in oncologic thoracic surgery are yet lacking.

Methods: This is a prospective cohort study. We included all patients who underwent anatomic lung resection between April 2023 and June 2024 without complicating factors according to inclusion and exclusion criteria. Anxiety, depression, stress, and quality of life were assessed preoperatively, at discharge, and at 3, 6, and 12 months postoperatively using questionnaires (PSS-10, HADS, and EORTC QLQ-C30 and LC13).

Results: A total of 98 patients were included in this study. In a preliminary analysis of the first 53 patients, elevated preoperative stress (PSS-10 >23) and anxiety scores (HADS >7) were observed in 28 (53%) and 19 (36%) patients, respectively, while elevated depression scores (HADS >7) were seen in 8 patients (15%). Elevated preoperative anxiety scores correlated with higher depression (p=0.004) and stress scores (p<0.0001). Additionally, we observed a quantitative association between higher preoperative anxiety scores and postoperative complications (Ottawa Classification ≥IIIa; p=0.3). Preoperative stress did not correlate with postoperative complications (p=0.5). In the overall cohort, the Global Health Score declined postoperatively but returned to baseline after 6 months. Patients with elevated preoperative depression scores showed a significantly lower Global Health Score immediately postoperatively compared to patients with normal depression scores (p=0.03) as well as persistently lower Global Health Scores throughout the follow-up period. Elevated preoperative anxiety and stress levels appeared to have no impact on long-term quality of life.

Conclusions: A significant proportion of patients undergoing anatomic lung resection show signs of impaired mental health preoperatively, which negatively affects the postoperative outcome and quality of life. These findings highlight the importance of early psycho-oncological interventions, for example in the context of prehabilitation programs.

P2.15 .21 Feasibility and Preliminary Efficacy of Multimodal Prehabilitation in Patients With NSCLC Receiving Neoadjuvant Therapy

R. Sebio-Garcia, Y.X. Chen, I. Bello, N. Reguart, R-R. Navarro, M.J. Arguis, M. Suarez, M. Sisó, G. Martínez-Pallí
Hospital Clinic de Barcelona, Barcelona/ES

Introduction: Patients with non-small cell lung cancer (NSCLC) who receive neoadjuvant therapy (NAT) can experience a decline in cardiopulmonary fitness (CRF) and pulmonary function during treatment. In this study we aimed to explore the feasilibity of a supervised multimodal prehabilitation program in patients with NSCLC receiving NAT and its preliminary efficacy to prevent potential declines in the aforementioned parameters.

Methods: This pilot prospective study recruited patients with NSCLC who were scheduled for NAT followed by surgical resection. Patients were invited to participate in a multimodal prehabilitation program during treatment and prior to surgery (9-12 weeks), including nutritional and psychological support plus supervised exercise training twice weekly. Our main objective was to assess the feasibility (recruitment rates, retention rates, adherence), safety, and preliminary efficacy to maintain CRF and pulmonary function during NAT

Results: Between June 2023 and March 2025, a total of 24 patients were screened for eligibility and 20 were approached after inclusion and exclusion criteria were applied. Of those, six patients refused participation (recruiting rate 70%). Attendance to supervised exercise training ranged from 1 to 20 sessions (median 8.5, Q1 - Q3 6.25 - 14.5) resulting in a median adherence of 63.5% (Q1 - Q3 37.4 - 73.6). Three patients discontinued exercise training during NAT (retention rate 79.6%). One patient was hospitalized twice due to side effects during treatment. No adverse events were reported related to prehabilitation. Changes in CRF and pulmonary function are shown in Table 1. We observed a non-significant decline in CRF during treatment, with most individuals showing mild reductions or even slight improvements in CRF (Figure 1) with age being the only factor positively correlated with mean change in VO2peak (r=.667, p=.050).

Conclusions: Multimodal prehabilitation during NAT appears feasible, safe and might prevent deterioration of cardiorespiratory fitness and pulmonary function.

P2.15 .22 A Nutritional Strategy to Mitigate Toxicities and Optimize Dose Intensity in Patients With Lung Cancer: The Nutricare Study

C. Presley[1],[2],[3], H. Antao[3], K. Kwan Ho Chui[4], J. Smith[5], P. Vibhakar[1],[3], M.K. Cohen[6], J. Bauman[7], S. Gandhi[8], J. Chandra[8], L. Pai[9], F.F. Zhang[6], C. Spees[3],[5]
[1]Division of Medical Oncology, Department of Internal Medicine, College of Medicine, The Ohio State University, Columbus/OH/USA ,[2]The Ohio State Comprehensive Cancer Center, Columbus/OH/USA ,[3]The James Cancer Hospital & Solove Research Institute, Columbus/OH/USA ,[4]Department of Public Health and Community Medicine, School of Medicine, Tufts University, Boston/MA/USA ,[5]School of Health and Rehabilitation Sciences, Division of Medical Dietetics, College of Medicine, The Ohio State University, Columbus/OH/USA ,[6]Friedman School of Nutrition Science and Policy, Tufts University, Boston/MA/USA ,[7]Fox Chase Cancer Center, Department of Hematology-Oncology, Philadelphia/PA/USA ,[8]The University of Texas MD Anderson Cancer Center, Pediatrics-Research, Houston/TX/USA ,[9]Tufts Medical Center, Medicine, Hematology/Oncology, Boston/MA/USA

Introduction: Patients diagnosed with lung cancer are often among the most malnourished of all patients with solid tumors and have a significant risk of developing treatment-related toxicities. Providing nutritional support with medically tailored meals and nutritional counseling may reduce both the prevalence and severity of treatment-related toxicities and improve relative dose intensity (RDI) of lung cancer treatment leading to better outcomes.

Methods: The NutriCare study (NCT04986670), a “Food is Medicine” intervention, was a national, multisite, randomized trial evaluating the impact of medically tailored meals plus weekly nutritional counseling (NutriCare) vs. informational control (NutriTool) on the outcomes of vulnerable patients with newly diagnosed lung cancer initiating treatment. Vulnerability was defined as: ≥65 years of age, underrepresented minority, rural resident, no health insurance, and/or income ≤130% of the federal poverty line. Participants completed a 90-minute baseline assessment within 8 weeks of study consent. Demographics, dietary intake, cancer stage, income, healthcare utilization, and adverse events, were collected via electronic medical records; patient surveys were performed at baseline, 3-months, and 8-months. Relative dose intensity, measured as a ratio of delivered dose intensity to scheduled dose intensity, was calculated by collecting treatment regimen information as well as associated treatment delays and dose changes. Descriptive statistics, inferential statistics and mixed effects regression models accounting for repeated measures were used for data analysis.

Results: Across four oncology centers in the US, 127 participants were randomized to the intervention arm (NutriCare n=70) or control arm (NutriTool n=57) from 11/2020-08/2022. After accounting for lung cancer type, staging, and systemic therapy indication, both study arms demonstrated similar treatment intensity (mean RDI of NutriCare = 0.868, mean RDI of NutriTool = 0.886). However, those randomized to the NutriCare group treated for limited stage SCLC (n = 5, mean RDI = 0.9) or stage IV NSCLC (n = 15, mean RDI = 0.923) as well as those receiving sequential radiation treatment (n = 2, mean RDI = 0.94) were found to have a greater RDI. In contrast, those randomized to the NutriTool group treated for limited stage SCLC (n =2, mean RDI = 1.0) or stage II NSCLC (n = 4, mean RDI = 0.942) or receiving sequential radiation (n = 1, mean RDI = 1.0) were found to have a greater RDI. Notably, those randomized to the NutriCare group had a greater risk of experiencing a grade 3 or higher adverse event than those randomized to the NutriTool arm (Risk Ratio = 1.8, 95%CI: 1.3-2.6), p=0.001) with the most prevalent adverse events among both arms being GI-related.

Conclusions: We found nutritional counseling and medically tailored meals improved RDI among patients with stage IV NSCLC as compared to nutritional information alone. While there are significant improvements in systemic therapies to treat lung cancer, further research is needed to identify nutritional strategies to ensure patients can experience the full benefits of lung cancer treatment.

MONDAY, SEPTEMBER 8, 2025 - 10:30 - 12:00

P2.15 .23 Uncertainty in Illness, Symptom Severity and Hope in Advanced Lung Cancer Patients Undergoing Immunotherapy

Y-H. Lai[1], M-P. Hsiao[2], C-C. Hsu[3], W-Y. Liao[4]
[1]National Taiwan University (NTU) / and NTU Cancer Center, Taipei/TW ,[2]National Taiwan University School of Nursing & Cancer Center, Taipei/TW ,[3]National Taiwan University Cancer Center, Taipei/TW ,[4]National Taiwan University Hospital, Taipei/TW

Introduction: Immunotherapy is a relatively new treatment options for advanced lung cancer (LC) patients. However, in the treatment process, uncertainty in illness remains a concern for patients. However, limited investigations have been reported. The purpose of this study is to explore the perceived uncertainty in illness, symptom severity, hope and their relationship in advanced LC patients undergoing immunotherapy.

Methods: We conducted a cross-sectional study with consecutive sampling to recruit advanced LC patients who had received at least one cycle of immunotherapy from two centers in Northern Taiwan. Patients were assessed of their perceived uncertainty (by Mishel's Uncertainty in Illness Scale), symptom severity and level of hope (by Herth's Hope Index). The descriptive statistics and Spearman's correlation were applied to analyze the data. Institute Review Board approval and patients' consents were obtained before patients' assessments.

Results: There were 140 patients recruited. The overall results showed that advanced LC patients perceived moderate to high levels of uncertainty, moderate levels of hope and mild to moderate levels of symptom severity. The top five symptoms included fatigue, weakness, appearance change, itchiness, and shortness of breath listed as the order of mean scores. The correlation analysis revealed that patients with higher symptoms level reported to have higher uncertainty and lower hope. Patients with higher uncertainty in illness reported to have lower perceived hope.

Conclusions: This study supported our assumptions that advanced LC patients undergoing immunotherapy had relatively higher uncertainty. Higher uncertainty and severer symptoms are associated with lower hope. Taken together, in order to increase LC patients' hope level, health care professional should assess and intervene more on patients' symptom management and their uncertainty concerns. Interventions and care model to decrease their illness uncertainty and symptoms to increase perceived hope are strongly suggested.

[1]Massachusetts General Hospital, Boston/MA/USA ,[2]EGFR Resisters, Chicago/IL/USA ,[3]The Ohio State University Wexner Medical Center, Columbus/OH/USA ,[4]Massachusetts General Hospital Cancer Center, Boston/MA/USA ,[5]Mayo Clinic, Rochester/MN/USA ,[6]University Hospitals Seidman Cancer Center, Cleveland/OH/USA ,[7]University of Connecticut, Farmington/CT/USA ,[8]Cancer Survivorship Provider Network, Cincinnati/OH/USA ,[9]Association of Community Cancer Centers, Fairfax Station/VA/USA ,[10]Association of Community Cancer Centers, Olympia/WA/USA ,[11]National Cancer Institute, Rockville/MD/USA ,[12]LUNGevity, New York/NY/USA ,[13]The University of Colorado Anschutz Medical Campus, Denver/CO/USA ,[14]H. Lee Moffitt Cancer Center & Research Institute, Tampa/FL/USA ,[15]American Cancer Society, Atlanta/GA/USA

Introduction: Advances in lung cancer early detection and treatment have increased the number of people living with lung cancer. Yet, there are no standards or guidelines specific to lung cancer survivorship, and how survivorship care is delivered for people with lung cancer in the United States (US) is unknown. We conducted a cross-sectional survey to characterize survivorship care delivery at US cancer centers, focusing on care available to lung cancer survivors, to inform future research, policy, and organizational efforts to improve survivorship care.

Methods: An interdisciplinary working group of the American Cancer Society National Lung Cancer Roundtable Survivorship Task Group, comprised of clinicians, patient advocates, and researchers with lung cancer expertise, and representatives from the Association of Cancer Care Centers (ACCC) and the Cancer Survivorship and Supportive Care Professionals Network, developed a 20-item survey about survivorship care delivery based on literature review and prior surveys. The sample included all National Cancer Institute (NCI)-designated Cancer Centers that serve adults and a subset of community cancer centers in the ACCC network. Using REDCap, an electronic survey was administered to site representatives using used a four-wave mailing approach (i.e., modified Dillman method): an introductory email and four reminders, sent every two weeks, to complete the survey. We conducted an interim analysis of responses from NCI-designated Cancer Centers; results from community cancer centers will be reported separately.

Results: The completion rate from NCI-designated Cancer Centers was 73% (47/64), of which 41 (87%) reported having a clinic or program to provide survivorship care. Nineteen survivorship programs (46%) defined a survivor as "a patient who has completed curative-intent treatment for cancer and is on surveillance or maintenance therapy" and the remaining 22 (54%) of programs used the definition, "any patient with a diagnosis of cancer or history of cancer." One-third (34%) of programs offer services specifically tailored to patients living with advanced cancer. Lung cancer survivors have access to a survivorship program at 73% of facilities, with 9 (22%) offering a lung cancer-specific survivorship clinic and 21 (51%) offering a general survivorship program that serves lung cancer survivors. Lung cancer-specific services include pulmonary rehabilitation and lung cancer support groups at 27% and 20% of programs, respectively. Advanced practice providers are the most common clinician providing survivorship care (93%). Across all survey respondents, the most cited barriers to providing survivorship care are "limited or no funding for a program" (53%), "clinician time being prioritized in other clinical service" (45%), insufficient staff (38%) and lack of leadership support (36%).

Conclusions: Survivorship care clinical programs exist at most NCI-designated Cancer Centers, though nearly half limit their focus to patients who have completed curative intent treatment, a narrower definition than the NCI-supported concept that patients are survivors "from the time of diagnosis until the end of life." Survivorship services for patients living with advanced cancer and lung cancer-specific clinics are limited. Funding, staffing and lack of leadership support for survivorship care are the main limiting factors. Research to demonstrate the value of lung cancer-specific survivorship care is urgently needed.

P2.15 .25 Trilaciclib'S Myeloprotection in 1L Advanced Solid Tumors: Lung Cancer Data Analysis

H. Feng, Q. Mei
Shanxi Bethune Hospital, Taiyuan/CN

Introduction: Chemotherapy-induced myelosuppression (CIM) is a common toxicityin chemotherapy, which often necessitates dose reduction, treatment delays, or regimen changes. CIM-related complications—such as severe anemia, infections, or bleeding—may increase medical costs, and significantly worsen the prognosis. Trilaciclib is a highly potent, selective, and reversible CDK4/6 inhibitor designed to protects HSPCs before chemotherapy, thereby reducing chemotherapy-induced HSPC damage. Furthermore, its transient T-cell suppression may favorably alter the tumor immune microenvironment, ultimately improving patient survival outcomes.

Methods: This analysis was based on data from a prospective study , which enrolled 25 advanced lung cancer patients receiving first-line chemotherapy-based treatment. Patients received trilaciclib (240 mg/m^2) via a 30-minute IV infusion within 4 hours before daily chemotherapy. The incidence of CIM and antitumor efficacy were observed during chemotherapy.

Results: Enrollment began in October 2023, and to date, 25 patients receiving first-line chemotherapy-based treatment have been enrolled. 22 were male, and 3 were female, with a median age of 68 (57-84) years. Histopathological subtypes included SqCC (6 , 24.0%), LUAD(2, 8.0%), and SCLC(17 , 68.0%). Trilaciclib was used as primary prophylaxis in 20 patients (80.0%) and secondary in 5 (20.0%). Treatment cycles and patient distribution: 1 (7, 28.0%), 2 (4 , 16.0%), 3 (8 , 32.0%), 4 (5 , 20.0%), and 5 (1, 4.0%). Chemotherapy regimens followed clinical guidelines. CIM incidence is shown in the figure 1.A total of 20 patients underwent antitumor efficacy evaluation, with ORR of 50.0% and DCR of 85.0%. Detailed results are shown in the figure 2.

Conclusions: Conclusion: As of cutoff, no enrolled patients developed grade IV CIM. Primary prophylaxis demonstrated superior myeloprotective effects. Study data indicate that trilaciclib provides favorable platelet protection, offering a clinical strategy to better manage chemotherapy-induced thrombocytopenia (CIT). In lung cancer, Trilaciclib exhibits clear myeloprotective benefits, significantly enhancing the safety of first-line chemotherapy.

Introduction: CLIMEDIN (NCT05372081) is a prospective, randomized clinical trial with 200 patients with advanced non-small cell lung cancer (NSCLC), funded by the Stavros Niarchos Foundation. It aims to evaluate the feasibility and effectiveness of online digital intervention regarding adverse events (AEs), quality of life (QoL), costs and the interrelation with clinical and molecular characteristics.

The purpose of this sub-analysis is to provide insights on the Real World Evidence resulting from the patient-reported AE data.

Methods: After their diagnosis, staging, and molecular analysis, all patients received the indicated treatment (mainly chemo-immunotherapy).

Patients reported digitally on their symptoms through the CareAcross online platform, at their convenience, by identifying which of the 22 pre-selected AEs they have been experiencing.

Through randomization, half of them subsequently receive personalized supportive information to assist their self-care; the other half only received generic information. The information did not constitute medical advice, nor was it intended to replace it.

This analysis focuses on the PROs and specifically the percentage of patients who reported each AE, at any point throughout their participation.

Results: Out of 200 patients, 188 reported their AEs, from 1 to 557 times throughout their participation (average of 37.3, median of 10 submissions per patient). Submissions contained an average of 3.1 AEs, excluding the 36.4% that indicated absence of any of the 22 preselected AEs.

AE frequencies ranged from 13% to 88%. The most frequently reported AEs were fatigue (88% of patients), cough (63%), anorexia (54%), nausea (51%), diarrhea (41%), constipation (41%), dyspnea (40%). Further analysis of patient subgroups formed by factors such as their age group, education level, urban or rural location, indicated only minor differences in the frequency of each reported AE.

The Table contains the percentage of patients reporting each AE once or more.

Adverse Event	% of patients reporting once or more (N=188)
Fatigue	88%
Cough	63%
Anorexia	54%
Nausea	51%
Diarrhea	41%
Constipation	41%
Dyspnea	40%
Weight Loss	37%
Bone Pain	34%
Dysgeusia	32%
Sleeping Problems	32%
Dry Skin	30%
Chest Pain	29%
Dysphagia	27%
Pruritus	23%
Stomatitis	21%
Fever	20%
Rash	20%
Hair Loss	19%
Vomiting	16%
Hemoptysis	13%
Peripheral Neuropathy	13%

Table: Frequency of AEs as digitally reported by patients

Conclusions: Patients engage with online platforms, even with a challenging diagnosis such as advanced NSCLC, illustrating the feasibility of online interventions.

The resulting Real World Data help improve the understanding of the experience of NSCLC patients. It also enables advanced analyses that have the potential to support decisions on patient-centered care, optimize resource allocation, and prevent the onset or aggravation of adverse events.

Finallym, the timely online reporting of AEs may facilitate improvement of patients' symptoms and quality of life by increasing the effectiveness of their oncology teams.

P2.15 .27 Symptom Screening Using the Patient-Generated Subjective Global Assessment Adds Value to Routine Clinical Review

C. Smith, I. Phillips
NHS Lothian, Edinburgh/GB

Introduction: NHS Lothian has developed a prehabilitation service for patients who have radiologically-diagnosed Stage III or IV lung cancer. This patient population tends to skew older, present with co-morbid conditions, and have a high symptom burden at diagnosis. These symptoms may affect or limit the treatment tolerated by, or offered to, these patients. Identifying and mitigating these symptoms may lead to a difference in treatment options available, patients' quality of life, and/or better outcomes.

Methods: A retrospective single-centre project was undertaken at St. John's Hospital, Livingston between June 2021 and February 2025. All patients saw a palliative care physician, physiotherapist and dietician within 2 weeks of a CT scan suspecting stage III or IV lung cancer. All patients were screened using the patient-generated subjective global assessment (PGSGA) for Nutritional Impact Symptoms (NIS). The PGSGAs were compared with initial respiratory clinic letters from TrakCare Electronic Patient Records to assess frequency and distribution of NIS reported in each setting.

Results: Data was available for 94 of 108 patients who attended prehabilitation. Median number of NIS per clinic review and PGSGA were 1 and 2, respectively. Screening identified additional symptoms in 44% of patients when compared to clinic review alone, with a median of 2 additional NIS detected in these patients. 9 NIS were identified more frequently in prehabilitation screening compared to in clinic, the commonest of these being reduced appetite and early satiety, swallowing problems, and constipation. The biggest discrepancies between screening and clinic findings were in early satiety (10 in screening, none in clinic) and reduced appetite (36 in screening, 24 in clinics). 4 NIS were exclusively identified by PGSGA screening: early satiety, dry mouth, mouth sores and adverse reaction to smell. 4 symptoms were more commonly recorded in clinic than via PGSGA. These were pain, fatigue, diarrhoea and vomiting, with pain being reported 150% more frequently in clinic compared to PGSGA screening.

Conclusions: PGSGA screening before prehabilitation is an effective way to identify additional, and often clinically under-recognised, NIS in patients with locally advanced or metastatic lung cancer. The next phase of this work will be to assess what treatments - and/or how many cycles of treatment - the relevant patients received, to understand whether that is related to their declared NIS burden at presentation.

Introduction: Cardiovascular disease (CVD) and cancer are the two leading causes of death worldwide. Among patients who had developed hyperlipidemia after Lorlatinib consumption, 55% did not have resolved hyperlipidemia even after taking lipid-lowering drugs in post-hoc analysis of CROWN study. This raises concerns that while Lorlatinib can bring long progression-free survival for cancer patients, these cancer survivors may now at risk of developing CVD. However, how to evaluate Lorlatinib-related hyperlipidemia's impact on CVD in this tumor-bearing population remains an unresolved question.

Methods: We reviewed 120 Lorlatinib-treated patients from ten tertiary medical centers. Since both inflammation and dyslipidemia play roles in atherosclerosis formation, we reviewed C-reactive protein (CRP), the biomarker of inflammation, and blood lipid levels before and after 3 months' Lorlatinib consumption. To check atherosclerosis early formation, we also reviewed the changes in maximum carotid intima-media thickness (CIMT) examined by B-ultrasound before and after 6 months' Lorlatinib consumption.

Results: In our real-world cohort, 89 patients who had Lorlatinib-related hyperlipidemia were retrospectively enrolled. After 3 months of lipid-lowering drug uptake, re-evaluation of blood lipid levels revealed that 56/89 (63%) patients had not reach normal levels. Among these patients, only 12 had CRP test before and after 3 months' Lorlatinib consumption, 83% (10/12) of which had their CRP decreased down within normal range. Among 4 patients who underwent carotid artery B-ultrasound examination before and after 6 months' Lorlatinib consumption, 2/4 patients had increased maximum CIMT (both from 1.5mm to 2.2mm) and 2/4 patients had decreased maximum CIMT (from 2.1mm to 1.9mm, 3.1mm to 1.9mm, respectively). This was intriguing as atherosclerotic plaque thickness did not parallel blood lipid levels.

Conclusions: Oncologists in the real world do not pay enough attention to lipid management in Lorlatinib-related hyperlipidemia patients, especially CRP inflammation biomarker and carotid artery B-ultrasound. Oncologists should form a multidisciplinary team with ultrasonographers and cardiologists to evaluate Lorlatinib-related hyperlipidemia's impact on CVD in these cancer survivors. As now, we are conducting a multi-center, prospective study addressing this important issue (Lipid-Long Study, NCT06876675).

P2.15 .29 Understanding the Psychosociological Burden of ALK+ NSCLC: Findings From the French Study «Living With ALK+ Cancer»

J. Cadranel[1], R. Corre[2], P. Roget[3], M. Wingler[4], S. Alliaume[5], L. Capdevielle[6], J. Mendes[6], A. Billard[6], A. Mogenet[7], B. Mennecier[8]
[1]Tenon Hospital, Paris/FR ,[2]Cornouaille Hospital Center, Quimper/FR ,[3]Lille University Hospital Center, Lille/FR ,[4]Patient en Réseau Association, Paris/FR ,[5]ALK+ ROS[1] Cancer Poumon Association, Saint-Cyr-au-Mont-d'Or/FR ,[6]Takeda France, Paris/FR ,[7]AP-HM North Hospital, Marseille/FR ,[8]Brabois University Hospital Center, Vandœuvre-Les-Nancy/FR

Introduction: ALK fusion positive (ALK+) adenocarcinoma accounts for about 5% of NSCLC. Their prognosis has been drastically improved by therapeutic sequences incorporating different generations of ALK inhibitors (ALKi), extending median overall survival from 12 months to several years. This prolonged survival on treatment may have sociological impacts in this usually young, active and nonsmoker population. This study aims to understand the impact of the disease and treatments on various aspects of ALK+ NSCLC patients' daily lives and perception of physicians.

Methods: « Living with ALK+ cancer » is a psychosociological survey conducted in two parts: a qualitative phase selecting areas of interest and the second phase quantifying their impact in 85 patients, 27 caregivers and 50 thoracic oncologists. Here, we present the results of the quantitative phase conducted between November 2024 and February 2025. To be enrolled in the study, patients in first line (1L) had to have started treatment at least a year prior to inclusion. Data collection was performed through self-administered online surveys, each one lasting approximately 35 minutes. Patients were recruited through patient associations or directly through their physicians. Thoracic oncologists and caregivers were not necessarily those of the patients.

Results: Seventy percent of patients had advanced disease, and 62% of them had brain metastases. 74% of participants were women. Median age was 57 years. Average current line duration at data collection was 2.4 years both for patients in 1L and 2L+. The figure presents a spider chart comparing the frequency of preidentified daily life difficulties based on patients' reports and physicians' perception. Psychological difficulties emerged as the most frequent daily challenges for patients, with common issues including feelings of insecurity (49%), anxiety (48%), anger (42%), and mood disorders (38%). Patients also faced professional challenges, including sick leave periods (26%) and reduced working hours (19%) due to the disease. Impact on driving ability was reported by 63% of patients, while only 10% stated that they had stopped driving, and only 26% indicated that this topic was addressed by their physician. Challenges in maintaining physical activity was also highlighted in 49% of patients and 42% reported a decrease or loss of libido, indicating an impact on intimate life.

Conclusions: Our study highlights the extensive challenges faced by patients with ALK+ NSCLC, emphasizing the need for comprehensive support systems that address both medical and non-medical aspects of patient care.

Figure: Spider Chart comparing the frequency of preidentified daily life difficulties: patients' reports (n=85) versus physicians' perception (n=50)

P2.15 .30 Impact of an Incidental Pulmonary Nodule Course Series on the Professional Development of Under-Resourced Multidisciplinary Teams

H. Sanders[1], M. Podsiad[1], D.Z. Liou[2], V. Mehta[3,4], K. DuBree[5], K. Sivertsen[6], E. Ho[7], G. LeMense[8], A. Wagh[9], J.T. Fathi[1]
[1]GO[2] for Lung Cancer, Washington/DC/USA ,[2]Stanford University School of Medicine, Stanford/CA/USA ,[3]Lung Center of Nevada, Comprehensive Cancer Centers of Nevada, Las Vegas/NV/USA ,[4]Kirk Kerkorian School of Medicine, Las Vegas/NV/USA ,[5]University of Maryland Upper Chesapeake Health, Bel Air/MD/USA ,[6]UW Health, Madison/WI/USA ,[7]City of Hope, Duarte/CA/USA ,[8]Bozeman Health, Bozeman/MT/USA ,[9]University of Chicago, Chicago/IL/USA

Introduction: While early detection in the high-risk screening population yields a 6% detection rate, lung cancer detection in the 1.6 million incidental pulmonary nodules (IPN) identified annually in the U.S. through imaging studies holds as much, if not more, promise. To improve early lung cancer detection in IPNs, this project aimed to provide affordable, current, and quality professional IPN-specific education for key healthcare providers (HCPs) and personnel, including nursing and allied health professionals in under-resourced and healthcare professional shortage areas.

Methods: Informed by current evidence and key stakeholders, including GO2 for Lung Cancer Centers of Excellence, we identified topics and subject-matter experts for the development of an IPN comprehensive course series. The GO2 Global Knowledge Center (GKC) team designed interactive activities, which underwent a thorough review process. Continuing Medical and Nursing Education credits were made available. The course series was promoted through the GKC messaging platform and other professional networks. Data was collected from registrations, post-tests and course evaluations and analyzed to determine the learner population served and impact of the IPN series.

Results: This project and reporting occurred from May 1, 2024, through March 20, 2025. Of 491 enrollments, 230 (47%) enrolled in at least one course. Learners consisted of Navigators (25%), Nurses (24%), Allied Health Professionals (11%), Medical Doctors (8%), and Other (13%) with more than 50% in Pulmonology/Respirology (31%), Patient Navigation (17%), Medical Oncology (10%). Of the 83% of learners practicing in the U.S., 30% practice in community hospitals and 19% in ambulatory settings, which may represent practice locations with limited access to subspecialists with expertise in IPN management. Additionally, 68% of learners reported serving urban populations, while 8% serve urban areas with broad catchment and 7% serve rural populations. Table 1. summarizes learner course evaluation responses, including course satisfaction, practice implications, and credit achievement. According to a recent Google search, this IPN course series appears to be the only one of its kind available.

Conclusions: Incidental pulmonary nodule-specific provider education enhances current knowledge and practice skills. This course series demonstrated value to multidisciplinary professionals, who commonly practice in under-resourced, non-academic, and geographically isolated settings. These multidisciplinary professionals serve an important role in IPN management and early lung cancer detection. By providing free and accessible education, knowledge gaps may be minimized, and lung cancer outcomes may be improved. This project informs future course project opportunities to reach and educate under-resourced multidisciplinary teams about lung cancer.

Table 1. Impact of Course Series for Learners

		Satisfaction with learning activity	Motivation to participate in this activity		Credit request type			Based on what I learned today, I will improve my practice by incorporating the following:

P2.15 .31 Integrating Biomarker Testing in Early-Stage Lung Cancer With a Nurse-Led Multidisciplinary Approach Using the 4R Oncology Model

R. Liu[1], L.C. Sakoda[2], M. Ragavan[1], J. Katzel[1], Z. Zhu[2], H. James[3], S. Martinez[2], M.Z. Yang[1], S. Tamima[3], J.M. Suga[4], C.P. Quesenberry[2], Y. Liang[5], R. Salomonsen[5], G. Ursino[5], M. Lupicka[5], C.B. Weldon[6], J.R. Trosman[6], J. Velotta[3]
[1]Kaiser Permanente Northern California, San Francisco/CA/USA ,[2]Kaiser Permanente Northern California, Pleasanton/CA/USA ,[3]Kaiser Permanente Northern California, Oakland/CA/USA ,[4]Kaiser Permanente Northern California, Vallejo/CA/USA ,[5]Oncology Business Unit, Gaithersburg/MD/USA ,[6]Centers for Business Models in Healthcare, Glencoe/IL/USA

Introduction: Nurses and Allied Health Professionals (AHPs) play a critical role in delivering timely and guideline-concordant multidisciplinary cancer care. For early-stage non-small cell lung cancer (NSCLC), biomarker testing is a recent guideline-based standard necessary to inform neoadjuvant and adjuvant therapy decisions. However, integrating timely biomarker testing in early-stage NSCLC care remains challenging and variable. The lack of expedient ordering causes delays in receiving testing results, therapy decisions and treatment initiation. The 4R Oncology model (4R=Right Info/Care/Patient/Time) has demonstrated effectiveness in facilitating timing and sequencing of care across specialties, including reducing time between biomarker testing and treatment decisions. We designed and evaluated a nurse and AHP-led approach using the 4R model to implement timely biomarker testing in early-stage NSCLC at a hospital in a large U.S. health system.

Methods: A prospective cohort study was conducted among patients with operable Stage I-III NSCLC who received the 4R model vs. those who received usual care (control). In the 4R group, we designed a systematic multidisciplinary process maximizing and expediting biomarker testing on biopsy or surgical samples. To ensure process consistency and expediency, testing was facilitated by a nurse-navigator and AHP team responsible for ordering, communication across specialties, and issue resolution. Patients referred to surgeons within the same hospital underwent either the 4R approach (one surgeon) or usual care (other surgeons) between January - December 2024. The rates and timing of biomarker testing were compared between the two groups.

Results: The patients in the 4R (N=42) and control group (N=139) were demographically similar (median age at surgery: 69 vs. 70 years; female: 64% vs. 62%; non-Hispanic White: 43% vs.52%; Elixhauser comorbidity index: 3.88 vs. 3.85; and Stage I: 79% vs. 77%). The rates of post-diagnostic biopsy and receipt of surgery as first treatment were similar (Table). The 4R-based (vs. usual care) approach improved the overall rates of biomarker testing (100% vs. 40%, p<0.001) as well as the rates of testing on diagnostic biopsy and surgical tissue. It also reduced the median time between surgery and receiving test results: 26 (control) vs. 6 days (4R).

Conclusions: Our 4R-based, nurse and AHP facilitated approach resulted in significant benefit, with increased biomarker testing and sooner return of results to guide decisions in a population with predominantly Stage I NSCLC. This intervention may inform other institutions' efforts to leverage nurse and AHP resources to improve biomarker testing in operable lung cancer patients.

Table: Timing and Rates of Biomarker Testing

Metric	4R n=42	Control n=139	p value
Patients who received biomarker testing*	100% (42/42)	40% (56/139)	**<0.001**
Diagnostic biopsy	69% (29/42)	67% (95/139)	1.00
Biopsy and biomarker testing on biopsy sample	79% (23/29)	26% (25/95)	**<0.001**
Neoadjuvant as first treatment	7% (3/42)	8% (11/139)	1.00
Surgery as first treatment	93% (39/42)	92% (128/139)	1.00
Surgery and biomarker testing on surgical sample	48% (19/39)	24% (31/128)	**0.005**
Time from surgery to biomarker test result (median)	6 Days	26 Days	**0.03**

P2.15 .32 Early Lung Cancer Detection and Multidisciplinary Care

W. Liao[1], J. Goss[1], T. Qureshi[1], S. Johnson[1], A. Harris[1], K. Dortch[1], A. Porter[1], Y. James[1], A. Patel[1], J. Roma[1], H. Marshall[1], C. Fehnel[1], A. Mehrotra[1], O. Ogbeide[1], P. Lammers[1], K. Tonkin[1], J. Machin[1], J. Zhao[1], T. Ng[1], M. Smeltzer[2], M.A. Ray[2], R. Osarogiagbon[1]
[1]Baptist Cancer Center, Memphis/TN/USA ,[2]University of Memphis, Memphis/TN/USA

Introduction: Lung cancer screening (LCS) and incidental pulmonary nodule programs (IPN) are associated with improved overall survival (OS); multidisciplinary care (MDC) enhances guideline concordance. We compared OS among patients diagnosed with lung cancer through LCS or IPN programs with, versus without, structured MDC within a regional community healthcare system.

Methods: Prospective observational study of patients enrolled into LCS and IPN programs in the 'Detecting Early Lung Cancer (DELUGE) in the Mississippi Delta' cohort cross-linked with institutional MDC database. We compared patients' demographic, clinical characteristics, and OS and constructed a Cox model to estimate hazard for death adjusting for age, sex, race, smoking history, insurance status and histologic type (aHR). We conducted a propensity-matched sensitivity analysis, matching for age, sex, race, insurance, rurality and clinical stage.

Results: From Jan 2015 to June 2024, 613 patients were diagnosed through LCS, 220 (36%) had MDC; 1913 through IPN, 818 (43%) had MDC; 2,526 in total through both early detection programs, 1038 (41%) had MDC (Table). There was a median of 1 (IQR 1-2) comorbidity across all subsets. The proportions with adenocarcinoma were 45% v 37% LCS, 56% v 43% IPN; small cell lung cancer: 11% v 16% LCS, 8% v 14% IPN (p=0.0005).

OS was significantly better with MDC (Figure). Aggregate 5-year OS rates were 65% (CI:56-76) v 54% (47-62) for LCS; 48% (44-53) v 35% (31-39) for IPN ; 51% (48-56) v 39% (36-43) for the combined programs. The aHR was significant for non-MDC in each early detection program; propensity-matching yielded similar results (Table).

Conclusions: Structured MDC was strongly associated with significantly better OS among patients diagnosed with lung cancer through LCS or IPN programs. For optimal results, multidisciplinary decision-making should be embedded within early lung cancer detection programs.

P2.15 .33 A Comparative Study of the Significance of GPT-Enabled Counseling and Management of Pulmonary Nodules

Y. Wang[1], C. Bai[2], Y. Song[2], Q. Cai[2], Y. Shen[3], X. Liu[4], D. Yang[5]
[1],[2]Zhongshan Hospital, Fudan University, Shanghai/CN ,[3]Yantai Yuhuangding Hospital, Yantai/CN ,[4]Qinghai University Affiliated Hospital, Nanning/CN ,[5]Zhongshan Hospital Fudan University, Shanghai/CN

Introduction: Effective pulmonary nodule management is critical for early lung cancer detection, yet faces significant challenges including inconsistent guideline implementation, limited patient awareness, uneven resource distribution, poor follow-up adherence, and insufficient psychological support. AI-powered specialized GPT models (e.g., BAIMGPT, DeepSeek GPT) address these issues through advanced natural language processing capabilities, offering intelligent patient consultations, preliminary risk assessments, and personalized management recommendations. The purpose of this study is to compare the performance of specialized AI model BAIMGPT with general-purpose models in pulmonary nodule management, validate the advantages of digital human technology in enhancing doctor-patient communication efficiency and diagnostic accuracy, and provide evidence-based support for optimizing intelligent healthcare products.

Methods: This study comprises three phases: (1) Literature review analyzing GPT applications in pulmonary nodule management; (2) BAIMGPT model development by a multidisciplinary team, optimizing eight key metrics (convenience, user-friendliness, safety perception, question comprehension, accuracy, voice interaction, visual assistance, and demand); (3) Multicenter evaluation using dual assessments: user ratings and blinded expert reviews of response accuracy against clinical guidelines. The research aims to establish evidence for specialized AI in nodule management through systematic comparison of BAIMGPT's performance against benchmarks, with particular focus on both technical efficacy and user experience metrics.

Results: This study conducted a comparative analysis of consultation experiences from 109 pulmonary nodule patients, revealing that the specialized BAIMGPT model significantly outperformed the general-purpose large language model DeepSeek GPT across multiple key metrics. In terms of emotional interaction, BAIMGPT achieved 92.7% satisfaction for friendliness and 89.0% for perceived safety through its digital human technology, demonstrating significant advantages over DeepSeek GPT's 41.3% and 38.5% respectively ($p<0.001$). Regarding functional experience, BAIMGPT's voice interaction (90.8% satisfaction) and visual interface (87.2% satisfaction) received high praise, while DeepSeek GPT scored no points due to lacking these features. In core competencies, BAIMGPT surpassed the control group in both question comprehension (88.1% vs 82.6%) and answer accuracy (85.3% vs 80.7%). Notably, 84.4% of patients rated BAIMGPT as "urgently needed," far exceeding DeepSeek GPT's 52.3%. These findings demonstrate that by integrating specialized knowledge bases with digital human interaction technology, BAIMGPT has not only enhanced the technical accuracy of medical consultations but also made breakthroughs in doctor-patient communication experience, establishing a "precision medicine + humanistic care" paradigm for AI applications in specialized disease management. The study recommends expanding sample sizes and incorporating objective physiological indicators for multidimensional validation in future research.

Conclusions: This study demonstrates the significant advantages of the specialized AI model BAIMGPT in pulmonary nodule management. Data shows BAIMGPT outperforms the general-purpose model DeepSeek GPT in emotional interaction , functional implementation , and core metrics . Notably, 84.4% of patients expressed urgent demand for BAIMGPT, significantly higher than the control group's 52.3%. The research validates the innovative value of combining "specialized medical knowledge with digital human technology," establishing a new paradigm of "precision medicine with humanistic care." Future studies should expand sample sizes, incorporate objective indicators, and deepen clinical integration, providing important references for AI applications in healthcare.

Introduction: Data retrieval in clinical research is often time-consuming and error-prone. Large Language Models (LLMs) have shown zero-shot capabilities in structuring unstructured clinical texts. These models could aid the data retrieval stage by exploiting the information reported in Electronic Health Records (EHRs). This study is conducted within the APOLLO 11 trial (NCT0550961), a multicentric Italian study which leverages a federated infrastructure for the analysis of advanced non-small cell lung cancer (NSCLC) data.

Methods: We evaluated four privacy-preserving LLMs on anonymized EHRs of 679 NSCLC patients from Fondazione IRCCS Istituto Nazionale dei Tumori di Milano. We assessed English/Italian prompts and zero/few shot techniques using the information extraction pipeline proposed by Wiest et al. We selected smoking, ECOG, histology, PD-L1, staging, T, N, M as multiclass variables and bone/brain/liver metastases as binary variables. Additionally, we examined if medical expertise could affect the extraction accuracy in a two-phase prompting study among experienced oncologists, resident oncologists and medical students. In the second phase, the medical user was asked to refine prompts, as "human-in-the-loop", according to the performance achieved in the first phase.

Results: Overall, few-shot prompting improved the average extraction performance compared to zero-shot. Additionally, few-shot, enriched with annotated examples from the original dataset, further increased the accuracy in variables like smoking and PD-L1 (Table 1). Histology and staging were originally unbalanced resulting in poor F1-score, while T, N, M remained the variables with the lowest performance (Table 1). LlaMa 8B achieved the highest average accuracy in few-shot with annotation (0.81), followed by Mistral 7B (0.69) and MedLlaMa and BioMistral (less than 0.5). An improvement of 10% in extraction accuracy was observed in phase two of the experiment for the medical students, especially in T and N staging. Experienced oncologists achieved comparable performance between the two phases for variables like staging and metastatic sites, demonstrating the impact of medical expertise on prompting.

Conclusions: LLMs demonstrated strong performance in extracting clinical data from EHRs, even with minimal prompt optimization. The findings also highlight the importance of leveraging domain-specific medical expertise to further enhance their effectiveness. This study confirms the feasibility of using LLMs to support clinicians and clinical study coordinators during the initial phase of data retrieval. However, subsequent steps such as quality check must remain distinct and human-supervised to ensure accuracy and resolve potential discrepancies. Notably, the study shows this approach reduces several months of manual data entry, while maintaining high performance.

Prompting	Smoking	ECOG	Histology	T	N	M	PD-L1	Staging	Liver metastases

P3.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL
TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.01.01 Asian-Americans With Tobacco Use History Are Less Often Eligible for Screening Than White Individuals With Lung Cancer

H. Yang[1], E. Choi[2], C. Shusted[1], H. Evans[1], J. Katcher[1], Y. Shieh[2], A. Vachani[3], J.A. Barta[1]
[1]Thomas Jefferson University, Philadelphia/PA/USA ,[2]Weill Cornell Medicine, New York City/NY/USA ,[3]University of Pennsylvania, Philadelphia/PA/USA

Introduction: The US Preventive Services Task Force (USPSTF) guidelines for lung cancer screening (LCS), which rely on age, smoking pack-years, and quit-years, have been shown to disproportionately exclude minority groups, including Asian-Americans. Recent recommendations propose eliminating quit-years - from the American Cancer Society (ACS) - or replacing pack-years with smoking duration. The objective of this multi-center study was to evaluate the impact of alternative LCS criteria on differences in screening eligibility (i.e., sensitivity) between Asian-American and White patients with lung cancer.

Methods: Asian-American and White patients with a lung cancer diagnosis between 2008-2024 were identified at two multi-center healthcare systems in Philadelphia and New York City. At Jefferson Health (JH), lung cancer cases were identified from the electronic health record and confirmed via chart review, while at Weill Cornell Medicine (WCM), cases were identified using both hospital-based cancer registry data and chart review. To ensure statistical power for racial comparisons, a representative subcohort of White patients was sampled at JH, whereas all available cases were included at WCM. Smoking status and quantitative smoking history were manually reviewed at JH, while at WCM, a natural language processing tool extracted smoking data from progress notes. Following data extraction, patients with a never-smoking history were excluded. LCS eligibility (age range-pack-years-quit-years) was assessed using USPSTF2013 (55-80-30-15), USPSTF2021 (50-80-20-15), USPSTF2021 with a 20- or 30-year smoking duration replacing pack-years, and ACS 2023 criteria (50-80-20, no quit-year restriction).

Results: The final cohort included 242 Asian-Americans (39.7% Chinese-Americans, 12.4% Vietnamese-Americans, 10.3% Korean-Americans, and 37.6% other Asian-American subgroups) and 431 White patients at JH (2015-2024), as well as 954 Asian-Americans and 3,304 White patients at WCM at WCM (2008-2024). In the combined cohort, Asian-American patients included a higher proportion of males (80.4% vs. 45.1%), lower mean pack-years (33.8 vs. 39.2), and a shorter mean quit-time (7.4 vs. 15.4 years) than White patients. The gap in screening eligibility between Asian-American and White patients was reduced with USPSTF2021 (4.8% [p=0.002] vs. 5.2% in USPSTF2013 [p<0.001]) and further narrowed with USPSTF2021 with a 30-year duration (3.4%, p=0.03), though differences remained statistically significant. The ACS criteria increased overall eligibility but showed the largest disparity (15.0%, p<0.001).

Conclusions: Revised criteria such as USPSTF2021 and USPSTF2021 with 30-year smoking duration reduced differences in screening eligibilty, but significant gaps persist. Future investigation of lung cancer in underserved populations should consider comprehensive evaluation of risk factors that are not currently included in determining LCS eligibility.

Lung Cancer Screening Eligibility by Race Among Lung Cancer Cases (n= 4,931)

	Asian-Americans n= 1,196		Whites n= 3,735		*p*	Difference in screening sensitivity
LCS Eligibility, n(%)						
USPSTF 2013	278	23.30%	1064	28.46%	<0.001	5.16%
USPSTF 2021	348	29.17%	1269	33.95%	0.002	4.78%
USPSTF 2021-Dur20*	410	34.37%	1420	37.99%	0.026	3.62%
USPSTF 2021-Dur30*	361	30.26%	1260	33.71%	0.029	3.45%
ACS 2023	475	39.82%	2049	54.82%	<.001	15.00%
Reasons for LCS Ineligibility, n(%)						
USPSTF 2021-Ineligible	515	43.17%	1883	50.37%		
Age						
<50 years old	57	11.07%	69	3.66%		
>80 years old	171	33.20%	663	35.21%		
Smoking intensity						
<20 pack-years	276	53.59%	802	42.59%		
Quit time ≥15 years	181	35.15%	1231	65.37%		

*USPSTF 2021-Dur20 or -Dur30 applies ≥20 or ≥30 years smoking duration, respectively, to USPSTF 2021 criteria in place of ≥20 pack-years.

P3.01.02 Association Between Age and Lung Cancer Risk: Evidence From Lung Lobar Radiomics

Y. Li, L. Shi
Zhejiang Cancer Hospital, Hangzhou/CN

Introduction: Previous studies have highlighted the prominent role of age in lung cancer risk, with signs of lung aging visible in computerized tomography (CT) imaging. This study aims to characterize lung aging using quantitative radiomic features extracted from five delineated lung lobes and explore how age contributes to lung cancer development through these features.

Methods: We analyzed baseline CT scans from the Wenling lung cancer screening program, consisting of 29,810 participants. Deep learning-based segmentation was used to delineate lung lobes. A total of 1,470 features were extracted from each lobe. The minimum redundancy maximum relevance algorithm was applied to identify the top 10 age-related radiomic features among 13,137 individuals without a history of tobacco use. Multiple regression was used to adjust for confounders in the association of age, lobar radiomics, and lung cancer. Linear, Cox proportional hazards, and parametric accelerated failure time models were applied as appropriate. Mediation analyses were conducted to evaluate whether lobar radiomic features mediate the relationship between age and lung cancer risk.

Results: Age was significantly associated with an increased lung cancer risk, particularly among individuals with current tobacco use (hazard ratio = 1.07, P = 2.81×10^{-13}). Age-related radiomics exhibited distinct effects across lung lobes. Specifically, the first-order mean (mean attenuation value) filtered by wavelet in the right upper lobe increased with age (β = 0.019, P < 2×10^{-16}), whereas it decreased in the right lower lobe (β = -0.028, P < 2×10^{-16}). Three features were independently associated with lung cancer risk at a Bonferroni-adjusted P value. Mediation analyses revealed that density and shape features partially mediated the relationship between age and lung cancer risk, while a suppression effect was observed in the first-order mean of the right upper lobe.

Conclusions: This study reveals lobe-specific heterogeneity in lung aging patterns through radiomics and their associations with lung cancer risk. These findings may contribute to developing new approaches for early intervention in lung cancer related to aging.

P3.01.03 Night Shift Work and Lung Cancer Risk: A Prospective Cohort Study With Mediator Analysis From the Uk Biobank

Y. Feng, B. Cheng, X. Zheng, J. He, W. Liang
the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: This study investigated the association between night shift work and lung cancer risk using data from the UK Biobank cohort of 278,650 participants, while exploring potential biological mediators and gene-environment interactions.

Methods: Cox proportional hazards models assessed relationships between current night shift status, lifetime duration, and frequency of night shifts with lung cancer incidence. Mediation analyses examined blood immune cell parameters and plasma proteins as potential mediating pathways. Polygenic risk scores evaluated genetic predisposition interactions.

Results: During a median follow-up of 10.4 years, 1,524 incident lung cancer cases were identified. A significant dose-response relationship was observed between increasing categories of current night shift work and lung cancer risk. Specifically, individuals engaged in some night shifts had a higher risk of lung cancer (HR 1.28, 95% CI: 1.06-1.55, P = 0.010, P for trend = 0.009). Subgroup analysis revealed that smoking status significantly modified this relationship, with smokers engaged in night shift work exhibiting a synergistic increase in lung cancer risk. Mediation analysis identified PRSS8, ALPP, and CEACAM5 as key mediators, collectively explaining over 25% of the total effect.

Conclusions: This study suggests that night shift work, particularly when combined with smoking, is associated with an increased risk of lung cancer. The identification of potential mediators such as PRSS8, ALPP, and CEACAM5 provides insights into the underlying biological mechanisms. Future research should validate these findings and explore targeted prevention strategies for high-risk populations.

Table 1 Current night shift work and lung cancer risk in the UK Biobank (N = 278,650)

	Category	Cases / person-years	Model 1	P-value	Model 2	P-value	Model 3	P-value

P3.01.04 Bootstrap-Based Mediation Mendelian Randomization Unveils Gut Microbiota-Driven Metabolic-Immune Networks in Lung Cancer

Y-L. Peng[1,2], J-T. Li[1,3], L. Wu[1], L-B. Tang[1,2], D-X. Cai[1], Z-R. Ren[1], Z. Guo[1], C. Lu[1], Z-H. Chen[1], H-H. Yan[1], Y. Deng[1], C-R. Xu[1,2], Q. Zhou[1,2]
[1]Guangdong Provincial People's Hospital, Southern Medical University, Guangzhou/CN ,[2]South China University of Technology, Guangzhou/CN ,[3]Shantou University Medical College, Shantou/CN

Introduction: Mendelian randomization (MR) with mediation analysis has gained widespread use in research, but reliable validation standards are still lacking. The gut microbiota-plasma metabolome-immune cell-lung cancer axis plays an important role in lung cancer development.

Methods: This unprecedented study included gut microbiota, metabolites, and immune cells genome-wide association studies from 4, 3, and 2 sources. 6 lung cancer-related datasets were collected from Finngen. The Bootstrap method was used to validate results obtained from traditional MR mediation analysis by Delta method, and we assessed the consistency and correlation between the results from both methods.

Results: The mediation effects calculated using the Bootstrap method showed consistency (Intraclass correlation coefficient: 1.000; Sum rank test P=0.978) and correlation (Spearman correlation: 0.999, P<0.001) with traditional MR. We identified that Herbinix abundance induces plasma total lipids in lipoprotein particles, increases CCR2 on CD62L+ myeloid dendritic cells, and reduces the incidence of lung cancer (OR: 1.004, 95% CI: 1.000~1.007). More than 80 mediation effects in the gut microbiota-plasma metabolome-immune cell-lung cancer axis were found. Furthermore, the results of the Delta method were validated using our constructed Bootstrap-mediated MR analysis and excluded some inconsistent results.

Conclusions: This study proposes a method based on the Bootstrap approach to validate the reliability of traditional MR mediation effects by Delta method. Using multiple mediation effects, we identified that Herbinix abundance induces plasma total lipids in lipoprotein particles, elevates CCR2 on CD62L+ myeloid dendritic cells, and raising the risk of lung cancer. Additionally, plenty of mediation effects in the gut microbiota-plasma metabolome-immune cell-lung cancer axis were found.

	Intraclass correlation	P of rank sum test	Spearman correlation	P	Pearson Correlation	P

P3.01.05 Decoding the Sleep Enigma: A Proteomic Mediation Analysis Linking Healthy Sleep Patterns to Lung Cancer Risk

Y. Feng, B. Cheng, J. He, J. He, W. Liang
the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: The biological link between sleep patterns and lung cancer remains an enigma. This study aims to explore how healthy sleep patterns modulate lung cancer risk through proteomic mediation.

Methods: This study analyzed 34,881 UK Biobank participants with complete proteomic and sleep profiles. A composite sleep score (0-5) incorporating five sleep parameters—duration, chronotype, insomnia, snoring, and daytime sleepiness—was constructed. Proteomic profiling quantified 2,862 plasma proteins using the Olink Explore 3072 platform. Sleep-associated proteomic signatures were developed through logistic regression with LASSO regularization to select key biomarkers. Associations between sleep patterns, proteomic profiles, and lung cancer risk were assessed via Cox models and structural equation modeling (SEM). Subgroup and sensitivity analyses validated result robustness.

Results: Higher healthy sleep scores were significantly associated with reduced lung cancer risk, with hazard ratios (HR = 0.579, CI = 0.345-0.973, p = 0.039) for a score of 3 and (HR = 0.513, CI = 0.305-0.863; p = 0.012) for a score of 4. Similar trends were observed in NSCLC and lung adenocarcinoma. Proteomic signature analysis revealed that protein signatures associated with healthy sleep scores had a significant protective effect against lung cancer (HR = 0.866, CI = 0.784-0.957, p = 0.005) and NSCLC (HR = 0.871, CI = 0.783-0.968, p = 0.011). Enrichment analysis further identified associations between healthy sleep scores and various biological processes, molecular functions, and pathways. PPI network analysis identified ERBB2, CDH1, and MME as key hub proteins. Additionally, mediation analysis identified 125 proteins mediating the relationship between healthy sleep scores and lung cancer risk, with CXCL17 showing the highest mediation proportion (47.62%).

Conclusions: This study highlights the association between healthy sleep patterns and lung cancer risk, identifying key proteins such as CXCL17 and WFDC2 through proteomic analysis.

P3.01.06 Lung Cancer in Incidentally Detected Pulmonary Nodules: Stratified Analysis by Smoking History and Nodule Morphology

F. Moura de Gouvêa, D.V.F.d. Carvalho, C.H.N. Bezerra, J.F.d.P. Moura, P.A. Sarmento, L.P. Lima, I.V. Secundo, T.N. Béder, C.F.J.d.S. Menezes, H.V.S.d. Fonseca, H.V.S.d. Fonseca, F.G.N.d. Silva, J.E.F.d. Fonte, L. Casali, R.L. Alencar, F.L. Didjurgeit, F.A.C. Sarmento Neto
Real Hospital Português de Beneficência em Pernambuco, Recife/BR

Introduction: Incidentally detected pulmonary nodules are an increasingly relevant source of lung cancer diagnosis, especially in patients not eligible for screening. We aimed to evaluate clinical and radiological features of lung cancers diagnosed through incidental nodules, stratified by smoking history.

Methods: This retrospective study included 72 patients diagnosed with primary lung cancer through incidental nodules between January 2023 and December 2024. Patients were categorized as never smokers (n=32) or with a smoking history (former or current, n=40). Variables included sex, age group, race, nodule location, density, contour, size, and TNM stage. Associations were analyzed using chi-square or Fisher's exact tests (p<0.05).

Results: Non-smokers were predominantly female (78.1%) and younger (median age: 61-70 years), while those with a smoking history were mostly male (65%) and older (median age: 71-80) (p<0.001 and p=0.033). Nodule location and size did not differ significantly. Solid nodules predominated in both groups (65.6% in non-smokers vs. 75.0% in smokers; p=0.653). However, non-smokers had a higher proportion of subsolid nodules: partially solid (21.9% vs. 17.5%) and ground-glass (12.5% vs. 7.5%), suggesting a distinct pattern, though not statistically significant. Irregular margins were more frequent in smokers (50% vs. 18.8%, p=0.006). Most nodules in both groups measured ≥15 mm (94% vs. 85%, p=0.394), and proportions ≥30 mm were similar (40.6% vs. 37.2%). TNM stage was available in 69 patients. Stage I was more frequent in non-smokers (76.9%) than in smokers (58.1%), while Stage III-IV disease occurred in 39.5% of smokers and 19.2% of non-smokers (p=0.446).

Conclusions: Lung cancers diagnosed via incidental nodules in non-smokers occurred more often in younger women with regular, subsolid nodules. Smokers had more irregular nodules and a trend toward advanced disease. These findings support tailored strategies for incidental nodule management that consider patients beyond traditional smoking-based risk groups.

Table 1

Demographic variables	Total (Cancer) N= (72)	People who never smoked N=32	Smoking History (n=31)	Actually smoke (n=9)	p

P3.01.07 Socioeconomic Inequalities and Lung Cancer Outcomes: Evidence From an Integrated EHR Database and State Cancer Registry Data

T.Y. Lee[1], C.C. Su[1], E. Choi[2], V.Y. Ding[1], M. Satoyoshi[3], A. Bhat[3], T. Chen[4], I. Luo[1], Y. Liu[1], S. Henry[3], L.M. Backhus[1,5], T.J. Ellis-Caleo[1], S.L. Gomez[6], N.S. Lui[1,5], A. Leung[5], C. Langlotz[5], J.W. Neal[1,5], A.W. Kurian[1,5], H.A. Wakelee[1,5], S-Y. Liang[4], S.S. Han[1,5]
[1]Stanford University School of Medicine, Stanford/CA/USA ,[2]Weill Cornell Medicine, New York/NY/USA ,[3]Stanford Health Care and Stanford University School of Medicine, Stanford/CA/USA ,[4]Sutter Health, Palo Alto/CA/USA ,[5]Stanford University, Stanford/CA/USA ,[6]University of California San Francisco, San Francisco/CA/USA

Introduction: With advances in therapy and early detection of lung cancer (LC), the number of LC survivors is rapidly increasing, underscoring the need to understand factors influencing their long-term outcomes. Neighborhood-level social drivers of health (SDOH) are crucial in cancer research, as they relate to access to healthcare and quality of care. However, previous studies on developing second primary LC (SPLC) and mortality among LC survivors have primarily focused on individual-level SDOH, often overlooking neighborhood influences. Many studies using electronic health records (EHRs) rely on data from single healthcare systems, which may have limited diversity of patient populations and uniformity clinical practice patterns. This study aimed to evaluate the associations between multiple SDOH and SPLC and overall mortality among LC survivors, leveraging an integrated database to address these gaps.

Methods: We utilized an integrated EHR database called Oncoshare-Lung, linking two independent healthcare systems—Stanford Health Care (academic) and Sutter Health (community)—and the California Cancer Registry, encompassing over 40,000 LC cases. We used patients' mailing addresses at initial primary LC (IPLC) diagnosis to calculate well-validated neighborhood-level SDOH indices at the census-tract level, including indices of concentration at the extremes (ICEs) that measure polarization between privileged and deprived populations. For SPLC and mortality analyses, we used cause-specific Cox regression and standard Cox regression, respectively, adjusting for demographic (e.g., smoking) and clinical factors (e.g., histology). Main exposures included the social vulnerability index and ICE indices for income, education, and race/ethnicity (Black/White) as quartiles.

Results: Among 43,965 patients diagnosed with IPLC and followed up for SPLC and mortality between 2000 and 2022 (Figure-1a), there were 1,314 SPLC cases and 31,750 deaths over 143,108 person-years (average follow-up: 3.3 years). The cohort included 51.2% (N=22,385) adenocarcinoma IPLC, 52.3% (N=22,854) female, 13.8% (N=6,030) Asian American/Pacific Islander, 6.6% (N=2,877) non-Hispanic Black/African American, and 7.3% (N=3,207) Hispanic. Our analysis revealed that the most deprived region in terms of ICE-Education (Figure-1b) was significantly associated with an increase in SPLC risk (hazard ratio [HR]:1.24, 95%CI: 1.06-1.46) and mortality (HR:1.24, 95%CI: 1.18-1.29) when compared with the most privileged region (Figure-1c).

Conclusions: This study underscores the importance of understanding socioeconomic disparities within communities and their impact on LC survivors' health outcomes. Survivors residing in segregated neighborhoods with greater concentration of low educational attainment face increased risks of SPLC and overall mortality, independent of sex, race/ethnicity and smoking status. Addressing these neighborhood-level SDOH disparities is essential for improving healthcare access and outcomes in this population.

P3.01.09 Survival Determinants and Socio-Demographic Disparities in Early Onset Lung Cancer in Young Adults: Insights From AI Modeling

M. Bou Zerdan[1], D. Balaji[2], I. Kar[2], S. Balaji[2], K. Canslan[2], S. Bozkurt[3], F. Ardeshir[1]
[1]Emory, Atlanta/GA/USA ,[2]Ankara University, Ankara/TR ,[3]Emory University School of Medicine, Atlanta/GA/USA

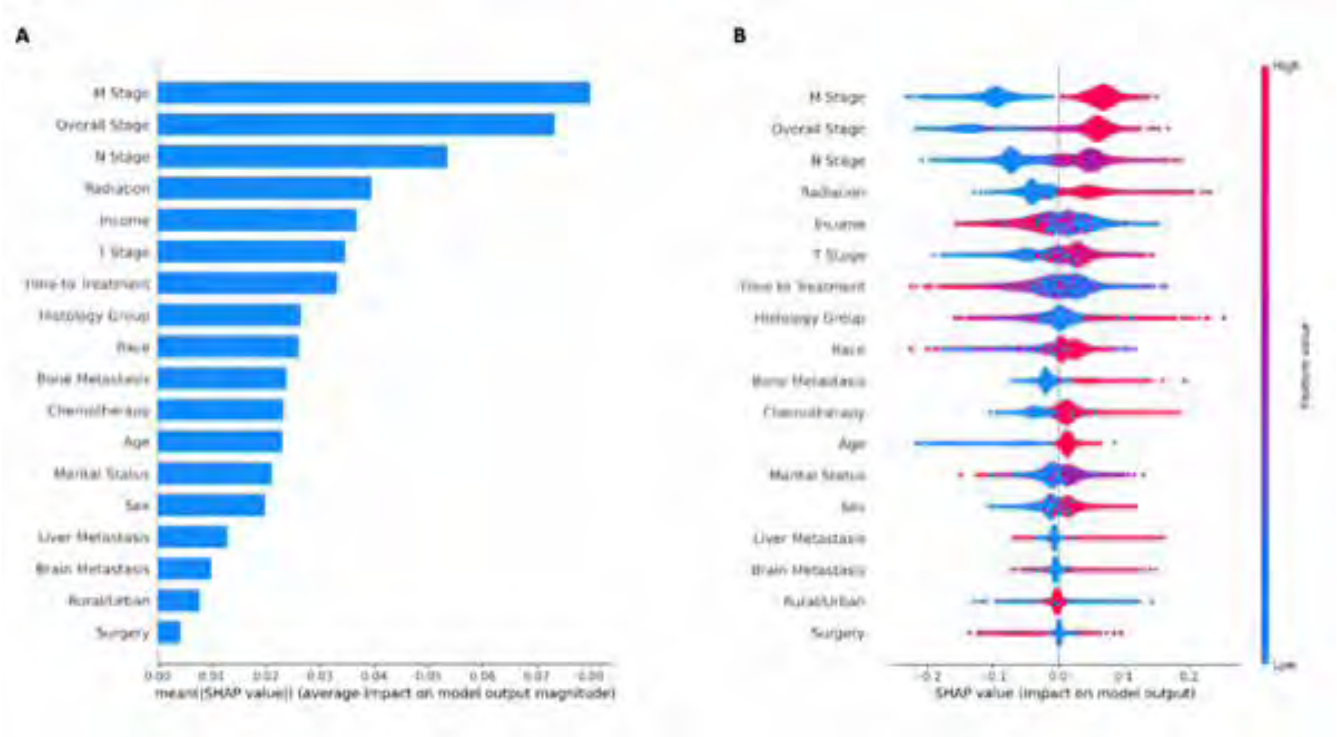
Introduction: The increasing trends in both incidence and mortality of lung cancer in women (LCW) are significantly more pronounced than those in men. Currently, the etiological mechanisms underlying a substantial proportion of LCW cases remain incompletely understood. Existing evidence suggests that female reproductive factors may be associated with lung cancer risk, but findings from relevant studies remain inconsistent, necessitating further validation.

Introduction: Early onset non-small cell lung cancer (NSCLC) accounts for 5% to 10% of cases and is becoming more prevalent, affecting more patients in the future. In this study, our goal was to employ machine learning to identify the key factors influencing the survival of these patients.

Methods: We analyzed data from the Surveillance, Epidemiology, and End Results (SEER) database for young adults aged 18-50yrs diagnosed with NSCLC between 2010 and 2021. We used a combination of classical statistical methods and machine learning techniques to identify survival determinants and assess disparities. Kaplan-Meier survival curves visualized differences in OS and time-to-treatment, with the log-rank test applied for group comparisons. Additionally, we employed SHapley Additive exPlanations (SHAP) to evaluate the contribution of each feature in our machine learning predictive models. The random survival model and the C-index were checked.

Results: From 2010 to 2021, 18,595 NSCLC patients aged 18 to 50yrs were identified, with a median age of 44.6yrs(SD = 6.0). Most patients (83.9%) were aged 40-50yrs, and the largest racial group was non-Hispanic White (60%), followed by non-Hispanic Black (14.5%). Over half (53.4%) were diagnosed at stage IV. Mean OS was 31.6 months (SD = 36.4), with a median OS (mOS) of 16 months (IQR: 5-43 months). Patients aged 18-29yrs had the longest survival (mOS: 34m), while those aged 40-50 had shorter survival (mOS: 15m, p=0.0001). Females had better outcomes than males (mOS: 20 vs. 12m, p=0.005), and higher income levels correlated with improved survival (HR low 1.45 vs high 1.09, p=0.001). SHAP modeling identified key factors affecting OS. Five-year OS rates were higher for stage I and II patients who started treatment within 2w of diagnosis, with rates of 91.4% for stage I and 77.9% for stage II. For stage III, 5-year OS improved when treatment was initiated 4-6w after diagnosis (45%), while stage IV patients had better outcomes at 8 weeks or more (19.9%). Stage IV patients who started treatment within 2 weeks exhibited significantly worse outcomes, likely due to the severity of the disease, which required rapid treatment (5 yr OS 14.3% vs. 19.9%)

Conclusions: While Machine learning is consistent with traditional survival modeling, it is more comprehensive in detecting factors that contribute to early onset NSCLC patients survival. Stage, income, and time from dx-to-tx were key factors influencing the OS of young adult NSCLC in the SEER database.



SHAP modeling identified key factors affecting OS

P3.01.10 Income, Tumour Stage, and Treatment in Patients With Non-Small Cell Lung Cancer: A Population-Based Study in the Netherlands

A. Eijkelboom[1], J.N.S. d'Hooghe[2], M. van der Sangen[3], M.M. van den Heuvel[4], L.I. Kroeze[5], G.M.H. Marres[6], P.W.A. Kunst[2], M.J. Aarts[1]
[1]Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht/NL ,[2]Onze Lieve Vrouwen Gasthuis, Amsterdam/NL ,[3]Catharina Hospital, Eindhoven/NL ,[4]Utrecht University Medical Centre, Utrecht/NL ,[5]Radboud University Medical Center, Nijmegen/NL ,[6]Albert Schweitzer Hospital, Dordrecht/NL

Introduction: The current study investigated the association between income, tumor stage at diagnosis, and treatment in non-small cell lung cancer (NSCLC) patients, stratified by Eastern Cooperative Oncology Group performance status score (ECOG-PS). Stratification by ECOG-PS was performed as it is part of the causal pathway between income and tumor stage, and income and treatment (i.e. a mediator).

Methods: Patients diagnosed with NSCLC between 2017-2022 were selected from the Netherlands Cancer Registry. Logistic regression was used to investigate the association between income and 1) tumour stage at diagnosis and 2) treatment. All analyses were stratified by ECOG-PS (PS0-1 vs PS2+). Median household income at postal code level (median 17 households per postal code) was used as proxy for income.

Results: A total of 71,025 patients were included. Patients with an intermediate or higher income were more likely to be diagnosed with stage III-IV tumours than those with a lower income. This was seen in patients with PS0-1 (odds ratio (OR)intermediate_vs_lower: 1.12, ORhigher_vs_lower: 1.12) and PS2+ (ORintermediate_vs_lower: 1.21, ORhigher_vs_lower: 1.28). In patients with PS0-1 and a stage II or III tumour, those with a higher or intermediate income more often received a tumour-directed treatment (stage II ORintermediate_vs_lower: 1.47, ORhigher_vs_lower: 1.54, stage III ORintermediate_vs_lower: 1.20, ORhigher_vs_lower: 1.30) (Figure). In patients with a stage IV tumour, those with a higher or intermediate income more often received systemic treatment, irrespective of performance status (PS0-1 ORintermediate_vs_lower: 1.29, ORhigher_vs_lower: 1.50), PS2+ ORintermediate_vs_lower: 1.22, ORhigher_vs_lower: 1.42).

Conclusions: Even in a country with an universal healthcare system like the Netherlands, large differences were seen between the treatments of NSCLC patients according to income. Our findings underline the importance of person-centred care, specifically focusing on the reasoning behind someone's treatment decision. Additionally, our results showed the importance of stratification by ECOG-PS.

P3.01.11 Lung Cancer in Young Patients Under 45 Years: Clinical Characteristics, Histology and Molecular Profile

P. Akhmedov[1,2], A. Allakhverdiev[1,2], E. Khatkova[1,2], E. Lukashova[1]
[1]The Loginov Moscow Clinical Scientific Center, Moscow/RU ,[2]Federal State Budgetary Educational Institution of Higher Vocational Education "The Russian University of Medicine", Moscow/RU

Introduction: Lung cancer in young patients under 45 years is relatively rare, but it has a number of clinical and biological features that distinguish it from a similar disease in the elderly. In recent years, thanks to the development of molecular oncology and targeted therapy, characteristic genetic drivers have been identified, which are more common in young patients. Despite this, the clinical behavior, histological subtypes and molecular profile of lung cancer in this age group remain poorly understood.

Methods: We conducted a retrospective single-center study at the Loginov Moscow Clinical Scientific Center between 2022 to 2024. The study included patients under the age of 45 with a confirmed diagnosis of non-small cell lung cancer. The following clinical parameters were analyzed for each patient: age, gender, smoking status and stage of the disease at the time of diagnosis. The histological classification of tumors was carried out in accordance with WHO recommendations. The molecular profile included the determination of driver mutations (EGFR, ALK, ROS1) using standard methods of molecular genetic testing.

Results: The study included 44 patients under the age of 45 with non-small cell lung cancer. The median age was 41 years (range 37-45 years). Women prevailed over men (24 versus 20). The most common histological type of tumor was adenocarcinoma - 36 (81.8%) cases. Squamous cell carcinoma and neuroendocrine tumors were detected in 4 (9.1%) patients in each group. 31 (70.5%) patients were smokers, and 3 (6.8%) patients were former smokers. Surgery was performed in 12 cases (27.3%). Distribution by stages of the disease: Stage IA - 5 (11.4%), IB - 4 (9.1%), IIA - 2 (4.5%), IIB - 5 (11.4%), IIIA - 1 (2.3%), IIIB - 4 (9.1%), IVA - 11 (25.0%), IVB - 4 (9.1%), IVC - 8 (18.1%). EGFR or ALK or ROS1 alterations were found in 16 patients (36.4 %) and PD-L1 expression in 11 patients (25.0%). Tabaco smokers had mostly no molecular alterations and negative PD-L1 expression

Conclusions: Lung cancer in young patients under 45 years is a rare but clinically and biologically unique form of the disease. Adenocarcinoma prevails in this age group and a significant proportion of patients have a history of smoking. The high detection rate of the disease in its late stages highlights the need to improve early diagnosis strategies. Additional studies of the molecular profile of tumors in young patients may contribute to the development of a more personalized approach to treatment.

P3.01.12 Associations Between Respiratory Diseases and Lung Cancer Risk, With New Insights Into Acute Infections

Q. Zhong[1], Y. Feng[1], B. Cheng[1], J. He[1], W. Liang[1]
[1]Department of Thoracic Surgery and Oncology, China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, the First Affiliated Hospital of Guangzhou Medical University, Guangzhou, [510120], China., Guangzhou/CN

Introduction: Respiratory diseases are significant risk factors for lung cancer; however, association between acute respiratory infections and the incidence of lung cancer requires further explore.

Methods: We conducted a large-scale prospective cohort study using data from the UK Biobank. This study involved participants aged 40 to 69 years who were recruited from 22 assessment centers across the UK between January 1, 2006, and December 31, 2010. Cox proportional hazards models were used to calculate the hazard ratios (HR) for newly diagnosed lung cancer based on the presence or absence of respiratory diseases. Additionally, mediation analysis was employed to identify potential biomarkers and mendelian randomization analysis was used to assess causal relationships between these diseases.

Results: During an average follow-up of 10.44 years (4,790,738 person-years), 2,189 participants developed lung cancer. Of these, 1,322 cases occurred among 107,007 individuals with respiratory diseases (incidence rate 27.6 per 10,000 person-years), whereas 867 cases were observed among 351,876 participants without respiratory diseases (incidence rate 7.9 per 10,000 person-years). Overall, respiratory diseases were associated with an elevated lung cancer risk (HR = 2.97, 95% CI: 2.75-3.21). Notably, acute respiratory infections including acute nasopharyngitis (HR = 3.41; 95% CI: 1.83-6.41) and influenza (HR = 3.90; 95% CI: 2.53-6.01), viral pneumonia (HR,9.86; 95% CI, 6.55-14.85), bacterial pneumonia (HR,6.28; 95% CI, 4.40-8.96)—showed significant associations with increased lung cancer incidence. In subtype analyses, squamous cell carcinoma demonstrated the strongest risk elevation (HR = 3.65; 95% CI: 3.06-4.36). Mediation analysis suggested that neutrophil counts contributed partially (proportion mediated up to 8%) between respiratory diseases and lung cancer. The Mendelian randomization results indicate a causal relationship between (COPD)(p=0.015,beta=0.09), tonsil and adenoids(p=0.01,beta=-11.8), interstitial lung diseases(p=0.02,beta=17) and lung cancer.

Conclusions: Acute respiratory infections increase the risk of lung cancer incidence. In future lung cancer screening programs, patients with these conditions should receive increased attention.

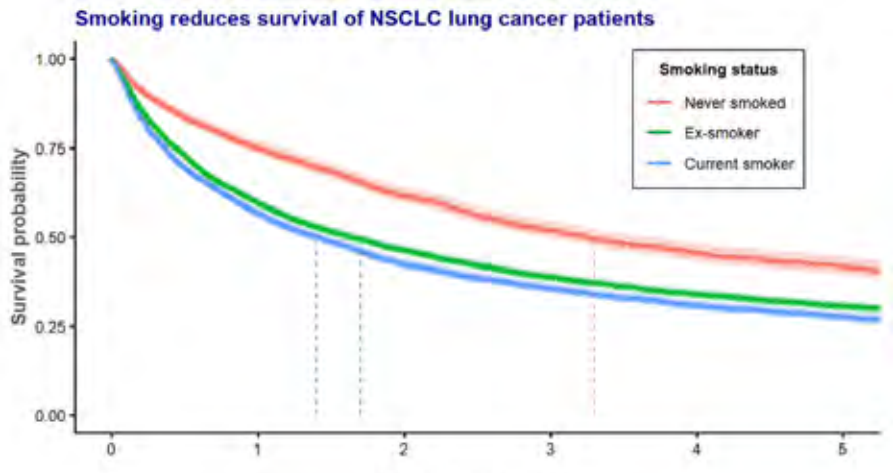
Introduction: Cigarette smoking is a major risk factor for lung cancer. Lung cancer in never smokers differs from lung cancer in smokers, with higher female prevalence, earlier onset, and greater proportion of adenocarcinoma, and increased chance of an associated genetic predisposition. This study aimed to explore differences in patient, disease and management factors between smokers, former smokers, and never smokers diagnosed with primary lung cancer, using an Australian registry-based dataset to describe real world lung cancer survival outcomes.

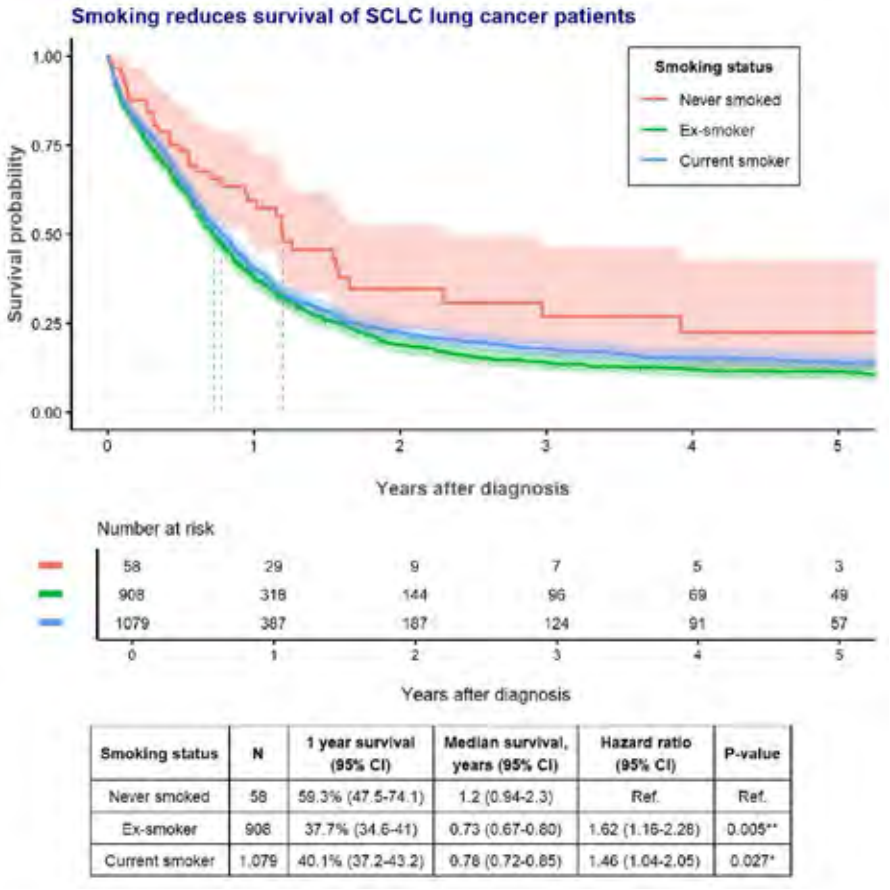
Methods: This retrospective cohort evaluated consecutively diagnoses registered into the Victorian Lung Cancer Registry in Australia from July 2011 to September 2024. Demographics, clinical outcomes and overall survival analyses were stratified smoking status defined as never, ex and current smokers.

Results: This study included 2,451 never smokers (12.8%), 9,954 ex-smokers (51.8%) and 6,799 current smokers (35.4%). Current smokers were younger at diagnosis (68 years IQR 60-75), never smokers 70 (IQR 61-79) and ex-smokers 73 (IQR 67-80). Never smokers were more likely female (70% vs 44% overall), less likely of Indigenous status (0.1% vs 1.0% overall) and more likely from a higher socioeconomic background (61% vs 47%). Never smokers had a ECOG performance score of 0 (47% vs 33% overall), and with no comorbidities (62% vs 44% overall). Median survival for NSCLC never smokers (n=15,292) was 3.3 years (95% CI 2.9-3.7), ex-smokers 1.7 years (HR 1.48 (1.39-1.58), p<0.001) and current smokers 1.4 years (HR 1.63 (1.52-1.75), p<0.001), Figure 1. Median survival for SCLC (n=2,045) never smokers was 1.2 years (95% CI 0.94-2.3), ex-smokers 0.73 years (HR 1.62 (1.16-2.28), p=0.005), and current smokers 0.78 years (HR 1.46 (1.04-2.05), p=0.027) Figure 2.

Conclusions: Smoking status affected the real world lung cancer survival outcomes in our Australian cancer registry. This highlights the importance of clearly defining and collecting smoking history in addition to smoking cessation strategies.



Smoking status	N	1 year survival (95% CI)	Median survival, years (95% CI)	Hazard ratio (95% CI)	P-value
Never smoked	2,133	75.0% (73.2-76.9)	3.3 (2.9-3.7)	Ref.	Ref.
Ex-smoker	8,075	59.7% (58.6-60.8)	1.7 (1.6-1.8)	1.48 (1.39-1.58)	<0.001***
Current smoker	5,084	56.8% (55.4-58.2)	1.4 (1.3-1.5)	1.63 (1.52-1.75)	<0.001***



Smoking status	N	1 year survival (95% CI)	Median survival, years (95% CI)	Hazard ratio (95% CI)	P-value
Never smoked	58	59.3% (47.5-74.1)	1.2 (0.94-2.3)	Ref.	Ref.
Ex-smoker	908	37.7% (34.6-41)	0.73 (0.67-0.80)	1.62 (1.16-2.26)	0.005**
Current smoker	1,079	40.1% (37.2-43.2)	0.78 (0.72-0.85)	1.46 (1.04-2.05)	0.027*

Introduction: Tracheal, bronchus, and lung (TBL) cancer is the leading cause of cancer-related death and the second leading cause of disability in women worldwide, with a growing burden over time. Despite evolving burden, TBL-cancer remains insufficiently studied across many regions.

Methods: Using the Global Burden of Disease analytical framework, we quantified the incidence, prevalence, mortality, disability-adjusted life years(DALYs), and years lived with disability(YLDs) attributable to TBL cancer and its attributable risk factors by age, year, and location across 204 countries and territories in women from 1990-2021. We projected TBL cancer deaths through 2050 using age-period-cohort modeling.

Results: Between 1990-2021, the global prevalence of TBL cancer in women rose from 381,144 (95% UI:356,712-403,802) to 1.1 million(1-1.2 million), deaths increased from 281,306 (259,309-301,716) to 674,006(595,385-747,508), and DALYs doubled from 7.1 million (6.6-7.7 million) to 15-million(13.5-16.6 million). By socio-demographic-index(SDI), the highest annual percentage change(APC) in age-standardized incidence rate(ASIR) was observed in high-middle-SDI countries at 1.36%. Regionally, South Asia recorded the greatest rise in both ASIR(1.71%) and age-standardized-mortality-rate(ASMR) (1.66%) from 1990-2021. In 2021, 39.24% of TBL cancer deaths in women were attributable to behavioral RF, 27.97% to environmental RF, and 2.45% to metabolic RF. In 2021, the highest incidence rate was seen in women aged 55+ years at 87.4 per 100,000, compared to 4.86 in those aged 20-54 and 0.03 in those under 20. By 2050, total deaths from TBL-cancer in women are projected to reach 1.4 million(1.1-1.8 million), with an ASMR of 14.45(11.3-18.3) per 100,000.

Conclusions: TBL-cancer accounted for 15.72% of all cancer causalities in women in 2021. Our findings highlight the urgent need for coordinated action by public health officials, policymakers, and clinicians to address the rising and underrecognized burden of TBL cancer in women, with projections indicating a continued increase in deaths through 2050.

Introduction: Tracheal, bronchus, and lung (TBL) cancer, significantly influenced by behavioral risk factors (BRF) such as smoking and dietary habits, represent a major health challenge in Organization for Economic Co-operation and Development (OECD) countries, where health policies and prevention strategies significantly influence cancer outcomes.

Methods: We estimated deaths, disability-adjusted-life-years(DALYs), years-lived with-disability(YLDs) due to TBL cancer attributable to BRF by age, sex, year and location across the 38 OECD countries from 1990-2021 using standardized global burden of disease framework.

Results: From 1990-2021, the total number of deaths due to TBL cancer attributable to BRF increased from 376,488(95% UI: 350,760-401,242) to 409,502(362,713-449,885), DALYs decreased from 9.3 million (8.7-9.9) to 8.7 million (7.9-9.5), and YLDs increased from 100,009 (72,064-128,799) to 126,973 (93,115-161,693). Nationally, Hungary recorded the highest age-standardized mortality rate (ASMR) of 29.21 per 100,000 in 2021, followed by Greece at 27.41, Poland at 27.32, and Turkey at 23.77, while the US observed an ASMR of 17.6 per 100,000. In terms of age groups, the 70-74 year-olds observed the highest death count at 77,299 (69,703-84,049) and DALYs were highest in the 65-69 age group at 1.6 million (1.4-1.7) in 2021. Regarding gender, females exhibited a higher increase in burden compared to males, with total percentage changes in deaths, DALYs, and YLDs for males versus females at -2% vs 49%, -16% vs 31%, and 14% vs 70%, respectively

Conclusions: In 2021, 60.63% of all TBL cancer-related deaths in OECD countries were attributable to behavioral risk factors (BRFs), with tobacco consumption accounting for the majority at 59.61%, followed by dietary risks at 2.47%. The substantial TBL cancer burden in OECD countries driven by behavioral risks, particularly tobacco use, demands urgent, coordinated action from both public health policymakers and clinicians to prioritize prevention and early intervention.

P3.01.16 Global Burden of Lung Cancer Attributed to High Fasting Plasma Glucose: A Benchmarking Analysis of G20 Countries (1990-2021)

V.S. Jetani[1], U. Gohel[2], D. Upadhyay[3], K.M. Patel[4], A.S. Sethi[5], P. Savaliya[6], A. Gopi[7], A. Aleem[8], H.A. Sami[9], G. Luthra[10], H.D. Desai[11]
[1]Epsom and St.Helier University Hospitals NHS UK, Epsom/GB ,[2]G.M.E.R.S Medical College and Hospital, Valsad/IN ,[3]Institute of Medical Sciences and SUM Hospital, Bhubaneswar/IN ,[4]Gujarat Adani Institute of Medical Sciences, Gujarat/IN ,[5]Government Medical College & Hospital, Chandigarh/IN ,[6]Surat Municipal Institute of Medical Education and Research (SMIMER), Surat/IN ,[7]Sree Gokulam Medical College and Research Foundation, Nellanad, Kerala/IN ,[8]CMU School of Medicine, Central Michigan University, Mount Pleasant/MI/USA ,[9]Trinity Health Oakland, Wayne State University, Pontiac/MI/USA ,[10]Central Michigan University, Saginaw/MI/USA ,[11]Gujarat Adani Institute of Medical Sciences, Bhuj/IN

Introduction: Tracheal, bronchus and lung(TBL)-cancer is a leading cause of cancer-related deaths globally, with tobacco as the primary risk factor; however, high fasting plasma glucose (HFPG), linked to diabetes and prediabetes, is increasingly recognized as a contributing factor. G20 countries, facing rising HFPG levels due to urbanization and lifestyle changes, bear a substantial burden of both diabetes and lung cancer, highlighting the need to address metabolic health in cancer prevention efforts.

Methods: From 1990 to 2021, TBL cancer deaths, disability adjusted life years(DALYs), and years lived with disability(YLDs) attributable to HFPG were estimated across G20 countries, with temporal trends evaluated using total percentage of change (TPC) by age, sex, year and location using standardized global burden of disease study-2021.

Results: From 1990 to 2021, the total percentage change(TPC) in the absolute burden of tracheal, bronchus, and lung (TBL) cancer showed substantial increases: deaths rose by 162% (95% UI: 130%-193%), DALYs by 132%(103%-163%), and YLDs by 194% (160%-231%). Nationally, the highest increase in deaths was observed in Indonesia(456%), followed by India (350%) and Saudi Arabia (336%), while the United Kingdom reported the lowest increase at 43%. By age group, individuals aged 70-74 years experienced the highest number of deaths (8,466; range: -1,647 to 19,201), whereas the greatest number of DALYs occurred in those aged 65-69 years (178,661; range: -35,683 to 404,782) in 2021. When stratified by sex, females experienced a higher overall increase in burden compared to males, with TPC in deaths at 238% vs. 136%, DALYs at 203% vs. 109%, and YLDs at 279% vs. 164%, respectively.

Conclusions: TBL-cancer attributable to HFPG accounted for 2.51% of all TBL cancer related deaths in 2021. The rising burden calls for coordinated efforts in public health policy, clinical care, and preventive strategies to address the intersecting challenges of metabolic dysfunction and cancer risk.

P3.01.17 Age-Sex Disparities in Global Burden and Trend of Lung Cancer and Its Attributable Risk Factors in the United Kingdom From 1990-2021

P.S. Gupta[1], J. Verma[2], G. Singh[3], D. Upadhyay[4], K. Patel[5], H. Zinzala[6], H.A. Sami[7], G. Luthra[8], A. Aleem[9], H.D. Desai[10]
[1]Kiran Multi-Super speciality hospital, Surat/IN ,[2]North Alabama Medical Center, Florence, Alabama/AL/USA ,[3]St Vincent's medical center, Quinnipiac university, Bridgeport/CT/USA ,[4]Institute of Medical Sciences and SUM Hospital, Bhubaneswar/IN ,[5]Gujarat Adani Institute of Medical Sciences, Gujarat/IN ,[6]Internal Medicine (Junior Resident), navsari/IN ,[7]Trinity Health Oakland, Wayne State University, Pontiac/MI/USA ,[8]Central Michigan University, Saginaw/MI/USA ,[9]CMU School of Medicine, Central Michigan University, Mount Pleasant/MI/USA ,[10]Gujarat Adani Institute of Medical Sciences, Bhuj/IN

Introduction: Tracheal, bronchus, and lung(TBL) cancer is the leading cause of cancer-related deaths in the United Kingdom, contributing to over 21% of all cancer mortality. It disproportionately affects older adults and socioeconomically deprived populations, with an increasing burden observed among women. This study aims to explore the current trends, disparities, and factors contributing to the lung cancer burden in the UK to inform targeted interventions and public health strategies.

Methods: Using Standardized global burden of disease-study, we estimated fatal and non-fatal health outcomes due to TBL-cancer and its attributable risk factors stratified by age,sex, year and location across the UK from 1990-2021.

Results: From 1990-2021, the total percentage change(TPC) in TBL cancer prevalence increased by 37% (95% UI: 30%-42%), DALYs decreased by 22%(19%-25%), and deaths declined by 9% (6%-15%). Compared to other high-income countries, the UK showed lower TPC in incidence (3% vs. 45%) and a greater decline in deaths(9% decrease vs. 31% increase). Regionally, Northern Ireland(NI) had the highest rise in incidence(63%), followed by Scotland (22%) and Wales(9%), while England saw a 1% decrease. For deaths, Northern Ireland increased by 37%, Scotland by 4%, with decreases in England and Wales. In 2021, DALYs peaked in the 70-74 age group(141,480; 134,071-146,571), and deaths were highest in those aged 75-79(7,220; 6,650-7,533). Females showed a greater burden than males: TPC in incidence(+49% vs. -20%), deaths(+31% vs. -29%), and DALYs(+12% vs. -38%). TBL cancer attributable to smoking accounted for 59.23% death of call TBL-cancer related deaths in 2021.

Conclusions: Our findings highlight the urgent need for policymakers to prioritize targeted prevention and management strategies, particularly for high-risk groups such as older adults, socioeconomically deprived populations, and women. Strengthening smoking cessation programs,improving early detection, and addressing regional disparities will be critical to reducing the burden of TBL-cancer in the UK.

P3.01.18 The Journey to a Lung Cancer Diagnosis: Reports From the LEAD Study

L. Kiel[1], M. Horiguchi[1], R. Kaufman[1], L. Tong[2], A. Morabito[1], K. Meza[3], O. Abioye[4], O. Fakorede[1], C. Mantz[1], R. Lederman[1], J. Marks[1], L. Alder[5], F. Wilder[6], C. Pozo-Kaderman[1], E. Warner[7], C-F.J. Yang[7], L. Sequist[7], N. Florez[1]
[1]Dana–Farber Cancer Institute, Boston/MA/USA ,[2]Boston University Chobanian & Avedisian School of Medicine, Boston/MA/USA ,[3]Baylor University, Houston/TX/USA ,[4]Allegheny Health Network, Pittsburgh/PA/USA ,[5]Duke Cancer Institute, Durham/NC/USA ,[6]Brigham and Women's Hospital, Boston/MA/USA ,[7]Massachusetts General Hospital, Boston/MA/USA

Introduction: Women are less likely to have lung cancer (LC) screening discussions with their healthcare providers (HCP) and may experience longer time to LC diagnosis compared to men. This multi-institution cohort study evaluated how sex, age, and cancer stage at diagnosis influenced the time interval from LC symptom(s) presentation to diagnostic events.

Methods: Patients ≥18 years old, diagnosed with LC stages I-IV within the prior 6 months, were enrolled at Dana-Farber Cancer Institute and Massachusetts General Hospital from 1/2024-5/2024. Patients completed a questionnaire exploring LC risk factors and perceptions of diagnostic timeliness. Objective diagnostic timepoints were abstracted from the electronic medical records (EMR). Wilcoxon tests compared results by age (younger: <50 vs older: ≥50), sex (male vs female), and LC stage (I-IIIB vs IV).

Results: Among 112 patients, most (63%) reported former or current tobacco use. Most tobacco non-users were female (76%). Based on EMR data, 14 patients were diagnosed from incidental findings and 17 from LC screening; 73 of 112 patients had information regarding initial date of symptom(s) presentation to an HCP. Median time-to-events are presented as days relative to this date of symptom(s) presentation to an HCP (Table 1). Time to biopsy and first visit with an oncology HCP were significantly faster for younger patients compared to older patients (3 vs 60 days; p=0.009, 12 vs 58 days; p=0.007; respectively). Similarly, time to treatment initiation was faster for younger patients (38 vs 98 days, p=0.005). No significant sex differences were observed from time of symptom(s) presentation to LC diagnosis and treatment initiation. Time from symptom(s) presentation to plasma biomarker testing (62 vs 155 days; p=0.035) and from tissue biopsy to treatment initiation (26 vs 36 days; p=0.040) were accelerated for patients with stage IV disease. Though not statistically significant, 12% of women, compared to 0% of men, reported that their HCP initially attributed their symptom(s) to anxiety instead of LC (p=0.538). Thirty-four of 105 patients (33%) believed that they experienced diagnostic delays despite seeking medical care, including a higher proportion of younger patients, though this was not statistically different than the older cohort (50% vs 30%; p=0.220).

Conclusions: Younger patients and patients with stage IV LC experienced faster time from symptom(s) presentation to diagnostic events in two large academic centers. While non-statistically significant, anxiety was a common LC symptom misattributed to women. Planned participant interviews will expand on this quantitative data and factors negatively impacting time to LC diagnosis.

Table 1. Days from First Presentation of Symptom(s) to an HCP to Diagnostic Event, Displayed as Median (Q1, Q3)

Event	Female (n= 49)	Male (n=24)	p-value	Older (≥50; n=62)	Younger (<50; n=11)	p-value	Stage I-IIIB LC (n=23)	Stage IV LC (n=50)	p-value	Total (n=73)

Introduction: Globally, lung cancer incidence and mortality are rising in women while declining in men. Understanding how these disparities may be affected by diagnosis and treatment decisions is crucial to improving outcomes for all patients and promoting equitable care for both men and women.

Methods: A systematic literature review was conducted using a PICOS framework to identify English-language publications reporting information on gender differences throughout the patient journey. The review examined differences in time to lung cancer diagnosis, access to biomarker testing, time from diagnosis to treatment initiation, treatment patterns, and outcomes. Embase, MEDLINE, MEDLINE In-Process, and Cochrane databases were searched for articles published between January 2004 and February 2024, as well as relevant conference proceedings and expert literature. Data from articles that provided adjusted estimates of gender comparison using regression analysis were reported.

Results: A total of 11,088 unique publications were identified, of which 9,710 were excluded based on initial screening; 1,366 were reviewed in full, of which, 126 were excluded due to lack of reporting on gender differences in diagnosis, testing, treatment, patient preferences, and outcomes. Eight of 11 studies showed that men were more likely to present with late-stage disease at diagnosis, while two studies showed that women were more likely to present with early-stage disease at diagnosis versus men (OR in these 2 studies: 1.85 and 1.30). Four of six studies reported that men started treatment earlier than women following diagnosis; for example, one study reported an average of 72 days for men and 87 days for women ($p<0.01$). Men were more likely to receive timely treatment for Stage I/II non-small-cell lung cancer (NSCLC). Alternatively, women were more likely to receive timely treatment for Stage III NSCLC. One analysis showed that older women were more likely to receive care not concordant with guidelines ($p=0.008$ vs younger women), and women with early-stage NSCLC (stage I and IIIa/b) were less likely to receive guideline concordant care. Only two reports indicated that men with NSCLC were less likely to receive biomarker testing (e.g. for select biomarkers including ROS1 and EGFR mutations and ALK rearrangement) compared with women. Treatment patterns were reported in 33 studies; overall, women were more likely to undergo treatment such as surgery or receive tyrosine kinase inhibitors (TKIs), while men were more likely to receive radiotherapy or chemotherapy. Of the six studies assessing patient preferences, women were more inclined to opt for surgery while men with NSCLC were more likely to choose radiotherapy, chemoradiotherapy, or end-of-life care. In general, women reported better responses (HR in individual therapeutic trials ranged from 0.53-0.88), longer progression-free survival (HR: 0.33-1.32) and improved overall survival (HR: 0.31-0.885) compared with men.

Conclusions: These data suggest gender differences in diagnosis receipt and treatment initiation, as well as treatment decisions and outcomes for patients with lung cancer. The synthesized evidence, although limited, should elevate the need to further solidify the evidence base and understand underlying reasons behind these differences. These efforts can advance this discussion to promote equitable care to everyone.

P3.01.20 Lung Cancer Risk Factors in 35,530 People From the UKLS Trial Who Have Never Smoked

L. Shire, J.K. Field, M.P.A. Davies
University of Liverpool, Liverpool/GB

Introduction: Lung cancer in people who have never smoked (LCiNS) is widely considered to be a distinct disease from cancer caused by smoking, with different aetiology and demographics. Whilst significantly less common than lung cancer in people who have smoked, it still accounts for 15% of lung cancers in the UK and is responsible for approximately 6000 deaths per year. Risk factors for LCiNS are poorly understood but have been widely studied in East Asian populations where rates are highest.

Methods: Questionnaire data completed by 75,948 participants in the UKLS trial was analysed: including 35,470 who never smoked (NS) with 58 lung cancers (0.16%) within the five-year follow-up from Public Health England (compared to 541 lung cancers in 40,418 people who smoked,1.34%). The Risk data for the LLPv2 risk model was available: age, sex, smoking duration, previous respiratory diseases, family history of lung cancer, previous history of cancer and exposure to asbestos. Statistical analysis included odds ratios (OR) and binary logistic regression for lung cancer within 5 years.

Results: All risk factors except for sex were significant in the whole cohort and in people who smoked (see Table). However, for LCiNS only older age and low socioeconomic status, measured by the most deprived quintile of Index of Multiple Deprivation, were significantly associated with increased risk. It is of note that the odds ratios were higher for LCiNS for both age (OR 4.30 vs 2.25) and deprivation (OR 2.87 vs 1.99). In contrast, lung disease was associated with lower LCiNS 5-year risk (OR 0.41 vs 2.01). In binary logistic regression with conditional backward selection, age (OR 4.35), deprivation (OR 2.72) and any lung disease (OR 0.37) were independently significant.

The limitation of this study is the low number of lung cancers in people who have never smoked, thus requiring a much larger study population for conclusive results. In addition, data on additional risk factors, second-hand smoke, air pollution, and occupational exposures, should be collected in a larger study.

Conclusions: This study demonstrated that LCiNS risk is driven by older age and socioeconomic deprivation. Surprisingly, in contrast to East Asian populations, a family history of lung cancer was not significant in this UK population, and neither was a personal history of cancer. Also, lung disease had a limited protective effect for LCiNS, indicating an interplay between smoking and risk associated particularly with COPD and emphysema (and to a lesser extent asbestos).

Table: Factors associated with 5 year lung cancer risk in UKLS Questionnaire		Odds Ratio (95% Confidence Interval)		
		All	Smokers	Never Smokers
Sex	M vs F	1.23 (1.05 - 1.45)	1.04 (0.88 - 1.24)	0.72 (0.42 - 1.24)

P3.01.21 Lifting the Smoke Screen: A Real-World Comparative Study of Lung Cancer in Never-Smokers Versus Ever-Smokers

P. Thamarai Selvan, A. Krishnamurthy, A. John, V. Ramshankar, S. Sundersingh, V. Radhakrishnan
Cancer Institute (WIA), Chennai/IN

Introduction: Despite smoking being inextricably associated with lung cancer, recent decades have witnessed a marked rise in the occurrence of lung cancer in non-smokers. The understanding of the disease biology and the clinical profile of lung cancer in non-smokers is still evolving. Here, we present our comparative retrospective real-world data on the clinico-epidemiological profile of lung cancer in smokers compared to non-smokers, from a tertiary care cancer centre in South India.

Methods: Data on all lung cancer patients treated at Cancer Institute (WIA) from 2017 to 2021 were extracted from medical records. Patients without histopathological confirmation of a carcinoma were excluded. The clinico-epidemiological details, driver mutation status, and survival status were captured. Differences between ever-smokers and never-smokers for continuous variables was assessed using the Chi-square test and categorical variables by the t-test. Overall survival (OS) was calculated using the Kaplan-Meier method and difference between groups was analysed by log-rank test.

Results: The study included 802 patients. Never-smokers comprised 53% (n=425) and Ever-smokers made up 47% (n=377). Majority of females were never-smokers [(n=261; 87.3%) vs (n=38; 12.7%)], whereas males were predominantly ever-smokers [(n=339; 67.4%) vs (n=164; 32.6%)]. The median age was less for never-smokers (55.6years), compared to ever-smokers (60.5years), with p-value of <0.001. The commonest forms of smoking were Cigarettes (n= 166/377; 44%), Beedis (n=147/377; 39%) and both in 18 (4.8%) patients, with a median of 30 pack-years. Passive smoking was seen in 36 patients (9.5%). Squamous cell carcinoma (19.1% vs 7.5%) and small carcinoma (14.3% vs 2.3%), had a higher occurrence in Ever-smokers, whereas Never-smokers were more likely to have adenocarcinoma (83.8% vs 57.9%). Never-smokers had a significantly higher distribution of metastatic lung cancer at diagnosis, compared to ever smokers (n= 356; 83.8% vs n= 255; 67.6% with p-value <0.001). Amongst non-small cell lung cancer patients (n=739), Never-smokers (n=416), driver alteration analysis was positive in 215 (51.7%), negative in 103 (24.7%), and not available in 98 (23.6%); whereas in ever-smokers (n=323), driver alteration was positive in 78 (24.1%), negative in 125 (38.7%) and not available in 174 (37.2%). Driver alterations were more frequently detected in never-smokers, while data was more often not available in ever smokers (p <0.001). The median follow-up was 41.9 months. The median OS in never-smokers (11.9 months; 95% CI 10.3-13.5 months) was significantly longer, compared to ever-smokers (7.3 months; 95% CI 5.9 - 8.6 months), p <0.001. Median OS was better in never-smokers across all stages. In patients harbouring a driver alteration, median OS was not significantly different between never and ever smokers (16.5 vs 15.3 months; p=0.057).

Conclusions: Lung cancer is never-smokers contributes to a significant proportion of the disease burden, tend present in later stages, are more likely to harbour a driver-alteration and have longer survival. Even among ever-smokers, more than a third harbour a driver alteration, reinforcing the need for universal testing for maximizing eligibility to effective targeted therapy. Survival of driver alteration positive lung cancer patients was similar between never- and ever-smokers.

P3.01.22 Deep Learning-Based CT Analysis Enhances Lung Cancer Risk Prediction in Never Smoking Women

T. Chaunzwa, D. Gomez, K. Ketosugbo, A. Enriquez, H. Bhat, P. Adusumilli, G. Rocco, M. Bott, K. Gray, J. Huang, J. Isbell, D. Molena, B. Park, V. Rusch, S. Sihag, D. Jones, A.P. Chidi
Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Lung cancer incidence is increasing among never smoking women but there are few risk assessment tools designed for this population. "Sybil," a validated, publicly available deep learning model applied to low-dose chest CT, is reported to predict lung cancer risk in patients who have smoked. There are limited data regarding its real-world performance, particularly in the high-risk population of never smoking women. We sought to compare lung cancer risk assessment using exposure data, an existing clinical risk calculator, and Sybil in a population of never smoking women.

Methods: We conducted a retrospective analysis of a prospectively maintained single institution thoracic surgery database. Patients included adult never-smoking women treated for lung adenocarcinoma between 2022 and 2024. Data regarding prevalence of factors associate with high lung cancer risk (asbestos, family history, prior cancer, marijuana use, secondhand smoke exposure) were collected. Lung cancer risk was calculated using the PLCOALL2014 model. Among patients with available CT chest imaging from 1 to 3 years prior to lung cancer diagnosis, Sybil was used to calculate lung cancer risk. Analyses were performed using Stata 18 (StataCorp, College Station, TX). Two-tailed p-values <0.05 were considered statistically significant.

Results: The study cohort included 216 never smoking women: median age 67 years, 59% White, 22% Asian; stage I (161/216, 75%), stage II (23/216, 11%), stage III (25/216, 12%), stage IV (7/216, 3%). Common risk factors included prior cancer diagnosis (81/216, 38%), secondhand smoke exposure (64/216, 30%), chronic pulmonary disease (47/216, 22%), and family history of lung cancer (44/216, 20%). Asbestos exposure (9/216, 4%) and marijuana use (8/216, 4%) were uncommon in this cohort. A total of 38 patients had CT imaging 1-3 years prior to diagnosis. Patients with prior imaging were more likely to be cancer survivors (63% vs. 32%, p<0.001) and to be diagnosed with stage I or in situ disease (89% vs. 71%, p=0.02). Median one-, three-, and six-year risks of developing lung cancer from the Sybil model were 3.9% (IQR 0.4-79%), 9.1% (2.8-35%), and 16.5% (7.4-75%), respectively. Using a risk threshold of 1.3%, Sybil predicted high one-year risk in 66%, three-year risk in 95%, and six-year risk in 100%. By contrast, the PLCOALL2014 model predicted six-year lung cancer risk of 0.16% (IQR 0.08-0.34%) in the full cohort and 0.2% (IQR 0.1-0.4%) among patients with a prior CT scan.

Conclusions: Sybil, a novel publicly available deep learning tool developed for analysis of screening CT imaging in smokers, predicts significantly higher lung cancer risk in a cohort of never smokers compared to existing clinical calculators. Future work will incorporate clinical, genomic, and deep learning data to better characterize the population of high-risk never smokers and develop personalized, scalable, population-based lung cancer screening protocols.

P3.01.23 The Impact of PM2.5 Exposure on the Genome of Patients With Lung Adenocarcinoma Who Have Never Smoked

P. Wang, J. Naso, R. Myers, C.H. Durney, C. Bartolomeu, A. McGuire, C. MacAulay, S. Lam, W.L. Lam, W.W. Lockwood
University of British Columbia, Vancouver/BC/CA

Introduction: Up to 25% of patients with lung cancer have never smoked. Due to the high mortality of lung cancer, this means that this subset of patients alone constitutes the fifth most deadly cancer worldwide, highlighting the need for understanding the underlying causes of lung cancer in these patients. While pollution exposure, specifically particulate matter smaller than 2.5 µm in diameter (PM2.5), is a leading risk factor for lung cancer in patients who have never smoked, its impact on the lung cancer genome in patients with defined levels of pollution exposure is unknown.

Methods: A total of 119 patients with lung adenocarcinoma who have never smoked and received lung resection at Vancouver General Hospital or Surrey Memorial Hospital in British Columbia, Canada between 2019 and 2024 were included in this study. These patients were categorized as having high (≥10 ug/m3/year) or low (<10 ug/m3/year) cumulative PM2.5 exposures by their residential history in the 20 years before their diagnoses. This classification was done using a model that combined Aerosol Optical Depth (AOD) retrievals with a chemical transport model using geographically weighted regression. DNA from these patients' FFPE tumor tissue and matched normal tissue underwent whole exome sequencing (WES) at a depth of 100x. Upon somatic variant calling for these samples with Mutect2, mutational signature profiling, analysis of driver mutations, copy number alteration analysis, and functional analysis will be conducted. This will reveal the features in the lung adenocarcinoma genome associated with high levels of PM2.5 exposure in patients who have never smoked.

Results: Preliminary analysis of a subset of 55 patients revealed that 51 patients had low cumulative PM2.5 exposure (mean: 6.61 µg/m3/year, SD: 1.86), while 4 patients had high exposure (mean: 29.7 µg/m3/year, SD: 16.05) over a 20-year period. The average tumor mutational burden was 10.23 mutations per megabase (SD: 5.84), and 20 patients harbored EGFR mutations (L858R or exon 19 deletion) while 4 had KRAS G12D mutation. An additional 64 patients' samples have been procured and are undergoing sequencing. Mutational signature and copy number alteration analysis for this group of patients is ongoing. Further updated results and integrated genomics analysis on the entire cohort will be presented at the Conference.

Conclusions: Overall, this study has the potential to identify unique molecular features in lung adenocarcinoma that are associated with high PM2.5 exposure, offering novel insights for therapeutic development and early detection, particularly in people who have never smoked.

P3.01.24 Economic Burden of Radon Attributable Non-Small Cell Lung Cancer: A Cost Analysis

D. Griffin[1], I.E. MacDonald[1], J.M. Danforth[1], D.D. Pearson[1], S. Mazher[1], R. Fu[1], S.I.A. Shamsi[1], M.M. Stephen[1], N. Liu[1], M.T. Warkentin[1], E. Spackman[1], D.R. Brenner[1], A.A. Gibson[1], M.L. Dean[1], V. Navani[1], W. Cheung[1], A.A. Goodarzi[1], D.A. Ezeife[1]
[1]University of Calgary, Calgary/AB/CA

Introduction: Lung cancer accounts for 23% of cancer deaths in Canada and is the leading cause of cancer deaths. Besides smoking, radon inhalation is the most prevalent cause of non-tobacco related non-small lung cancer (NSCLC). Long term radon exposure results in a 16% increase in lifetime risk of lung cancer per 100 Bq/m3. Estimates are 2402 - 3377 lung cancer cases are attributable to radon in Canada in 2025. We estimated the economic burden of radon attributable lung cancer from the Canadian healthcare system perspective.

Methods: We evaluated the cost of radon attributable NSCLC based on radon attributable risk (PAR) estimates. Based on estimates in literature, 62% of NSCLC in nonsmokers are diagnosed at stage IV. The remaining 38% of stages I-III cancers were broken down according to current early-stage distributions reported in the literature. Direct healthcare costs were estimated including consult and follow up physician visits, bronchoscopy, next-generation sequencing, laboratory and imaging costs, surgery, radiation and systemic therapy costs. Costs were obtained from the provincial medical benefit schedule, national health technology assessment reports, local experts and the literature and were then weighted by prevalence of treatment type as represented in the reviewed chart data. In stage IV NSCLC, treatment costs were applied for the median duration of response for the first line regimens followed by the second line regimens in the actionable (estimated 30%) and non-actionable NSCLC (estimated 70%) settings. All costs are in CAD$ adjusted for inflation to January 2025.

Results: Radon attributable NSCLC in 2025 is estimated to cost the healthcare system an overall $511,401,937 from diagnosis to completion of treatment at the median PAR estimate of 2890 NSCLC diagnoses [range $425,047,562 (for 2402 diagnoses) to $597,579,357 (for 3377 diagnoses)]. Total cost for treatment of all Stage I, II and III NSCLC diagnoses were $8,774,925, $3,803,535 and $47,740,347 respectively, at the median PAR estimate. Stage IV NSCLC comprised 86% of total costs with NSCLC containing actionable mutations taking up a disproportionate 31% of total costs while only representing 19% of estimated cancer diagnoses. At the median PAR estimate, radon attributable NSCLC costs approximately $1,401,101 per day, or $973 per minute in Canada.

Conclusions: Our results demonstrate the costs of radon attributable NSCLC in the era of precision medicine. Radon attributable NSCLC results in substantial costs to the health care system. Future work will determine the impact of radon reduction strategies in decreasing the economic burden of NSCLC.

Introduction: Residential radon exposure is a significant risk factor for lung cancer, being the second cause after tobacco consumption, and the first in never smokers. According to the World Health Organization (WHO), radon is responsible for approximately 3% to 14% of all lung cancer cases. Despite this, the molecular mechanisms underlying radon-induced carcinogenesis remain poorly understood. In this study, we investigate the relationship between residential radon exposure and a set of molecular alterations in non-small cell lung cancer (NSCLC) patients.

Methods: A total of 207 patients with confirmed NSCLC were included in the study. Radon exposure was measured at an Accredited Laboratory using alpha-track radon detectors (CR-39; Radosys Ltd, Budapest, Hungary) which are the most reliable technique and recommended by the Nuclear Safety Council. Pre-treatment tumor biopsies were analyzed using next-generation sequencing (NGS).

Results: Sixty percent of patients were male. The average age at diagnosis was 65 years. Regarding the histological subtype, the majority were adenocarcinomas (71%). At the time of diagnosis, 65% of patients presented with metastatic disease, 23% were at a locally advanced stage (stage IIIA-C), and 12% were diagnosed at an early stage (stage IA-IIB). Regarding smoking status, 9% of patients were never-smokers, 54% were former smokers, and 37% were current smokers. Median residential radon concentration in our cohort was 78 Bq/m3 (IQ25-75%: 45-137); min 4 Bq/m3, max 1,035 Bq/m3. A molecular alteration was identified in 141 patients (68%). Specifically, 6% of tumors harbored an ALK translocation, and 10% had EGFR common mutations. Other targetable alterations included KRAS G12C mutations (10%), BRAF V600E (2%), MET amplification (1%), MET exon 14 skipping mutations (2%), and HER2 alterations—including amplification or exon 20 insertions—in 2% of cases. Additionally, ROS1 fusions and RET fusions were each identified in 0.6% of tumor Overall, patients whose tumors harbored targetable molecular alterations—excluding BRAF V600E and KRAS G12C mutations—were significantly more exposed to higher levels of residential radon compared to those without such alterations (139 Bq/m3 vs. 68 Bq/m3; $p < 0.001$). Specifically, patients whose tumors carried druggable gene fusions were exposed to significantly higher radon levels (144 vs. 88 Bq; $P < 0.001$). More specifically, ALK-positive NSCLC patients had markedly higher radon exposure compared to ALK-negative cases (142 Bq/m3 vs. 74 Bq/m3; p=0.006). In contrast, tumors harboring a BRAF mutation (including non V600E) were associated with significantly lower radon exposure (39 Bq/m3 vs. 78 Bq/m3; p=0.034).

Conclusions: Druggable gene fusions in non-small cell lung cancer are significantly associated with higher levels of residential radon exposure. These findings suggest a potential link between residential radon exposure and the development of specific molecular alterations, particularly ALK rearrangements. Further research is warranted to explore the biological mechanisms underlying this association and to assess the implications for lung cancer prevention and targeted therapy strategies.

P3.01.26 Respiratory Hazard Index Is Associated With Lung Cancer Development in Underrepresented Lung Cancer Screening Individuals

F. Weinberg, H. Ouyang, E. Abrol, T. Hill, A. Hulbert, K. Kovitz, R. Nguyen, M. Wright, L. Liu, M. Pasquinelli
University of Illinois Chicago, Chicago/IL/USA

Introduction: Lung cancer (LC) is the leading cause of cancer -related mortality in the United States. Lung cancer screening (LCS) in high-risk individuals with LDCT significantly reduces LC mortality. Generally, approximately 1% of individuals undergoing LCS develop LC. At UI Health, an academic health system serving the west and south sides of Chicago, patients in our majority, minority-based LCS program have a higher rate of LC development. Therefore, we aim to understand clinical and population-based social determinants of health (SDOH) metrics that may be associated with higher rates of LC development.

Methods: We used logistic regression to assess the effect of demographic and SDOH metrics on cancer diagnosis as well as high and low Lung-RADS scores. Lasso regularization was applied for variable selection due to its ability to shrink some coefficients to zero, thereby improving model interpretability. The optimal regularization parameter (lambda) was determined via 10-fold cross-validation.

Results: We conducted a retrospective analysis of clinical data and linked geospatial level SDOH metrics for 2645 patients enrolled in our hybrid LCS program at UI Health from 2015-2024. Of these individuals, 96.4% did not develop LC (NLC), while 3.6% developed LC (DLC). Individuals in the NLC group had a higher percentage of low Lung-RADS scores (<2) whereas those in the DLC group had a higher percentage of high Lung RADS (3+). Among 30 population-level SDOH metrics, we found that the Respiratory Hazard Index (RHI), the ratio of air toxic exposure (~187 chemicals) concentrations to health-based reference concentrations, was higher at all geospatial levels (zipcode, community, census) in LCS individuals with baseline high Lung-RADS scores compared to individuals with low scores (Zipcode: 0.384 vs. 0.379 (p=0.09), Community: 0.390 vs 0.385 (p=0.034), Census: 0.383 vs. 0.376 (p=0.057)). Therefore, we looked at the effect of RHI (as well as other factors) on lung cancer development and found that there was a trend towards higher RHI scores and lung cancer development at the census tract level (Table 1).

Conclusions: This is the largest study to characterize the demographic and population-level SDOH in a hybrid LCS Program primarily serving underrepresented individuals. LCS individuals with higher Lung-RADS scores, which are associated with higher rates of LC detection, as well as higher Respiratory Hazard Index (RHI) scores, are more likely to develop LC. The current study suggests that exposures to air toxics may significantly impact the development of LC, especially amongst underrepresented LCS populations which warrants further investigation.

Using the median and 75th cutoff for RHI
(In this case, median and 75th quantile are the same for this variable)

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.01.27 Environmental Carcinogenesis in Lung Cancer: Sodium Arsenite-Induced PML Dysregulation and LINE-1 Activation

K. Whelan, S. Mathavarjah, J. Salsman, A. Wallace, V. Martinez, G. Dellaire
Dalhousie University, Halifax/NS/CA

Introduction: Lung cancer is the leading cause of cancer-related mortality, with rates of lung cancer increasing in non-smokers. Thus, other environmental carcinogens pose a significant risk for the development of lung cancer. Sodium arsenite (NaAsO2) is a known environmental carcinogen implicated in lung cancer development. NaAsO2 exposure has been associated with the activation of LINE-1 (L1) retrotransposons. L1 activation commonly occurs in cancer cells and is linked to genomic instability, and activation of innate inflammatory pathways, both being hallmarks of cancer. The promyelocytic leukemia protein (PML), a tumour suppressor, is under-expressed in lung cancer and has been recently implicated in the suppression of L1. This study examines the role of PML in arsenic induced L1 activity and their potential contributions to lung cancer pathogenesis.

Methods: Human bronchial epithelial (HBEC3-KT) and small airway epithelial (HSAEC1-KT) cell lines were treated with low doses (0.08-10μM) of NaAsO2. Immunofluorescence microscopy (IF), Western blot, qPCR, and ELISA-based assays were used to assess PML localization and L1 activation. A L1 retrotransposition reporter assay was used to assess L1 integration. A cGAMP ELISA assay was used to assess the inflammatory cGAS response to double stranded DNA in the cytoplasm.

Results: Immunofluorescence microscopy revealed that NaAsO2 exposure led to cytoplasmic accumulation of PML and a reduction in nuclear PML bodies (PML NBs). Given that PML plays a role in suppressing L1 retrotransposons, and that arsenic exposure has been shown to increase L1 activity, we used RT-qPCR to assess L1 expression and found increased endogenous L1 activation following NaAsO2 treatment. Additionally, a L1 reporter assay confirmed upregulated L1 integration in NaAsO2 treated cells, which was suppressed by PML overexpression. Using IF we observed co-localization of endogenous PML and L1 ORF1P in both NaAsO2 and control cells within the nucleus. We also observed an increased abundance in ORF1P puncta in NaAsO2 treated cells compared to untreated cells. The nuclear co-localization of PML and ORF1P suggests that there may be a nuclear function of PML in L1 suppression. We also assessed downstream inflammatory consequences of arsenic-induced L1 activation using a cGAMP ELISA assay and found that PML overexpression was able to eliminate cGAS activation. These results suggest that degradation of PML by NaAsO2 is detrimental for L1 suppression and may pose a significant step in the development and progression of lung cancer due to the ability of L1 to create genomic instability and activate inflammatory pathways.

Conclusions: These findings suggest that NaAsO2 exposure activates L1 and disrupts PML NBs, both of which are implicated in genomic instability and tumor suppression. Chronic NaAsO2 exposure may promote lung cancer development by degrading PML, thereby impairing its ability to repress L1 activity. This arsenic-induced and unsuppressed L1 activity could enhance genomic instability and activate inflammatory pathways, such as the cGAS-STING pathway, contributing to tumor progression. Understanding the mechanisms for arsenic induced L1 activity is essential for identifying environmental risk factors, understanding lung cancer development, and developing early screening strategies to improve patient outcomes.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.01.28 Household Air Pollution and Mitochondrial DNA Fragmentation

E. Francis[1], B. Blechter[1], W. Hu[1], K. Salmons[2], D. Barr[3], R. Cawthon[4], N. Rothman[1], K. Steenland[3], M.L. Clark[2], Q. Lan[1]
[1]National Cancer Institute/ National Institutes of Health, Bethesda/MD/USA ,[2]Colorado State University, Fort Collins/CO/USA ,[3]Rollins School of Public Health, Emory University, Atlanta/GA/USA ,[4]University of Utah, Salt Lake City/UT/USA

Introduction: Lung cancer is the leading cause of cancer-related death globally and the seventh among never smokers. Though cigarette smoke is the principal lung cancer carcinogen, air pollution is also a significant risk factor. With declining smoking rates and rising air pollution, understanding air pollution's role in lung cancer is essential. Fine particles with diameters of 2.5 micrometers and smaller (PM2.5) have been linked to lung cancer. Though the mechanism remains unclear, prior studies noted that exposure to PM2.5 is associated with mitochondrial DNA copy number, a measure of mitochondrial quantity. Mitochondrial loss occurs with aging and is associated with several age-related diseases. To explore these relationships, we examined the association between PM2.5 and intermediary biomarkers suspected to reflect lung cancer risk, including total mitochondrial DNA copy number (mtDNA), mtDNA fraction with breaks (mtDNAfb) and mtDNA fraction without breaks (mtDNAfwb), in Peru and Guatemala, countries with a high prevalence of household air pollution. This is the first study to assess the association between PM2.5 and mtDNA fragmentation.

Methods: From 2018 - 2020, participants in Peru and Guatemala were enrolled in a randomized control trial (Household Air Pollution Intervention Network, HAPIN) to evaluate the effect of transitioning from burning biomass to cooking with liquefied petroleum gas (LPG), a cleaner alternative to traditional biomass fuels, on health outcomes and intermediary biomarkers. Participants were randomized into an intervention arm, which received an LPG stove, or a control arm, which continued using biomass fuel. Biological samples and personal 24-hour PM2.5 concentrations were collected at baseline and 18 months post-intervention. Generalized estimating equations explored the association between PM2.5 and three endpoints (total mtDNA, mtDNAfb, and mtDNAfwb). Models were adjusted for batch, age and randomization arm, and sensitivity analyses further adjusted for body mass index (BMI; kg/m2) and education.

Results: 219 never-smoking older women (age >50 years) from Peru (n=84) and Guatemala (n=135) were included in our analyses. Though no association was observed between PM2.5 and total mtDNA (B= -0.0002, 95% confidence interval (CI): -0.069, -0.069), a 1 standard deviation (SD) increase in PM2.5 exposure was associated with a 3.89% (B= -0.04, 95% CI: -0.06, -0.01) decrease in mtDNAfb and a 2.1% (B= 0.02 ,95% CI: 0.002, 0.04) increase in mtDNAfwb. In Guatemala, 1 SD increase in PM2.5 exposure was associated with a 5.29% (B = -0.05, 95% CI: -0.09, -0.01) decrease in mtDNAfb and a 3.0% (B= 0.03 ,95% CI: 0.007, 0.05) increase in mtDNAfwb. Similar findings were appreciated when adjusting for BMI and education. Noteworthy findings were neither observed in analyses restricted to Peruvian participants nor in analyses assessing the effect of the intervention.

Conclusions: We observed that increased exposure to PM2.5 is associated with a decrease in mtDNAfb and an increase in mtDNAfwb. Notably, a population-based cohort study in Asia identified an association with lower mtDNAfb values and increased risk of lung cancer in female never-smokers. Future investigation is needed to validate our findings.

P3.01.29 Identifying Long Term Air Pollution Exposure for Lung Cancer Risk in Canada

R.L. Myers[1], C. Bartolomeu[1], S. Borden[1], K. Kiland[1], M. Brown[1], C.H. Durney[1], M. Brauer[2], S. Lam[1], C.M. Tammemagi[3]
[1]BC Cancer Research Institute, Vancouver/BC/CA ,[2]University of British Columbia, Vancouver/BC/CA ,[3]Brock University, St. Catharines/ON/CA

Introduction: Lung cancer in persons who have never smoked is on the rise globally, and accounts for up to 33% of lung cancers diagnosed in Canada. A strategy to identify light and never tobacco users who are at high risk and who may benefit from lung cancer screening (LCS) is urgently needed. In 2013, the International Agency for Research on Cancer (IARC) classified outdoor air pollution and particulate matter less than 2.5 µm in diameter (PM2.5) as a carcinogen to humans and a cause of lung cancer. There are challenges to estimating lifetime air pollution exposure, as satellite-based air pollution data is only available from 1995 onward. This limits our ability to accurately estimate the risk of lung cancer associated with air pollution, which may be particularly relevant for individuals who do not qualify for LCS due to smoking exposure and/or history. Our study aims to compare the predictive accuracy of using cumulative air pollution exposure to predict lung cancer risk when air pollution is estimated from residential histories which are taken at different periods and for different time durations.

Methods: A case-control study design was employed with all participants enrolled sequentially through early detection studies at BC Cancer, Vancouver. The cumulative outdoor PM2.5 exposure was estimated using a high-spatial resolution global exposure model based on postal codes for all residences occupied going back 20 years. The associations between lung cancer and current, 3-, 5-, 10-, and 20-year annual mean PM2.5 exposures were evaluated using odds ratios (OR) with 95% confidence intervals (CI). Predictive performances were evaluated using the receiver operator characteristic area under the curve (AUC).

Results: In this study, 59 of 616 (9.6%) participants were diagnosed with lung cancer, 32 (52.8%) were female. Lung cancer was detected in 11.1% of women and 7.9% of men. Mean age was 66.7 (SD 7.0, range 42-80). Current, former, and never tobacco users comprised 11%, 54%, and 34% of the sample respectively.

Twenty-year annual mean exposure was statistically significantly higher than that based on the current address (7.02 vs 6.25; $p<0.001$). Foreign-born Canadians had significantly higher cumulative air pollution exposure than Canadian-born when evaluating 3, 5, 10, and 20-year annual mean exposures ($p=0.02$) but no significant difference was seen when only the current address was used ($p=0.08$). Five percent of Canadian-born individuals had lung cancer vs 17% of foreign-born Canadians ($p<0.001$). The odds ratio for lung cancer ~ air pollution (PM2.5) adjusted for age and sex for the first (earliest) collected one year of exposure was 1.055, 95% confidence interval (CI) 0.997-1.116, $p=0.063$; AUC=0.579), and for the most recent one year of exposure was 0.978 (0.883-1.158; $p=0.797$; AUC=0.551).

Conclusions: Incorporating accurate estimates of air pollution exposure into risk assessments and risk prediction models for ever- and never-smoking individuals is of great public health and clinical importance. Our study suggests that measurement of air pollution exposure over an extended period is more predictive than just using current residence.

P3.01.30 The Relationship of Particular Matter 2.5 and Mortality Rate of Patients With Lung Cancer and Lag Time Effect in Northern Thailand

B. Chewaskulyong, C. Pankongngam, T. Jaruwattanakun, P. Rangrongrajitpoom, P.T. Treeyapong, W. Chaiwong, C. Pothirat, S. Saeteng, A. Tantraworasin
Chiang Mai University, Chiang Mai/TH

Introduction: Open burnings, agricultural, and forest fires contribute significantly to particulate matter (PM) pollution in Chiang Mai, Thailand particularly during the dry season. In this study, we investigated the association between increased monthly particulate matter (PM) with an aerodynamic diameter ≤ 2.5 µg/m 3 (PM2.5) levels and mortality among patients with lung cancer receiving treatment at a tertiary care center in Chiang Mai.

Methods: A retrospective observational cohort study was conducted on patients with non-small cell lung cancer at all stages, receiving treatment at Chiang Mai University Hospital (Maharaj Nakorn Chiang Mai Hospital) from January 2012 to December 2016. Using a generalized linear model with Poisson distribution, we analyzed the association between PM levels and daily non-accidental mortality, adjusting for other pollutants (SO2, NO2, CO, and O3), as well as temperature, humidity, and wind speed.

Results: The annual average PM2.5 concentration in Chiang Mai was 32.7 µg/m3 . After adjusting for confounding variables, including other pollutants and meteorological factors, we found that every 10 µg/m3 increase in both PM2.5 and PM10 was significantly associated with an increased likelihood of mortality among patients with lung cancer (lag 0 month adjusted incidence rate ratio (IRR) for PM2.5: 1.175; 95% CI: 1.093 - 1.263; lag 3 months IRR for PM2.5: 1.079; 95% CI: 1.005 - 1.158; lag 0 month IRR for PM10: 1.125; 95% CI: 1.067 - 1.185; lag 3 months IRR for PM10: 1.063; 95% CI: 1.010 - 1.119). Mortality rates were higher in Mae Hong Son province, among patients with large cell histology and stage IIIA lung cancer. Additionally, higher PM2.5 levels were associated with lower humidity and higher atmospheric pressure.

Conclusions: PM10 and PM2.5 are associated with monthly mortality among patients with lung cancer, with a lag time of three months. Policymakers should implement measures to reduce PM exposure in high-risk areas, and healthcare providers should closely monitor patients, extending follow-up beyond a few days to three months.

P3.01.31 Physical Characterization of PM2.5 - Effects on Cellular Uptake, Dispersion, and Lung Cell Interactions

I. Mendoza Montealegre, J. Salsman, G. Dellaire, G. Maksym
Dalhousie, Halifax/NS/CA

Introduction: Environmental pollutants resulting from urban expansion, climate change, and forest fires produce airborne particles that are associated with increased rates of cardiorespiratory diseases. Particulate matter smaller than 2.5 microns (PM2.5) can penetrate deep into the lungs, where it may damage the alveolar epithelium (AE). These particles possess a chemical profile that is unique to their source—e.g., urban pollution, forest fires, or industrial emissions. The chemicals associated with PM2.5 are likely delivered to the AE, eliciting an inflammatory response. However, the physical properties of these particles—such as size, morphology, and aggregation—can independently induce cellular damage. Understanding the physical characteristics of PM2.5 prior to in vitro exposure experiments is essential for determining how factors such as solvent, concentration, and processing methods influence its properties and subsequent cellular interactions. Given the established link between PM2.5 and lung cancer, investigating these physical interactions is fundamental for understanding its broader implications for lung health.

Methods: To characterize the physical properties of commercially sourced urban PM2.5 (NIST 2786), scanning electron microscopy (SEM) was used to examine particle shape and surface features. Dynamic light scattering (DLS) was employed to assess particle size distribution and aggregation as a function of concentration (µg/mL) following sonication and dilution in different solvents. Human bronchial epithelial cells (HBECs; ATCC CRL-4051) were exposed to 10 µg/mL of PM2.5 for 24 hours in 2D culture. SEM was used to observe particle-cell interactions, while transmission electron microscopy (TEM) was employed to examine intracellular localization of the particles.

Results: SEM imaging revealed that PM2.5 exhibits irregular shapes, porous surfaces, and a size range extending from 2.5 µm to the nanoscale. This porosity increases the surface area, potentially providing additional binding sites for toxic chemicals. DLS analysis demonstrated that both solvent type and particle concentration influence aggregation behaviour. Solvents such as ethanol and water promoted increased aggregation, whereas PBS and DMSO facilitated better dispersion. Higher particle concentrations reduced the effectiveness of sonication, suggesting that lower concentrations yield more consistent and physiologically representative particle distributions. SEM images of HBECs exposed to PM2.5 showed cell surface protrusions extending toward the particles, indicating an active uptake mechanism. TEM confirmed internalization of PM2.5, with particles localized within membrane-bound vesicles. These findings suggest that PM2.5 is internalized by HBECs, potentially enabling the intracellular delivery of associated toxic compounds.

Conclusions: This study highlights the complex interactions between PM2.5 and lung epithelial cells, demonstrating that physical properties such as irregular morphology and porosity may enhance their capacity to adsorb and deliver harmful chemicals. Characterizing particle aggregation and dispersion is critical for accurately modelling physiological exposure conditions. These findings provide evidence that PM2.5 is internalized by HBECs, supporting the hypothesis that such particles serve as vectors for cellular uptake of toxic compounds. Understanding these interactions is essential for elucidating the role of environmental pollutants like PM2.5 in lung carcinogenesis.

P3.01.32 Association of Long-Term Exposure to Fine Particulate Matter, Ozone, and Greenness With Lung Cancer Risk

J.H. Lee, N.E. Kim, J-Y. Lee
Ewha Womans University, Seoul/KR

Introduction: Considering the increasing incidence of lung cancer in never smokers, research is needed on the risk of lung cancer due to exposure to air pollution. We investigate the association between lung cancer incidence and long-term exposure to air pollution including particulate matter less than 2.5 µm or less in diameter (PM2.5), ozone (O3) and normalized difference vegetation index (NDVI), widely used metric for quantifying the health and density for vegetation representing greenness.

Methods: This is a population-based case-control study using covering 7,155 lung cancer patients and 28,620 controls selected from National Sample Cohort-National Health Insurance Service in Korea from 2002 to 2019, matched by propensity score at 1:4 ratios with age, sex, and enrollment year. Individual-level long-term exposure to PM2.5, O3 and NDVI was assessed based on region of residence. Kaplan-Meier analysis and the log-rank test were used to examine the statistical significance of differences in lung cancer incidence according to the distribution of air pollution and green space. The Cox proportional hazards model estimates the effects of air pollution and green space on lung cancer risk by adjusting for available confounding factors such as age, gender, smoking status, household income, residential area, body mass index, and Charlson Comorbidity index. Adjusted hazard ratios (aHRs) with 95% confidence intervals (CIs) were calculated for lung cancer risk.

Results: The lung cancer group showed lower body mass index, higher rural residence, higher pack-years of smoking, and higher Charlson comorbidity index. The Kaplan-Meier analysis of lung cancer incidence rates according to air pollution and green space levels showed that the cumulative incidence of lung cancer was higher when O3 was high and NDVI was low ($p < 0.001$, $p < 0.001$, respectively). The level of exposure to air pollution was analyzed by dividing it into tertiles. PM2.5 showed an increase in the lung cancer risk in the 3rd tertile (aHR =1.064; 95% CI =1.006-1.127); O3 showed an increase in the lung cancer risk regardless of tertile (aHR=1.421; 95% CI= 1.342-1.503), NDVI showed a significant protective effect in the 3rd tertile (aHR=0.709; 95% CI = 0.658-0.764). Subgroup analysis according to sex and smoking status showed that PM2.5 had a risk effect especially in never-smoker males, O3 had a significant lung cancer risk in males and never-smoker females, and NDVI showed a protective effect against lung cancer regardless of sex and smoking status.

Conclusions: This study provides evidence that PM2.5, O3, and greenness influence lung cancer development.

P3.01.33 Global Trends in Tracheal, Bronchus, Lung Cancer Burden From Household Air Pollution

S. Lao, F. Li, W. Wang, W. Liang
The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Tracheal, bronchial, and lung (TBL) cancers, largely attributable to household air pollution (HAP), remain a critical public health challenge, particularly in low- and middle-income countries. Using data from the Global Burden of Disease 2021 (GBD), this study evaluates global trends in HAP-related TBL cancer burden from 1990 to 2021 and projects future trends to 2051.

Methods: The study extracted data on deaths and disability-adjusted life years (DALYs) from the GBD 2021 and assessed the burden of TBL cancer attributable to HAP by sex, age, region, and socio-demographic index (SDI). The age-period-cohort (APC) model was used to examine the independent effects of age, period, and cohort on the burden of TBL cancer attributable to HAP. The Bayesian age-period-cohort (BAPC) model was applied to predict future trends in the burden of TBL cancer attributable to HAP over the next 30 years.

Results: From 1990 to 2021, the global burden of TBL cancer due to HAP for deaths and DALYs cases decreased by 39.2% and 44.1%, respectively, with the steepest declines in high SDI regions. Conversely, mortality and DALYs rates rose in Oceania and sub-Saharan Africa. The global age-standardized mortality rate (ASMR) peaked in the 85-89 age group, and the age-standardized disability rate (ASDR) peaked in the 70-74 age group. Males experienced a higher burden than females, with significant differences observed across SDI regions. Projections suggest that mortality and DALYs rates will rise over the next 30 years, with a higher burden forecast for females.

Conclusions: Despite significant reductions in the global burden of TBL cancer from HAP, the disease remains a major issue in low SDI regions, particularly in China. Projections for the next 30 years indicate increasing mortality and DALYs rates, with a disproportionate impact on women. These findings highlight the urgent need for targeted policies to reduce HAP exposure, especially in low SDI regions.

P3.01.34 Associating Pollution-Related Anthracotic Pigments Within Normal Lung Tissue With Lung Cancer Characteristics

L. Fung[1,2,3,4], B. Joseph[2], T. Lo[1,4], J. Naso[2], A. McGuire[2,3], E. Lim[1,4]
[1]University of British Columbia, Vancouver/BC/CA ,[2]Vancouver Coastal Health Research Institute, Vancouver/BC/CA ,[3]Vancouver General Hospital, Vancouver/BC/CA ,[4]Edwin SH Leong Centre for Healthy Aging, Vancouver/BC/CA

Introduction: Worldwide, particulate matter (PM) pollution with an aerodynamic diameter of less than 2.5 µm (PM2.5) is the second most common cause of lung cancer after tobacco smoking. Thus, there is an urgent need to understand the adverse effects of air pollution on lung cancer development. While pollution-associated anthracotic pigment (black carbon deposits) can be seen in hematoxylin and eosin (H&E) slides of background lung tissue from tumor resections and heavy anthracosis has been associated with clonal expansions of cells harbouring oncogenic mutations, microscopic anthracotic pigment is not commonly used for pollution exposure estimates because there is currently no standard quantitative measure of anthracosis.

Methods: We developed an automated pixel classifier method using QuPath to quantify anthracotic pigment. Our method involves two pixel classifiers in which one is optimized to detect dark-coloured regions, and the other is optimized to detect H & E negative regions. Applying these classifiers in succession allows the anthracotic regions to be isolated and quantified as a proportion of the total tissue area.

Results: In 64 H&E whole slide images of normal lung tissue from never-smoker lung cancer patients, we observed a significant correlation between the quantity of anthracosis (Figure 1) and 3-year PM2.5 exposure estimated based on patient addresses in three years prior to diagnosis ($R = 0.28$, $p < 0.05$). Notably, 20-year PM2.5exposure, EGFR mutation status, and histologic growth were not significantly associated with the degree of anthracosis.

Conclusions: Our data indicate that our automated quantification of anthracotic pigment on H&E slides may be representative of geographically estimated recent PM2.5 exposures. Importantly, our method can be used in large scale studies to relate anthracotic pigment to clinical and molecular correlates in lung cancer patients, to further our understanding of how air pollution promotes lung cancer development. Expansion of our study to an additional 95 cases and correlations with genomic, transcriptomic, and methylation profiling data are in progress.

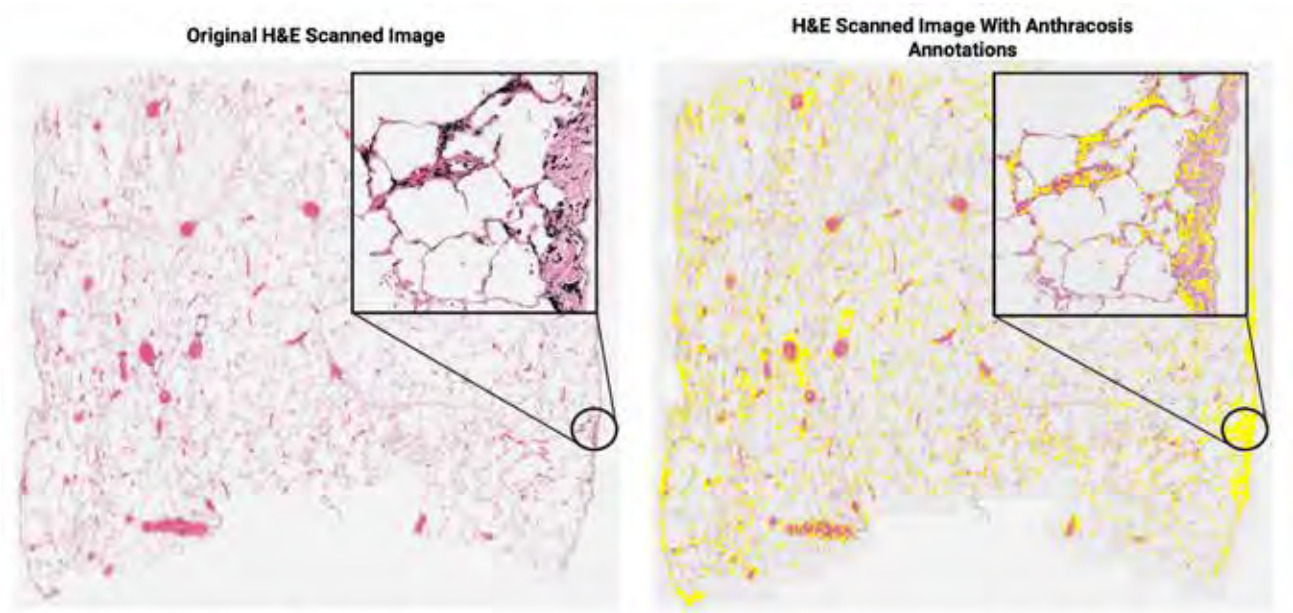

Figure 1: Before and after application of the anthracosis quantification method. The yellow overlay indicates anthracotic pigment as identified by our method. Relative to total tissue area, anthracotic pigment comprised 0.31% of this tissue.

P3.01.35 Air Pollution and Lung Cancer Risk by Smoking Status: Findings From the Uk Biobank

A. Issanov[1], R. Meza[2], S. Lam[3], M.C. Tammemägi[4], T.J.B. Dummer[1]
[1]University of British Columbia, Vancouver/BC/CA ,[2]BC Cancer Research Institute, Vancouver/BC/CA ,[3]Provincial Health Services Authority, Vancouver/BC/CA ,[4]Brock University, St. Catharines/ON/CA

Introduction: Lung cancer (LC) is one of the most diagnosed cancers and remains the leading cause of cancer-related deaths worldwide. While smoking is the primary risk factor, 15-20% of LC cases globally—and up to 50% in certain Asian countries—occur in people who have never smoked (PNS). Air pollution has been identified as a major risk factor in this population. However, many previous studies have focused on regions with severe pollution or relied on outdated environmental data that may not reflect current exposure levels. This study aims to address these gaps by examining the relationship between air pollution and LC in both people who smoked (PS) and PNS using data from the UK Biobank, a recent, large-scale population-based prospective cohort study from the UK, where pollution levels are comparatively lower.

Methods: The UK Biobank includes sociodemographic, behavioral, environmental, family history, self-reported medical history, linked hospital records, and cancer registry data from over 480,000 participants without a history of lung cancer or any cancer diagnosis within five years prior to enrollment. Residential concentrations of particulate matter—specifically fine particles (PM ≤2.5 µm/m3)—and nitrogen dioxide (NO2) at baseline were estimated using land-use regression models. The association between these air pollutants and incident lung cancer was assessed using Cox proportional hazards models. Covariates were selected based on the disjunctive cause criterion and included age, sex, education, income, second-hand smoke exposure, glycated hemoglobin (HbA1c), family history of lung cancer, personal history of cancer, history of chronic obstructive pulmonary disease, history of tuberculosis, presence of long-term illness, body fat percentage, and physical activity.

Results: The mean annual concentrations of PM2.5 were 10.1 µg/m^3 and 9.9 µg/m^3 in PS and PNS, respectively (Figure 1). During the 6-year follow-up period, 1,583 and 239 incident LC cases among PS and PNS were identified, corresponding to absolute risks of 0.72% and 0.09%, respectively. Among PS, associations were observed between LC risk and both natural log-transformed PM2.5 (HR = 4.49; 95% CI: 1.70-11.8) and log-NO_2 (HR = 1.52; 95% CI: 1.08-2.16). In contrast, no associations were found in PNS for log- PM2.5 (HR = 1.26; 95% CI: 0.19-8.20) or log-NO_2 (HR = 1.07; 95% CI: 0.57-2.00).

Conclusions: In a region with comparatively low pollution, our findings suggest that air pollution is associated with an increased risk of lung cancer among people who smoked, but not among people who have never smoked.

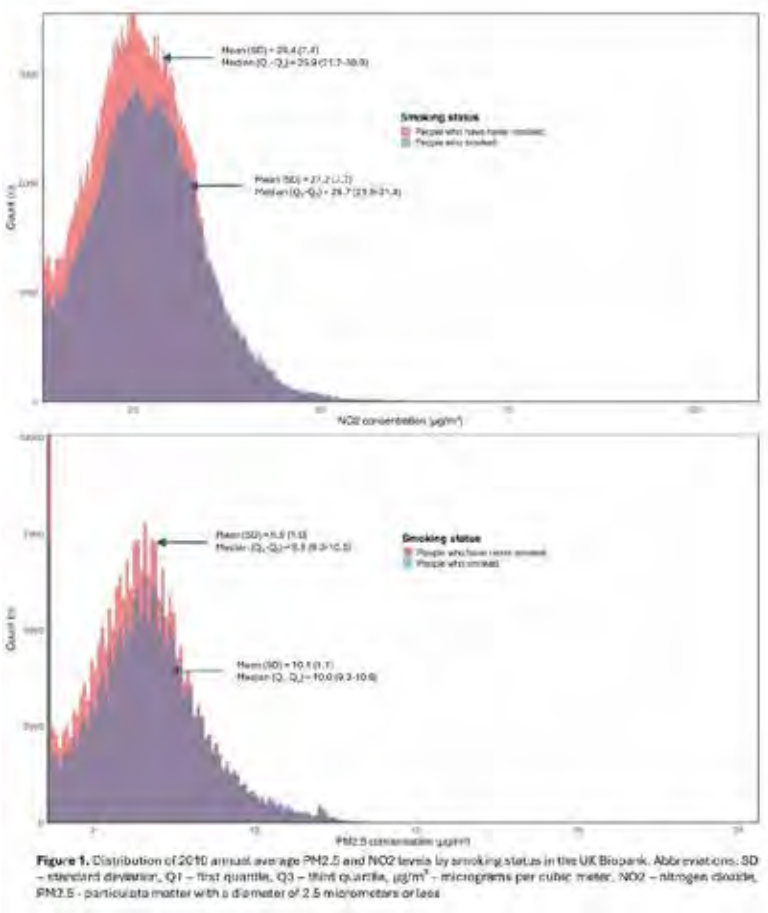

Figure 1. Distribution of 2010 annual average PM2.5 and NO2 levels by smoking status in the UK Biobank. P3.01.36 Feasibility of Implementing a Virtual Nursing-Led Smoking Cessation Clinic for Patients With Cancer

S. Choi, M. Ku, J. Do, Y. Liang, I. Tymoshyk, A. Feng, S. Dhanju, C. Dunphy, L. Eng
Princess Margaret Cancer Centre, Toronto/ON/CA

Introduction: Continuing to smoke after a diagnosis of cancer can worsen both cancer and treatment-related outcomes. Despite the importance of smoking cessation in cancer care, patients often find it challenging to quit smoking. Moreover, many patients interested in quitting may not be provided with adequate support or opportunities to be connected to smoking cessation resources. Given the advances in virtual care, we piloted a virtual nursing-led smoking cessation clinic to follow up with cancer survivors who were identified using tobacco at their initial clinic visit but were never offered or initially declined referral to cessation support.

Methods: A virtual nursing-led clinic was piloted from November 2023 to May 2024 at the Princess Margaret Cancer Centre (Toronto, Canada). The clinic was operated by a trained oncology nurse for one half day per week. The nurse received training in motivational interviewing, providing support towards cessation, and assessing and referring patients. Using the electronic health record system, EPIC, monthly reports were generated of new patients diagnosed with cancer who reported smoking within 6 months of their initial visit but were either not offered referrals to smoking cessation support or initially declined a referral. Patients were called weekly up to four times through the clinic until successfully contacted. Descriptive statistics were used to characterize the feasibility outcomes.

Results: From November 2023 to May 2024, a total of 191 patients were eligible for contact by our virtual clinic. Among the eligible patients, the median age was 64 years old (range: 26 to 94 years) and 63% were male. The most common disease sites were head and neck (16%), gastrointestinal (15%), hematological (15%), and lung (10%). A total of 339 calls were conducted and an average of 1.4 calls (range: 1 to 4) were needed to successfully reach a patient. A total of 22 clinics were conducted, where an average of 22 calls were made per clinic. Most patients (73%) reached after one call, while 13% required two calls, and 15% required three or more calls. Among the patients reached (n = 196), the average duration per call was 3.6 minutes (range: 1 to 15 minutes). Among patients contacted, 14% accepted a referral for smoking cessation support, while among those who declined, 36% had already quit prior to receiving a phone call. For patients accepting a referral, call durations were slightly longer (5.5 minutes vs. 2.7 minutes, $p < 0.001$). Common patient reported barriers to accepting a referral included a lack of readiness to quit, stress and exposure to second-hand smoke.

Conclusions: A virtual nurse-led smoking cessation clinic is feasible to help provide referrals to supporting smoking cessation among patients with cancer who initially declined support or have never been offered support. Many patients declining referral to support had already quit smoking, while other barriers include stress, exposure to second-hand smoke, and readiness to quit. Strategies to minimize and reduce these barriers should be further explored.

P3.01.37 Time-Dependent Analysis Reveals the Dual Role of Smoking in Non-Small Cell Lung Cancer Immunotherapy

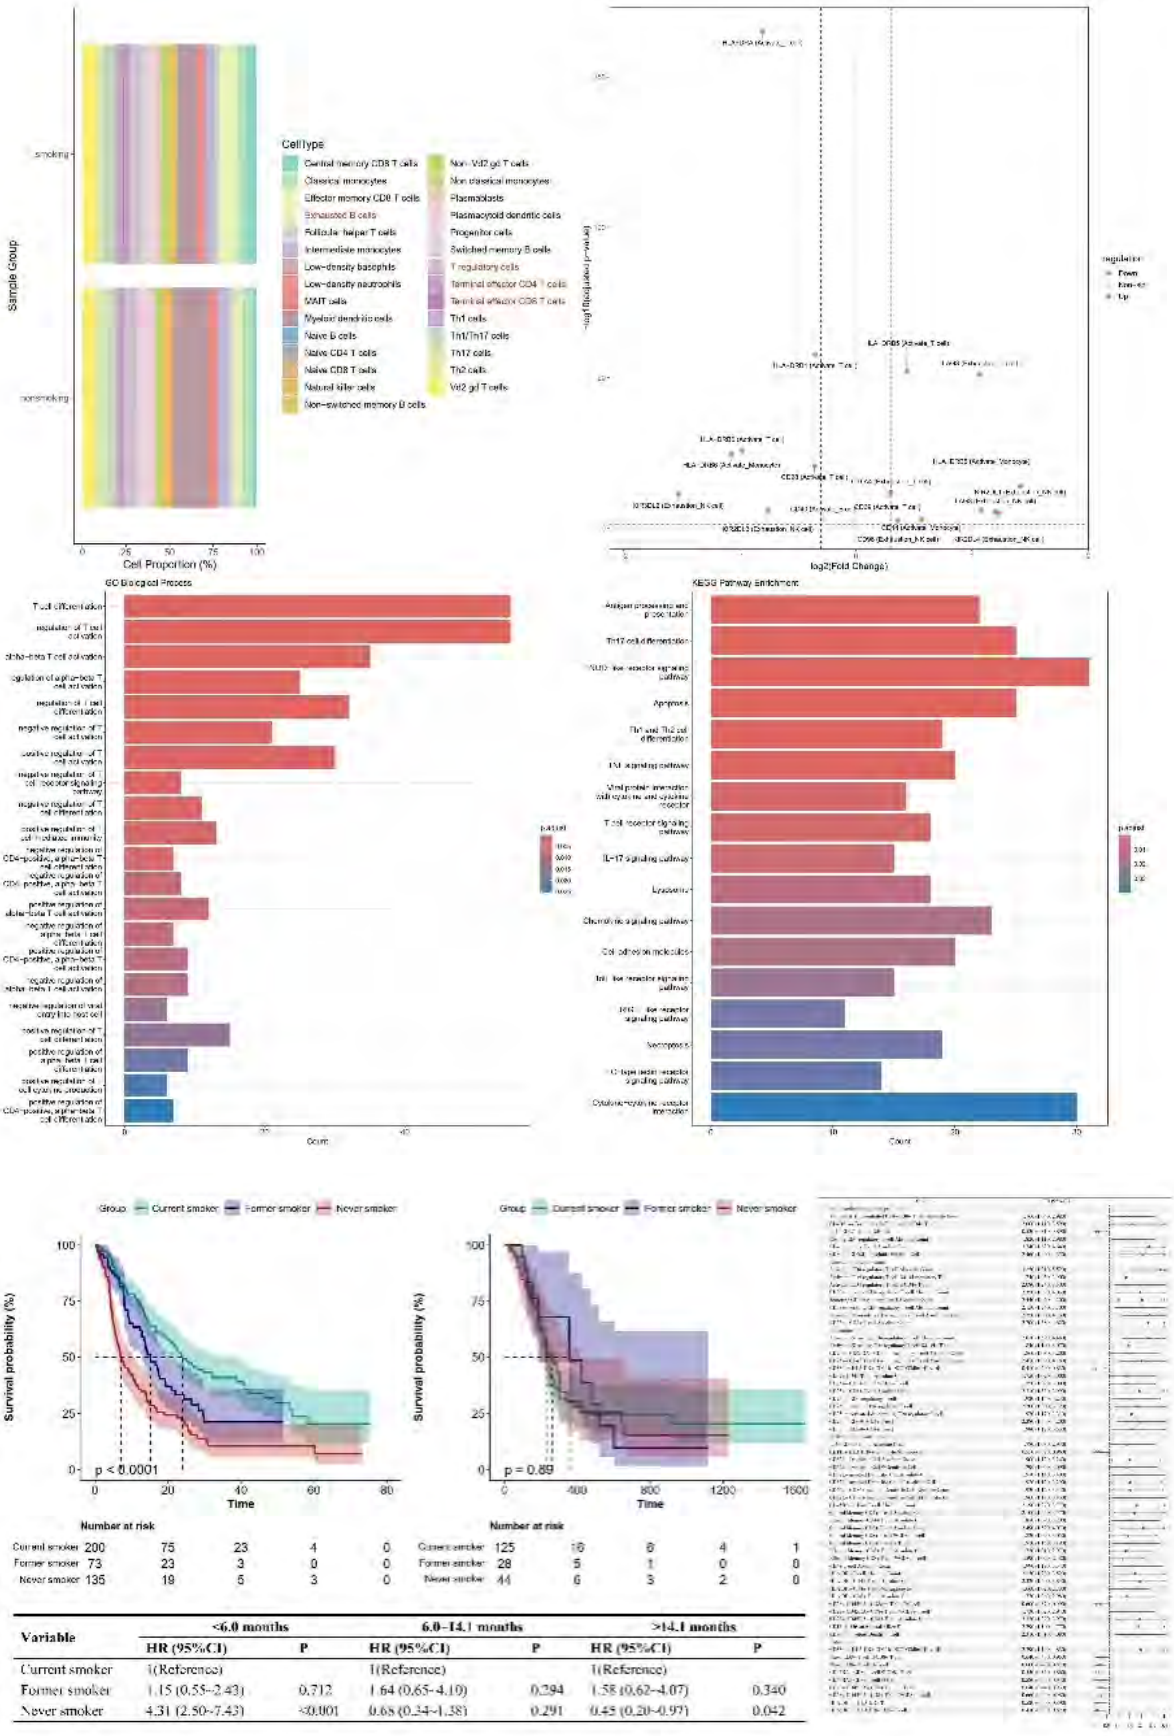
Y-L. Peng[1,2], Z-J. Huang[1], A-X. Yang[3], L-B. Tang[1,2], Z. Guo[1], L. Wu[1], Z-R. Ren[1], J. Chen[1], J-T. Li[1,4], Y. Deng[1], Z-H. Chen[1], C-R. Xu[1], Q. Zhou[1], J-P. Long[1], C. Lu[1]
[1]Guangdong Provincial People's Hospital, Southern Medical University, Guangzhou/CN ,[2]South China University of Technology, Guangzhou/CN ,[3]Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hongkong/CN ,[4]Shantou University Medical College, Shantou/CN

Introduction: Smoking history is a risk factor for lung cancer, but its role in immunotherapy remains unclear. This study investigates the impact of smoking on lung cancer immunotherapy and its effects on immune cells. This study was previously presented at ACLC 2024. The current update incorporates clinical data from SCLC patients, along with Mendelian randomization (MR) and single-cell analyses to validate findings.

Methods: This study enrolled patients from Guangdong Provincial People's Hospital, who were stratified by pathological type into SCLC and NSCLC groups. Kaplan-Meier analysis were used to access the impact of smoking history on immunotherapy efficacy. Time-dependent cox regression using a time-stratified method was used when the Schoenfeld residuals test failed. MR and single-cell analyses were employed to investigate the impact of smoking on immune cells.

Results: Kaplan-Meier analysis suggested smoking might be a protective prognostic factor in NSCLC, but this effect was not observed in SCLC. Further analysis of NSCLC employed time-stratified Cox regression due to violation of proportional hazards assumption. In patients with PFS less than 6.0 months, never smokers had shorter PFS (HR: 4.31; 95%CI: 2.50~7.43). In patients with PFS beyond 14.1 months, never smokers showed longer PFS (HR: 0.45; 95%CI: 0.20~0.97). Both MR and single-cell analyses revealed that smoking history simultaneously increased both activated and exhausted/tolerant immune cell populations. Similarly, both pro-tumor and anti-tumor immune cell populations were significantly increased.

Conclusions: This study demonstrates that smoking history exerts dual effects on NSCLC immunotherapy. Single-cell and MR analyses suggest this temporal dynamic may stem from concurrent increases in activated, exhausted, and tolerant immune cell populations. Specifically, the initial therapeutic advantage likely results from predominant immune activation, while progressive treatment resistance correlates with accelerated immune exhaustion and tolerance development in smokers. Smoking cessation may represent a viable strategy to improve long-term immunotherapy outcomes in NSCLC.



Variable	<6.0 months		6.0–14.1 months		>14.1 months	
	HR (95%CI)	P	HR (95%CI)	P	HR (95%CI)	P

P3.01.38 Effect of Smoking Cessation Duration on Lung Cancer Incidence: A Nationwide Retrospective Cohort Study in Korea

M.G. Choi[1], M-H. Kim[2], H.J. Kim[3], E.M. Chun[1]
[1]Mokdong Hospital, College of Medicine, Ewha Womans University, Seoul/KR ,[2]Seoul Hospital, College of Medicine, Ewha Womans University, Seoul/KR ,[3]Inje University Sanggye Paik Hospital, Seoul/KR

Introduction: It is well-known that smoking cessation can mitigate lung cancer risk in smokers compared with those who continue smoking. Nevertheless, the extent to which smoking cessation duration mitigates lung cancer risk remains unclear. In this study, we aimed to analyze the association between smoking cessation duration and the reduction in lung cancer incidence using large-scale health insurance data from South Korea.

Methods: In this retrospective cohort study, we utilized the cohort from the Korea National Health Insurance Corporation. Approximately 50% of the adults aged ≥50 years who underwent health examinations in 2009-2013 were randomly sampled. The index date was defined as the last health examination date between 2009 and 2013. The midpoint of the interval between the date of the examination where they reported quitting and the date of the preceding examination was used to estimate the quit date. The participants were classified into three groups: never-smokers, former smokers, and current smokers, and the incidence rates of lung cancer were compared among these groups.

Results: We analyzed 165,512 individuals selected through propensity score matching (82,756 never-smokers, 41,378 former smokers, and 41,378 current smokers). (Figure 1) Lung cancer risk significantly decreased after two years of smoking cessation (2-3 years after cessation: hazard ratio 0.760, p<0.001) but remained higher than that of never-smokers for up to 10 years. (Figure 2) Subgroup analyses revealed similar tendencies among males, whereas no consistent patterns were observed among females. Light smokers (<20 pack-years) reached lung cancer risk levels comparable to never-smokers after seven years of cessation, whereas heavy smokers (≥20 pack-years) required nine years to reach such levels.

Conclusions: This nationwide cohort study highlights the significant impact of smoking cessation duration on lung cancer risk, emphasizing the substantial benefits of even short-term cessation regardless of prior smoking history.

P3.01.39 From Nodule-Free to Nodule-Positive: Blood Biomarkers Bridge Smoking and Lung Cancer Risk

W. Ye[1], W. Zhang[2], D. Xiong[2], H. Zhou[2], J. He[1], W. Liang[1]
[1]the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]Clinical Laboratory, Guangzhou Cadre Health Management Center, Guangzhou No. [11] People's Hospital, Guangzhou/CN

Introduction: While smoking is a recognized risk factor for lung cancer, the biological pathways linking smoking to early-stage pulmonary nodule progression remain unclear. This study explored the mediating role of blood biomarkers in smoking-associated lung cancer development among individuals with pulmonary nodules.

Methods: We retrospectively analyzed a cohort of 1,586 individuals who underwent routine low-dose CT and blood tests from 2017 to 2024. All participants had no detectable lung nodules in 2017 but developed nodules ≥6 mm by 2024. Dynamic measurements of 40 blood biomarkers were extracted from multiple follow-up timepoints. We first applied linear mixed-effect models to assess whether smoking status modified the temporal trajectories of blood markers. Subsequently, both univariate and joint mediation analyses were conducted to evaluate whether these biomarkers mediated the effect of smoking on lung cancer diagnosis, using multiple imputation and bootstrap procedures. Four extraction strategies for mediators (initial value, latest value, peak value, mean value) were compared. A structural equation model (SEM) and PCA-based clustering were used to visualize and stratify mechanism subtypes.

Results: Linear mixed-effects models showed that smokers exhibited significantly steeper increases in biomarkers compared to non-smokers, including CEA (0.035 ng/mL/year vs. 0.012 ng/mL/year, p = 0.001) and RBC (0.14×10^9/L/year vs. a slight decline, p = 0.002). LY% declined faster in smokers (p = 0.022), indicating impaired immunity. Similar trends were observed for NEUT, CHOL, TG, and ApoB, suggesting smoking-related immunometabolism alterations. However, per-patient slope mediation analyses showed no significant indirect effects. Cross-sectional mediation modeling identified significant average causal mediation effects (ACME) for RBC (ACME = 0.0055, p = 0.024), MCV, MONO%, AST, NA1-IgA, and UBG (p < 0.05 for all), with mediation proportions ranging from 10.6% to 50.1%. SEM revealed parallel indirect pathways, indicating a multifactorial mechanism. Unsupervised clustering based on biomarker principal components identified three subtypes with distinct lung cancer risks: Cluster 1 (9.8%), Cluster 2 (2.1%, p < 0.01). Cluster 1 had a higher risk (OR = 1.87, 95% CI: 0.90-3.59), while Cluster 2 had a lower risk (OR = 0.79, 95% CI: 0.43-1.38), reflecting divergent immunometabolism profiles among smokers.

Conclusions: Smoking accelerates immunometabolism alterations during pulmonary nodule evolution, with select blood biomarkers (e.g., CEA, MCV, MONO%) mediating its oncogenic impact. Integrative modeling identified a high-risk biological subtype with a nearly fivefold increase in lung cancer risk, supporting biomarker-driven stratification in smokers with indeterminate nodules.

P3.01.40 10 Years Post Implementation of a Smoking Cessation (SC) Program in Regional Cancer Centres in Ontario, Canada:Successes and Ongoing Challenges

W.K. Evans[1,2], M. George[1], R. Crotta[1], B. Pradeep[1], G. Espino[1]
[1]Ontario Health (Cancer Care Ontario), Toronto/ON/CA ,[2]McMaster University, Hamilton/ON/CA

Introduction: In 2012, Cancer Care Ontario began screening for the smoking status of new ambulatory cancer patients in Ontario's 14 regional cancer centers (RCCs). Individuals who had smoked in the past 6 months were to be advised of the health benefits of (SC) and current tobacco users were offered referral to SC services (SCS). RCCs were required to appoint a Regional SC champion and in 2015, to begin submitting data on the proportion of new ambulatory cancer patients screened for tobacco use, advised on the benefits of quitting, and referred to comprehensive SC support services. In 2018, RCCs were encouraged to implement an opt-out approach when utilizing the 3As (Ask, Advise, Act) brief SC intervention model. The provincial program supported RCCs with data management, a clinical leader who provided educational sessions at RCCs on the value of SC; e-learning modules for providers and patients; posters/pamphlets on the benefits of quitting for patients and other ongoing resources. Although the volume of new ambulatory patients per center varies widely (130 to 1,000 per month), each center receives the same amount of central funding support for SCS.

Methods: The individual RCC SC program performance metrics are reviewed quarterly with the regional champions and during an annual in-depth discussion of successes and challenges with provincial and regional leadership. Trends since the beginning of data capture in 2015 and results from the Q2 2024/25 review are presented against targets and access to SCS.

Results: Since 2015, the performance metrics for screening, advising and referring current tobacco users to SC services have shown steady improvement, except during Covid 19. However, the performance by RCC has shown considerable variability across the 14 centers. In Q2 of 2024/25, the provincial rate (PR) for screening for tobacco use was 63.5%, range 40.4-96.0%; six centers exceeded the provincial target of 75%. Greater variability existed in advising (PR 68.1%, range 0-91%) and referring patients to cessation services (PR 69.7%, range 13.8.-98.3%). Five RCCs have dedicated on-site quit coaches, 10 RCCs have internal referral options (e.g., STOP program, hospital pharmacists, on-site group sessions) and all centers can refer to a quit line (Health811). Three centers use survey questions at electronic kiosks to ask about tobacco use, quit attempts and cessation aids alongside regular symptom management screening tools. Inconsistencies in the SCS offerings across RCCs and limited adoption of the tobacco use survey hamper the program's ability to evaluate the effectiveness of the SCS interventions in helping cancer patients quit. Challenges to uniform implementation include size of cancer center, population demographics, extent of funding and human resources for internal SCS supports, variable SC offerings, different EMRs and/or recent implementation of new IT systems (EPIC, Cerner, Mosaiq, Aria), and variable access to free NRT. The introduction of virtual visits during the Covid 19 pandemic contributed to a reduction in all metrics.

Conclusions: Best performance was seen in RCCs with committed leadership, HCP role descriptions that included responsibility to discuss SC with patients, funding appropriate for patient volumes, access to free NRT and on-site counselling.

P3.01.41 Impact of Smoking Status on Survival and Radiation Toxicity in Lung Cancer Patients Receiving RT

J.S. Pavão[1], M.T. Bento[1], T.R. Dias[1], L.B. Assunção[1], G.L. Cunha[1], R.B. Aguiar[1], J.V. Melo[2], R. Ferrari[3], G.B. Freire MD[3], E. Fuks MD[3], L. Franco MsC[3], P. Canary MD MsC[3], C.E. Almeida PhD[3], D. Przybysz MD[3]
[1]Petropolis Medical School, Petrópolis/BR ,[2]CTO (oncology therapy center), Petrópolis/BR ,[3]RadioSerra Radiation Therapy, Petrópolis/BR

Introduction: Although smoking is widely recognized as a leading cause of lung cancer, its direct impact on radiotherapy outcomes—particularly regarding survival and treatment-related toxicity—remains insufficiently understood. This study aims to clarify the relationship between smoking status, radiation-induced pulmonary toxicity, and survival outcomes in lung cancer patients undergoing radiotherapy, with the goal of informing more personalized and effective treatment strategies.

Methods: A retrospective review was conducted on 207 lung cancer patients treated with radiotherapy from 2020 to 2024. Patients were categorized based on smoking status: active smokers (11%), ex-smokers (50%), and non-smokers (39%). Radiotherapy was delivered with either curative or palliative intent. Key dosimetric variables included lung volumes receiving at least 5% (V5%) and 20% (V20%) of the prescribed dose, along with mean lung dose (MLD). Primary endpoints were overall survival (OS) and incidence of Grade ≥2 radiation pneumonitis. OS was analyzed using Kaplan-Meier estimates and Cox proportional hazards models; toxicity data were assessed using chi-square tests.

Results: Active smokers had significantly worse OS compared to non-smokers (median OS: 12 vs. 20 months, p=0.004). Ex-smokers showed intermediate survival outcomes, suggesting ongoing effects of past tobacco exposure, with 2-year OS ranging from 68.1% to 78.9%. Grade ≥2 radiation pneumonitis was more prevalent among active smokers (22%) than non-smokers (12%, p=0.03), and they also experienced higher rates of pulmonary fibrosis. Dosimetric analysis revealed significantly elevated V20% values in smokers, indicating greater exposure of lung tissue to harmful radiation levels. No significant differences were observed in MLD or V5% between groups. These findings highlight the dual negative impact of active smoking on both survival and radiotherapy-induced toxicity.

Conclusions: Active smoking is associated with significantly reduced survival and increased pulmonary toxicity in lung cancer patients receiving radiotherapy. Higher V20% values among smokers may partially explain the increased incidence of radiation-induced lung injury. These results underscore the importance of integrating smoking cessation programs into oncologic care and the potential value of personalized, adaptive radiotherapy planning for patients who smoke. Future research should explore the underlying biological mechanisms—such as tumor hypoxia and inflammation—that may mediate these effects, aiming to further refine treatment approaches for this high-risk population.

P3.01.42 Transitions in Cigarette and E-Cigarette Use in the PATH Study: A Multistate Transition Model Analysis of Us Adults by Race and Ethnicity

R. Torres Alvarez[1,2], A.F. Brouwer[3], J. Jeon[3], E. Jimenez-Mendoza[3], R. Meza[1,2]
[1]BC Cancer Research Institute, Vancouver/BC/CA ,[2]University of British Columbia, Vancouver/BC/CA ,[3]University of Michigan, Ann Arbor/MI/USA

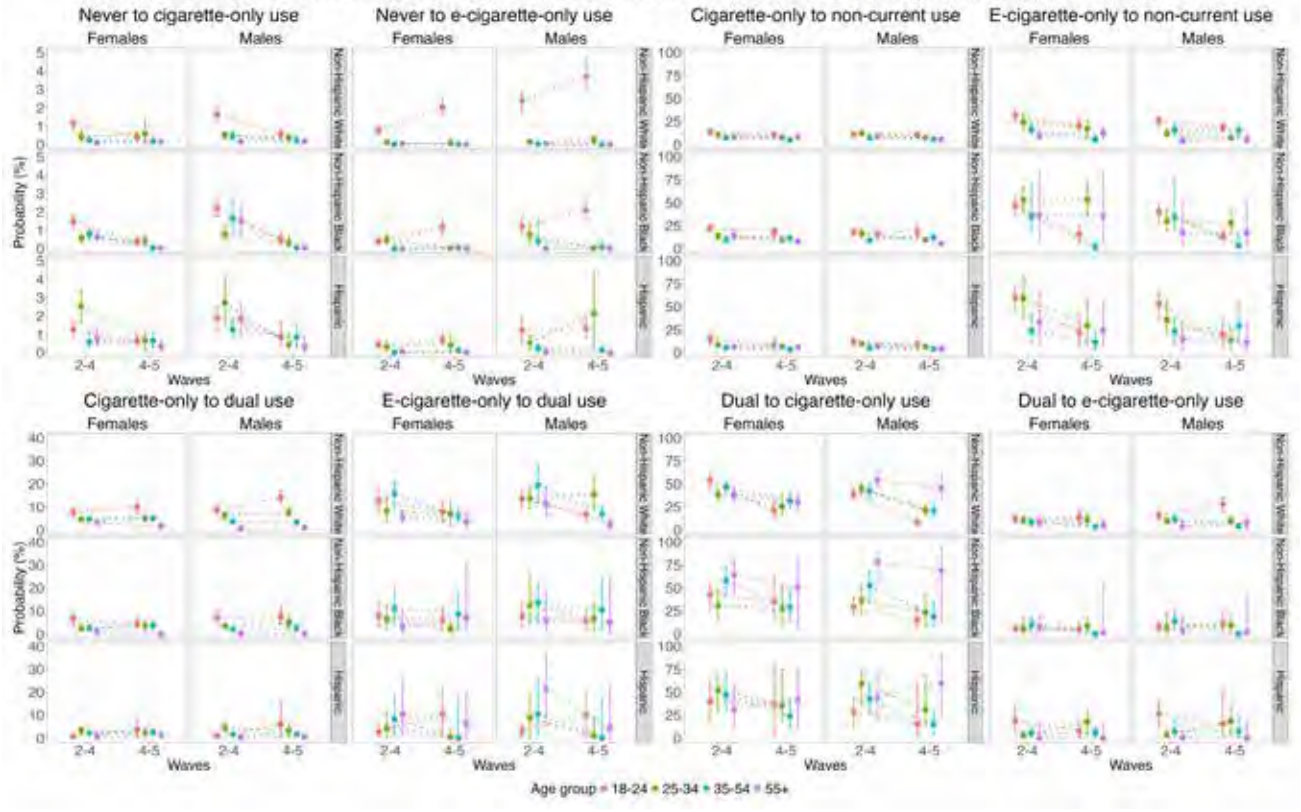
Introduction: While e-cigarette use has increased in US adults, cigarette smoking has reached historical lows, particularly in younger adults. However, use patterns and trends vary considerably by race and ethnicity.

Methods: We used a Markov multi-state transition model to estimate probabilities of exclusive and dual cigarette and e-cigarette use initiation, cessation, and switching between these products using data from the Population Assessment of Tobacco and Health Study (PATH). We calculated transition probabilities (%) for two, two-year PATH wave-periods (Wave 2-4 [2015-17] and Wave 4-5 [2017-19]) by sex (Males/Females), age (18-24, 25-34, 35-54, 55+ years), and race/ethnicity (Non-Hispanic White (NHW), Non-Hispanic Black (NHB), Hispanic).

Results: Cigarette initiation probabilities decreased between the two periods across all racial/ethnic and age groups, with the largest declines observed among NHB and NHW individuals and smaller declines among Hispanic adults. E-cigarette initiation had the opposite pattern, with the greatest increases in NHW adults ages 18-24, with initiation rising from 2.4% to 3.7% for males and from 0.8% to 2.0% for females. Cigarette cessation probabilities decreased for all groups, with the most significant decline in NHB males aged 55+ (from 15.5% to 5.3%). E-cigarette cessation decreased in most groups, with the largest declines in the NHB individuals aged 18-24 or 35-54. The probability of transitioning from cigarette-only to dual-use remained approximately constant in most groups, but there was a statistically significant increase in NHW males, rising from 8.6% to 14.0%. The transition from e-cigarette-only to dual-use significantly declined for NHW males aged 18-24 or 55+. Transitions from dual to cigarette-only use statistically significantly decreased among NHW females aged 18-24 or 35-54 and males in all age groups except 55+. However, transitions from dual to e-cigarette-only use increased in most groups, although these changes were not statistically significant.

Conclusions: Transitions in cigarette and e-cigarette use across race/ethnicity and age groups are changing, revealing declines in cigarette-only initiation, with the most significant decreases among NHB and NHW individuals. E-cigarette initiation is on the rise, particularly among young NHW adults. These patterns indicate a shift toward e-cigarette use among younger NHW adults, while adult cigarette use continues to decrease across all demographics.

Figure 1. One-year transition probabilities of exclusive and dual cigarette and e-cigarette use initiation, cessation, and switching for adults in the Population Assessment of Tobacco and Health Study (PATH). Each panel shows the probabilities and their confidence intervals from 2015-2017 (waves 2-4) and 2017-2019 (waves 4-5) by age, sex, and race/ethnicity.



Keywords: e-cigarettes, cigarettes, transition probabilities

P3.01.44 Comparison of Age-Adjusted Charlson Comorbidity Index and Modified Frailty Index as a Postoperative Prognostic Indicator for Lung Cancer

M. Yotsukura, R. Sakata, T. Haruki, Y. Yoshida, S-i. Watanabe
National Cancer Center Hospital, Tokyo/JP

Introduction: With the increase in the number of elderly patients with lung cancer, comorbidities at the time of surgery are becoming more important when considering surgical indications. We investigated the usefulness of the Age-adjusted Charlson Comorbidity Index (ACCI: an index based on 19 factors including heart disease, diabetes, liver function, history of cancer, and age) and the Modified Frailty Index (mFI-11: an index based on 11 factors including hypertension, diabetes, and a history of angina pectoris) in predicting prognosis.

Methods: We included 422 patients aged 75 years or older who underwent resection of primary lung cancer at our hospital between 2007 and 2012 in this study. We calculated the ACCI and mFI-11 for each patient and retrospectively examined their relationship with postoperative prognosis.

Results: The median age of the patients was 78 years (range: 75-87). The ACCI scores were 4/5/6/≥7 in 210 (49.8%)/130 (30.8%)/48 (11.4%)/33 (7.8%) patients, respectively. The mFI-11 scores were 0/1/2/≥3 in 171 (40.5%)/170 (40.3%)/68 (16.1%)/13 (3.1%) patients, respectively. The estimated 5-year survival rates for mFI-11 of 0/1/2/≥3 were 82.3%/83.1%/84.3%/65.3%, respectively, with no difference among the scores (p=0.56). For ACCI, the estimated 5-year survival rates for 4/5/6/≧7 were 86.6%/79.5%/73.6%/77.6%, respectively, with a significant difference among the scores (p=0.04). Univariate analysis showed that patients with vascular invasion (p<0.01), non-adenocarcinoma (p=0.03), a history of smoking (p<0.01), lobectomy or more (p=0.04), male (p=0.04), stage 2 or more (p<0.01), and ACCI 5 or more (p=0.01) had a poor prognosis. In multivariate analysis, vascular invasion (p<0.01), pathological stage 2 or more (p<0.01), and ACCI 5 or more (p=0.01) were shown to be independent poor prognostic factors.

Conclusions: Although both the ACCI and mFI-11 are used as indicators of postoperative comorbidities and surgical tolerance, the non mFI-11 but ACCI is useful as a prognostic factor for lung cancer patients aged 75 years or older after surgery.

Keywords: Comorbidity Index, Frailty Index

P3.01.45 Restrictive Lung Function and Smoking Increase Lung Cancer Risk in Tuberculosis Survivors: A Cohort Study

Y-G. Lee, H-I. Gil, B-G. Kim, H. Lee, Y.H. Kim, H. Nam, S-Y. Ham, D-Y. Kang, J-U. Song
Samsung Kangbuk Hospital, Seoul/KR

Introduction: Tuberculosis (TB) survivors are at an elevated risk for lung cancer due to chronic inflammation and following pulmonary damage. Although prior studies have consistently shown a link between previous TB infection and increased lung cancer risk, specific pulmonary functional abnormalities predictive of lung cancer development remain unclear. This study aimed to investigate the pulmonary function patterns and additional clinical risk factors significantly associated with lung cancer occurrence in a cohort of TB survivors

Methods: Using data from the Kangbuk Samsung Cohort Study (2011-2021), we analyzed 9,734 TB survivors (median follow-up: 12.3 years). Lung function was assessed via prebronchodilator spirometry and categorized as normal (FEV1/FVC ≥0.7, FVC ≥80% predicted), restrictive (FEV1/FVC ≥0.7, FVC <80%), or obstructive (FEV1/FVC <0.7). Lung cancer diagnoses were confirmed by linkage with the Korea National Cancer Incidence Database, excluding cancers diagnosed within one year of baseline assessment to avoid reverse causation. Multivariable Cox proportional hazards models evaluated associations between lung function, smoking, alcohol consumption, comorbidities, and lung cancer risk, adjusting for age, sex, and covariates.

Results: Participants were predominantly male (65.4%), with an average age of 41.2 years. Over a median follow-up of 12.3 years, lung cancer developed in 22 participants. Univariate analysis identified restrictive (HR 2.58, 95% CI 1.00-6.65; p=0.050) and obstructive pulmonary patterns (HR 6.48, 95% CI 2.05-20.43; p<0.001), older age (HR 2.35 per 5-year increase; p<0.001), heavy smoking (≥20 pack-years; HR 6.62; p<0.001), diabetes (HR 6.40; p=0.003), and alcohol consumption (≥20 g/day; HR 3.05; p=0.019) as significant risk factors for lung cancer. In multivariable models, restrictive lung function (HR 2.94, 95% CI 1.00-8.65; p=0.050), age (HR 2.35; p<0.001), and heavy smoking (HR 3.00; p=0.050) persisted as independent risk factors. Obstructive lung function lost significance after adjusting for covariates, indicating confounding by smoking.

Conclusions: This study highlights restrictive lung function, likely indicative of post-TB fibrotic changes, heavy smoking, and older age as significant predictors of lung cancer development in TB survivors. The findings underscore the utility of spirometry in identifying high-risk individuals and emphasize the need for surveillance strategies to enhance early detection and prevention of lung cancer in this vulnerable population. Our results suggest that post-TB fibrotic changes may contribute to oncogenesis, supporting the importance of monitoring lung function in TB survivors.

P3.01.46 Characterization of Patients With Lung Cancer Not Meeting Lung Cancer Screening Criteria: Identifying a High-Risk Group Beyond Tobacco Smoking

J.C. Laguna[1,2,3], A. Moll[1], M. Jiménez[2], J. Mena-Guerrero[2], M. Potrony[1], L. Moreno[1], E. Grau[1], T. Gorria[1,2,3], M. Ferriol-Galmés[2,4], M. Liu[2], O. Castillo[2], N. Reguart[1,2], A. Arcocha[1], X. Solé[1,2], J.A. Puig-Butillé[1], C. Teixido[1,2], T. Ramon y Cajal[1], L. Mezquita[1,2,3]
[1]Hospital Clinic Barcelona, Spain/ES ,[2]Institut D'Investigacions Biomèdiques August Pi I Sunyer (IDIBAPS), Barcelona/ES ,[3]University of Barcelona, Barcelona/ES ,[4]Universidad Politecnica de Cataluña, Barcelona/ES

Introduction: Lung cancer screening (LCS) based on smoking criteria reduces mortality through early detection. However, many non-small cell lung cancer (NSCLC) cases arise in individuals excluded from LCS programs. We aimed to characterize the clinical and tumor profiles, as well as familial and individual susceptibility in patients with NSCLC who didn't meet LCS criteria to identify a high-risk population beyond tobacco smoking.

Methods: Prospective study of 350 patients with all-stages NSCLC treated at Hospital Clinic (Spain) between 10/2020-01/2025. After signature of the informed-consent form, patients had a personal interview to collect personal/family history of cancer (three-generation pedigree) (PHC, FHC), demographic data, and exposure to environmental carcinogens. Clinical and tumor data was collected from medical records. Patients were classified as LCS-eligible or ineligible at the time of NSCLC diagnosis according to Nelson criteria (50-74 years old (yo) current or former smokers [who had quit ≤10 years ago] who had smoked >15 cigarettes a day for >25 years or >10 cigarettes a day for >30 years). The patient/tumor/family profile was analyzed in each LCS-ineligible group and compared with LCS-eligible patients.

Results: Out of 350 patients enrolled, 217 (62%) didn't meet LCS criteria, due to age (34%), NSCLC diagnosis >10 years after tobacco cessation (25%), never-smoking status (21%), or low tobacco exposure (19%). Among LCS-ineligible group, median age was 43 in <50 yo (30-49) and 79 in >74 yo (75-90) groups, 47% were female (53% of female in those aged ≤ 50 yo), 28% non-smokers, 70% with FHC of 1st-degree relative and 31% with PHC. 59% of cases were diagnosed at stage IV, with adenocarcinoma as predominant histology (78% vs. 64%, p<0.001). A high prevalence of driver alterations was observed in the LCS-ineligible group (80% vs. 52%, p<0.001), including 30% KRASm (n=64), 24% EGFRm (n=51) and 8% ALKf (n=17). Different prevalence was observed in LCS-eligible group, with 31% KRASm (n=39), 4% EGFRm (n=5) and <1% ALKf (n=1) in LCS-eligible patients. Regarding FHC, the prevalence of 1st-degree affected relatives was similar in both groups (69% in the LCS-ineligible group vs. 74% in the LCS-eligible group). However, the LCS-ineligible group due to non-smoking status showed the highest rate of FHC (82%), particularly colorectal (20%), breast (18%), and lung (12%) cancers with a median of two 1st-degree relatives affected. Surprisingly, we don't find a higher rate of FHC among young compared to LCS-eligible patients (59 vs 74%). Distinct PHC spectra was observed between groups: non-smoking-related tumors such as breast (20%), prostate (19%), and colorectal (13%) cancers were more frequent in LCS-ineligible patients vs. urinary bladder (32%) and head and neck cancers (10%) in LCS-eligible patients.

Conclusions: LCS current criteria exclude a significant proportion of individuals that will develop NSCLC. FHC may help to identify a high risk-population in LCS-ineligible group, particularly in non-smokers which may benefit of LCS. However, a deeper characterization of this population is needed to develop more inclusive criteria for LCS.

Introduction: Lung cancer is a major public health problem. Computed tomography lung cancer screening (LCS) significantly reduces lung cancer mortality. The most effective and efficient ways to implement LCS are unknown. The ENGAGE framework adapts screening intervals based on a dynamic, individualized assessment of tradeoffs between expected benefits and potential harms related to screening. ENGAGE has been shown to be superior to fixed interval and other adaptive screening-interval approaches. The ENGAGE approach estimates lung cancer risk, incorporates life expectancy, and uses simulation to estimate the optimum time to the next screening. The PLCOm2012 lung cancer risk prediction model was adapted for application in ENGAGE by categorizing some of the continuous predictors. We present ENGAGE versions of PLCOm2012 and their validation.

Methods: Cox proportional hazards regression was used to derive models. The outcome was incident lung cancer diagnosed within six years. Predictors included age, race and ethnicity, education, BMI, COPD, personal history of cancer, family history of lung cancer, and smoking status, smoking intensity, smoking duration, and quit-years in former smoking individuals. BMI and smoking intensity were converted from continuous into 4-level categorical variables (Table 1). Three models were produced with varied race/ethnicity categorization (Table 1). Predictive performances of these models were evaluated in PLCO intervention arm and NLST validation data. Comparisons were made between ENGAGE models and a Cox version of the original PLCOm2012 model. Predictive performance and calibration was evaluated using Harrell's c-statistic or receiver operating characteristic area under the curve (AUC), Brier statistic, Expected/Observed ratio, and Spiegelhalter's statistic p-value.

Results: Table 1 presents the models, and Table 2 compares their predictive performances. All models demonstrated good and comparable discrimination, calibration and validation.

Conclusions: Models with categorized continuous variables and variable race/ethnicity predictors demonstrated good predictive performance making them useful in simulation modeling and for different sociodemographic settings.

Table 1. Hazard ratios and 95% confidence intervals for predictors in three ENGAGE versions of the PLCOm2012 and the original PLCOm2012 (Cox model) version

Predictors	6-Race Model N=36,558	3- Race Model N=36,558	No-Race Model N=36,558	Cox PLCOm2012 N=36,498

P3.01.48 Familial Lung Cancer and Hereditary Patterns in NSCLC - Implications for Risk Redefinition

S. Wu[1], A. Esposito[1], A. Shroeder[2], C. Bestvina[1], M. Platta[1], M. Sacco[1], A. Pezeshk[1], K. Lugtu[1], M. Drazer[1], E. Vokes[1], S. Mukherjee[2], K. Odunsi[1], M. Garassino[1]
[1]University of Chicago, Chicago/IL/USA ,[2]Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: While tobacco remains the primary cause of lung cancer, up to 25% of cases occur in never-smokers, suggesting additional risk factors. A positive family history (FHx) increases risk by 2 to 3 folds, pointing to a heritable component that may interact with environmental exposures. Lung cancer incidence is rising in younger women and now surpasses that of men under 65; notably, lung cancer in never-smokers is more common in females. These patterns underscore the need to better define high-risk populations, where genetic susceptibility and environmental factors may contribute. This study evaluates the burden and patterns of cancer FHx in lung cancer to inform future risk stratification.

Methods: We retrospectively analyzed a curated cohort of 2,037 lung cancer patients with clinical, demographic, and social history at the University of Chicago (2014-2024). Patterns associated with family history and genetic profiles were evaluated.

Results: Among the 2,037 lung cancer patients, 92.2% (n=1,879) had non-small cell lung cancer (NSCLC) and 7.7% (n=158) had small cell lung cancer (SCLC). Mean age at diagnosis was similar (65.4 for NSCLC vs. 66.1 for SCLC). Adenocarcinoma was the most common NSCLC subtype (84.0%), with 41.0% diagnosed at Stage IV. Among SCLC patients, 72.2% had extensive-stage disease. Most NSCLC patients were female (55.8%) and White (56.5%), followed by African American (33.0%) and Asian (3.6%). Overall, 18.6% of the cohort were never smokers. Among NSCLC patients with available family history data (n = 1,839), individuals were categorized into three groups: those reporting a lung cancer FHx (LCa FHx, 27.0%), a non-lung cancer FHx (non-LCa FHx, 46.4%), or no FHx of cancer (NegCa FHx, 26.6%). Females were significantly overrepresented in both the LCa FHx (60.9%) and non-LCa FHx (57.1%) groups, with no sex difference observed in the NegCa FHx group. FHx patterns also differed by race, with White (76.2%) and Black (67.7%) patients more likely to report any FHx of cancer than Asian. In early-stage NSCLC (Stage I-III), White and Black females were significantly more likely than their male counterparts to report a family history of lung cancer, with 1.37-fold and 2.0-fold higher, respectively ($p = 0.0179$ and 0.0197). This sex difference was insignificant in Stage IV, though a similar trend remained. Among former smokers, ATRX mutations were significantly more common in females ($\log_2 OR = -1.97$, FDR = 0.027), suggesting a sex-specific molecular pattern in NSCLC patients with a smoking history. Exploratory analysis using nominal p-values ($p < 0.05$) revealed sex-specific trends in FHx-associated mutations, including RET, AXL, ATR, EPHA5, and APC in males, and GRIN2A, ALK, EPHA3, ERBB2, CSF3R, RAD51, and STAT3 in females.

Conclusions: Cancer family history is common in lung cancer patients, particularly among women, and may reflect patterns of familial lung cancer. These findings support redefining high-risk populations using family history, sex, and ancestry. Underrepresented groups, such as those of Asian ancestry, highlight the need for multi-center studies. Prospective studies with detailed history and genetic testing are essential to uncover familial lung cancer, define genetic mechanisms, and guide personalized risk models, screening, and treatment strategies.

P3.01.49 A Pro-Mitotic Gene Expression Module in Small Airways Links COPD Severity to Non-Small Cell Lung Cancer

V.d.G. Pereira de Souza[1], E.A. Vucic[1,2], C. Zhang[3,4], B.Z. Wu[3,4], G.L. Stewart[1], C. MacAulay[1], S. Lam[1], K.S.S. Enfield[1,5], K.L. Thu[3,4], W.L. Lam[1,5]

Introduction: Chronic obstructive pulmonary disease (COPD) is the third leading cause of death globally, while lung cancer is the leading cause of cancer-related mortality worldwide. Cigarette smoking is the primary risk factor for both diseases; however, COPD confers a six-fold increased risk of lung cancer, independent of smoking history. The severity of COPD, indicated by decreasing forced expiratory volume in one second (FEV1%), is the strongest clinical predictor of lung cancer risk. We hypothesized that molecular signatures from small-airway tissues associated with reduced FEV1% could provide insights into the cancerization process in COPD-affected lungs.

Methods: We performed weighted gene co-expression network analysis on small airway epithelial (SAE) transcriptional profiles from 267 patients to investigate transcriptional changes associated with COPD severity and lung cancer risk. Functional enrichment analyses were conducted to characterize the biological processes associated with COPD severity. To determine whether SAE modules were transcriptionally active in lung tumors, we conducted a module preservation analysis using adenocarcinoma (LUAD; n = 433) and squamous cell carcinoma (LUSC; n = 474) tumor samples from TCGA dataset. Tumors were further analyzed for DNA, mRNA, and protein-level alterations (including mutation, copy number variation, and gene expression changes) in module genes associated with COPD severity. An independent cohort of sputum and bronchial biopsies (n = 3,270) was used to validate these findings. Finally, we performed functional experiments in airway epithelial (HBEC) and LUAD (H1299) cell lines to explore the functional role of genes in the COPD module.

Results: We identified a gene module containing 31 genes correlated with FEV1% and COPD status. This module was enriched for pathways regulating cell cycle progression, mitotic checkpoints, and DNA damage repair and was preserved in lung tumors (MedianRank = 1 LUAD and 2 LUSC). Multi-omic analysis of LUAD and LUSC tumors revealed that genes within this module underwent frequent somatic alterations, including TP53, which was frequently mutated, subjected to copy number variations, and transcriptionally dysregulated. LUAD tumors with alterations in module genes showed increased genomic instability compared to those without, including a significantly higher tumor mutational burden, enrichment for cell cycle activation, and downregulation of DNA repair pathways. Cytological and morphological abnormalities were validated in sputum and bronchial biopsies with increased lung cancer risk, correlating with reduced FEV1%. Among the 31 genes in this module, PLK4 was upregulated in reduced FEV1%. Since PLK4 deregulation is known to cause centriole overduplication, leading to centrosome amplification (CA) and genomic instability, we investigated its effects on these phenotypes in HBEC and LUAD cells. Overexpression of PLK4 significantly increased CA in both cell types, reinforcing its role in genomic instability related to lung cancer.

Conclusions: Our findings provide evidence that lung cancer arises in the context of COPD from the transformation and oncogenic selection of small airway epithelial cells in which a pro-mitotic transcriptional program is activated. These data suggest that repetitive tissue injury and repair in COPD, exacerbated by smoking-induced damage, promote a transcriptional landscape conducive to tumorigenesis. These findings have implications for biomarker discovery and early detection in high-risk individuals.

P3.01.50 Association Between Chronic Lung Diseases and Lung Cancer: A Bidirectional Two-Sample Mendelian Randomization Study

W. Zhu[1], C. Liang[2]
[1]china-japan friendship hospita, Beijing/CN ,[2]China-Japan Friendship Hospital, Beijing/CN

Introduction: Chronic lung diseases, including chronic obstructive pulmonary disease (COPD), idiopathic pulmonary fibrosis (IPF), asthma, and sleep apnea, share common risk factors with lung cancer, but their causal relationships remain unclear. This study employed bidirectional Mendelian randomization (MR) to investigate potential causal links between these conditions and major lung cancer subtypes.

Methods: We analyzed summary-level genetic data from large GWAS cohorts, including 20,898 chronic lung disease cases and 51,603 lung cancer cases. Single nucleotide polymorphisms (SNPs) associated with exposures ($p < 5\times10^{-7}$) were selected as instrumental variables. Inverse-variance weighted (IVW), MR-Egger, and weighted median methods were applied, with sensitivity analyses to assess pleiotropy and robustness.

Results: In forward MR analyses, COPD was causally associated with increased risk of lung adenocarcinoma (β=1.15, 95% CI: 1.01-1.32, P=0.0398) and squamous cell carcinoma (β=1.27, 1.05-1.58, P=0.0138). Reverse MR confirmed bidirectional relationships, showing all lung cancer subtypes increased COPD risk (all P<0.005). Asthma demonstrated unidirectional causality with squamous cell carcinoma (forward MR: β=1.24, 1.05-1.46, P=0.0125), but no reverse association (P=0.117). Similarly, sleep apnea showed forward effects on squamous cell carcinoma (β=1.00, 1.00-1.00, P=0.0456), though reverse analysis was unfeasible due to insufficient SNPs. No significant associations were detected for IPF in either direction (all P>0.05).

Conclusions: Chronic inflammation and shared etiological pathways may underlie the COPD-lung cancer relationship, while asthma and sleep apnea may promote squamous cell carcinoma via distinct mechanisms. These findings highlight the need for targeted screening in high-risk populations and further exploration of molecular interactions.

P3.01.51 Evidence Synthesis of Non-Screen-Eligible Cohorts and Implications for Lung Cancer Advocacy

L. Fine[1], U. Basu-Roy[1], M. Futrell[1], B. Leonard[1], E. Ell[2], E. Wu[2], A. Agarwal[2], V. Mittal[2], D. Moghanaki[3], K. Norris[4], M. Reid[5], J. Feldman[6]
[1]LUNGevity Foundation, Bethesda/MD/USA ,[2]Health Advances, San Francisco/CA/USA ,[3]David Geffen School of Medicine at UCLA, Los Angeles/CA/USA ,[4]Lung Cancer Foundation of America, Los Angeles/CA/USA ,[5]Roswell Park Comprehensive Cancer Center, Buffalo/NY/USA ,[6]Lung Cancer Patient and Advocate and Founder EGFR Resisters, Chicago/IL/USA

Introduction: Of the more than 234,000 people who will be diagnosed with lung cancer in 2025, roughly ~50% are ineligible for screening according to current USPSTF criteria. This limitation leaves many patients vulnerable to late-stage or delayed diagnosis and high mortality.

Methods: LUNGevity partnered with Health Advances to conduct an analysis of data from 9 separate cohorts outside of 2021 USPSTF guidelines. The quantitative and qualitative study was conducted with no a-priori hypothesis to see where the evidence leads. It included a review of 80 unique publications; real-world EMR and claims data, government databases, and in-depth interviews with 3 KOLs/subject matter experts.

Results: First, several barriers were identified that prevent screening of non-USPSTF cohorts today, including a high bar of evidence to change the guidelines, disease perception, and current technology shortfalls with LDCT. Historically only randomized controlled clinical trials supplemented with large cohort studies have driven expansion of screening eligibility. Secondly, it demonstrated elevated risk levels above the general population for each cohort. We conducted a structured prioritization of how LUNGevity and the advocacy community may reach targeted populations. Several of these cohorts have strong evidence bases as well as defined and accessible populations. Cohorts include: 1) Smoking history outside guidelines; 2) Personal history of cancer; 3) Family history of lung cancer; 4) Pulmonary comorbidities and 5) Asian Female (no smoking history). See Diagram.

Conclusions: Opportunities exist for the advocacy community to drive inclusion of the criteria for people with smoking history of >15 years since quit, adding nearly 5 million more eligible people. Additionally, there are potential ways to reach and impact other high priority cohorts. Finally, our analysis explores the possible role of risk-based models and emerging technologies including blood tests in shifting the balance of benefits/risk in favor of screening moderate-risk cohorts.

P3.01.52 Unseen Risks: Rethinking Lung Cancer Screening for Hispanic Communities

C. Olazagasti[1], C. Jani[2], D. Jayram[2], A. Meneses[1], A. Salazar[2], J. Montano[1], E. Rodriguez[1], F. Penedo[1], T. Crane[1], G. Lopes[1]
[1]Sylvester Comprehensive Cancer Center, Miami/FL/USA ,[2]University of Miami Miller School of Medicine, Miami/FL/USA

Introduction: Lung cancer screening (LCS) using low-dose computed tomography (LDCT) has been shown to significantly improve early detection and survival rates, as evidenced by landmark trials supporting LDCT's role in reducing lung cancer mortality. However, existing guidelines, particularly those from the U.S. Preventive Services Task Force (USPSTF), may miss many high-risk individuals. Emerging evidence suggests that expanding eligibility criteria, such as incorporating the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO) risk model, could better capture individuals at risk by considering a wider range of factors. The GUIAR trial (Promoting Lung Cancer Screening Awareness and Implementation in Hispanics/Latinx Head and Neck Cancer Survivors, NCT06124508) aims to address disparities in LCS among Hispanic/Latinx populations, investigating barriers to screening and comparing eligibility between USPSTF and PLCO criteria.

Methods: In the GUIAR trial, we assessed LCS eligibility in Hispanic/Latinx survivors of head and neck cancer (HNC) through survey-based tools. We identified patients who met USPSTF criteria and separately categorized those who qualified under PLCO criteria but not USPSTF. PLCO eligibility was evaluated in two ways: assuming White race and assuming Hispanic race, creating distinct groups for comparison. Variables including gender, smoking status, COPD, cancer history, family history, age, cigarettes per day, smoking years, pack-years, and BMI were compared across groups using chi-square tests for categorical data and Mann-Whitney U tests for continuous data.

Results: Since August 2024, 199 patients have been screened, with 18 enrolled based on USPSTF criteria. Of those not enrolled, 16 patients met PLCO Hispanic criteria, and 21 met PLCO White criteria with a risk score above 1.5%. Compared to USPSTF criteria, patients eligible under PLCO were significantly older (PLCO Hispanic: 81 ± 11.6 vs. 65 ± 7.3 years, $p < 0.01$; PLCO White: 78.8 ± 12 vs. 65.1 ± 7.2, $p < 0.001$), had a lower BMI (PLCO Hispanic: 23.8 ± 3.7 vs. 26.6 ± 3.1, $p = 0.076$; PLCO White: 23.5 ± 3.7 vs. 26.6 ± 3.1, $p = 0.026$), and smoked fewer cigarettes per day (PLCO Hispanic: 21 ± 7.7 vs. 27.5 ± 7.5, $p = 0.026$; PLCO White: 21.4 ± 9.0 vs. 27.5 ± 7.5, $p = 0.026$). No significant differences were observed in gender, COPD, cancer history, family history, or pack-years.

Conclusions: Our findings underscore the limitations of USPSTF criteria in identifying high-risk Hispanic HNC survivors for LCS. By using PLCO criteria, eligibility expanded significantly, with variations based on racial classification. More patients qualified under PLCO when race was classified as White, revealing the complexity of screening Hispanic populations. These patients were older, had lower BMI, and smoked fewer cigarettes per day, suggesting that USPSTF criteria may miss at-risk individuals with different risk profiles. Incorporating broader models like PLCO could improve early detection and help reduce disparities in lung cancer mortality.

P3.01.53 Germline EGFR Mutations Are Enriched in the Southeast United States and Associated With High Penetrance of Non-Small Cell Lung Cancer

J. O'Brien, R. Ramaker, L. Alder, J. Clarke
Duke University Hospital, Durham/NC/USA

Introduction: Routine use of next generation sequencing in non-small cell lung cancer (NSCLC) has enabled identification of multiple targetable oncogenic variants and germline variants that may predispose patients to cancer. Recent publications suggest that 1% of patients with NSCLC harbor germline EGFR mutations and that 55% of these individuals were affected by NSCLC. We sought to better understand the prevalence of germline EGFR mutations.

Methods: We performed a retrospective analysis of patients with clinical germline mutations catalogued within the Duke Molecular Registry of Tumors and patients who enrolled in the Duke CATHGEN study, which enrolled patients who presented to the cardiac catheterization laboratory for any reason for germline genetic testing. Of patients who underwent testing, patients with EGFR mutations were identified. We queried the dataset from the All of Us Research Program to identify individuals with germline EGFR mutations and their geographic location. This program is an ongoing federally funded study that seeks to sequence one million or more individuals and prospectively monitor their health data. We also queried the gnomAD database which is an international genome aggregation database composed of exome and genome sequences from ~800,000 individuals.

Results: A total of 68 individuals with germline EGFR mutations were identified in the data from the All of Us Research program in a total of 414825 (1 in 6000). We found 85 total individuals with germline EGFR mutations were identified in the gnomAD dataset in a total of 807050 (1 in 9400). The most common mutations in both datasets were T790M, E330K, R776H, V843I, D761N, P596L, and T725M. Four of the most common EGFR variants, T790M, R776H, D761N, and T725M, have been associated with hereditary lung cancer representing 60% of identified mutations across both datasets. Germline EGFR T790M mutations were regionally enriched in the southeast United States in this cohort. We identified 3 individuals with germline EGFR mutations in the Duke CATHGEN study cohort of 10,000 patients tested, all of which were T790M mutations. Of these individuals, one has been diagnosed with lung cancer and another has a diagnosis of lung nodules. This represents a tenfold increase in the EGFR T790M germline mutation frequency in the Duke catchment area compared with the data from All of Us or gnomAD datasets. We have also identified 23 patients in seen in our clinics over the last 8 years with putative EGFR germline mutations, 20 with NSCLC, 3 with other malignancies.

Conclusions: Multiple variants of germline EGFR mutations are found across the United States and internationally. The most common of these germline variants are associated with a hereditary risk for lung cancer. Prevalence of germline EGFR T790M mutations is enriched in the southeast United States. Given the increased hereditary risk, this warrants studies investigating the role of familial testing and screening in these individuals.

P3.03.01 Rb Inactivation as a Hallmark of Squamous Transformation in EGFR-Mutant Lung Cancers

M.Y. Jeng, A. Dymun, A. Elkrief, A.L. Richards, S.R. Yang, M.T.A. Donoghue, M.G. Kris, C. Rudin, C. Wilhelm, A. Quintanal Villalonga, H.A. Yu
Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Histologic transformation to squamous carcinoma (LUSC) is a resistance mechanism in EGFR-mutant lung adenocarcinoma (LUAD), occurring in 5-8% of patients receiving osimertinib and associated with poorer outcomes. While our prior work implicated the AKT pathway as a promoter of LUSC transformation, a comprehensive genomic characterization of this process remains lacking.

Methods: We performed genomic characterization (MSK-IMPACT) on EGFR-mutant specimens undergoing LUSC transformation, including pre- and post-transformation tumors from TKI-treated patients. Time-to-treatment discontinuation (TTD) was analyzed in patients with EGFR-mutant lung cancer on frontline osmertinib (n=177). Xenograft models of squamous transformation (HCC827 cell lines overexpressing Myc and myrAKT +/- Rb inactivation) were treated with osimertinib, and cellular phenotype was assessed using immunohistochemistry (IHC) and single-cell RNA sequencing.

Results: Among patients with EGFR-mutant lung cancer undergoing LUSC transformation (n=20), 50% and 60% had alterations in the AKT or Rb pathway, respectively. In contrast, patients with never-transforming EGFR-mutant LUAD (n=1515) trended towards fewer alterations in the AKT (18%) or Rb (32%) pathways. Patients with EGFR-mutant LUAD harboring Rb and/or AKT (Rb/AKT) pathway mutations (n=70) experienced shorter TTD on frontline osimertinib (median 18 vs 23 months, p=0.03; Figure 1) compared to a Rb/AKT wild-type cohort (n=107); TP53 co-mutations were similar between groups. In xenograft models treated with osimertinib, Rb inactivation via CRISPR deletion of Rb1 or upstream regulators (CDKN2A/B) promoted a squamous-like phenotype, demonstrated by increased P40 and CK5/6 protein expression and single-cell transcriptomic profiling (Figure 2). Rb inactivation also resulted in more rapid in vivo tumor growth during osimertinib treatment compared to controls.

Conclusions: Rb and AKT pathway alterations occur often in EGFR-mutant lung cancers with LUSC transformation and are associated with shorter osimertinib benefit. Rb inactivation promoted a squamous-like phenotype and osimertinib resistance in preclinical models. Detecting these mutations may help identify patients at high risk of treatment resistance and transformation.

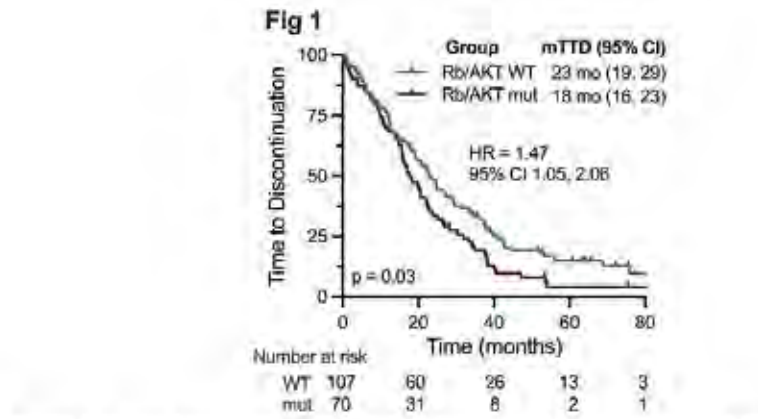

Figure 1. Kaplan-Meier curve of median time-to-treatment discontinuation (mTTD) for patients with *EGFR*-mutant lung cancer on frontline osimertinib with (mut) and without (WT) Rb/AKT pathway mutations.

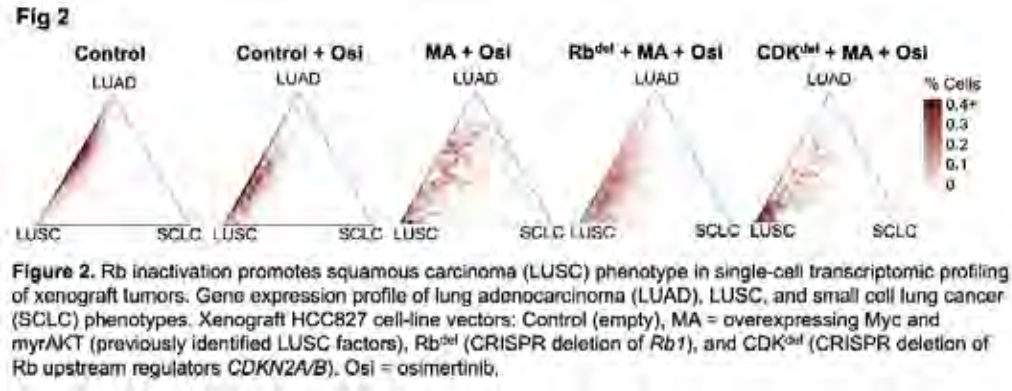

Figure 2. Rb inactivation promotes squamous carcinoma (LUSC) phenotype in single-cell transcriptomic profiling of xenograft tumors. Gene expression profile of lung adenocarcinoma (LUAD), LUSC, and small cell lung cancer (SCLC) phenotypes. Xenograft HCC827 cell-line vectors: Control (empty), MA = overexpressing Myc and myrAKT (previously identified LUSC factors), Rb^{del} (CRISPR deletion of *Rb1*), and CDK^{del} (CRISPR deletion of Rb upstream regulators *CDKN2A/B*). Osi = osimertinib.

P3.03.02 WEE1 as the Target for Circumvention of ARID1A Mutation-Driven Osimertinib Resistance in EGFR-Mutated Lung Cancer

S. Yano[1], K. Fukuda[1], S. Nanjo[1], S. Takeuchi[1], S. Arai[1], S. Sato[1], H. Kotani[1], A. Nishiyama[1], H. Sakaguchi[1], K. Ohtsubo[1], H. Taniguchi[1], T.G. Bivona[2]
[1]Kanazawa University, Kanazawa/JP ,[2]University of California, San Francisco, San Francisco/CA/USA

Introduction: Osimertinib, a third-generation epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI), is widely used as a first-line treatment for EGFR-mutant non-small cell lung cancer (NSCLC). Despite its efficacy, resistance—particularly in cases involving central nervous system (CNS) metastases—remains a major clinical challenge, with the underlying mechanisms largely unknown. This study aimed to investigate the mechanisms driving osimertinib resistance and identify novel therapeutic strategies.

Methods: Using a mouse model of leptomeningeal carcinomatosis (LMC), we induced osimertinib resistance and performed next-generation sequencing to characterize resistance-associated mutations. Additionally, we analyzed clinical samples to correlate ARID1A status with progression-free survival in patients receiving osimertinib.

Results: Among these, mutations in the AT-rich interacting domain-containing protein 1A (ARID1A) gene were the most prevalent in resistant cells. Functional assays revealed that ARID1A knockout in parental cells and wild-type ARID1A gene expression in resistant cells played a critical role in conferring osimertinib resistance. A CRISPR-Cas9 knockout screen identified WEE1 kinase inhibition as potent enhancers of apoptosis in ARID1A-mutant osimertinib-resistant cells. Mechanistically, ARID1A-mutant cells exhibited reduced expression of genes involved in cell cycle regulation and DNA repair, rendering them particularly sensitive to WEE1 inhibition. In vivo, the combined inhibition of EGFR and WEE1 significantly suppressed tumor growth in the LMC mouse model. Clinically, patients with ARID1A mutations had markedly shorter median progression-free survival on osimertinib (6.25 vs. 18.0 months, p=0.0036) than those with wild-type ARID1A.

Conclusions: These findings suggest that ARID1A mutations are critical biomarkers for osimertinib resistance and highlight WEE1 inhibition as a promising therapeutic approach for ARID1A-mutant osimertinib-resistant NSCLC.

P3.03.03 Mechanisms of Osimertinib Tolerance in Mutant EGFR Lung Cancer PDX Models

N-A. Pham[1], Q. Li[1], A. Arivajiagane[1], Y. Inoue[1], M. Mikubo[1], K. Hueniken[1], N. Leighl[1], G. Liu[1], M-S. Tsao[2]
[1]Princess Margaret Cancer Centre, Toronto/ON/CA ,[2]University Health Network, Toronto/ON/CA

Introduction: Understanding the cell state transitions of EGFRmut-driven drug-tolerant or persister states leading to acquired genetic resistance alterations remain obscure. Investigations on tumor biopsies from advancing disease are a challenge due to limited timepoints, specimens and low tumor cellularity. We here evaluated the drug tolerant states of two patient-derived xenograft (PDX) lung adenocarcinoma models with osimertinib (osi) sensitive EGFRL858R and EGFRex19del mutations to study the mechanisms of drug tolerance.

Methods: PHLC4672 was established from a liver metastatic lung adenocarcinoma with EGFRL858R of a patient previously treated with osi followed by standard of care conventional chemo- and radiation therapies. PHLC137 was derived from a primary resected lung adenocarcinoma with EGFRex19del mutation (Stewart et al., J Clin Oncol 2015;33:2472-80). Viable cryo-banked donor tumor fragments were grown in the subcutaneous flank of NOD SCID mice. Osimertinib was orally administered daily at 25 mg/kg until the mean lowest tumor volume was reached and continued 2 weeks on osi to endpoint. Bulk and single-nuclear RNA (snRNA) sequencing methods were used to identify differential expressed genes (DEGs) between osi- and vehicle-treated tumors based on fold changes in each model. Gene set enrichment analysis was performed on DEGs based on Hallmark 2020, Molecular Signatures Database, to identify enriched pathways.

Results: PHLC4672 showed an osi-induced G1 tumor growth arrest without size reduction, typical of a stable disease response. This contrasted to PHLC137 that formed drug-tolerant-persister (DTP) tumor following marked initial tumor size reduction. Single cell and bulk RNA analyses showed that the drug tolerant cell state in tumors of PHLC4672 compared to vehicle-treated tumors was associated with primarily a down regulation of proliferation associated genes including G2M checkpoint, E2F targets, mitotic spindle and glycolysis. In addition to down regulation of proliferation associated pathways, PHLC137 DTP tumor showed an upregulation in genes enriched in pathways associated with NFκB, epithelial mesenchymal transition and stress pathways including P53 and apoptosis.

Conclusions: Drug tolerance in osimertinib-induced DTP and non-DTP tumors showed variable common growth arrest and distinctive changes in pathway alterations. These results provide additional insights to vulnerabilities and molecular cell adaptation associated with tumors to osimertinib-induced responses.

Keywords: drug tolerant persister, osimertinib, patient derived xenograft

P3.03.04 Aggressive Lymph Node Dissection Is Linked to Poor Survival and Impaired Anti-Tumor Immunity in Non-Small Cell Lung Cancer

M. Agkoç[1], D. Gashi[2], A. Engin[3], Ö.F. Sağlam[4], E. Çetin Aktaş[3], B. Kılıç[5], G. Deniz[3], A. Turna[5]
[1]Erzurum City Hospital, Erzurum/TR ,[2]Imperial College St Mary's Hospital, London/GB ,[3]Aziz Sancar Institute of Experimental Medicine, Istanbul/TR ,[4]Tokat State Hospital, Tokat/TR ,[5]Istanbul University-Cerrahpaşa, Cerrahpaşa Medical School, Istanbul/TR

Introduction: Perioperative systematic nodal dissection has been recommended for its survival benefit by improving staging accuracy and optimizing adjuvant treatment in patients with non-small cell lung cancer (NSCLC). However, the optimal extent of dissection and the ideal number of lymph nodes to be removed remain subjects of debate.

Methods: A total of 378 patients diagnosed with NSCLC who underwent surgical mediastinal staging prior to pulmonary resection at our institution between January 2010 and December 2023 were included. Propensity score (PS) matching was performed for variables including age, gender, smoking history, histopathological diagnosis, and pathological T and N status, resulting in a 1:1 ratio between groups with a low (<45) and high (≥45) number of dissected lymph nodes. Blood samples were collected before surgery and 4 weeks after. Lymphocytes were isolated from removed mediastinal lymph nodes (MLNs), and cytotoxic T lymphocyte (CTL) and natural killer (NK) cell phenotypes, functions, and anti-tumor activity against a lung cancer cell line were assessed.

Results: Demographic and clinical characteristics before and after PS matching are shown in Table 1. In the PS-matched cohort, patients in the low lymph node dissection group had a significantly longer median survival compared to those in the high dissection group (138 months vs. 68 months (odds ratio, 0.613, 95% confidence interval, 0.441 - 0.852; p = 0.003). CTLs isolated from MLNs exhibited significantly lower cytotoxicity compared to blood CTLs following lung cancer cell stimulation in patients who underwent aggressive lymph node dissection (p = 0.001). Similarly, NK cell anti-tumor activity was significantly reduced in this group compared to controls (p = 0.037) (Figure 1).

Table 1.

	Before PSM analysis			*After PSM analysis*

P3.03.05 Proteomic Analysis of Pleural Mesothelioma

T. Tagawa[1], T. Tokunaga[2], A. Haro[1], N. Miura[1], K. Yamazaki[1], T. Takenaka[2]
[1]NHO Kyushu Medical Center, Fukuoka/JP ,[2]Kyushu University, Fukuoka/JP

Introduction: Pleural mesothelioma (PM) represents one of the most aggressive and lethal human malignancies, arising within a highly specialized tumor microenvironment (TME). In recent years, cancer-associated metabolic reprogramming within the TME has emerged as a pivotal area of interest, particularly for enhancing the efficacy of immunotherapeutic approaches against various malignancies. However, the specific metabolic pathways that can be targeted in PM remain unclear. In this study, we conducted an in-depth proteomic analysis to elucidate the predominant metabolic pathways and key enzymes associated with PM.

Methods: Tumor specimen and corresponding normal pleural tissue samples were obtained from patients undergoing surgical resection for PM at our institution. The samples were processed into lysates and subjected to a large-scale targeted proteomics platform, known as in vitro proteome-assisted MRM for protein absolute quantification (iMPAQT). This platform allows for the absolute quantification of approximately 1100 metabolic enzymes.Principal-component analysis of protein expression level for the metabolic enzymes and gene set enrichment analysis were performed to compare expression level of enzymes between tumor and normal tissue.

Results: Our analysis identified 297 metabolic enzymes that were significantly upregulated in tumor samples compared to normal pleural tissue, while three enzymes were found to be decreased. Among various human metabolic pathways, the enzymes associated with the cofactor biosynthesis pathway demonstrated the most pronounced increase in tumors compared to normal pleural tissue. Notably, metabolic enzymes involved in folate metabolism, heme synthesis, and pyrimidine nucleotide metabolism were significantly upregulated in PM tumor samples.

Conclusions: This study has identified key metabolic pathways and enzymes within the TME of PM. These findings may serve as a foundation for developing novel therapeutic strategies for PM.

P3.03.06 Integrated Bulk and Single-Cell Transcriptomics Reveals Immune Ecotype Heterogeneity in EGFR-Mutated Lung Adenocarcinoma

S.X. Zhang, Y.J. Shen, C.C. Zhang, L.Q. Qian, Z.P. Ding, W. Feng, X.L. Fu
Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Over 50% of lung adenocarcinoma (LUAD) cases in non-smoking Asian populations exhibit EGFR mutations. However, these EGFR-mutated (EGFR-mut) patients often demonstrate limited responsiveness to immune checkpoint inhibitors (ICIs). Furthermore, there is scant clinical evidence supporting the efficacy of neoadjuvant targeted therapies in early-stage EGFR-mut LUAD, and most advanced-stage patients eventually develop resistance to targeted therapies. Therefore, it is essential to explore the characteristics of the tumor immune microenvironment in EGFR-mut tumors and to identify potential interventions that could improve the effectiveness of ICIs.

Methods: We prospectively collected 22 LUAD samples (August 2021-November 2023) for single-cell RNA sequencing (scRNA-seq) and retrospectively collected 141 LUAD samples (December 2023-June 2024) for bulk RNA sequencing (RNA-seq) at Shanghai Chest Hospital (SCH) from surgical resection patients without neoadjuvant therapy. Public RNA-seq data from 1515 LUAD cases were integrated to form two cohorts: a discovery cohort (SCH bulk data [n=141] + 876 public samples) and a validation cohort (22 SCH scRNA-seq samples + 639 public samples). Using EcoTyper, a machine-learning framework, we identified conserved LUAD cell states and ecotypes and analyzed their abundance differences between EGFR-mut and EGFR-wild-type (EGFR-wt) tumors. These cell states were further validated in the scRNA-seq dataset to enable single-cell functional characterization.

Results: Bulk RNA-seq included 141 patients (59 stage I, 60 stage IIA-IIIA, 22 stage IIIB-IV), and scRNA-seq encompassed 22 samples (3 AIS, 5 MIA, 6 stage I, 5 stage IIA-IIIA, 3 stage IIIB-IV). EGFR mutation subtypes (n[19del] = 47; n[L858R] = 48; n[wt] = 46) were balanced in SCH bulk data. Seven conserved LUAD ecotypes (E1-E7) were identified in discovery cohort and well recovered in validation cohort. EGFR-mut tumors exhibited elevated E5 (p=0.00014) and E6 (p=0.034) abundance but reduced E7 levels (p=0.024). Early-stage EGFR-mut cases showed diminished E2 abundance (p=0.015), an ecotype structurally resembling tertiary lymphoid structure (TLS) with B cells-S02, CD4T-S01, CD8T-S02, plasma cells-S02, and NK-S01. E2-enriched samples correlated strongly with TLS-associated gene signatures (p<0.0001). In a public neoadjuvant cohort (GSE207422, n=24), elevated baseline E2 abundance was associated with a higher likelihood of achieving major pathological response.

Conclusions: EGFR-mut tumors exhibits a distinct immune ecotypic profile characterized by enriched E5/E6 and diminished E7. The low abundance of E2, a TLS-like ecotype, in early-stage EGFR-mut patients suggests a relatively “immune-cold” microenvironment that may underlie poor ICI responsiveness. Specific mechanisms warrant further investigation to potentially provide more personalized treatment strategies for different immune subtypes.

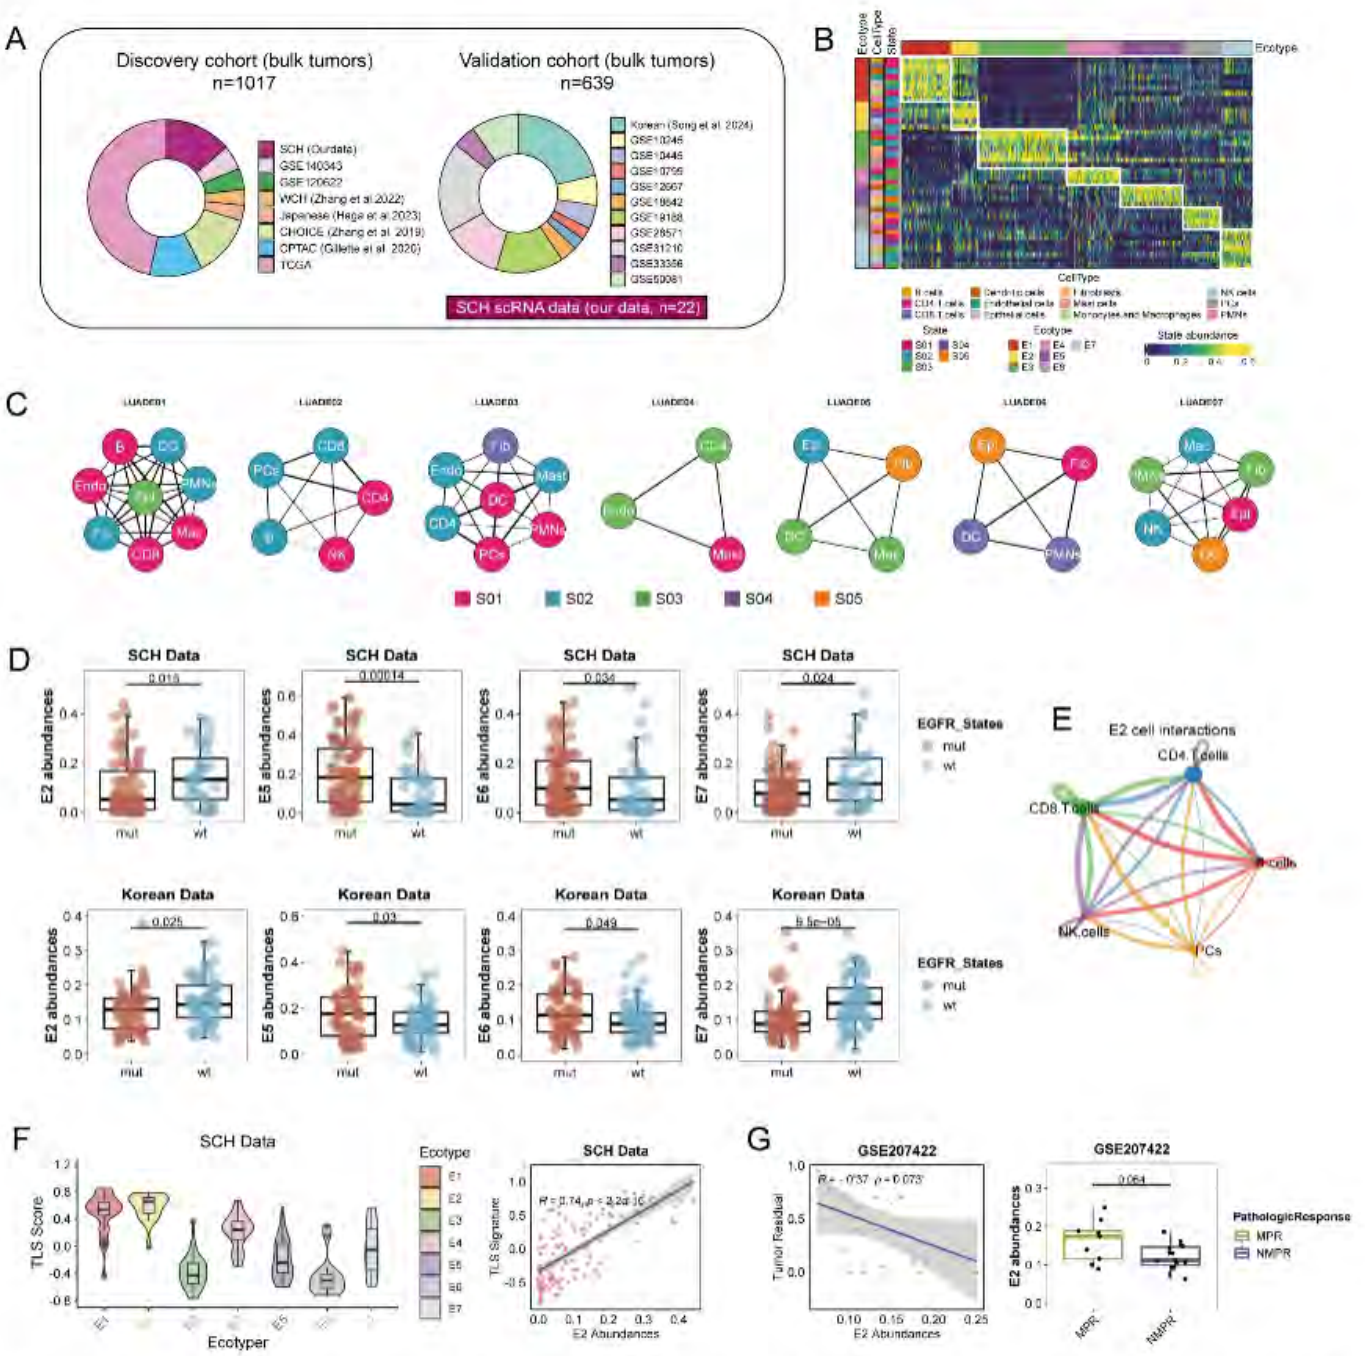

Figure Overview. (A) Discovery and validation cohorts employed for cell state and ecotype identification via EcoTyper. (B) Cell state abundance profiles in the discovery cohort, with cell states organized into seven ecotypes (E1–E7). (C) Ecotypes composition depicted as network diagrams. (D) Variations in E2, E5, E6 and E7 abundance between EGFR-mut and EGFR-wt patients. (E) The cell-cell interactions within E2 from CellChat. (F) Positive correlation between E2 abundance and TLS gene signature (GSVA score). (G) Association between E2 abundance and major pathological response (MPR) following neoadjuvant therapy.

P3.03.07 Characterization of Live Cell Repository for Tumor Derived Pleural Mesothelioma Cells and Cancer Associated Fibroblasts

S. Changkhong[1,2], M. Ronner[1,2], F. Schlaepfer[1,2], E. Felley-Bosco[3], I. Schmitt-Opitz[1,2], M. Meerang[1,2]
[1]University Hospital Zurich, Zurich/CH ,[2]University of Zurich, Zurich/CH ,[3]University of Lausanne, Lausanne/CH

Introduction: The use of primary cells cultivated from fresh patient material for research can overcome the limitations of long-term cell line cultures. Cancer-associated fibroblasts (CAFs) are a significant component of the tumor microenvironment, exhibiting heterogeneity and functional diversity. Here, we aimed at characterizing low-passage primary cultures of pleural mesothelioma (PM) enriched with PM and/or CAF cells to investigate cell-cell communication.

Methods: We generated primary cultures from 236 tissue specimens and characterized the doubling time of these cell cultures using MTT assays. Cell origin was evaluated by immunohistochemistry (IHC) with the epithelial marker pan-Cytokeratin (pan-CK), followed by mesothelial markers (podoplanin and WT1) in FFPE cell blocks. If corresponding tumor tissue was available, it was also assessed for the expression of tumor suppressor proteins often lost in PM, including BAP1 and p16. Cultures enriched for pan-CK negative cells were likely enriched with CAFs. We selected four cultures (CAF1-CAF4) showing complete pan-CK negativity for assessment of their functional heterogeneity. These cultures exhibited fibroblastic morphology and positivity for mesenchymal (Vimentin; VIM) and/or myofibroblast (α-SMA) markers. The intensity of these markers was scored as weak (1), moderate (2), and strong (3). Histo (H)-score (intensity multiplied by % positive cells, range 0-300) was calculated. VIM H-score was >250 in all cultures, while α-SMA was heterogeneous, ranging from negative H-score (<5), low (5-100), to high (>100). For co-culture experiments, we used two PM cells verified by extensive copy number variation, identical to the original tumor and non-PM cells generated from pleural effusion of patients without mesothelioma. Cell proliferation after co-culture was assessed using the mitotic marker Phospho-histone 3 (PH3) by immunofluorescent staining (IF), evaluated in tumor or mesothelial cells (pan-CK+) and fibroblast (pan-CK-) fractions. Additionally, we confirmed the findings using the proliferation marker Ki-67, assessed by flow cytometry.

Results: We identified 49 cell cultures with high expression of pan-CK (H-score >150). Among these, 31 cultures showed positivity for mesothelial cell markers or concordant BAP1 and p16 immunoreactivity with tumor tissues. We also identified 98 PM cultures expected to be enriched with fibroblasts (pan-CK H-score <150, median 29.8). The 4 cultures selected for co-culture experiments exhibited distinct doubling time (CAF1 (VIM+, SMAlow): 96.46 h; CAF2 (VIM+/SMA-: 111.4 h; CAF3 (VIM+/SMAhigh): 336.7 h; CAF4 (VIM+/SMA-): 137.3 h). In co-culture experiments assessing PH3, we observed a tendency for the CAF1 culture to inhibit the growth of both PM and non-PM cells, while other cultures did not. Due to the low number of PH3-positive cells, which led to high variability between experiments, we employed Ki-67 staining to further test the effect of CAF1 in tumor growth inhibition. Preliminary analysis of Ki-67 staining indeed indicated a tendency for reduced growth of PM and non-PM cells in the presence of CAF1 cells. Additionally, CAF2-4 proliferated less when co-cultured with tumor cells, while CAF1 did not.

Conclusions: Our study provides an initial characterization of a large repository of mesothelioma-derived cell cultures, composed of cells with heterogeneous characteristics and functions. These cell cultures can be utilized to investigate cell-cell communication and other tumor dynamics.

P3.03.08 Patient-Derived Tumour Organoids Recapitulate Keratinizing Lung Squamous Cell Carcinomas

C. Cahill
Trinity College Dublin, Dublin/IE

Introduction: Current treatment options for patients with lung cancer often have limited efficacy and significant toxicity, highlighting the need for more targeted and personalized approaches. However, many pre-clinical models fail to accurately represent intratumour heterogeneity and recapitulate the tumour microenvironment. This is partly responsible for the poor translation of clinical findings to approved therapies. Understanding the unique histological features that define lung cancer subtypes is essential to improving treatment options. Squamous cell carcinomas (SCCs) are the second most common subtype of lung cancer and are commonly pathologically diagnosed by the presence of keratinisation features, including keratin pearls, intracellular-bridges, abundant inflammation, and necrosis. Patient-derived organoids (PDOs) are 3D, self-organising tissue structures, derived from stem cells, which maintain tumour heterogeneity. Our objectives are to create a standardized protocol to develop lung cancer PDOs, to investigate the ability of PDOs to replicate the histological features of the keratinizing SCC subtype of lung cancer, and to use these models for drug testing studies.

Methods: Lung tumour tissue was obtained following surgical resection from consenting patients with lung cancer. PDOs were established from lung tumour tissue and maintained in CultrexTM extracellular matrix solution and specialised growth media. PDOs were imaged regularly to monitor expansion and morphology. PDOs were fixed in paraformaldehyde and immunofluorescent staining was performed to investigate the structural features of the organoid cultures, and to confirm expression of tumour markers and keratinocyte markers. PDO imaging data was compared with histopathological findings for the original tumour tissue using FFPE tissue blocks generated by the histopathology department of St. James's Hospital, Dublin.

Results: We created a standardized protocol to establish lung cancer PDO cultures from patients with lung adenocarcinomas and SCCs. We demonstrated that PDOs display patient-variable growth timelines but that the growth potential is not associated with the disease stage of the tumour. Importantly, PDOs were confirmed to express -tumour subtype-specific markers. Additionally, we established PDOs from patients presenting with invasive, keratinizing lung SCC. Keratin pearl structures spontaneously developed in these PDOs, matching the keratinizing pattern demonstrated by hematoxylin and eosin staining of the original tumours. These PDOs also demonstrated invasive features in culture, with cells migrating beyond the edges of the Cultrex™ gel and establishing 2D adherent layers outside the matrix. PDOs were confirmed to express lung SCC-specific markers, which were also expressed in the parent tissue. Additionally, PDOs were confirmed to express keratinocyte markers, further demonstrating recapitulation of histological features of the tumour. Future work involves treating these PDOs with standard-of-care therapies and comparing drug responses to the treatment outcomes of patients from whom the PDOs were developed.

Conclusions: PDOs have the capability to replicate key histological features of the original tumour, providing a more accurate reflection of tumour phenotypes, including keratin structures, which may impede drug delivery and better mimic hard-to-treat tumours. This highlights organoids as a valuable tool in pre-clinical drug testing. By better capturing tumour heterogeneity, organoid models have the potential to guide the development of novel targeted therapies and improve outcomes for patients with lung cancer.

P3.03.09 Synonymous Mutations in PDGFRA Exons 12 and 18 Correlate With Reduced Survival and Serum Iron Levels in Non-Small Cell Lung Cancer

X. He
Cancer Hospital Affiliated to Xiangya Medical School, Central South University, Changsha/CN

Introduction: PDGFRA (Platelet-Derived Growth Factor Receptor Alpha), a member of the receptor tyrosine kinase (RTK) family, serves as the receptor for platelet-derived growth factors (PDGF). It plays critical roles in tumor angiogenesis, tumor microenvironment maintenance, and normal vascular development. Aberrant PDGFRA signaling is implicated in gastrointestinal stromal tumors, hepatocellular carcinoma (HCC), glioblastoma (GBM) and so on. Recent studies highlight that synonymous mutations can modulate gene expression and protein function, contributing to disease pathogenesis.

Methods: We analyzed PDGFRA mutations in 302 patients with non-small cell lung cancer (NSCLC). Genetic testing results of patients were obtained using second or third generation sequencing data. The Chi-square test was employed to analyze the correlation between PDGFRA mutations and clinicopathological characteristics as well as treatment efficacy. Logistic regression analysis was used to assess the association between PDGFRA mutations and serum iron levels. Patient survival was analyzed using the Kaplan-Meier method, and comparisons were made using the Log-rank test. The COX regression model was applied for both univariate and multivariate risk analyses. Statistical analyses were performed using SPSS 27.0, and a P value < 0.05 was considered statistically significant.

Results: PDGFRA mutations were detected in 34.77% (105/302) of tumors, with a high prevalence of synonymous mutations in exon 12 (23.51%, 71/302). Co-occurring synonymous mutations in exons 12 and 18 were observed in 9.27% (28/302) of cases, while other mutations accounted for 1.99% (6/302). Compared to wild-type patients (median survival: 27.4 months), those with exon 12 mutations alone had reduced survival (24.2 months; P = 0.035), and patients with dual exon 12/18 mutations exhibited even worse outcomes (19.7 months; P < 0.0001). Notably, exon 18 mutations further diminished survival in exon 12-mutated cases (P = 0.036).PDGFRA mutations were associated with smoking (P = 0.069) and primary resistance to first-line chemoimmunotherapy (PD vs. DCR; P = 0.037). Intriguingly, dual exon 12/18 mutations correlated with decreased baseline serum iron levels (P < 0.0001), and multivariate analysis identified low serum iron as an independent risk factor for poor prognosis (HR = 4.216; P = 0.001).

Conclusions: In advanced NSCLC, co-occurring synonymous mutations in PDGFRA exons 12 and 18 may impair treatment response and survival via serum iron depletion. The underlying molecular mechanisms warrant further investigation.

P3.03.10 Establishment of Patient-Derived Organoids From EBUS-TBNA Cytological Samples in Lung Cancer Patients

M. Acosta-Plasencia[1], J.P. Orozco[2], C. Lucena[2], Y. He[1], A. Altuna-Coy[1], R. Na[1], Y. Liu[1], T. Díaz[1], C. Agustí[2], R.M. Marrades[2], A. Navarro[1]
[1]University of Barcelona, Barcelona/ES ,[2]Hospital Clínic de Barcelona, Barcelona/ES

Introduction: One of the major challenges in the generation of lung cancer (LC) tumor organoids (LCOs) is their predominant derivation from surgical samples, and therefore, from patients in early stages of the disease. Obtaining samples from non-surgical patients is usually limited and often insufficient for organoid establishment and has, to date, focused on primary tumor sampling. In this study, we aimed to evaluate the effectiveness of growing LCOs using tumor cells that have undergone lymphatic metastasis, obtained through mediastinal endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA), and assess whether these organoids preserve the histopathological characteristics of the patients and can serve as a complementary diagnostic tool.

Methods: Cytological samples were obtained by EBUS-TBNA from 13 patients: 10 with non-small cell lung cancer (NSCLC) (7 adenocarcinomas, 2 squamous cell carcinomas, and 1 pleomorphic carcinoma) and 3 with small cell lung cancer (SCLC). The majority were metastatic patients (60%). The presence of tumor cells in all samples was confirmed by ROSE. Samples were enzymatically processed and cultured in Matrigel with an enriched medium optimized for LCO growth.

Results: Overall, the initial success rate of establishing LCOs from EBUS-TBNA samples was 61%. All SCLC samples were successfully established, while only 50% of NSCLC samples succeeded. Morphological analysis revealed differences compared to LCOs previously derived from primary tumor tissue in early stages. The new LCOs displayed larger growth and a “rosette”-like structure. Moreover, they retained the immunophenotypic characteristics of the primary tumors, with P40 expression in squamous subtypes and TTF1 in adenocarcinomas. The average culture time required to utilize LCO samples for immunohistochemistry was 20 days.

Conclusions: LCOs derived from EBUS-TBNA samples reproduce the histopathological features of the patient’s tumor, making them an innovative strategy to optimize sample utilization and study metastatic populations. Since EBUS-TBNA often needs to be repeated at different times due to insufficient sample volume for all currently required markers, we consider that LCOs emerge as a new potential source of material for these analyses, also paving the way for future personalized treatment studies.

P3.03.11 Anlotinib Exerts a Protective Effect on Radiation Lung Injury Through the Regulation of the Immune Microenvironment Mediated by M2c Macrophages

H. Wang[1,2], H. Xu[3], E. Dai[4], S. Que[5], S. Zhai[6], G. Zhong[3], J. Wang[7], Z. Wang[7], X. Zhou[7], W. Feng[1,2,7]
[1]Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou/CN ,[2]Postgraduate training base Alliance of Wenzhou Medical University (Zhejiang Cancer Hospital), Hangzhou/CN ,[3]College of Clinical Medicine, Hebei University of Engineering, Handan/CN ,[4]The Second School of Clinical Medicine, Zhejiang Chinese Medical University, Hangzhou/CN ,[5]The Second School of Clinical Medicine, Zhejiang Chinese Medical University,, HangZhou/CN ,[6]Department of Radiation Oncology, Changzhou jintan first people's hospital, Changzhou/CN ,[7]The Department of Thoracic Radiotherapy, Zhejiang Cancer Hospital, Hangzhou/CN

Introduction: Radiation-induced lung injury (RILI) is a prevalent complication associated with thoracic tumor radiotherapy. The aim of this study is to elucidate the role and mechanism of anlotinib in the progression of RILI.

Methods: The radiation pneumonia mouse model, idiopathic pulmonary fibrosis mouse model, and fibrotic cell model were successfully established. Pathological staining, qPCR, Western blot, ELISA, transcriptome sequencing, and cell co-culture experiments were employed to evaluate the protective effects of anlotinib on lung injury and elucidate its underlying biological mechanisms.

Results: 1.Anlotinib exhibits a protective effect against acute, subacute, and chronic radiation-induced lung injury.Compared with mice in the irradiation group, anlotinib treatment was found to ameliorate local hair loss, decrease acute inflammatory exudation and alveolar septum thickening, and suppress local collagen deposition as well as interstitial transformation of lung tissue.2.Anlotinib has the potential to delay the progression of bleomycin-induced idiopathic pulmonary fibrosis.Compared to the bleomycin injection group, anlotinib treatment mitigated weight loss in mice, decreased inflammatory cell infiltration and localized alveolar septum thickening, and inhibited collagen deposition as well as the interstitial transformation process within lung tissues.3.At the cellular level, anlotinib can inhibit the TGFβ-induced epithelial-mesenchymal transition process.At the cellular level, anlotinib inhibited the production and activity of TGF-β. Compared with the TGF-β1 induction group, anlotinib treatment significantly decreased the expression levels of mesenchymal markers.4.The progression of pulmonary fibrosis are intricately linked to alterations in the lung immune microenvironment mediated by macrophages.Transcriptome sequencing results indicated that the progression of pulmonary fibrosis were associated with significant enrichment of signaling pathways related to the immune microenvironment. Immunohistochemistry findings suggested that the antifibrotic effects of anlotinib were closely linked to changes in the lung tissue immune microenvironment mediated by M2-type macrophages.5.The protective effect of anlotinib on lung injury is intricately associated with M2c macrophages. The supernatant from the radiation-damaged cell culture medium (representing a radiation-damaged microenvironment) exhibited a tendency to promote the transformation of macrophages into the M2c subtype. Anlotinib demonstrated significant drug sensitivity towards M2c macrophages, effectively inhibiting the expression of M2c macrophage-associated active factors.

Conclusions: Anlotinib exhibits protective effects in both the lung injury mouse model and the fibrotic cell model. These protective effects are attributed to anlotinib's inhibition of TGFβ-induced epithelial-mesenchymal transition, its modulation of pulmonary immune microenvironment, and its suppression of M2c macrophages. In conclusion, anlotinib may serve as a promising candidate for the prevention and treatment of RILI.

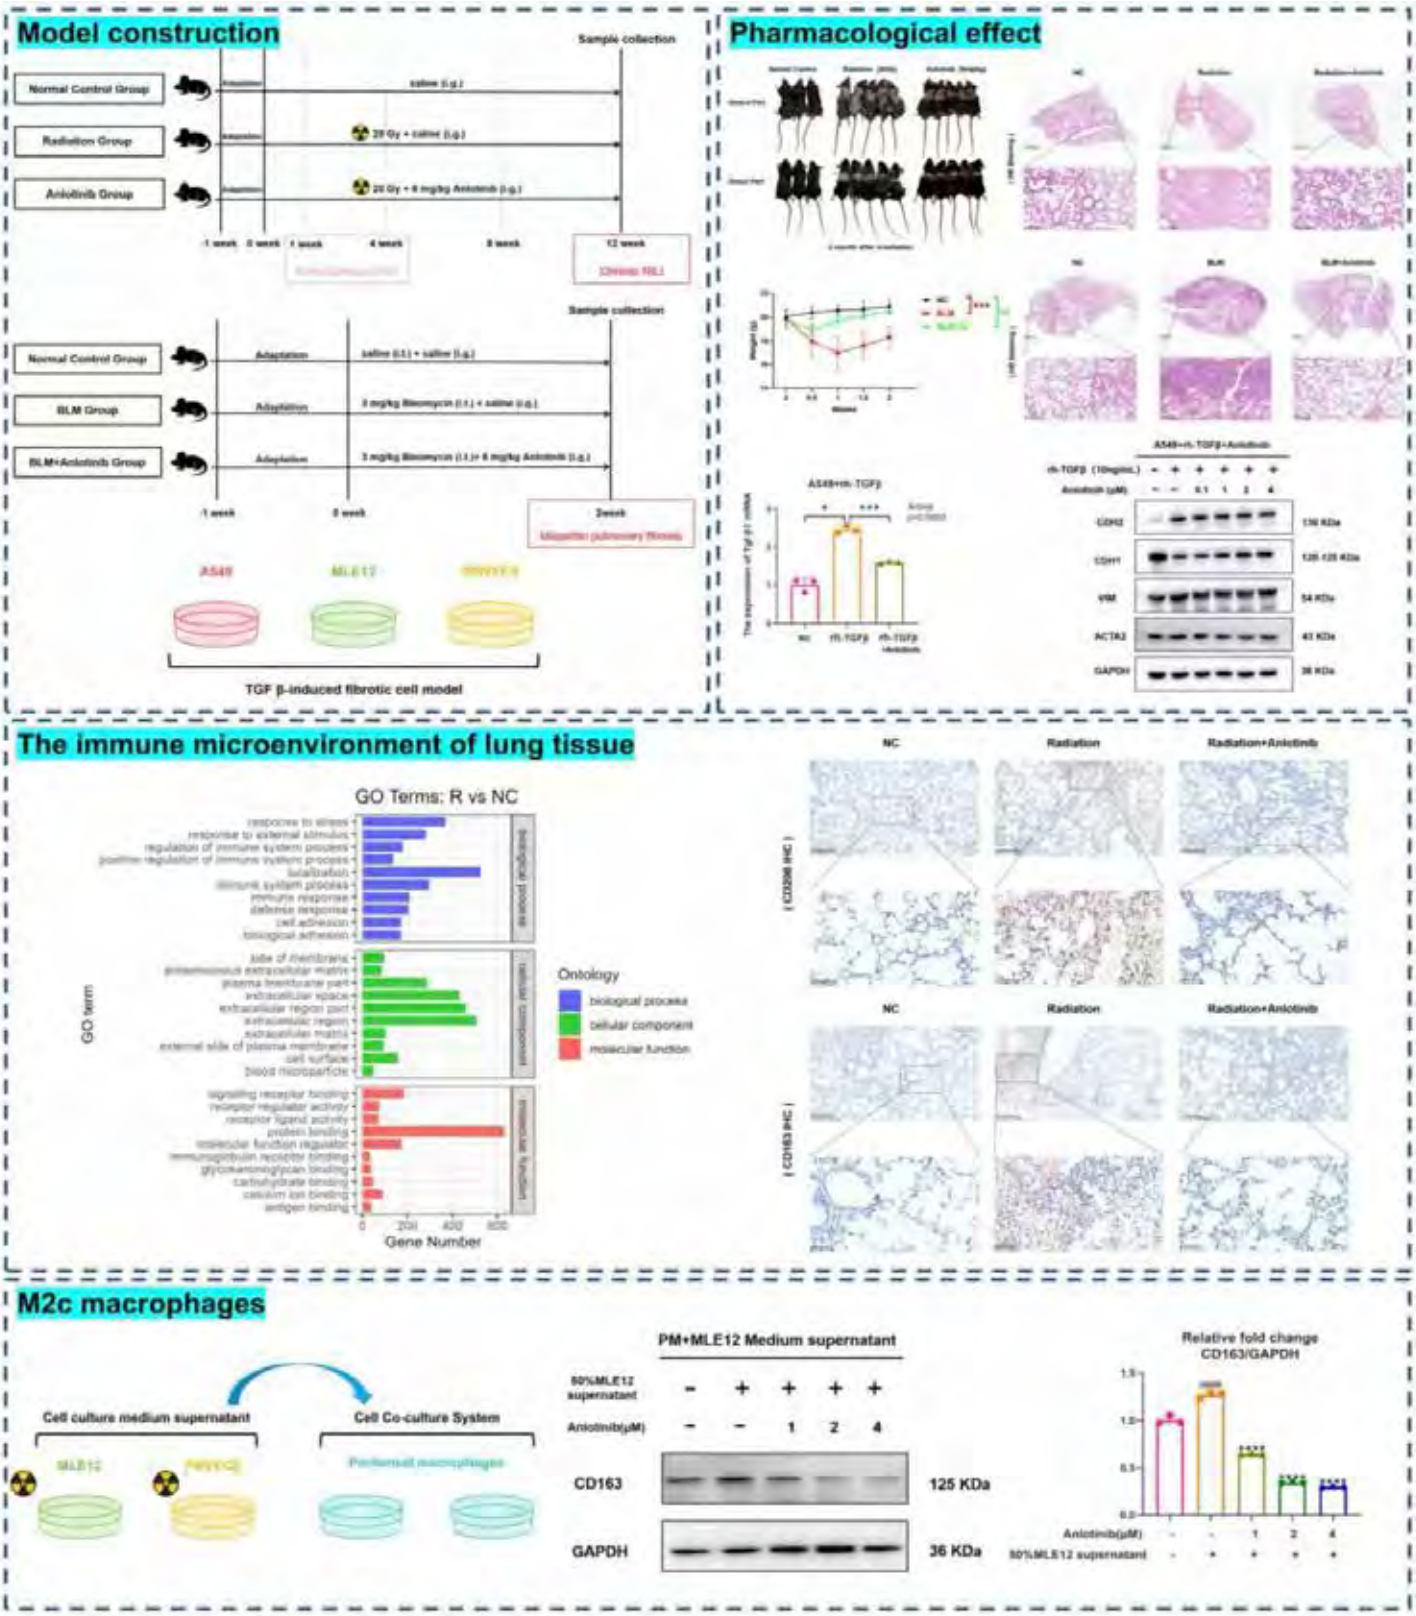

Illustration: The working flow chart of this study.

P3.03.12 YAP-Driven Modulation of HER3-Mediated Adaptive Resistance to RET Inhibitors in RET-Altered Cancer

T. YAMADA[1], Y. Katayama[1], S. Yano[2], K. Takayama[1]
[1]Kyoto Prefectural University of Medicine, Kyoto/JP ,[2]Kanazawa Graduate school of Medical Sciences, Kanazawa/JP

Introduction: Molecular targeted therapies have revolutionized cancer treatment, including RET-TKIs for RET fusion-positive tumors. Selpercatinib and pralsetinib have demonstrated high efficacy in lung and thyroid cancers; however, acquired resistance remains a major challenge. Resistance mechanisms involve on-target RET mutations (e.g., G810C/S/R) and off-target alterations, such as MAPK pathway reactivation and MET/FGFR1 amplification. Overcoming resistance is hindered by tumor evolution and heterogeneity. This study investigates adaptive resistance mechanisms during early RET-TKI treatment and explores novel therapeutic strategies to prevent resistance development, aiming to enhance treatment efficacy and improve clinical outcomes for patients with RET-aberrant cancers.

Methods: Four RET-aberrant cancer cell lines were tested for sensitivity to selpercatinib and pralsetinib. Resistance mechanisms were explored using RNA sequencing, phospho-RTK arrays, ChIP, and luciferase assays. Clinical specimens from RET fusion-positive lung cancer patients were analyzed for YAP expression and its correlation with treatment outcomes.

Results: Our study revealed that RET-aberrant cancer cells with low sensitivity to RET-TKIs exhibited ERK reactivation after prolonged treatment, suggesting adaptive resistance. Phospho-RTK profiling identified HER3 activation as a key mechanism underlying this resistance. HER3 knockdown suppressed ERK reactivation and enhanced sensitivity to RET-TKIs. Further analysis demonstrated that YAP activation, triggered by RET-TKI treatment, directly induced HER3 transcription. YAP knockdown inhibited HER3 expression, reducing resistance to RET-TKIs. High YAP expression correlated with poor RET-TKI response, and pharmacologic YAP or HER3 inhibition sensitized RET-aberrant cells to RET-TKIs. In vivo, co-administration of selpercatinib and afatinib significantly suppressed tumor growth compared to selpercatinib alone. A retrospective analysis of RET-fusion positive NSCLC patients showed that high pre-treatment cytoplasmic YAP expression was associated with shorter progression-free survival and overall survival following selpercatinib treatment. These findings suggest that YAP-HER3 axis activation drives adaptive resistance, and its inhibition may enhance RET-TKI efficacy in RET-aberrant cancers.

Conclusions: Our study highlights the critical role of the YAP-HER3 axis in mediating resistance to RET-TKIs in RET-aberrant cancer cells. We demonstrated that the activation of YAP and HER3 contributes to adaptive resistance, which remains a major hurdle in the effectiveness of molecular targeted therapy. Importantly, our findings suggest that co-targeting YAP and HER3 alongside RET-TKIs could provide a promising strategy to overcome this resistance and enhance therapeutic efficacy. Moreover, we identified a subset of patients with RET-aberrant cancers who exhibit low sensitivity to RET-TKIs, suggesting that these patients could benefit from a tailored treatment approach specifically targeting the YAP/HER3 axis. This novel therapeutic strategy has the potential to advance personalized medicine by refining patient selection and optimizing treatment regimens, ultimately leading to improved clinical outcomes for patients with RET-aberrant cancers. Further studies are warranted to validate these findings and explore the clinical applicability of YAP and HER3 inhibition in combination with RET-TKIs.

P3.03.13 HLA II Genetics Shapes Lung Cancer Immunosurveillance

E.A. Olumuyide, M. Saffern, D. Chowell, R. Samstein
Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: The risk of developing cancer is one's lifetime is about 50% after the sixth decade of life and it is associated with internal factors such as inherited mutations in DNA repair genes, replication errors, and environmental factors. Lung cancer is the most common cancer worldwide and the leading cause of cancer-related deaths worldwide. Recent advances in immunotherapy demonstrate the need to understand the complex choreography of immune genetics and cancer risk, as well as how antigen presentation, particularly MHC molecules, shapes cancer immunosurveillance. MHC molecules are encoded by the polygenic HLA locus, which is the most polymorphic region of the human genome, therefore the possibility of presentation of diverse tumor antigens to the immune system. We hypothesize that germline heterozygosity at the HLA locus allows for binding of a greater repertoire of antigens that can be presented to the immune system, thereby decreasing lung cancer risk.

Methods: We used clinical and genetic information from over 390,000 individuals in the UK Biobank to study how HLA zygosity affects lung cancer risks among smokers. To study the mechanism behind this, we used a carcinogen murine model that allows us to assess tumor multiplicity across MHC homozygous and MHC heterozygous genotype groups. To explore how immune surveillance defers between genotypes, we used flow cytometry to explore early immunosurveillance across multiple mice genotypes and using cell lines we developed from the carcinogen model, we explored how tumor cell MHC II shapes tumor surveillance.

Results: We show that germline heterozygosity at the HLA class II loci confers decreased risk of cancer among smokers. Furthermore, we showed using murine models that maximal heterozygosity at the HLA locus (H2 in mice) leads to decrease tumor incidence, which we further show is due to increase in T lymphocytes in the tissue microenvironment at early tumor development. We further show using murine models that loss of HLA class II on the cancer cells as well as epithelial cells ameliorate this protective effect against cancer risks.

Conclusions: Our findings demonstrate that HLA class II heterozygosity enhances tumor immunosurveillance and reduces lung cancer risk, highlighting the critical role of immune genetics in cancer susceptibility. These results provide a foundation for developing immunopreventive strategies targeting MHC II neoantigens.

P3.03.14 PCSK9-Mediated Immune Escape as a Mechanism of Acquired Resistance to PD-1/PD-L1 Blockade

G-L. Jie[1], Z-Q. Cao[1], J-Z. Wang[1], Y. Wang[2], L-L. Xia[1], S. Lu[1]
[1]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, shanghai/CN ,[2]Shanghai Jiaotong University School of Medicine, shanghai/CN

Introduction: Despite the significant clinical success of immune checkpoint blockade (ICB) in patients with non-small cell lung cancer (NSCLC), most patients developed acquired resistance during the treatment. Understanding the mechanisms of acquired immune resistance is essential for identifying novel therapeutic targets to overcome resistance.

Methods: We utilized patient-level data and a murine model to identify molecules associated with ICB resistance. An immune-resistant murine model was developed through chronically persistent ICB exposure, and single-cell RNA sequencing was conducted. The underlying mechanisms were evaluated using in vitro experiments, including western blot analysis, quantitative polymerase chain reaction, flow cytometry, immunofluorescence staining, and immunoprecipitation. In vivo experiments were conducted to investigate the efficacy of anti-PD1 therapy alone or in combination with various therapeutic strategies in immunocompetent mouse models.

Results: Through RNA sequencing and in vitro validation, we identified elevated PCSK9 expression in NSCLC patients with acquired resistance to ICB therapy compared to baseline tumors. PCSK9 overexpression impaired CD8+ T cell function, reducing the immune response to anti-PD1 therapy in vivo. Mechanistically, persistent IFN-γ stimulation induced PCSK9 upregulation via the JAK1-STAT1 pathway, which subsequently activated the KEAP1-NRF2 pathway, promoting immune evasion through dampening the function of CD8+ T cells. Inhibition of PCSK9 or JAK1-STAT1 pathway restored sensitivity to anti-PD1 treatment in immune-resistant models. Notably, the combination of PCSK9 inhibitor with anti-PD1 therapy demonstrated enhanced antitumor activity compared to monotherapy in immunocompetent mouse models.

Conclusions: Our preclinical study identified PCSK9 upregulation as a mechanism of acquired resistance to PD1/PD-L1 blockade in NSCLC. These findings support the therapeutic potential of combining PCSK9 inhibition with anti-PD1 therapy to overcome immune resistance. A phase II clinical trial investigating the efficacy of tolecimab (an anti-PCSK9 antibody) in combination with sintilimab (an anti-PD1 antibody) in NSCLC who have failed first-line Immunotherapy is currently ongoing (ChiCTR2500099426).

Introduction: Non-Small Cell Lung Cancer (NSCLC) is the most common form of lung cancer. Most patients with NSCLC harbor epidermal growth factor receptor (EGFR) mutations like T790M/L858R (EGFRTL), L858R (EGFRLR), and exon 19 deletion (EGFRD19). While Osimertinib (Osi) is the standard treatment for patients with EGFR mutations, resistance to the drug inevitably develops, leading to therapeutic failure. The role of the tumor microenvironment (TME) in driving resistance remains underexplored, limiting the development of more effective therapies. Therefore, we employ in vitro models and genetically engineered mouse models (GEMMs) to investigate potential bypass mechanisms of Osi resistance using RNA sequencing (RNAseq), single-cell RNA sequencing (scRNAseq) and high-resolution transcriptomics.

Methods: In vitro studies: Osi-sensitive (OsiS) NSCLC cell lines (H1975 for EGFRTL; PC9 for EGFRD19; and H3255 for EGFRLR) were used to generate Osi-resistant (OsiR) cells, and RNAseq adopted to investigate resistance mechanisms. Differences in morphology, proliferation, migration and aggressiveness between OsiS and OsiR cells were assessed by microscopy, wound healing, cell cycle, and proliferation assays. Mitochondrial activity and morphology were analyzed using confocal microscopy and bioanalytical assays, including gas mass spectrometry and liquid chromatography.

In vivo studies: GEMMs harboring EGFR mutations (EGFRTL, EGFRLR , EGFRD19) were used to study resistance mechanisms in vivo (see Figure 1), with scRNAseq and spatial transcriptomics employed to explore gene expression changes and cellular interactions within the TME, focusing on the crosstalk between tumor and immune cells.

Results: In vitro studies revealed that H1975 OsiR cells exhibit increased migration, altered cell cycle dynamics, and nuclear structure abnormalities compared to OsiS cells, underscoring their more aggressive phenotype. Preliminary RNAseq analysis identified resistance-associated pathways, including mitochondrial dysfunction in Osi resistance. Metabolic profiling further uncovered mitochondrial and bioenergetic alterations in OsiR cells.

scRNAseq data from EGFR-mutant GEMMs revealed significant differences in tumor-immune infiltrates interaction compared to healthy controls. OsiR GEMMs are currently being interrogated by scRNAseq to elucidate resistance-driving pathways and TME crosstalk mechanisms.

Conclusions: By integrating high-resolution transcriptomics, in vivo models, and in vitro assays, this study provides novel insights into the molecular and cellular mechanisms of Osi resistance in EGFR-mutant NSCLC. These findings may pave the way to develop personalized therapies to address resistance, a major clinical challenge for patients with EGFR-mutant NSCLC.

P3.03.16 CXCR2+ Neutrophils Influence Immunotherapy Efficacy in NSCLC Patients With KL Subtype

X. Li, C. Zhao, L. Cheng, H. Wang
Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: KRAS mutation is a common driver mutation in non-small cell lung cancer (NSCLC), and patients carrying this mutation may benefit from immunotherapy. However, patients with LKB1 deletion (KL subtype) rarely respond to immunotherapy, and the mechanism has not been clarified.

Methods: We retrospectively collected patients with KRAS mutation-positive advanced or postoperative recurrence NSCLC diagnosed in Shanghai Pulmonary Hospital from March 2024 to March 2025, and all patients received first-line chemotherapy combined with PD-1 monoclonal antibody therapy. We focused on analyzing the response of KRAS mutation combined with other mutations to immunotherapy. At the same time, the homologous KRASG12DLKB1−/−(KL) and KRASG12DTP53−/−(KP) lung cancer mouse models were respectively given different interventions and single cell sequencing was used to investigate the possible reasons for the non-response of KL subtype tumors to immunotherapy.

Results: A total of 137 patients were included in our analysis cohort, ranging in age from 48 to 88 years, with a median age of 69 years, including 114 males and 23 females. Of these, 33 patients had NGS results, 16 patients with TP53 mutations (KP subtype), 6 patients with LKB1 deletion (KL subtype), and the remaining 11 patients with other mutations or no mutations (other). Only 1 in 6 patients with the KL subtype achieved partial disease response (PR), compared to more than half of patients with the KP subtype (9/16). At present, PFS data is not mature. The single-cell sequencing results of animal models showed that there was a large number of neutrophils infiltrating in KL lung cancer, and CXCR2+ neutrophils were the main subgroup. When CXCR2 inhibitors combined with PD-1 monoclonal antibody were used to treat KL mouse tumors, it was found that the tumors of mice were significantly regression.

Conclusions: KL subtype patients are not sensitive to chemotherapy combined with immunotherapy. The infiltration of CXCR2+ neutrophil may be the key reason affecting the efficacy of chemoimmunotherapy in KRAS positive lung cancer. CXCR2 inhibitors may enhance the anti-tumor efficacy of PD-1 monoclonal antibody.

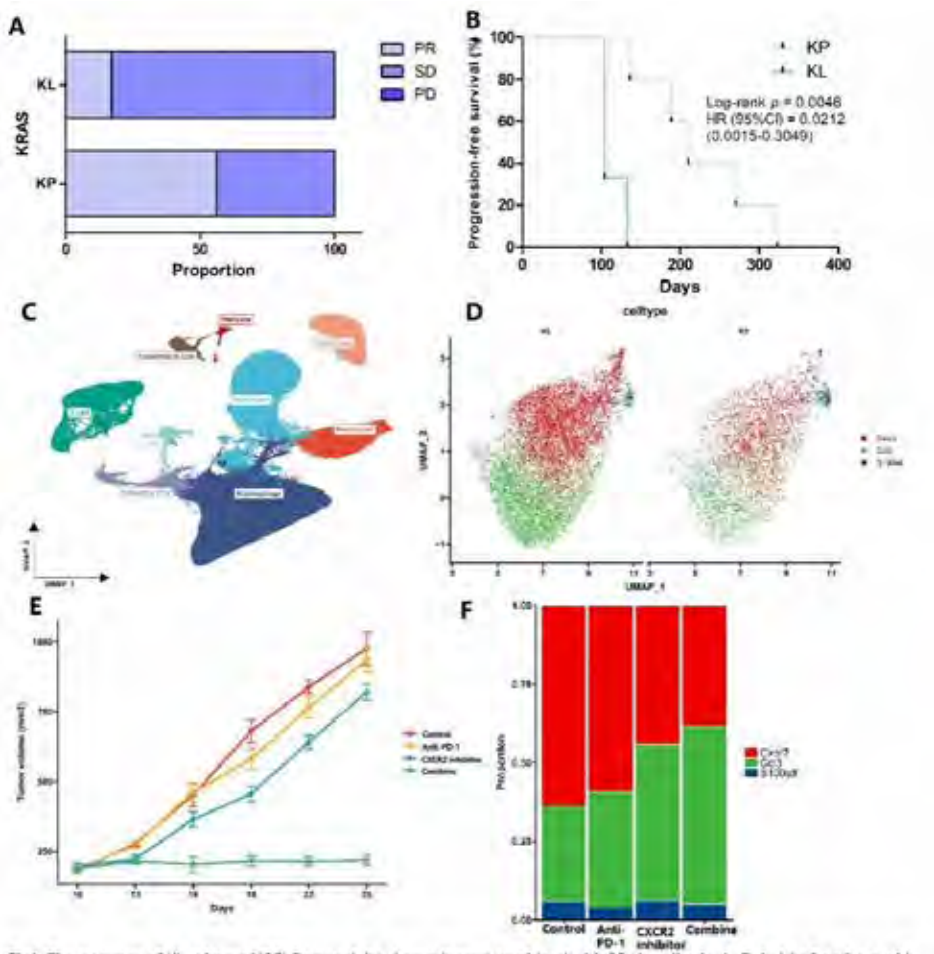

Fig1. The response of KL subtype NSCLC treated by chemotherapy combined with PD-1 antibody. A. Only 1 in 6 patients with the KL subtype achieved partial disease response (PR), compared to more than half of patients with the KP subtype (9/16). B. The PFS was longer in KP subtype patients compared with KL subtype. C-F. CXCR2+ neutrophils were the main subgroup in KL subtype. The KL mouse tumors were significantly regression when CXCR2 inhibitors combined with PD-1 monoclonal antibody were used to treat them.

P3.03.17 Intermittent Caloric Restriction Synergies With KRAS(OFF) Inhibitors in Preclinical Models of KRASG12C Lung Adenocarcinoma

E. Garbo[1], P. Scaparone[2], I. Savinelli[2], R. Gribaudo[2], E. Patrucco[2], M. Cani[1], P. Bironzo[1], F. Passiglia[1], C. Ambrogio[2], S. Novello[1]
[1]University of Turin, AOU S. Luigi Gonzaga, Orbassano/IT ,[2]Molecular Biotechnology Center, University of Torino, Torino/IT

Introduction: The role of fasting-mimicking diets, including intermittent caloric restriction (ICR), in oncology remains controversial due to limited prospective evidence and an unclear mechanistic explainability, particularly in oncogene-driven non-small cell lung cancer (NSCLC). Given the rationale that promoting the GDP-bound state of KRAS may increase the availability of binding sites for KRAS(OFF) inhibitors, we investigated whether ICR could enhance their efficacy in preclinical models.

Methods: For in vitro studies, we utilized NRAS-/-; HRAS-/-; KRASlox/lox KRASG12C MEFs, both with and without loss of heterozygosity (LOH). Cells were cultured in either complete medium (CM) or nutrient-restricted (NR) medium containing 0.5% fetal bovine serum (FBS). Cells were treated with sotorasib with increasing concentrations to determine half-maximal inhibitory concentrations (IC50). For in vivo experiments, syngeneic murine lung adenocarcinoma (LUAD) cell lines were injected subcutaneously in C57BL/6 mice. Tumor volumes were measured every 48 hours using calipers, and final measurements were assessed post-mortem following surgical excision. ICR was implemented as 24 hours of complete fasting followed by 24 hours of ad libitum refeeding, repeated throughout the treatment course. We established six distinct treatment arms with 2 mice each combining ICR with either vehicle control, selumetinib (MEK-inhibitor), or adagrasib.

Results: In vitro experiments conducted on KRASG12C cell lines, with or without KRAS LOH, demonstrated lower IC50 values for sotorasib in cells cultured under NR conditions compared to those in CM (Figure 1A). In the in vivo experiment, all experimental groups underwent ICR for 27 days, while control groups were maintained on an ad libitum diet for the same duration. Tumor growth was most markedly reduced in the groups receiving adagrasib, consistent with its known efficacy (Figure 1B-C). Notably, mice treated with the combination of adagrasib and ICR exhibited a significantly lower median tumor volume increase compared to all other treatment groups ($p < 0.05$, Figure 1B). In contrast, vehicle- and selumetinib-treated groups displayed comparable tumor growth, with no significant differences observed between ICR and non-ICR conditions (Figure 1B-C). Regarding safety, longitudinal monitoring of body weight revealed no significant changes throughout the treatment period across all groups, indicating that ICR was well tolerated (Figure 1D).

Conclusions: These preliminary findings suggest that ICR specifically enhance the activity of KRAS(OFF) inhibitors in KRASG12C LUAD models. No safety concerns were observed during the in vivo experiments, supporting the potential feasibility of this combinatorial approach.

Figure 1. IC_{50} of the in vitro experiments (A), tumor volume changes (B), resected tumor specimens (C), and mice's body weight variations of in vivo experiments (D).

P3.03.18 Single-Cell Transcriptomic Analyses of Lung Immune Cells Reveal That Mitf-Driven Plcb1HighMacrophages Induce Radiation-Induced Lung Injury

H. Zhang, F. Xia, S. Cai, Y. Liu, Y. Song, J. Yang, Y. Hu, L. Zhang, Q. Zhou, J. Sui, Y. Wang
Chongqing University Cancer Hospital, Chongqing/CN

Introduction: Radiation-induced lung injury is a significant clinical challenge, particularly due to the development of radiation pneumonitis. This study aimed to construct a mouse model of radiation-induced lung injury, identify macrophage subpopulations associated with radiation-induced pneumonia using single-cell transcriptome sequencing, and elucidate the molecular mechanisms underlying macrophage pro-inflammatory signaling.

Methods: A mouse model of radiation-induced lung injury was established by administering a thoracic irradiation dose of 15 Gy. The occurrence of radiation pneumonitis was confirmed using small-animal Micro-CT, HE staining, and Masson staining. Single-cell RNA sequencing was performed on 78,991 cells from nine samples, divided into three groups: non-irradiated, 7 days post-irradiation, and 30 days post-irradiation. Macrophages were analyzed using t-distributed stochastic neighbor embedding (tSNE) dimensionality reduction, and differential gene expression and Gene Ontology (GOBP) enrichment analyses were conducted. Transcriptional regulatory analysis was performed using SCENIC to identify key transcription factors.

Results: Analysis revealed a gradual increase in neutrophils and macrophages in the lungs post-irradiation. tSNE analysis identified eight macrophage subclusters, with cluster 0 being the most abundant and highly expressing genes such as Kcnip4, Ext1, Plcb1, Agap1, and Lrmda. Plcb1, associated with pro-inflammatory signaling and calcium regulation, was significantly upregulated in cluster 0. Monocle2 pseudotime trajectory analysis showed that clusters 0, 1, and 2 exhibited strong stemness characteristics. GOBP enrichment analysis indicated cluster 0 was enriched in pathways related to inflammatory responses, immune responses, and neutrophil recruitment. Cluster 0 cells secreted higher levels of chemokines (Ccl3, Ccl6, Cxcl2, Cxcl3), identifying them as pro-inflammatory macrophages (Plcb1high Macrophages). SCENIC analysis revealed Mitf as a key transcription factor in Plcb1high Macrophages, with high Regulon specificity and co-expression correlation with Plcb1 target genes. Mitf was implicated in promoting macrophage polarization and chemokine secretion, exacerbating inflammatory processes.

Conclusions: Mitf-mediated Plcb1high macrophages play a pro-inflammatory role in radiation-induced lung injury. These findings suggest that targeting Mitf could inhibit macrophage polarization and mitigate radiation-induced lung damage, offering a potential therapeutic strategy.

P3.03.19 SFRP2highCAFs Trigger CD8+T Cell Apoptosis to Sustain Abscopal Resistance to Radioimmunotherapy in Lkb1-Mutant Lung Tumors

Y. Zeng[1,2], Y. Zhang[1], Z. Dong[1]
[1]Nanfang hospital, Southern Medical University, Guangzhou/CN ,[2]Institute of Cancer Stem Cell, Dalian Medical University, Dalian/CN

Introduction: Patients with LKB1-mutant tumors frequently exhibit primary resistance to immunotherapy, thereby limiting the efficacy of current treatment modalities. In this context, the integration of radiotherapy with immunotherapy, and its ability to induce an abscopal effect, offers a promising strategy to overcome this challenge. Nevertheless, the occurrence of abscopal responses following radioimmunotherapy remains lower than anticipated, and the underlying mechanisms restraining this effect are yet to be fully elucidated.

Methods: Murine bilateral lung tumor models (Lkb1-KO) were treated with radioimmunotherapy. Multi-compartment immune profiling was applied to assess differences in immune activation between the irradiated and distant tumors. In CAF-specific Sfrp2 knockout models, single-cell RNA sequencing was employed to elucidate the role of SFRP2-high CAFs, with subsequent validation performed via in vitro co-culture assays.

Results: In the bilateral Lkb1-KO lung tumor model, radioimmunotherapy, compared to monotherapy, markedly suppressed tumor growth in the irradiated field but not in the abscopal site. Multi-compartment immune profiling analyses demonstrated that radioimmunotherapy induced immune activation in irradiated tumors and elicited robust CD8+ T cell priming in tumor-draining lymph nodes. However, the LLC1-sgLkb1 model demonstrated suppressed CD8+ T cell infiltration in abscopal unirradiated tumors post-radioimmunotherapy. Further single-cell transcriptomic analyses revealed that Lkb1 deficiency orchestrates a dominant accumulation of SFRP2high cancer-associated fibroblasts (CAFs) within abscopal niches. These CAFs were found to upregulate transcriptional programs associated with T cell apoptosis while concurrently suppressing survival signals. In vitro co-culture assays further demonstrated that SFRP2high CAFs induce pronounced apoptosis in CD8+ T cells, thereby contributing to the diminished immune infiltration and the failure to control distant tumor growth.

Conclusions: This study uncovers SFRP2high CAFs as central executors of abscopal resistance in LKB1-mutant tumors, inducing CD8+ T cell apoptosis to undermine effective antitumor immunity. targeting SFRP2high CAFs may prevent CD8+ T cell apoptosis and reactivate the abscopal effect in LKB1-mutant lung cancer.

Introduction: Cancer-associated cachexia (CAC) occurs in up to 80% of the patients with advanced cancer, and leptomeningeal carcinomatosis (LM) developed in 3-10% of the patients with advanced-stage lung cancer. Treatment options for the LM are limited, and there is currently no U.S. FDA-approved pharmaceutical agent for the CAC. Aptamers are small oligonucleotides considered as chemical antibodies. Here we report the APC2, a novel aptamer-cisplatin conjugate, for the LM and CAC in lung cancer.

Methods: The lung cancer LM orthotopic mouse model served as the platform for aptamer identification (in vivo SELEX) and the model for the CAC. The aptamer was conjugated with cisplatin to form APC2. This study compared the efficacy of APC2 plus pemetrexed vs cisplatin plus pemetrexed for body weight maintenance and tumor suppression in mice bearing LM and CAC. The drugs were administered intravenously, the mouse body weight was measured daily, and the tumor burden was monitored via the In Vivo Imaging System.

Results: The APC2 showed a ~3% blood-brain barrier penetration rate. Signals for AP2, the backbone aptamer for the APC2, were detected in the brain regions related to the CAC. Efficacy studies showed that APC2 plus pemetrexed worked better than cisplatin plus pemetrexed for both body weight maintenance and tumor control. The circulating IL-6 levels were lower in the APC2 plus pemetrexed treatment group.

Conclusions: The APC2 is a novel aptamer-cisplatin conjugate that possessed a 3% blood-brain barrier penetration rate. The APC2 plus pemetrexed represents a new approach for lung cancer LM and CAC. Although further studies on mechanism elucidation are necessary, our data suggests its future translational potential.

P3.03.22 Tumor Treating Fields (TTFields) Downregulate DNA Repair and Show Efficacy in Small Cell Lung Carcinoma Preclinical Models

R. Engelman[1], L. Somri-Gannam[1], T. Borkum[1], R. Blatt[1], D. Gerasimova[1], S. Cahal[1], C. Tempel Brami[1], M. Shai[1], E. Dor-On[1], I. Tzchori[1], T. Torres[2], A. Haber[1], M. Giladi[1], U. Weinberg[3], Y. Palti[1]
[1]Novocure Ltd, Haifa/IL ,[2]Novocure Inc, Fort Lauderdale/FL/USA ,[3]Novocure GmbH, Baar/CH

Introduction: Small cell lung cancer (SCLC) is a highly aggressive malignancy, representing 10-15% of all lung cancer cases. Current standard-treatment includes combination chemotherapy with a platinum-based agent plus etoposide, administered alongside immunotherapy and concurrent thoracic radiotherapy. The study described herein aimed to examine the efficacy of TTFields for treatment of SCLC and examine the effect of TTFields together with the standard chemotherapy agents.

Methods: Human SCLC cell lines H196 and DMS-53 were treated with TTFields (H196: 1.62 V/cm RMS, 150 kHz, 120 h; DMS-53: 1 V/cm RMS, 150 kHz, 72 h), alone or with the cisplatin and etoposide (H196: 0.15 µM cisplatin, 0.3 µM etoposide; DMS-53: 0.25 µM cisplatin, 0.5 µM etoposide). Efficacy was measured by analyzing cell count, colony formation, and apoptosis induction. The overall effect was calculated by multiplying cell count with colony formation. Expression of proteins from the Fanconi-Anemia-BRCA pathway for DNA repair was examined using western blot analysis. DNA damage was tested with fluorescence microscopy detection of H2AX. TTFields efficacy was further evaluated in vivo, in mice orthotopically inoculated with murine KP3 SCLC cells. 7 days after inoculation, TTFields or sham-heat were continuous applied for 9 days. Tumor volume was examined by magnetic resonance imaging (MRI) at treatment end. Tumor weight was also measured.

Results: TTFields reduced cell count, induced apoptosis, and provided an increased overall effect relative to control in both cell lines. While cisplatin plus etoposide also demonstrated efficacy by these measures, the effects were augmented when TTFields were applied concomitantly with these chemotherapies. TTFields downregulated the expression of proteins from the Fanconi-Anemia-BRCA pathway: BRCA2, FANCJ, FANCD2, and FANCA in both cell lines. TTFields alone, as well as cisplatin plus etoposide, had limited effect on DNA damage, while co-application of these treatments significantly elevated DNA damage relative to control and to the two treatment options alone (i.e. TTFields and cisplatin plus etoposide). Furthermore, TTFields significantly reduced tumor growth relative to control in the mouse model.

Conclusions: Our results demonstrate efficacy of TTFields for the treatment of SCLC in preclinical models, and a potential advantage for TTFields concomitant with standard-of-care chemotherapies. The enhanced efficacy of cisplatin and etoposide with TTFields may be attributed to the induction of DNA damage and downregulation of key DNA repair pathways by TTFields. Future studies will include immunotherapies together with TTFields and combination chemotherapy.

P3.03.23 Circular Rna Vaccine Synergizes With Anti-PD-1 to Augment Therapeutic Efficacy in Lung Cancer

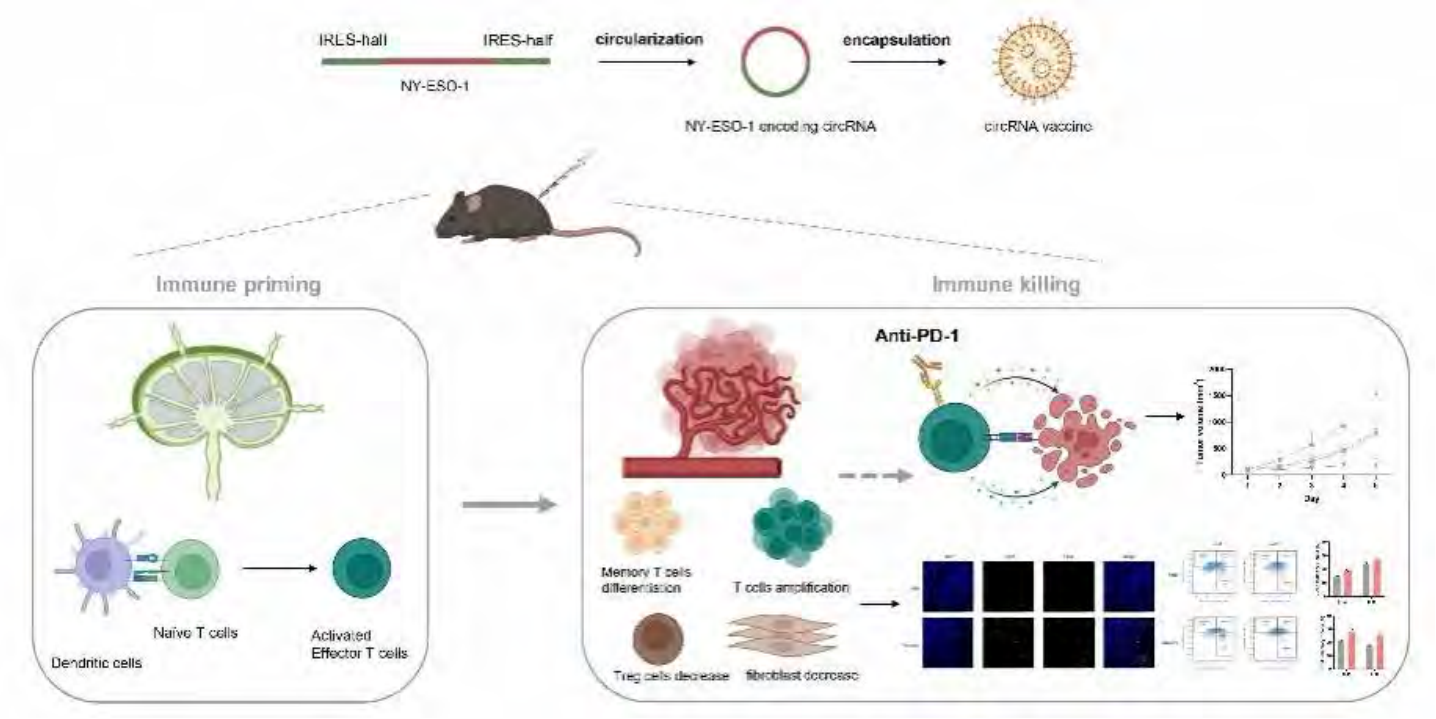
S. Chen, Z. Liu, J. Cai, M. Qiu
Peking University People's Hospital, Beijing/CN

Introduction: The successful deployment of RNA vaccines in infectious disease has accelerated the exploration of RNA-based platforms for cancer immunotherapy. Circular RNA (circRNA), characterized by its covalently closed structure, has emerged as a promising candidate for cancer vaccine development due to superior stability, prolonged half-life, and scalable manufacturing compared to linear mRNA. Here, we report a novel circRNA vaccine for its prophylactic efficacy and synergistic therapeutic potential with anti-PD-1 for lung cancer treatment.

Methods: The circRNA vaccine encoding NY-ESO-1 (a highly immunogenic cancer-testis antigen) was synthesized using our proprietary circular RNA platform and encapsulated in lipid nanoparticles. A mouse lung cancer model was established by subcutaneous implantation of LLC cells overexpressing NY-ESO-1. Tumor-infiltrating immune profiles were analyzed via immunofluorescence and single-cell transcriptome sequencing.

Results: The circRNA vaccine showed superior therapeutic efficacy compared to its mRNA counterpart, with a significantly increased proportion of apoptotic cells and decreased proliferating cells in tumor tissues after vaccination. Immunofluorescence staining revealed enhanced CD8+ T cells infiltration and reduced Treg cells population in the tumor microenvironment (TME). Additionally, the preliminary results of single-cell transcriptome sequencing showed that vaccination-induced alterations in the immune cell landscape. Increased infiltration of T cells and dendritic cells in tumor indicating enhanced antigen presentation and T cell activation, and decreased fibroblasts and endothelial cells potentially associated with inhibited tumor invasion and metastasis. In prophylactic models, intramuscular vaccination of circRNA vaccine significantly inhibited tumor growth and prolonged survival. Mechanistically, increased mature dendritic cells and memory-phenotype T cells in tumor tissues with corresponding decreases in the spleen, suggesting migratory infiltration. Given the low clinical responsiveness of lung cancer to immunotherapy, we investigated the synergistic effect of circRNA vaccine with anti-PD-1. Combination therapy significantly improved therapeutic outcomes, achieving over 90% tumor inhibition rata with complete response in 1/5 mice.

Conclusions: Our novel circRNA vaccine exhibits superior prophylactic and therapeutic effects against lung cancer, particularly through synergistic enhancement of immune checkpoint inhibitors. The vaccine mediates TME remodeling by promoting inflammatory transformation. This study proposes a promising strategy for lung cancer patients.



Keywords: RNA vaccine, immunotherapy, tumor microenvironment

P3.03.24 Oxydock: Optimizing Lung Cancer-Targeted Therapy Through Oxygen-Responsive Molecular Docking

A. Pemmaraju, S. Sodhi, N. Spinelli
Great Neck South High School, Lake Success/NY/USA

Introduction: Tumor hypoxia in lung cancer tumor microenvironment (TME) is highly prevalent. Through various adaptations, cancer cells not only thrive in hypoxia but are also resistant to treatment including novel targeted therapies. Computational docking has revolutionized drug discovery for lung cancer, but hypoxic TME poses significant challenges for making reliable predictions by altering protein structures. Current programs, such as AutoDock Vina, do not account for hypoxia-induced protein structural changes, leading to discrepancies between its predictions and in-vivo outcomes. In this study, we aimed to engineer an in-silico docking platform for accurate prediction in hypoxic lung cancer TME.

Methods: We created 'OxyDock', a novel docking platform that integrates hypoxia-driven post-translational modifications (PTMs), including phosphorylation, acetylation, and methylation into its algorithm enabling binding prediction in both normoxic and hypoxic conditions. The platform was created from scratch by modifying the 3D structures of proteins and ligands obtained from PDB files and PubChem. Eleven receptor-ligand pairs were selected for validating and training of OxyDock based on published experimental IC_{50} data in normoxia and hypoxia. XGBoost machine learning model was used to further refine the docking simulator based on experimental data. IC_{50} values were converted into binding affinities (ΔG) using the Cheng-Prusoff equation. Relationship between OxyDock's predicted ΔG values and experimental data was assessed using Pearson's correlation. We conducted linear regression for each drug-protein pair to model relationship between predicted and experimental ΔG values (fig 1). Root Mean Squared Error (RMSE) for both OxyDock and AutoDock Vina predictions was calculated and Bland-Altman plots used to visualize the agreement between experimental and predicted ΔG values. We also performed feature importance analysis to determine key factors influencing binding affinity predictions by XGBoost model.

Results: OxyDock outperformed Autodock Vina, achieving a RMSE of 1.16 kcal/mol compared to 2.85 kcal/mol for AutoDock Vina, with stronger correlation to experimental binding (r = 0.95 vs. r = 0.85). OxyDock's predictions were also accurate in 'outlier' situations such as Erlotinib-EGFR interaction, wherein the binding is stronger in hypoxia. Oxydock accurately predicted a higher binding affinity (ΔG = -8.7 kcal/mol) in hypoxia compared to normoxia (ΔG = -8.01 kcal/mol), mimicking experimental findings. This was possible because of XGBoost integration whose most important features were mainly ligand properties such as molecular weight and partition coefficient.

Conclusions: Our data supports the superiority of OxyDock over AutoDock in predicting drug binding under physiologically relevant conditions, making it a promising tool for designing targeted therapies for lung cancer.

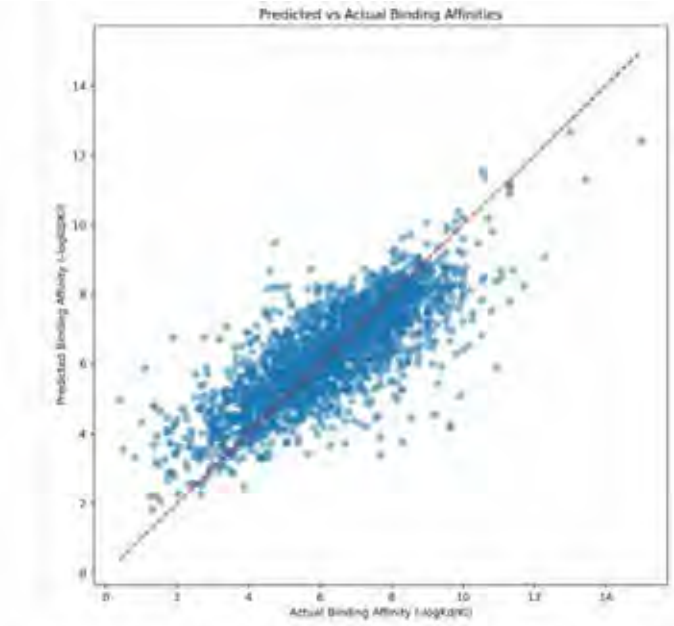


Figure 1: *Predicted vs. actual binding affinities for OxyDock simulations. Each point on the scatter plot represents a different protein-drug pair with X-axis representing the binding affinities predicted by OxyDock and the Y-axis showing the actual experimental binding affinities. The red line represents the line of perfect correlation. If a point is close to this red line, it means that OxyDock's prediction is very close to the actual experimental result.*

P3.03.25 A Combination Therapy Strategy That Targets Both KRAS-G12C and GSK3 for Non-Small Cell Lung Cancer

X. Gong[1], X. Ye[2], Y. Ding[1], J. Wu[2], C. Chen[1], Z. Yang[1], H. Cai[2]
[1]Fujian Medical University Union Hospital, Fuzhou/CN ,[2]Xiamen University, Xiamen/CN

Introduction: Lung cancer is the leading cause of cancer mortality, and nearly 80% of cases are non-small cell lung cancer (NSCLC). KRAS mutants, including G12C, are critical cancer drivers that used to be difficult to drug Despite progresses in allosteric KRAS-G12C inhibitors, e.g. sotorasib and adagrasib,, their drug response is still suboptimal. Here, we employ a high-throughput drug screening pipeline to identify compounds that potentially sensitize NSCLC to KRAS-G12C inhibitors, and further investigated the molecular pharmacological mechanisms.

Methods: We screened nearly 6,000 compounds and 16 classes of novel targets that synergize with the KRAS G12C inhibitor sotorasib to suppress KRAS G12C-mutant NSCLC cell lines. Drug synergy was scored using the HSA (Highest Single Agent) and Bliss independence models. Promising synergistic combinations were further validated through low-throughput assays to prioritize candidates with optimal Chou-Talalay combination indices (CI values). RNA-seq was employed to investigate the molecular output of combination therapy, and the nominated downstream pathways and targeted molecules were further interrogated via biochemical and cell biology methods.

Results: The GSK3 inhibitor LY2090314 emerges as a compound that sensitizes NSCLC cell lines to KRAS G12C inhibitors. LY2090314 and KRAS-G12C inhibitors synergized to induce the apoptosis of lung adenocarcinoma and squamous cell carcinoma cell lines, and suppressed the growth of lung tumor xenografts. Interestingly, LY2090314 played the tumor suppressive role by targeting GSK3β, but the mechanism was not dependent on Wnt/β-catenin signaling pathway. We uncovered multiple affected metabolic pathways promoting reactive oxygen species (ROS) that may at least partially account for the synergistic effect. Blocking ROS rescued the cancer cell lines from the KRAS-GSK3 combination therapy. We will employ CRISPR knockout to further validate the target.

Conclusions: We uncovered a GSK3 inhibitor LY2090314 that sensitized NSCLC to KRAS-G12C inhibitors, and proposed a new pharmacological mechanism for the combination therapy. Notably, LY2090314 previously went through a Phase-2 clinical trial for leukemia that had validated its safety. Therefore, our repurposing has potential to translate into clinical therapies that may benefit cancer patients harboring KRAS-G12C mutations.

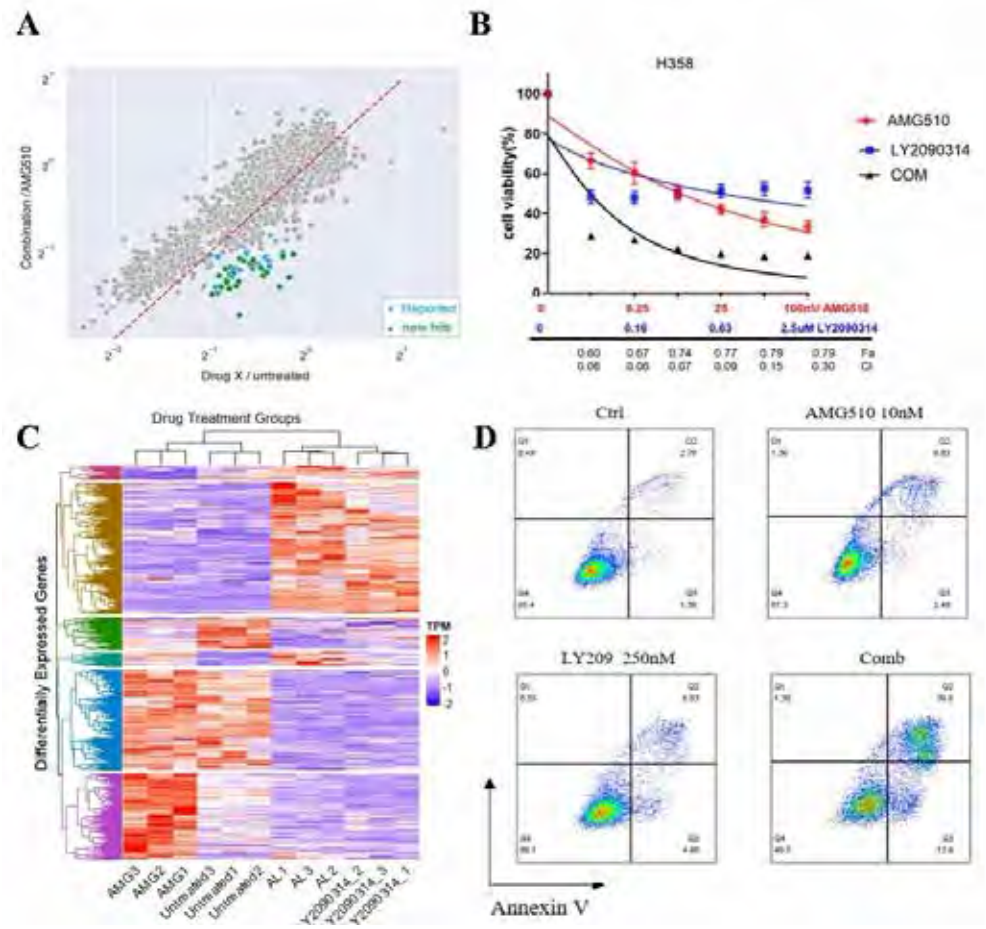

Figure. High-throughput drug screening reveals that GSK3 inhibition synergistically enhances the efficacy of KRAS G12C inhibitors in KRAS G12C-mutant lung cancer.

P3.03.26 Ir-Metal Framework Loaded With Radiation-Responsive Anti-Angiogenic Prodrugs for Enhanced Radiotherapy Efficacy

Q. Zhang
Shanghai Chest Hospital, Shanghai Jiao Tong University, school of Medicine, Shanghai/CN

Introduction: The efficacy of radiotherapy is often hindered by radioresistance, particularly in tumor hypoxia and abnormal angiogenesis.

Methods: This study presents a novel approach using the iridium metal framework (Ir-MF), pazopanib prodrug (P), and SH-Polyethylene Glycol-NH2 (SH-PEG-NH2)-based Ir-MF@PP system to enhance the efficacy of radiotherapy. The Ir-MF serves as both a carrier and radiosensitizer, combined with a radiation-responsive anti-angiogenic pazopanib prodrug for targeted vascular delivery.

Results: The Ir-MF sensitizes tumor cells to radiotherapy by generating reactive oxygen species (ROS), allowing for effective treatment at lower doses while minimizing damage to healthy tissues. Furthermore, radiotherapy triggers the controlled release of pazopanib, a multi-targeted tyrosine kinase inhibitor primarily targeting vascular endothelial growth factor (VEGF), to normalize tumor vasculature, improving blood perfusion and oxygenation. This dual strategy not only increases local drug concentration and safety but also enhances the overall efficacy of radiotherapy by addressing the tumor hypoxia and abnormal blood supply.

Conclusions: Its effectiveness has been validated at both the cellular and animal levels, where it sensitizes tumors to radiotherapy either directly through Ir-MF or indirectly by inducing vascular normalization, thereby enhancing treatment efficacy and achieving superior tumor killing effects, paving the way for more precise and effective lung cancer treatments.

P3.03.27 The TXNRD1-IGF2BP3 Axis Promotes EGFR-TKI Resistance and Identifies a Therapeutic Vulnerability in NSCLC

M. Yang
Cancer Hospital, Chinese Academy of Medical Sciences, Beijing/CN

Introduction: Acquired resistance to epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) remains a major challenge in non-small cell lung cancer (NSCLC). The thioredoxin reductase-1 (TrxR1) system plays a critical role in cellular redox homeostasis. Thioredoxin-1 (Trx1) encoded by the TXN1 gene, reduces reactive oxygen species (ROS), while TrxR1, encoded by the TXNRD1 gene, catalyzes the reduction of oxidized Trx1. Given the upregulation of the Trx1 pathway in cancer, the TrxR1 system may be a potential non-oncogene addiction target for overcoming acquired resistance.

Methods: Data-independent acquisition mass spectrometry (DIA-MS) was used for plasma proteomic profiling. Immunoprecipitation mass spectrometry (IP-MS) identified protein interactions, and RNA sequencing (RNA-seq) screened transcripts. Lentiviral transfection was employed to generate TXNRD1-overexpressing (oe) cell lines, mouse xenograft models were established to assess therapeutic efficacy. The HCC827 rezivertinib-resistant cell line (RR) was generated by continuous exposure to rezivertinib (BPI-7711) until reaching 100-fold of the initial IC50.

Results: Elevated Trx1 protein levels in plasma correlated with reduced sensitivity to BPI-7711, a third-generation EGFR-TKI, in NSCLC patients (Fig. 1A). Similarly, in resistant xenograft models, increased serum Trx1 expression was also associated with diminished EGFR-TKI efficacy (Fig. 1B). While Trx1 protein expression showed no significant difference between HCC827/RR and parental cells, TrxR1 protein levels were notably higher in HCC827/RR cells (Fig. 1C-D), indicating that TXNRD1 may be the key driver of resistance. Overexpression of TXNRD1 in HCC827 cell lines enhanced resistance to BPI-7711, decreased intracellular ROS levels, and attenuated EGFR-TKI-induced apoptosis (Fig. 1D-G). Transcriptomic profiling of HCC827 versus HCC827/RR cells (Group 1), and TXNRD1-oe versus control cells (Group 2), identified three differentially expressed genes through integrative analysis with IP-MS data from Group 2. Based on expression dynamics and specificity, IGF2BP3 was validated as a TXNRD1 downstream effector, whose upregulation was confirmed in both resistant and TXNRD1-oe cell lines via co-immunoprecipitation and Western blot (Fig. 1H-L). Mechanistically, IGF2BP3 mediates EGFR-TKI resistance by facilitating a metabolic shift from glycolysis to oxidative phosphorylation. Kaplan-Meier analysis of public datasets revealed that concurrent high expression of TXNRD1 and IGF2BP3 was associated with the poorest overall survival in NSCLC (Fig. 1M). Notably, combining the TrxR1 inhibitor Auranofin with BPI-7711 significantly enhanced anti-tumor efficacy and reversed drug resistance (Fig. 1N-O).

Conclusions: This study reveals a novel mechanism of EGFR-TKI resistance mediated by the Trx1/TrxR1 system and the TXNRD1-IGF2BP3 axis in NSCLC. Targeting TrxR1 with Auranofin could restore sensitivity to EGFR-TKI, highlighting a potential therapeutic strategy to overcome resistance.

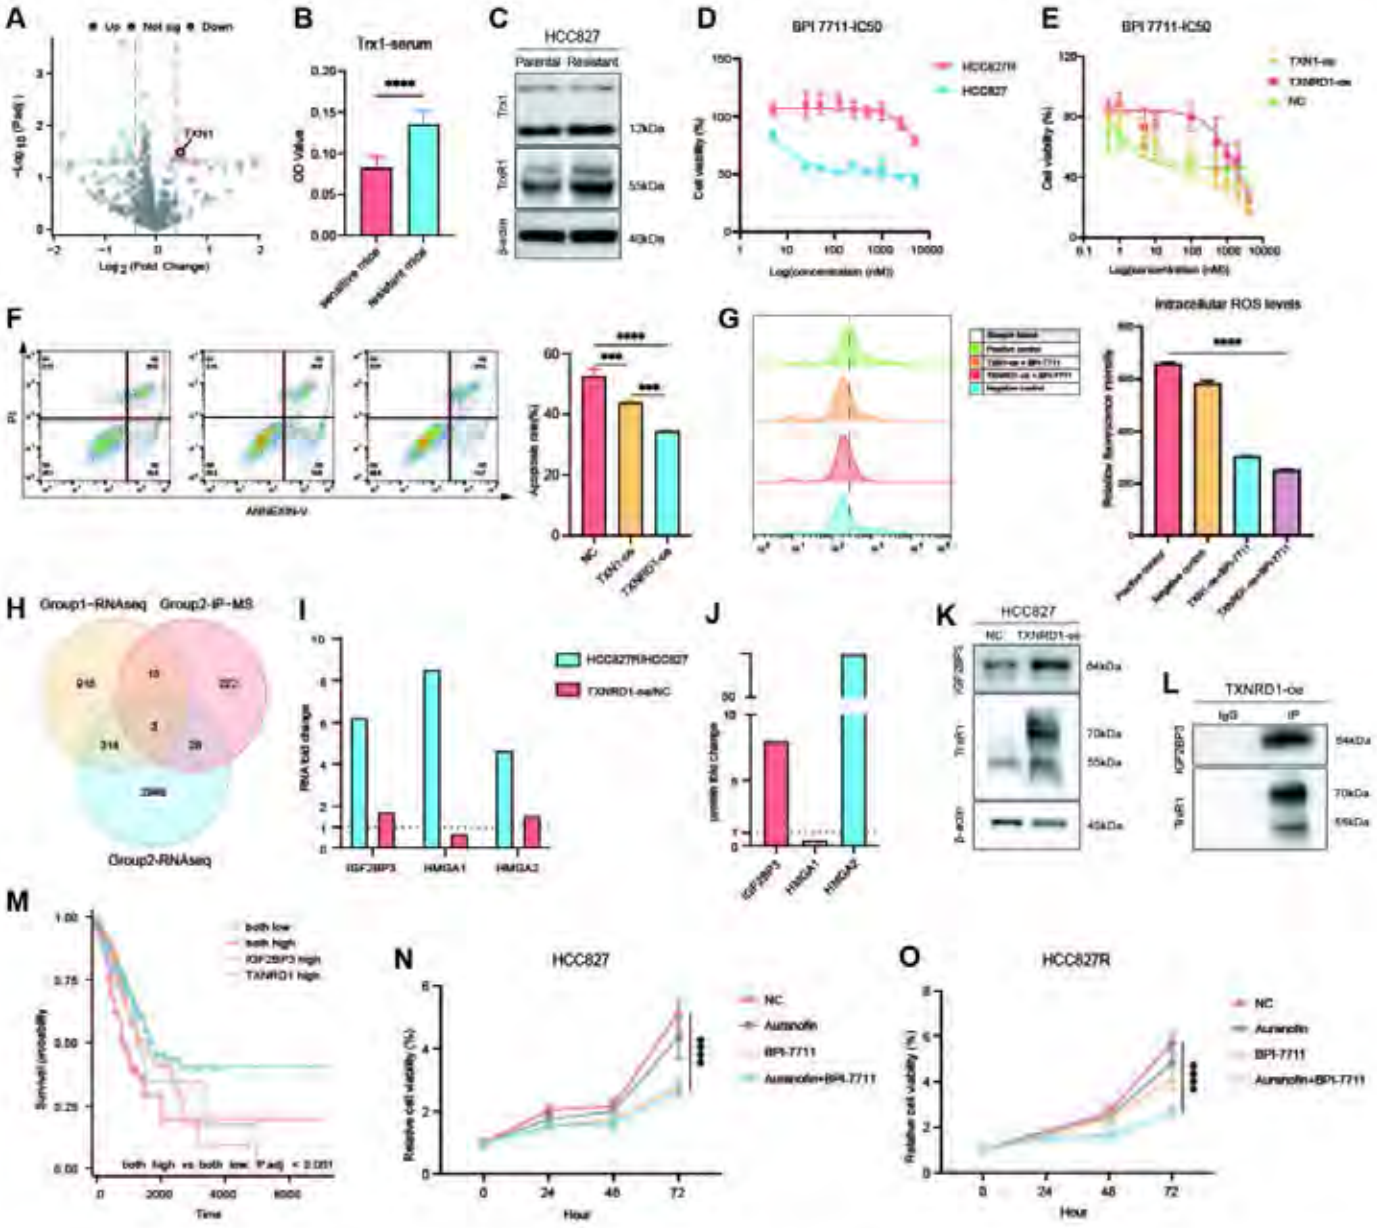

Figure 1. The TXNRD1-IGF2BP3 axis promotes acquired EGFR-TKI resistance in NSCLC
(A) Plasma Trx1 levels were negatively correlated with BPI-7711 sensitivity in NSCLC patients.
(B) Serum Trx1 expression was elevated in xenograft models resistant to BPI-7711 treatment.
(C) Western blot showed comparable Trx1 but elevated TrxR1 expression in HCC827/RR cells compared to parental HCC827.
(D) Cell viability curves indicated the successful generation of HCC827/RR.
(E) Cell viability curves indicated increased resistance to BPI-7711 in TXNRD1-oe but not TXN1-oe cells.
(F) Cell apoptosis analyses in TXNRD1-oe, TXN1-oe and control cells treated with BPI-7711(20nM) for 48 hours.
(G) Intracellular ROS levels detected by flow cytometry in TXNRD1-oe, TXN1-oe and control cells.
(H) The overlapping of RNA-seq and IP-MS data from Group1 and Group2, identified three genes potentially correlated with TXNRD1.
(I) RNA -seq validation of IGF2BP3 and HMGA2 upregulation in HCC827/RR and TXNRD1-oe cells.
(J) IP-MS validation of IGF2BP3 and HMGA2 upregulation in TXNRD1-oe cells.
(K) Western blot confirmed overexpression of TXNRD1 increased IGF2BP3 protein level.
(L) CO-IP assays demonstrated protein-protein interaction between TrxR1 and IGF2BP3.
(M) Concurrent high expression of TXNRD1 and IGF2BP3 correlated with the poorest overall survival in LUAD-TCGA database.
(N-O) Combination of Auranofin (TrxR1 inhibitor) and BPI-7711 significantly suppresses cell viability in both parental and HCC827/RR cells.

P3.03.28 Tumor Treating Fields (TTFields) Concomitantly With Anti-PD-1 and Cisplatin in a Mouse Model of Non-Small Cell Lung Cancer

B. Brant[1], Y. Barsheshet[1], T. Voloshin[1], T. Kan[1], T. Haj Khalil[1], S. Zisman-Rozen[1], L. Koren[1], A. Vorontsov[1], B. Koltun[1], C. David[1], A. Klein-Goldberg[1], E. Zemer-Tov[1], A. Haber[1], M. Giladi[1], U. Weinberg[2], Y. Palti[1]
[1]Novocure Ltd, Haifa/IL ,[2]Novocure GmbH, Baar/CH

Introduction: Tumor Treating Fields (TTFields) are low-intensity, intermediate-frequency alternating electric fields that disrupt mitotic processes in cancer cells, promoting immunogenic cell death and enhancing antitumor immunity. TTFields therapy administered concomitantly with immune checkpoint inhibitors (ICIs) or chemotherapy is approved for metastatic non-small cell lung cancer (NSCLC) following progression on platinum-based treatment. The ongoing LUNAR-2 clinical trial (NCT06216301) is evaluating first-line TTFields administered concomitantly with pembrolizumab and platinum-based chemotherapy in metastatic NSCLC. The current study examines the efficacy of this concomitant treatment in preclinical models.

Methods: C57BL/6 mice were orthotopically implanted with LL/2 lung carcinoma cells. After 7 days, the mice received TTFields (150 kHz, continuous for 10 days) or sham (heat), and either vehicle or a treatment regimen consisting of anti-PD-1 (10 mg/kg), cisplatin (1 mg/kg), and pemetrexed (6 mg/kg), administered via intraperitoneal injection every 72 hours (three doses total), starting on day 2 of TTFields. Four groups were studied: control, TTFields alone, anti-PD-1/cisplatin/pemetrexed (PCP), and TTFields administered concomitantly with PCP. Tumor localization was confirmed at study start by MRI. Tumor volumes were measured at study end with calipers. Tumor-infiltrating lymphocytes (TILs) were assessed by flow cytometry. IFN-γ and Granzyme B expression in CD8+ T cells was evaluated following PMA/ionomycin restimulation.

Results: Mice treated with the concomitant TTFields plus PCP regimen had significantly smaller tumors compared to all other groups. PCP and TTFields plus PCP induced increased infiltration of CD3+ T cells, particularly CD8+ T cells. The TTFields plus PCP group showed a marked increase in IFN-γ-producing CD8+ T cells, alongside elevated Granzyme B expression compared to control and TTFields-only groups.

Conclusions: TTFields administered concomitantly with standard immunochemotherapy enhanced tumor control and augmented the cytotoxic immune response in a mouse model of NSCLC. These preclinical findings support the therapeutic potential of this approach.

Keywords: Tumor Treating Fields, NSCLC, anti-PD-1

P3.03.29 IAM1363 Is a Potent, Selective, and Irreversible HER2 and Pan-HER2 Mutant Small Molecule Inhibitor for the Treatment of HER2-Driven NSCLC

Z.J. Huang, K. Chen, A. Adams, L. Kulyk, C. Zhao, J. Park, H. Zhang, B. Liu, L. Gomez, M. Anderson, P. Harvey, F. Manby, P. Olson, T. Miller, N. Josephson
Iambic Therapeutics, Inc, San Diego/CA/USA

Introduction: Alterations of HER2 have been identified in NSCLC, with ~3% of cases harboring HER2 amplifications and ~2% having activating mutations. Trastuzumab deruxtecan (T-DXd), a HER2-specific antibody-drug conjugate, is an approved therapy for relapsed NSCLC with HER2-activating mutations or protein overexpression (IHC3+). However, its clinical benefit is limited by suboptimal response durability in some patients and a notable risk of treatment-related toxicities, including interstitial lung disease. These challenges highlight ongoing unmet medical needs and opportunities for safer, more effective therapies in this population. Small molecule inhibitors to HER2 have the potential to treat HER2-driven NSCLC. However, due to structural homology between EGFR and HER2, many HER2 kinase inhibitors also inhibit EGFR, leading to dose-limiting toxicities.

Methods: IAM1363 was evaluated through a series of biochemical assays, cell-based studies, and animal models to comprehensively characterize its activity in NSCLC.

Results: IAM1363 is a potent, irreversible and selective Type II inhibitor of HER2, preventing phosphorylation and activation of wild-type HER2 and variants with activating mutations in the tyrosine kinase domain. It exhibited >500-fold biochemical selectivity for HER2 over EGFR and >400-fold cellular selectivity in HER2- versus EGFR-driven cell lines. This selectivity translated into potent activity in vitro, effectively inhibiting HER2-dependent cell growth and survival, while showing minimal impact on EGFR-driven cells. In vivo, IAM1363 is highly active in mouse models of HER2 amplified or mutant NSCLC, including CDX and PDX tumor models. In multiple NSCLC xenograft models tested, IAM1363 demonstrated equivalent or superior anti-tumor activity compared to T-DXd. Furthermore, IAM1363 showed synergistic activity in vitro and in vivo when combined with other anticancer agents, including T-DXd. Importantly, IAM1363 demonstrated robust anti-tumor activity in an intracranial model of HER2-amplified NSCLC, validating its ability to cross the blood brain barrier and achieve therapeutic effects in the CNS. IAM1363 treatment resulted in tumor regression across a wide range of pre-clinical models of HER2-driven cancers and it was well tolerated at therapeutic doses. Furthermore, IAM1363 demonstrated favorable PD and PK characteristics with sustained inhibition of HER2 phosphorylation in vitro and preferential enrichment within HER2-expressing tumors relative to plasma. As a result, anti-tumor activity was readily achieved with both standard QD and BID dosing, suggesting that substantial efficacy may be attainable with more flexible dosing schedules.

Conclusions: Based on its high selectivity, broad anti-tumor activity across biomarker-positive nonclinical models, and brain penetrance, IAM1363 is anticipated to be an effective treatment for HER2 amplified or mutant NSCLC patients, including for patients with CNS metastases. IAM1363 is currently being evaluated in a phase 1/1b clinical trial (NCT06253871).

P3.03.30 Activation of EGFR Signaling Mediated by PTPRR Methylation Causes Resistance to KRAS Inhibitor Sotorasib

H. Kanemura[1], T. Takehara[1], O. Maenishi[1], S. Tomida[2], N. Iwawaki[1], K. Kunimasa[3], T. Nakayama[4], S. Watanabe[4], S. Suzuki[1], K. Sakai[1], K. Nishio[1], K. Nakagawa[1], H. Hayashi[1], T. Teramura[1], K. Yoesaka[1]
[1]Kindai University, Faculty of Medicine, Osaka-sayama/JP ,[2]Okayama University Hospital, Okayama/JP ,[3]Osaka International Cancer Institute, Osaka/JP ,[4]Kishiwada City Hospital, Kishiwada/JP

Introduction: KRASG12C inhibitors such as sotorasib have demonstrated clinical benefit in KRASG12C-mutant non-small cell lung cancer (NSCLC); however, primary and acquired resistance remains a major clinical challenge. The underlying mechanisms of resistance remain incompletely understood.

Methods: We established sotorasib-resistant NSCLC cell lines harboring KRASG12C mutations and analyzed molecular alterations using phospho-kinase arrays, immunoblotting, microarray, and next-generation sequencing. Functional validation was performed by siRNA-mediated knockdown, PTPRR overexpression, and colony formation assays. The impact of EGFR blockade was evaluated in vitro and in vivo using xenograft mouse models. DNA methylation of PTPRR promoter regions was assessed using bisulfite sequencing and TCGA datasets. Immunohistochemistry and clinical data were analyzed to assess the association between PTPRR expression and clinical outcomes in patients with KRASG12C- or EGFR-mutant NSCLC treated with sotorasib or osimertinib, respectively.

Results: Sotorasib-resistant clones displayed persistent ERK phosphorylation despite effective KRASG12C inhibition, accompanied by increased EGFR activation. Phospho-RTK arrays and western blotting identified the phosphorylation of tyrosine residues on EGFR, particularly Y1173. Expression profiling revealed marked downregulation of the tyrosine phosphatase PTPRR in resistant cells, which was linked to promoter hypermethylation. Co-immunoprecipitation confirmed direct interaction between PTPRR and EGFR. Functionally, PTPRR knockdown induced resistance and EGFR/ERK reactivation, whereas PTPRR re-expression suppressed EGFR phosphorylation and restored sotorasib sensitivity. Combined inhibition with cetuximab and sotorasib overcame resistance in vitro and in xenograft models without significant toxicity. Clinically, low PTPRR expression in tumor specimens was associated with shorter progression-free (median 4.3 vs. 7.5 months; HR 3.27, 95% CI: 0.76-14.0) and overall survival (median 7.5 months vs. not reached; HR 3.21, 95% CI: 0.70-14.7) in patients with KRASG12C-mutant NSCLC receiving sotorasib. When comparing patients with and without PTPRR expression at the time of EGFR TKI resistance, those with PTPRR expression exhibited a significantly shorter PFS on osimertinib (median of 91 days versus 372 days; HR not estimable), highlighting a broader role for PTPRR in modulating EGFR dependency across oncogenic contexts.

Conclusions: Our findings identify PTPRR as a critical regulator of EGFR phosphorylation and a key determinant of resistance to KRASG12C inhibitors. DNA methylation-mediated suppression of PTPRR leads to EGFR/ERK pathway activation and loss of sotorasib efficacy. Dual blockade of KRASG12C and EGFR is an effective therapeutic strategy, particularly in tumors with reduced PTPRR expression. Furthermore, PTPRR expression may serve as a biomarker to stratify patients who could benefit from EGFR inhibition in KRASG12C-mutant NSCLC. These insights support the rationale for incorporating epigenetic and phosphatase profiling into resistance monitoring and combination therapy strategies.

P3.03.31 Transcriptomic Profiling Identifies a Prognostic and Predictive Inflammatory Signature in Patients With Lung Adenocarcinoma

A. Al-Bzour[1], N. Al-Bzour[1], M. Hashki[1], Y. Estaitia[1], O.M. Younis[2], J. Alrawabdeh[2], S. Abualinin[1], B. Ricciuti[3], F. Abu Rous[4]
[1]Jordan University of Science and Technology, Irbid/JO ,[2]University of Jordan, Amman/JO ,[3]Dana-Farber Cancer Institute, Boston/MA/USA ,[4]Henry Ford Health, Detroit/MI/USA

Introduction: Circulating inflammatory markers such as neutrophil-to-lymphocyte ratio are promising biomarkers in non-small cell lung cancer (NSCLC) patients. However, inflammatory transcriptomic biomarkers have not been well studied. Here, we constructed a transcriptomic-based inflammation signature and validated its prognostic and predictive value in LUAD.

Methods: We analyzed RNA-seq data from 507 lung adenocarcinoma (LUAD) patients and 59 normal controls from The Cancer Genome Atlas (TCGA). Inflammation-related genes (IRGs) were obtained from GeneCards, and differentially expressed genes (DEGs) were identified using DESeq2 with a threshold of |Log2FC| > 0.5 and adjusted p-value < 0.05. Prognostic biomarkers were selected using LASSO regression, followed by univariate and multivariate Cox proportional hazard models. We developed a risk score using significant genes, and patients were stratified into high- and low-score groups using the median as the cut-off value. Survival analysis for Overall Survival (OS) and progression-free Survival (PFS) was performed using Kaplan-Meier curves and log-rank tests. Functional enrichment analysis was conducted using Gene Ontology (GO). External validation was performed using independent GEO cohorts (GSE29013, GSE30219). Additionally, we used multiple machine learning models to assess the predictive value of inflammation-related genes for immune checkpoint inhibitor (ICI) response across four GEO datasets.

Results: We identified 3,083 DEGs between LUAD and normal samples, of which 872 were inflammation-related. LASSO regression and Cox analysis revealed three independent prognostic biomarkers: ADM, LOX, and NEFL, all associated with poor survival (P-value < 0.05). The risk score model effectively grouped patients into high-score and low-score groups. The high-score group had significantly worse PFS and OS than the low-risk group (P-value < 0.05). Functional enrichment analysis highlighted pathways related to neuronal signaling and extracellular matrix remodeling in tumor cells compared to normal tissue. Molecular analysis revealed distinct protein and gene expression profiles between risk groups, with proteins such as ERBB3 and MAPK9 overexpressed in the low-risk group. In contrast, SERPINE1 and SMAD3 were overexpressed in the high-risk group. External validation confirmed the prognostic utility of the risk model in independent cohorts. A machine learning model was developed using inflammation-related DEGs to predict ICI response based on transcriptomic data from four GEO cohorts. After training multiple models, LightGBM demonstrated the best performance when applied to a merged dataset of 68 patients and 42 genes, achieving an accuracy of 0.89 and an AUROC of 0.8. Using SHAP (Shapley Additive Explanations) analysis, we identified the key genes driving the model's predictions. The results showed that IL7 (SHAP Importance: 0.2722, p = 0.0018) and SLC2A1 (SHAP Importance: 0.2058, p = 0.0130) are significant predictors of ICI response, suggesting their potential as biomarkers in LUAD.

Conclusions: We constructed an inflammation score based on gene expression in LUAD patients. The signature depended on 3 inflammation genes significantly associated with survival. The high-inflammation group was associated with better OS, PFS, and DSS. Machine learning models demonstrated that inflammation-related genes could predict ICI response with high accuracy across multiple datasets.

P3.03.32 Multi-Omic Characterization of ALK Fusion LUADs Reveals Overactivation of DNA Replication as a Contributor to ALK TKI Resistance

Kravis Center for Molecular Oncology, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[4]Bioinformatics Core Facility, Memorial Sloan Kettering Cancer Center, New York, NY, New York/NY/USA ,[5]Antitumor Assessment Core, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[6]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[7]Druckenmiller Center for Lung Cancer Research, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[8]Precision Pathology Center, Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Lung adenocarcinomas (LUADs) driven by ALK gene rearrangements represent around 5% of LUADs and can be effectively treated with ALK-targeted therapies. However, resistance to these therapies inevitably develops in almost all cases, limiting long-term treatment success. While secondary mutations in ALK or other genes have been well studied as drivers of resistance, approximately 25% of cases exhibit resistance through non-genomic mechanisms. In this study, we have investigated the non-mutational mechanisms involved in ALK TKI resistance.

Methods: We performed a multi-omic analysis of ALK-fusion clinical samples (RNAseq, bisulfite sequencing, targeted mutational profiling) and patient-derived xenografts (PDXs) (RNAseq, single-cell RNAseq) before and after ALK TKI treatment.

Results: Mutational profiling of clinical samples revealed that approximately 50% of resistant ALK fusion-positive tumors harbor ALK mutations, with 24% of those showing ALK double mutations. Other significant genomic alterations observed in ALK TKI-resistant samples included MYC amplification and MET amplification. RNA sequencing analysis of resistant samples (n=27) revealed upregulation of DNA replication and cell cycle pathways, compared to TKI-sensitive clinical samples (n=24). Methylome characterization identified prominent hypermethylation of promoter regions in resistant samples. Integration of RNA sequencing and methylation data revealed few genes exhibiting concordant changes in both RNA and methylation levels, suggesting that the transcriptomic alterations associated with ALK resistance are not primarily regulated through methylation-driven epigenetic mechanisms. Characterization of 9 ALK-fusion PDXs confirmed upregulation of DNA replication and cell cycle pathways in resistant versus sensitive models. We next evaluated 3 highly sensitive PDXs before treatment and after relapse by scRNAseq. Resistant cells exhibited enrichment in a variety of pathways, including DNA replication, epithelial-to-mesenchymal transition (EMT), Hippo signaling, and TGF-β signaling, among others. These results suggest that TKI resistance mechanisms are complex and varied, with cells potentially relying on different molecular pathways to evade the effects of treatment. Given that the overactivation of the DNA replication pathway emerged as one of the most significant pathways associated with resistance in both clinical samples and patient-derived xenografts (PDXs), we next delved into the role of this pathway in driving ALK TKI resistance. We generated lorlatinib-resistant ALK cell lines (H3122 and H2228) through prolonged exposure of cells to lorlatinib. Resistant cells showed elevated expression of DNA replication-related proteins, including MYC, BRCA1, ORC1, and E2F1, and accumulated in the synthesis phase compared to wild-type cells. To target DNA replication and cell cycle pathways, we employed carfilzomib, an FDA-approved proteasome inhibitor. Combination of carfilzomib and lorlatinib strongly synergized, promoted cell death and induced cell cycle arrest in ALK-resistant cell lines by inhibiting DNA replication proteins. Ectopic overexpression of E2F1, CHEK1, ORC1 and EXO1 in wild-type cells increased lorlatinib IC50 and the number of drug-tolerant persister cells in vitro. In vivo experiments using ALK-driven PDXs confirmed that the combination of lorlatinib and carfilzomib significantly delayed tumor growth in TKI-acquired resistant PDXs (n=2), while showing a mild effect in models exhibiting primary mechanisms of resistance (n=2).

Conclusions: Overactivation of DNA replication contributes to ALK TKI acquired resistance and can be overcome with the proteasome inhibitor carfilzomib.

P3.03.33 Clinical and Genomic Landscape of BRAF-Mutant NSCLC Patients From the AACR GENIE BPC Cohort

E. Vignaud[1], C. Nicq[1], K-A. Baffert[1], P. Saintigny[2], A. Swalduz[2], S. Ortiz-Cuaran[2]
[1]Cancer Research Center of Lyon, Lyon/FR ,[2]Cancer Research Center of Lyon / Centre Léon Bérard, Lyon/FR

Introduction: Activating mutations in BRAF occur in ~4% of NSCLC, and are classified into three functional classes based on kinase activity and signaling mechanisms. BRAF V600X mutations (Class I) are the most common and result in constitutive kinase activation, leading to cancer cell proliferation and survival. Non-V600 mutations (Class II and Class III) collectively account for ~50% BRAF mutations in NSCLC, in contrast to other malignancies that are predominantly driven by BRAF V600E. BRAF mutation classes might define different clinical and molecular features, and clinical outcomes.

Methods: Here, we describe the clinical and genomic landscape of BRAF-mutant (BRAFm) NSCLC patients from the AACR GENIE BPC cohort (v17, data accessed in March 2025).

Results: A total of 27,858 NSCLC patients were identified. BRAF mutations were observed in ~6% of patients (n=1,623). Patients with concurrent EGFR driver alterations (n=78) were excluded from subsequent analyses. The BRAFm NSCLC cohort included patients with Class I (24,6%, n=380), Class II (22%, n=341) or Class III (22%, n=340) mutations. Compound BRAF mutations (e.g., > 2 Class I, II or III mutation) were observed in ~6% of patients (n=64). Overall, 883 (57%) of BRAF mutations occurred at one of the following five residues: V600 (n=380; 24,6%); G469 (n=201; 13%); G466 (n=127; 8,2%); D594 (n=102; 6,6%) and N581 (n=73; 4,7%).No difference in the age, ethnicity or sex distribution across mutation classes was observed. Most patients in the three classes were white with lung adenocarcinoma. Patients with compound BRAF mutations presented comparable clinico-pathological characteristics.Median OS from the date of molecular diagnosis was s 46.3, 48.5 and 40.1 months for classes I, II and III, respectively. OS was not statistically significantly different between the groups. The date of diagnosis was not available in the database.Among patients with co-mutations (60,6%, 937/1,545), Class I patients harbored co-mutions in SETD2 (22.6%), ATM (11.5%), SMAD4 (9.3%) and PIK3CA (8.8%). Co-alterations in STK11 were observed in 23% and 20.4% of Class II and Class III patients, respectively. Concurrent mutations in KRAS were higher in Class III patients (27%), compared to Class II (18.4%). TP53 mutation was the most common co-alteration across all 3 classes.The median TMB was significantly higher in tumors with Class II (9.52 mt/MB, P<0.001) or Class III (10.4 mt/MB, P<0.001) mutations, compared to Class I (6.94 mt/MB). Notably, compound BRAF mt presented the highest mediant TMB (14.7 mt/MB).

Conclusions: The AACR GENIE BPC initiative provides annotated clinical and tumor genomic data for BRAF-mutant NSCLC patients, and depicts the molecular and clinico-pathological differences between BRAF-mutation classes, indicating that BRAF-mutant NSCLC is not a single entity.

P3.03.34 Assessment of Minimal Residual Disease Using Liquid Biopsy in Patients With EGFR-Mutated Lung Cancer Treated With Osimertinib

C. Delahaye[1], A. Casanova[2], E. Taranchon-Clermont[1,3], A. Doussine[1], C. Decamps[1], M. Vienne[1], J-P. Cerapio[1], A. Anton[2], E. Devienne[3], V. Dongay[3], J. Milia[3], G. Favre[1,2], O. Calvayrac[1], A. Pradines[1,2], J. Mazieres[1,3]
[1]Cancer Research Center of Toulouse, INSERM UMR[1037], CNRS UMR[5071], Toulouse III Paul Sabatier University, TOULOUSE/FR ,[2]Institut Claudius Regaud, IUCT-O, Laboratory of Medical Biology, TOULOUSE/FR ,[3]Toulouse University Hospital, Thoracic Oncology Department, Toulouse/FR

Introduction: Drug tolerance is one of the major mechanisms driving resistance to targeted therapies (TT), but the dynamics and molecular heterogeneity underlying the adaptive drug response in patients is still unknown. Here, we used iterative liquid biopsies from lung cancer patients to characterize minimal residual disease (MRD) and predict treatment outcome using circulating tumor DNA (ctDNA) and circulating tumor cells (CTC).

Methods: LUNG-RESIST (NCT04222335) is a prospective research study enrolling EGFR-mutant adenocarcinoma patients treated by osimertinib frontline. We collected blood samples at baseline, 1 month and every 3 months until progression. The initial EGFR mutation (EGFRm) was monitored in ctDNA by digital PCR. CTC were enriched and isolated based on their size, absence of leucocyte staining and viability, to perform single-cell transcriptomic.

Results: 40 patients were enrolled with a median progression-free survival (mPFS) of 14.5 months (95%CI, 8.5-24.5 months). 70% patients had detectable EGFRm in ctDNA at baseline, and complete clearance at 1 month was associated with a favourable mPFS. Clinical relapse could be anticipated 3 months ahead based on ctDNA increase for 9/20 patients. CTC-like cells were collected at baseline and MRD from respectively 31/40 and 29/40 patients, and at clinical progression for 12/22 patients who relapsed, for a total number of 1,510 cells. The single-cell transcriptomic data on CTC will be presented at the congress, and should provide a better insight into the dynamics of molecular events occurring throughout the adaptive response in patients.

Conclusions: We report the first molecular profiling of ctDNA and CTC during the adaptive response to osimertinib in lung cancer patients. Monitoring the response and predicting the clinical outcome for EGFR-mutant lung cancer patients undergoing TT treatment can be done using ctDNA level as a biomarker. The isolation of CTC-like cells represents a non-invasive approach to study drug tolerance and ultimately develop new combinatory treatments to prevent relapse.

P3.03.35 Association of Intestinal Flora and Metabolites With Bone Metastasis in Patients With Non-Small Cell Lung Cancer

Y. Xin, J-X. Li, D. Zang, J. Chen
THE SECOND HOSPITAL OF DALIAN MEDICAL UNIVERSITY, Dalian/CN

Introduction: Lung cancer is the most common cause of cancer-related death worldwide, and bone is a common site for lung cancer metastases, which occurs in up to 40% of patients with non-small cell lung cancer (NSCLC). Gut microbes are considered as the "second genome" of humans and are implicated in many diseases. However, the relationship between intestinal flora and bone metastasis of NSCLC remains unclear.

Methods: We collected baseline fecal samples from104 patients with newly diagnosed lung cancer, 61 patients with bone metastasis (M group), and 43 patients without bone metastasis (N group). We conducted metagenomic and metabolomic sequencing to compare the differences in gut microbiota and metabolites between the two groups. At the same time, we collected baseline serum samples from 112 NSCLC patients with bone metastasis and 151 NSCLC patients without bone metastasis. Serum cholesterol levels at baseline were quantified using ELISA.

Results: Our results showed that the abundance of bacteroides and prevotella in group N was significantly higher than that in group M. Metabolomic analysis showed that the cholesterol level in group M was significantly higher than that in group N ($P<0.05$). KEGG analysis revealed enrichment of cholesterol(pos_60) related pathways, such as ovarian steroid production, aldosterone synthesis and secretion, Cushing's syndrome, and cortisol synthesis and secretion. Serum cholesterol levels in patients with bone metastasis were higher than those without bone metastasis ($P<0.0001$), which was consistent with the trend of intestinal metabolites.

Conclusions: Dysregulation of intestinal flora and abnormal cholesterol metabolism may promote bone metastasis of NSCLC. Elevated serum cholesterol may be used as a predictor of NSCLC bone metastasis, and regulation of intestinal flora and cholesterol metabolism may be a potential therapeutic strategy.

P3.03.36 Whole Genome Doubling Drives Genomic Instability and Poor Postoperative Outcomes in Stage I Driver-Negative Lung Adenocarcinoma

M. Torasawa[1], K. Shiraishi[2], A. Mochizuki[2], K. Takahashi[1], Y. Shiraishi[2], S-i. Watanabe[3], Y. Goto[3], R. Hamamoto[2], T. Kohno[2]
[1]Juntendo University of School of Medicine, Tokyo/JP ,[2]National Cancer Center Research Institute, Tokyo/JP ,[3]National Cancer Center Hospital, Tokyo/JP

Introduction: Stage I driver-negative lung adenocarcinoma (DN-LUAD) patients without actionable genomic alterations are currently not aggressive candidates for perioperative chemotherapy. However, 30-40% of these patients can experience recurrence after surgery, highlighting the need for more accurate risk prediction. Whole genome doubling (WGD) is common in human cancers and leads to chromosomal instability, but its impact in patients with stage I LUAD remains poorly understood.

Methods: We performed deep whole genome sequencing (WGS; tumor depth: 100-120x, normal depth: 30x, paired-end reads: 150 bp) and transcriptome profiling on resected pStage I (UICC 8th) DN-LUAD specimens. Somatic mutations, copy number alterations (CNA), and structural variations (SV) were analyzed. Tumors were classified as WGD-positive when more than half of the autosomal tumor genome displayed at least two copies at the major somatic copy number. Tumor transcriptome profiles were evaluated using Gene Set Enrichment Analysis (GSEA).

Results: We analyzed 77 patients (stage IA: n = 42, stage IB : n = 35) with a median age of 67 years (range 32-83), 32% female, and 69% smokers. Median follow-up for censored patients was 67.7 months. WGD was detected in 46.8% (n = 36) of tumors and was significantly associated with higher tumor mutation burden, CNA, and SV loads (p < 0.0001) (Figure A). TP53 mutations were significantly more frequent in WGD patients (69.4% vs. 36.6%, p = 0.004), and CDKN2A copy number loss was numerically higher in WGD patients (19.4% vs. 9.8%, p = 0.36). GSEA revealed significant enrichment of DNA repair and cell cycle-related pathways (e.g., HALLMARK_DNA_REPAIR and G2M_CHECKPOINT) in WGD patients (q < 0.0001). Recurrent-free survival (RFS) was significantly shorter in WGD patients (median RFS: 43.3 months vs. not reached; HR 2.30, 95% CI: 1.21-4.37; p = 0.01), with 5-year RFS rates of 42.1% (95% CI: 25.4-58.0%) and 63.8% (95% CI: 46.5-76.8%), respectively (Figure B). Notably, patients with concurrent TP53 mutations and WGD had the poorest RFS (log-rank p = 0.001), while patients with TP53 mutations but without WGD had similar recurrence risk as those without TP53 mutations (Figure C).

Conclusions: WGD increases genomic instability in DN-LUAD, leading to cell cycle and DNA regulation abnormalities. The co-occurrence of WGD and TP53 mutations significantly increases the risk of postoperative recurrence even in stage I disease, suggesting the need for intensified perioperative treatment strategies for this high-risk subgroup.

P3.03.37 Target Lipid Metabolism in Immune Microenvironment: Immunotherapy Sensitization and Combinatorial Strategies for NSCLC With Liver Metastases

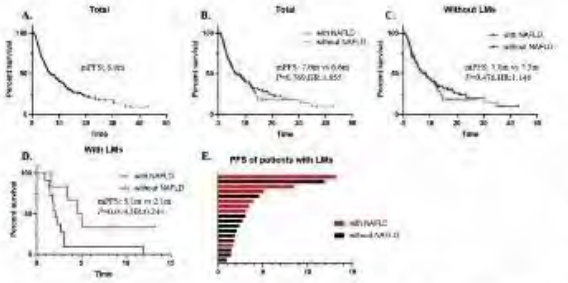
Y. Fang, C. Su
Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Liver metastasis represents a critical factor contributing to immune therapy resistance in advanced non-small cell lung cancer (NSCLC), with its underlying mechanism closely associated with the unique hepatic lipid metabolism microenvironment. Prior clinical data indicate that NSCLC patients with liver metastasis and non-alcoholic fatty liver disease (NAFLD) exhibit a significantly higher response rate to PD-1 inhibitors (ORR: 38% vs 12%, p<0.01). Magl expression is markedly upregulated in Kupffer cells and tumor-associated macrophages (TAMs) of these patients. However, the molecular mechanisms underlying its regulation of the immune microenvironment remain elusive. This study aims to elucidate the cross-organ regulatory network that activates anti-tumor immunity through lipid metabolism reprogramming-mediated macrophage polarization via the MAGL-CB2/TLR4 axis.

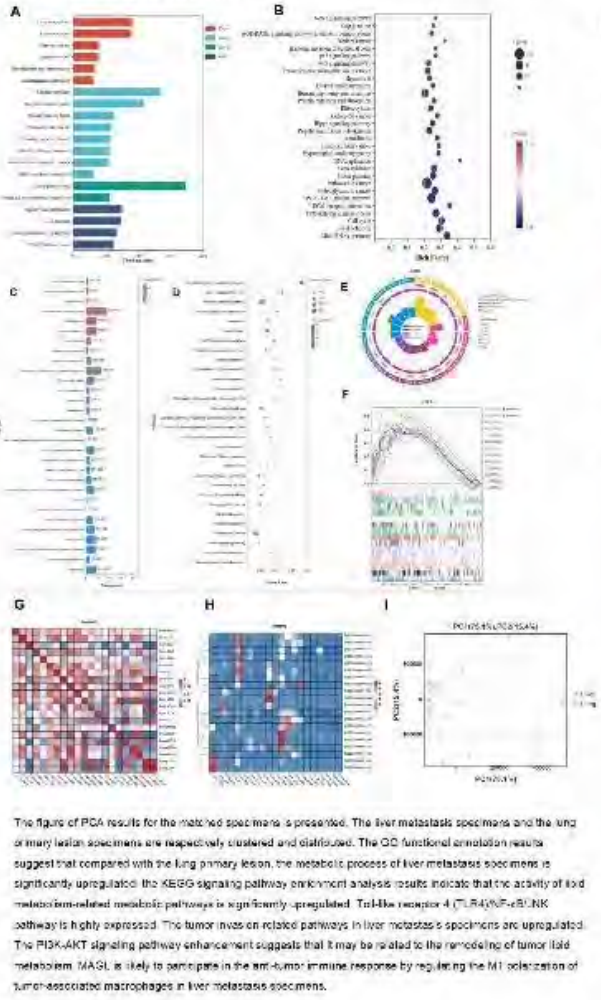
Methods: Collected paired biopsy specimens of primary lesions and liver metastases, and quantified the TAMs subgroups and T cell infiltration through mIHC (CD68/CD163/CD8). The in situ lung cancer liver metastasis animal model (C57BL/6-LLC) was established. By knocking out MAGL or using agonists to intervene in the CB2/TLR4 pathway, the phenotypic transformation of macrophages was analyzed through flow cytometry and spatial transcriptome analysis. Lipidomics (LC-MS) combined with transcriptomics (scRNA-seq) was employed to parse the co-variation network of fatty acid metabolites and immune gene modules in liver metastases.

Results: In the NAFLD+ group, MAGL expression in liver metastases was 3.2-fold higher than in primary liver lesions (p = 0.003). The proportion of lipid-laden macrophages (CD68+CD86+F4/80+Ly-6G+LipidTOX Deep-Red+) in tumor tissues significantly increased after immunotherapy (p = 0.001), particularly following synergistic immune sensitization, with a 2.7-fold increase in CD8+ T cell density (p = 0.008). MAGL hydrolyzes 2-AG into arachidonic acid, activating the dual CB2/TLR4 signaling pathway (50% reduction in phosphorylated ERK/NF-κB levels). This process induces Kupffer cells to polarize toward the M1 phenotype (the proportion of iNOS+ cells increasing from 12% to 41%) and recruits CXCL9+CD8+ T cells (a 2.3-fold increase in infiltration). Based on the metabolic-immune interaction network, the SREBP1-MAGL-CXCL9 axis was identified as a biomarker for predicting immunotherapy response (AUC = 0.83).

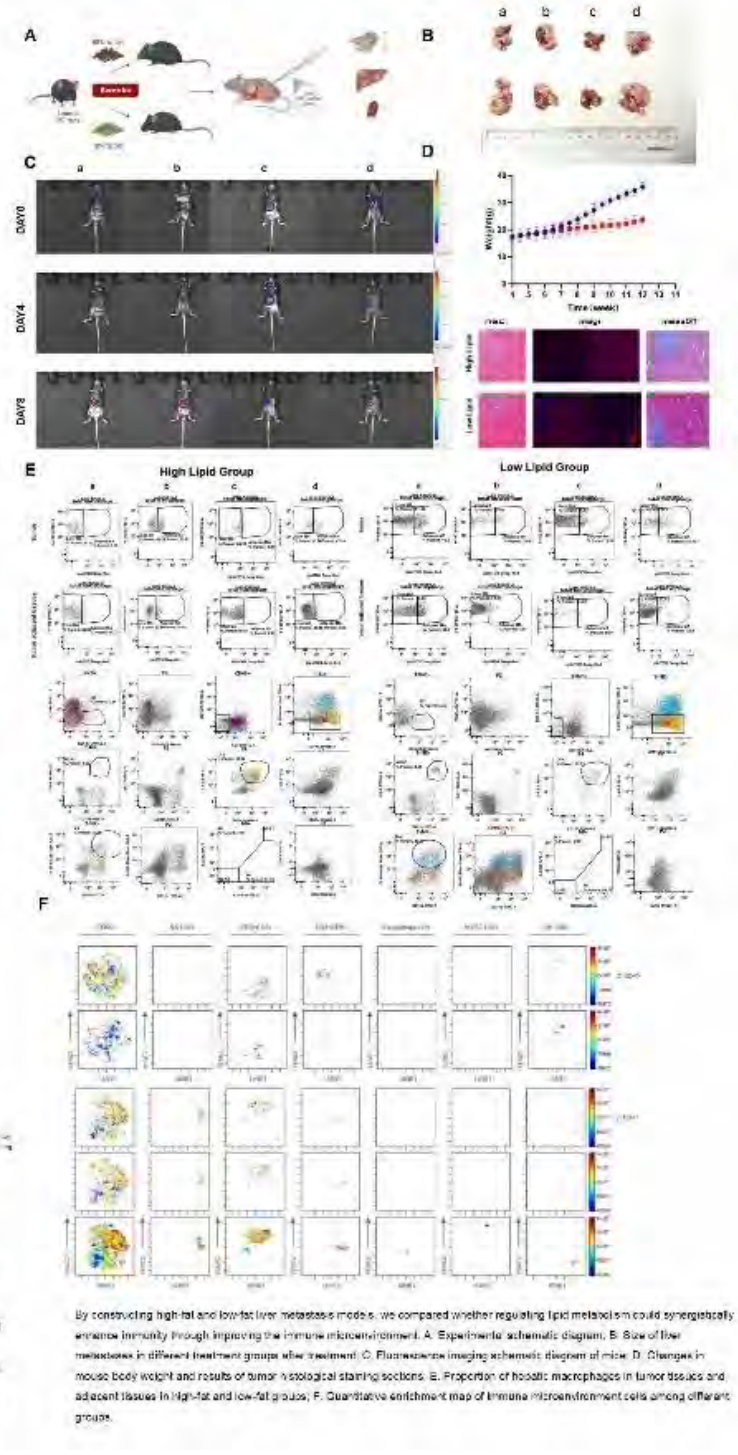
Conclusions: This study demonstrates that the hepatic lipid metabolism enzyme MAGL remodels the polarization of Kupffer cells/TAMs, thereby promoting the establishment of an anti-tumor immune microenvironment. Targeting the MAGL-CB2/TLR4 axis can reverse the immunosuppressive features of liver metastases and offers a novel “metabolic sensitization” strategy for patients resistant to PD-1 blockade therapy.



The median progression-free survival (PFS) for the entire group of patients with NSCLC receiving immunotherapy was 8.8 months. The median PFS for patients with NAFLD and those without NAFLD was similar (7.0 months vs. 6.5 months, P = 0.759, hazard ratio [HR]: 1.050, 95% confidence interval [CI]: 0.738 - 1.507) (Figure B). However, in the subgroup of patients with liver metastasis, the median PFS of patients with NAFLD was significantly longer than that of non-NAFLD patients (5.1 months vs. 2.1 months, P = 0.014, HR: 0.244, 95% CI: 0.078 - 0.813).



The figure of PCA results for the matched specimens is presented. The liver metastasis specimens and the lung primary lesion specimens are respectively clustered and distributed. The GO functional annotation results suggest that compared with the lung primary lesion, the metabolic process of liver metastasis specimens is significantly upregulated. the KEGG signaling pathway enrichment analysis results indicate that the activity of lipid metabolism-related metabolic pathways is significantly upregulated. Toll-like receptor 4 (TLR4)/NF-κB/NK pathway is highly expressed. The tumor invasion related pathways in liver metastasis specimens are upregulated. The PI3K-AKT signaling pathway enhancement suggests that it may be related to the remodeling of tumor lipid metabolism. MASL is likely to participate in the anti-tumor immune response by regulating the M1 polarization of tumor-associated macrophages in liver metastasis specimens.



By constructing high-fat and low-fat liver metastasis models, we compared whether regulating lipid metabolism could synergistically enhance immunity through improving the immune microenvironment. A. Experimental schematic diagram. B. Size of liver metastases in different treatment groups after treatment. C. Fluorescence imaging schematic diagram of mice. D. Changes in mouse body weight and results of tumor histological staining sections. E. Proportion of hostile macrophages in tumor tissues and adjacent tissues in high-fat and low-fat groups. F. Quantitative enrichment map of immune microenvironment cells among different groups.

P3.03.38 Oncolytic Virus Effectively Delivers CD47 Blockade to Suppress Tumour Growth in Preclinical NSCLC Models

R. Hoshi[1], A.P.Y. Lau[1], G. St-Laurent[2], M. Ahmadi[2], W.L. Lee[1], T. Azad[2], K.L. Thu[1]
[1]Unity Health Toronto, University of Toronto, Toronto/ON/CA ,[2]Université de Sherbrooke, Sherbrooke/QC/CA

Introduction: CD47 regulates an innate immune checkpoint that inhibits the phagocytic function of macrophages and dendritic cells. Cancer cells exploit CD47 to prevent their destruction by phagocytes and subsequent activation of anti-tumour immunity. As such, CD47 is a promising immunotherapeutic target and numerous antibody-based therapeutics that inhibit CD47 are being investigated in clinical trials. CD47 is overexpressed in up to 60% of non-small cell lung cancers (NSCLC), highlighting the potential utility of CD47 blockade for treating lung tumours. We have found that genetic inactivation of CD47 within lung cancer cells significantly impairs the growth of orthotopic lung tumours in mice. Yet, monoclonal antibodies targeting CD47 (CD47-Ab), a common modality for delivering CD47 blockade in the clinic, did not affect tumour growth in mice. This result is consistent with the poor efficacy of CD47 blockade observed in lung and other cancer patients in clinical trials. We have also seen that CD47-Ab bind to various cells abundant in the blood (eg. erythrocytes, neutrophils and platelets), consistent with toxicities commonly seen in patients treated with CD47 blockade (ie. anemia, neutropenia, and thrombocytopenia). Taken together, results in our preclinical NSCLC models and patients in clinical trials suggest that alternative approaches for administering CD47 blockade are needed to harness its therapeutic effects. We suspect that the limited efficacy and toxicity of CD47 blockade in patients is attributable to the ubiquitous expression of CD47 and failure of intravenously delivered therapeutics to reach tumour tissues in amounts sufficient to elicit anti-tumour effects. We hypothesize that targeting CD47 blockade preferentially to lung tumour tissues is required to realize its therapeutic potential, and that oncolytic viruses (OVs) can be leveraged to do so. In this study, we evaluated the anti-tumour efficacy of a novel OV engineered to deliver CD47-targeted therapy in two syngeneic NSCLC models.

Methods: We synthesized an attenuated vesicular stomatitis virus encoding a mouse-specific fusion protein (VSV-FP) that blocks CD47 function. Subcutaneous LLC or CMT167 tumours grown in immunocompetent mice were treated with 3 doses of PBS (100uL), VSV-FP or a control OV encoding green-fluorescent protein (VSV-GFP; 1x106 pfu/dose) administered intratumorally. Tumour volume and body weights were monitored over the course of treatment to assess the therapeutic effects and tolerability of virotherapy.

Results: OVs were well tolerated in mice as no significant differences in body weight were observed across treatment groups over the course of the study. VSV-GFP (control) and VSV-FP significantly inhibited tumour growth in both models ($p<0.01$). Although there was no difference in the therapeutic effects of VSV-GFP and VSV-FP in the LLC model, VSV-FP elicited stronger tumour growth inhibition than VSV-GFP in the CMT167 model ($p<0.01$). Notably, VSV-FP abrogated CMT167 tumour growth for 12 days, with 2/8 mice appearing to have near complete responses.

Conclusions: VSV-FP effectively suppressed lung tumour growth in mice. Our results indicate that OVs can be used to harness the therapeutic potential of CD47 blockade in NSCLC. Future studies will focus on identifying combinatorial approaches to potentiate and prolong their anti-cancer effects.

Keywords: CD47, immunotherapy, oncolytic virus

P3.03.39 Deep Learning Based Multiplex Imaging Platform for High Throughput ADC Targets Expression Quantification and Biomarker Discovery in NSCLC

M. Mints[1], R. Elran[1], R. Gluskin[1], S. Bookstein[1], J. Reeves[1], K. Bloom[1], E. Markovits[1]
[1]Nucleai, Tel Aviv/IL

Introduction: Recent developments in cancer treatments have not only seen the emergence of multiple targeted therapies but also the emergence of immunotherapy, antibody- drug conjugates (ADCs) and multi-specific antibodies. To properly stratify patients for optimal treatment, novel paradigms of biomarker identification and quantification are needed, as neither targeted mutation calling nor immunohistochemistry fully captures the intra-tumor heterogeneity nor subcellular expression of target protein expression. Multiplex immunofluorescence (mIF) can capture the protein expression of a large number of proteins simultaneously, enabling parallel assessment of a large number of drug targets. Here we describe a high-plex spatial proteomics platform integrated with AI-driven data analysis to be used for evaluating and quantifying individual drug targets and their combinations in non-small-cell lung cancer (NSCLC).

Methods: 87 tumor microarray cores from NSCLC patients were stained with a 23-marker mIF panel, of which 16 are potential ADC targets. Utilizing Nucleai's deep learning (DL)-based analysis pipeline, marker positivity was determined by a DL-classifier for each segmented cell, followed by assignment to 9 cell types by known protein expression profiles. For each detected tumor cell, the membrane intensity of target proteins was quantified by calculating the mean intensity and five intensity quantiles (0.1, 0.25, 0.5, 0.9). Five clinically actionable markers (CD56, CEACAM5, EGFR, HER2, and MSLN) had their protein intensity levels annotated by expert mIF annotators into 4 intensity bins (0, +1, +2, +3) at both cellular (n=693) and core (n=87) levels. Using the membrane intensity quantiles and core-level intensity annotations, we trained a multiclass classifier to predict optimal intensity thresholds through 20-fold cross-validation. These thresholds were utilized to classify tumor-core intensity levels by applying them to the 0.75 quantile of tumor cells membrane target proteins intensity. Furthermore, tumor cell target protein expression levels were classified into four intensity bins using the predicted intensity thresholds.

Results: The predicted core target protein expression levels demonstrated excellent concordance with manual expert annotations, achieving nearly 100% accuracy across all intensity bins for CD56 and EGFR, and between 80-90% accuracy for MSLN and HER2. However, the model had difficulties distinguishing between 0 and 1+ core expression levels for CEACAM5, primarily due to nonspecific background staining, highlighting the necessity for rigorous antibody validation in mIF intensity quantification. We further evaluated the model's performance in single-cell intensity level classification, utilizing annotations not included in the model's training as a validation set. In this context, the model achieved over 90% accuracy for most intensity levels, with the exceptions being CEACAM5-1+ and HER2-1+, due to difficulties differentiating between low expression levels and high background stain

Conclusions: In this study, we present a novel method for quantifying membrane protein expression levels, enabling precise inference of cell- and patient-level intensities for ADC targets. This approach offers a cost-effective solution for screening for treatment eligibility and provides the capability to calculate intensity-based spatial features that can model protein expression distribution and heterogeneity across the tumor area. These advancements facilitate the development of intensity-based biomarkers, improving patient stratification and treatment outcomes.

P3.03.40 PRMT9 mRNA Stabilized by IGF2BP1 in an m6A-Dependent Manner Promotes Proliferation and Metastasis of Lung Adenocarcinoma Cells

J-H. Chen
Guangzhou Twelfth people's Hospital, Guangzhou/CN

Introduction: PRMT9 is aberrantly expressed in various cancers, including lung adenocarcinoma (LUAD). This study aimed to investigate the expression pattern and functional role of PRMT9 in LUAD and explore its underlying mechanisms.

Methods: PRMT9 expression was analyzed in LUAD tissues, normal tissues, and cell lines. PRMT9 knockdown in A549 and H1568 cells assessed its effects on migration, invasion, and the RAS/MEK/ERK signaling pathway. The role of IGF2BP1 in PRMT9 mRNA m6A modification was examined. Functional assays were conducted with IGF2BP1 knockdown or overexpression, and pathway inhibition studies validated PRMT9's role. In vivo experiments further confirmed findings.

Results: PRMT9 mRNA and protein levels were significantly higher in LUAD tissues and cancer cell lines compared to normal tissues and cells. Knocking down PRMT9 in A549 and H1568 cells significantly reduced cell migration, invasion abilities, and the activation of the RAS/MEK/ERK signaling pathway. The abnormal expression of PRMT9 was associated with its mRNA m6A modification, which was regulated by IGF2BP1. The expression of IGF2BP1 was also higher in LUAD tissues and cancer cells. Knocking down IGF2BP1 reduced PRMT9 m6A modification and inhibited cell viability, migration, invasion, and RAS/MEK/ERK signaling pathway activation. Overexpression of IGF2BP1 promoted cell viability, migration, and invasion, which were reversed by PRMT9 knockdown. PRMT9 overexpression activated the RAS/MAPK signaling pathway, and blocking this pathway attenuated the effect of PRMT9 on LUAD metastasis. In vivo experiments confirmed that knocking down PRMT9 inhibited tumor growth and decreased the protein levels of RAS, pMek1/2, pErk1/2, and Ki67, while increasing caspase-3 levels.

Conclusions: PRMT9 is overexpressed in LUAD and promotes cancer progression by activating the RAS/MAPK signaling pathway. The abnormal expression of PRMT9 is associated with its mRNA m6A modification regulated by IGF2BP1. Targeting PRMT9 or the RAS/MAPK signaling pathway may provide new therapeutic strategies for LUAD.

P3.03.41 FOXO3A Regulates NSCLC Radiotherapy Resistance Through PINK1/Parkin Pathway of Protective Mitophagy

S. Luo
Tongji University Affiliated Pulmonary Hospital, Shanghai/CN

Introduction: Radiotherapy resistance has become one of the major causes of radiotherapy failure among patients with non-small cell lung cancer (NSCLC), and its underlying mechanism remains unclear. In recent years, the influence of cell mitochondrial autophagy on tumor radiotherapy resistance and its regulatory mechanism is one of the research hotspots.

Methods: We constructed stable radiotherapy-resistant NSCLC cell models A549/X and H520/X and the radioresistance of the cells was also verified. Subsequently, through high-throughput transcriptomic sequencing analysis and experimental verification, we found that the FOXO3a gene and mitochondrial autophagy PINK1/Parkin pathway in NSCLC radiotherapy-resistant cell lines were indeed consistent and upregulated more reactively than those of parental cells. The effect of gene expression status of FOXO3a-PINK1/Parkin pathway on the survival outcome of NSCLC was analyzed by TCGA database. Next, we inoculated nude mouse xenografts with siRNA to interfere with FOXO3a gene and shRNA to construct radiotherapy-resistant stable transtrains of NSCLC with stable knockdown of FOXO3a gene, and detected the association and regulation of FOXO3a gene expression levels with radioresistance and mitochondrial autophagy PINK1/Parkin pathway at the cellular and animal levels.

Results: The expression level of FOXO3a gene in NSCLC radioresistant cells was significantly positively correlated with the level of mitophagy and the expression level of PINK1/Parkin pathway. The gene expression status of FOXO3a-PINK1/Parkin pathway had an adverse effect on the survival outcome of NSCLC and was positively correlated with the radioresistance of cells. FOXO3a regulates radiotherapy resistance to NSCLC by regulating the PINK1/Parkin pathway of mitophagy.

Conclusions: FOXO3a regulates NSCLC radioresistance by regulating the mitochondrial autophagy PINK1/Parkin pathway, which may provide a new molecular intervention target and therapeutic entry point for intervening and improving the radioresistance of NSCLC in clinical practice.

Introduction: Anaplastic lymphoma kinase (ALK) rearrangements occur in 5-8% of non-squamous non-small-cell lung cancer (NSCLC) cases. While ALK tyrosine kinase inhibitors (TKIs) are effective first-line treatments, resistance inevitably develops. Immune checkpoint inhibitors (ICIs) have shown limited clinical benefits in ALK-rearranged NSCLC, necessitating novel salvage strategies post-ALK-TKI failure. Here, we analyzed the immune-related gene expression profiling (irGEP) in patients with ALK-rearranged NSCLC with the aim of evaluating the tumor microenvironment and identify potential therapeutic strategies.

Methods: This study utilized samples from the ALCURE trial (UMIN000038934), a prospective observational, multicenter study exploring the efficacy and resistance mechanisms of alectinib in patients with ALK-rearranged NSCLC. All patients were treated with alectinib as 1st line therapy, and pre-treatment tumor tissue receiving alectinib was analyzed using the NanoString nCounter PanCancer IO 360 Panel, which includes 750 immune-related genes with 20 housekeeping genes.

Results: Among the 249 patients who participated in the ACLURE trial, irGEP analysis was performed on 52 patients for whom residual nucleic acid samples of sufficient quality and quantity were available. The patient characteristics were consistent with those previously reported for patients with ALK-rearranged NSCLC. Programmed cell death-ligand 1 tumor proportion score (PD-L1 TPS) was available for 20 patients, of whom 12 had high (≥ 50%) and 8 had low expression (< 50%). In the high PD-L1 expression group, upregulation of genes associated with CD8+ TILs recruitment, such as CXCL9 and CXCL10, was observed. The genes encoding the inhibitory immune checkpoint molecules IDO1 and LAG3 were also highly upregulated, suggesting T cell exhaustion in the high PD-L1 expression group. Also, irGEP analysis revealed distinct immune profiles according to CD8A expression. The high CD8A expression group demonstrated decreased expression of CDH1, which encodes E-cadherin, and increased expression of SNAI1, indicative of epithelial-mesenchymal transition. Conversely, the low CD8A expression group upregulated the expression of ANGPT2, which encodes angiopoietin-2, and FLT1 (VEGFR1), suggesting enhanced tumor angiogenesis, which may contribute to the insufficient infiltration of T cells into the tumor. Progression-free survival of alectinib was tended longer in the high CD8A expression group compared with the low CD8A expression group (HR, 0.49 with 95% CI of 0.18-1.35).

Conclusions: High CD8 positive T cells infiltration in ALK-rearranged tumor might be associated with longer duration of alectinib efficacy. Anti-angiogenic therapies may enhance anti-tumor immunity and potentially augment the efficacy of alectinib in patients with ALK-rearranged NSCLC harboring low CD8 positive T cells infiltration.

P3.03.43 Gut Klebsiella Pneumoniae Drives Lung Cancer Progression by Modulating Macrophage Hpgds and Suppressing the PGJ2-PPAR? Signaling Pathway

Z. Hu, H. Liu, J. Chen
Tianjin Medical University General Hospital, Tianjin/CN

Introduction: The mechanisms that the gut microbiota influences lung cancer remain to be elucidated. Klebsiella pneumoniae (KP), a gut conditional pathogen commonly causing disease after antibiotic-induced gut microbiota dysbiosis, whose impact on lung cancer remains to be investigated.

Methods: Gut microbiota dysbiosis was induced by a four-antibiotic cocktail on a mouse subcutaneous tumor model bearing Lewis Lung Carcinoma, while the gut KP colonization model was established by gavage after clindamycin treatment. 2bRAD-M sequencing was used to screen for bacterial species. Metabolomics and single-cell transcriptomics were employed to investigate the tumor microenvironment. In vitro, a co-culture model of KP-colon organoid epithelium-macrophages-tumor cells was constructed to validate cell proliferation assays and signaling pathways.

Results: Subcutaneous tumor-bearing mice treated with antibiotic cocktail exhibited distinct growth velocity, and were classified into ABXS (small tumors) and ABXB (large tumors) groups based on tumor size. 2bRAD-M sequencing revealed that gut KP was significantly enriched in the ABXB group. Metabolomic analysis showed that the arachidonate-PGJ2 pathway exhibited the most significant differences. Single-cell transcriptomics, immunofluorescence, and TCGA adenocarcinoma transcriptomics indicate that the key enzyme HPGDS, which regulates PGJ2 metabolism within tumors, is specifically localized to macrophages and is associated with prognosis. In vivo and in vitro experiments further validated that KP promoted PGJ2 metabolic reprogramming by influencing HPGDS expression in tumor-related macrophages, thereby accelerating tumor progression. Further analysis of mouse tumor transcriptomes and in vitro co-culture systems revealed that KP inhibits the synthesis and secretion of PGJ2 in macrophage. This subsequently suppresses the dephosphorylation of PPARγ at the Ser273 within tumor cells, affects the function of the transcription factor complex PPARγ-RXRα, and subsequently regulates downstream P53/P21 and cell cycle-related pathways to promote tumor cell proliferation.

Conclusions: Gut Klebsiella pneumoniae promotes lung cancer progression by modulating macrophage HPGDS and regulating the PGJ2-PPARγ signaling pathway. And further translational research is ongoing.

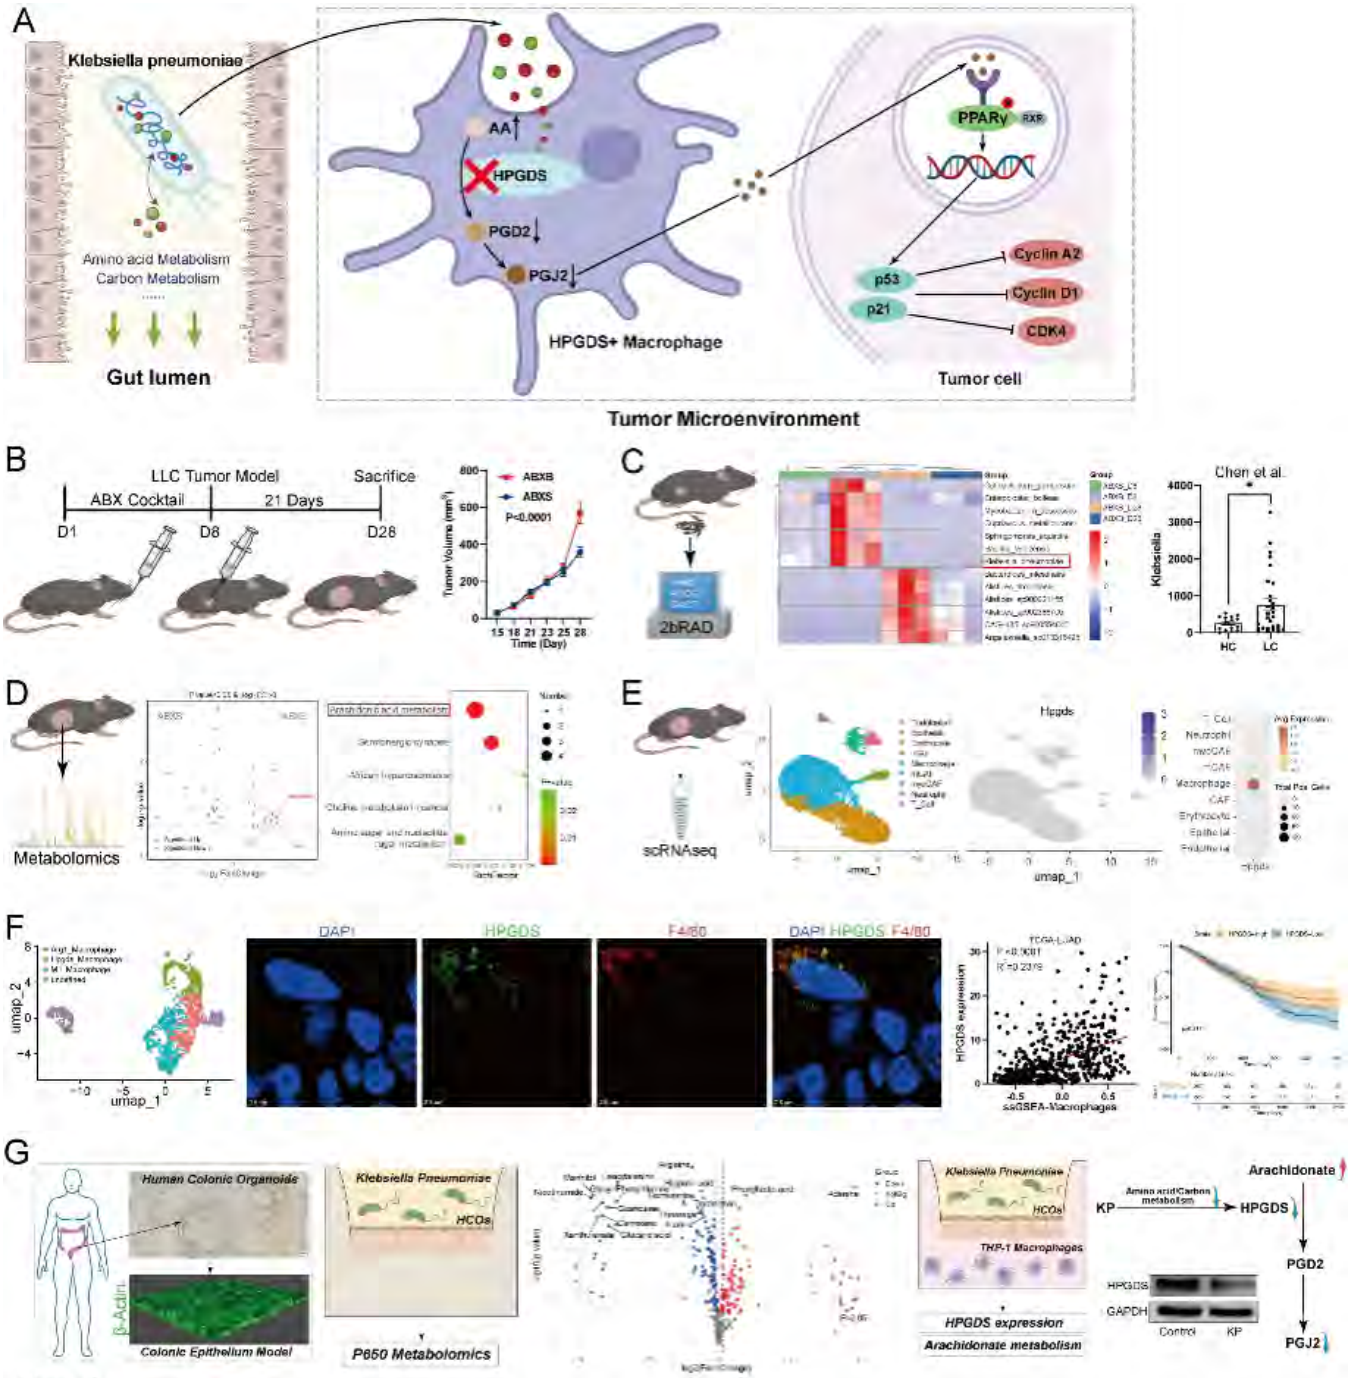

Figure 1

(A) Schematic diagram of the mechanism: Intestinal Klebsiella pneumoniae (KP) regulates amino acid metabolism and other mechanisms, affecting PGJ2 metabolic reprogramming in tumor-infiltrating HPGDS+ macrophages, thereby modulating the PGJ2-PPARγ signaling pathway in tumor cells to promote tumor progression.

(B) In a subcutaneous LLC cell tumor model after 7 days of antibiotic cocktail clearance, tumor progression exhibited obvious polarization. Samples were divided into the ABXS group (small tumors) and the ABXB group (large tumors) based on tumor size.

(C) 2bRAD-M sequencing revealed that KP was one of the significantly different microorganisms in the ABXB group, and this was validated in external datasets.

(D) Metabolomic analysis revealed that the levels of metabolites such as PGJ2 and the arachidonic acid metabolic pathway were the main differentially expressed metabolic pathways in tumor tissue.

(E) Single-cell transcriptomic analysis showed that the key enzyme HPGDS, which regulates arachidonic acid-PGJ2 metabolism in tumor tissue, was specifically expressed in a macrophage subpopulation, and this was validated in external data analysis.

(F) Single-cell analysis further clarified the characteristics of the HPGDS+ macrophage subpopulation. Immunofluorescence validation of tumor tissue confirmed the specific expression of HPGDS in macrophages. Simultaneously, TCGA data analysis showed that HPGDS expression levels were positively correlated with macrophage enrichment scores and were associated with patient prognosis.

(G) An in vitro colon organoid epithelial model was constructed using colon tissue extracts to achieve a co-culture system of intestinal KP and extra-intestinal macrophages. Metabolomic validation showed that KP mainly affects HPGDS expression and PGJ2 metabolic reprogramming in macrophages by consuming amino acids.

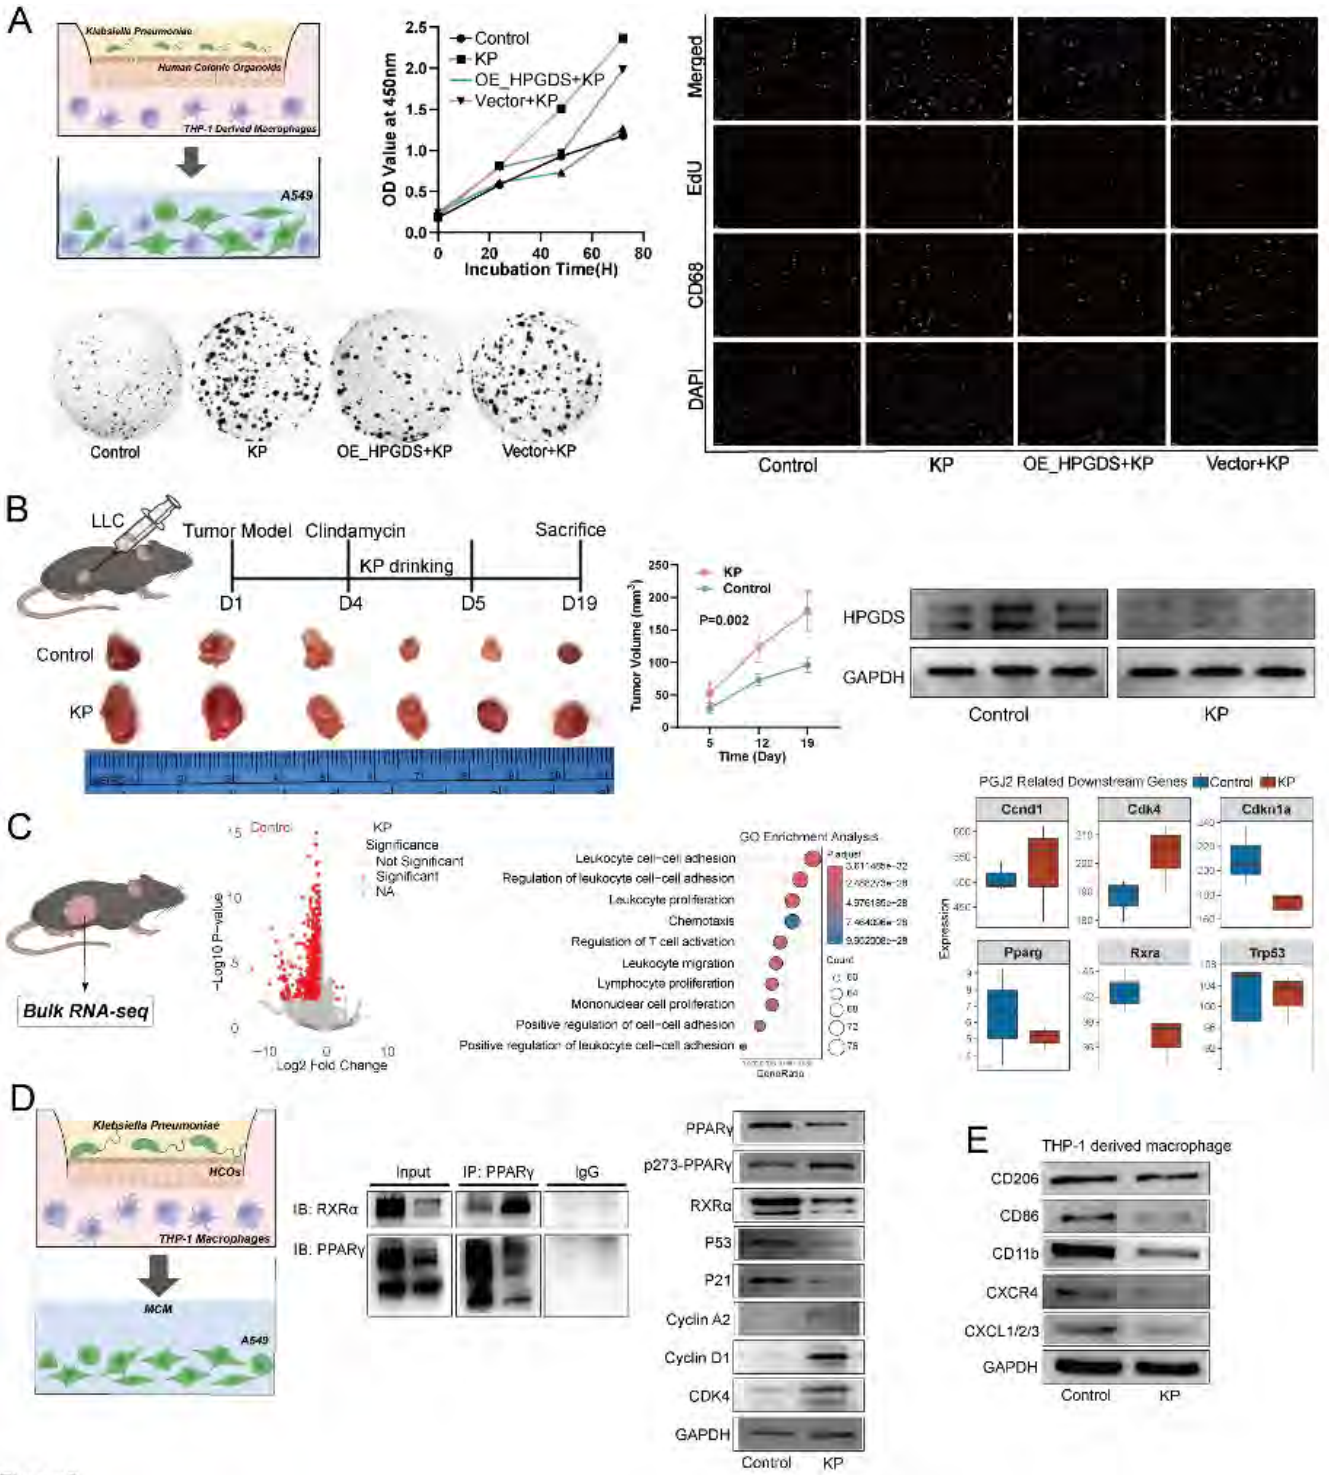

Figure 2
(A) In vitro co-culture experiments confirmed that intestinal Klebsiella pneumoniae (KP) promotes tumor cell progression by affecting HPGDS/PGJ2 metabolic reprogramming in macrophages.
(B) In vivo experiments revealed that KP can inhibit HPGDS expression in mouse tumor tissue and significantly promote tumor progression.
(C) Bulk RNA-seq analysis of mouse tumor tissue showed that intestinal KP can affect immune cell infiltration in tumor tissue and regulate the PGJ2 downstream receptor PPARγ signaling pathway.
(D) In vitro experiments, A549 cells treated with conditioned medium from KP-treated macrophages showed altered phosphorylation of the PGJ2 receptor PPARγ at Ser273 and its binding to RXRα in the cytoplasm, further regulating the activity of the downstream P53/P21/CyclinA2/CyclinD1/CDK4 signaling pathway.
(E) Discussion: Changes in the expression of macrophage surface markers CD11b, CD206, CD86, and CXCL, etc., after KP co-culture suggest that KP may also participate in tumor microenvironment regulation by affecting macrophage polarization and other functions.

Introduction: While immune checkpoint inhibitors (ICI) have significantly improved survival among patients with non-small cell lung cancer (NSCLC), the emergence of resistance mechanisms remains a challenge. We aim to elucidate the underlying resistance mechanisms by characterizing the genomic and molecular features of tumor immunogenicity in a cohort of NSCLC patients.

Methods: Patients diagnosed with NSCLC treated with ICI-based strategies at the Catalan Institute of Oncology-ICO Badalona, were prospectively enrolled (ImmunoLung PI-19-275). Samples were obtained through flexible bronchoscopy during diagnosis process. Comprehensive tumor genomic profiling was performed by whole-exome sequencing (WES) and RNA sequencing (RNA-seq), from those samples with enough quality material, conducted at the National Center for Genomic Analysis.

Results: Of 48 patient samples, 29 were available for deep genomic profiling. Patient characteristics included: mean age 66 years-old (range 43-85), 83% male, 17% female; 90% current or former smokers; ECOG PS 0/1: 83%, and ECOG PS 2: 17%. Histologic subtypes included 55% adenocarcinoma (ADC), 31% squamous cell carcinoma (SCC), and 14% NSCLC-NOS. At diagnosis, 60% were stage IV and 40% stage III. High PD-L1 expression (≥50%) was observed in 25% of tumors (IHC SP Ventana 263). All patients received anti-PD(L)1 based strategies either alone or in combination with chemotherapy or other ICI. Oncogenic drivermutations detected in primary lung tumors included KRAS (27%), SMARCA4 (17%), STK11 (14%), KEAP1 (10%), MYC amplification (7%), PIK3CA (7%), and ALK translocation (3%). Additionally, key alterations in the IFNγ signaling pathway were identified, including a splice site mutation in JAK2 (c.2131A>G, p.Ile711Val) and one polymorphism in TAP2 (c2059T>C, p.Ter687Gln). Notably, we detected a high prevalence (n=5, 17%) of truncating SMARCA4 mutations, a key regulator of chromatin remodeling associated with poor cancer prognosis. None of the SMARCA4-mutated tumors exhibited high PD-L1 expression, with a mean PD-L1 expression of 8%, compared to 27% in non-SMARCA4-mutated tumors (p=0.06). In our cohort, high PD-L1 expression (≥50%) correlated with improved median overall survival (OS) of 30.9 months (95% CI 0-89), compared to 14.5 months (95% CI 9.3-19.7) in tumors with PD-L1 <50% (p=0.37).

Conclusions: Our study reveals the genomic heterogeneity of NSCLC that contributes to tumor immunogenicity. Interestingly, we identified a high frequency of SMARCA4 mutations in advanced-stage NSCLC, and these alterations were associated with lower PD-L1 expression, potentially contributing to immune response capability in patients receiving ICI-based therapies. These results highlight the need to consider chromatin remodeling gene alterations as potential predictive biomarkers to ICI and warrants further investigation to expand and validate our results.

INCLIVA Biomedical Research Institute., Valencia/ES ,[4]Hospital Clínico Universitario., Valencia/ES ,[5]Hospital Clínico Universitario, Valencia/ES ,[6]University of Valencia, Valencia/ES

Introduction: Despite the improvement in precision medicine and the widespread use of checkpoint inhibitors (CPIs) combined with platinum-based chemotherapy (CIT), non-small cell lung cancer (NSCLC) remains the leading cause of cancer-related mortality globally. Approximately 30% of NSCLCs harbor KRAS mutations, with the G12C variant being the only one currently targetable in the second-line setting. However, beyond genomic alterations, the tumor microenvironment (TME) has emerged as a critical determinant of therapeutic response and resistance, particularly to CIT. Among the multifaceted mechanisms at play, oxidative stress has been shown to modulate CPI efficacy through altered PD-L1 expression and immune cell infiltration. Nevertheless, the precise immunometabolic interplay within the TME of KRAS-driven tumors remains insufficiently understood.

Methods: We prospectively collected tumor samples from 47 patients with treatment-naïve advanced NSCLC with an ECOG performance status of 0-1 and no significant comorbidities, candidates to receive CIT. Both KRAS wild-type and mutant tumors were included, while those harboring EGFR, ALK, or ROS1 alterations—identified via an extended molecular panel—were excluded. RNA was extracted from samples with ≥30% tumor cellularity and processed using the TruSeq RNA Access Kit (Illumina), followed by paired-end sequencing on the NovaSeq 6000 platform.Transcriptomic data were pre processed via nf-core/rnaseq. Differential gene expression analysis was conducted using DESeq2, with downstream gene set enrichment analysis (GSEA). The immune landscape was inferred using CIBERSORT and ESTIMATE algorithms. Associations between gene expression, immune composition, and clinical outcomes were evaluated using Spearman correlation, Cox multivariate modeling, and Kaplan-Meier analysis.

Results: Among the 47 analyzed cases (34 male, 13 female; median age 63.5 years, 46.8-81.5), 26 harbored KRAS mutations and 21 were KRAS wild-type. PD-L1 expression was broadly distributed (0-100%) and balanced between groups ($p = 0.355$). All the patients received a I line with CIT. Notably, KRAS-mutant tumors were associated with significantly shorter progression-free survival (PFS; $p = 0.01$). Transcriptomic analysis underlined 83 differentially expressed genes between KRAS-mutant and wild-type tumors, with 11 showing $|log2FC| > 1$. GSEA demonstrated a marked downregulation of immune-related pathways—including antigen processing, interferon signaling, and T cell-mediated cytotoxicity—in KRAS-mutant tumors. Conversely, genes associated with metabolism and oxidative stress were upregulated. Among them, EDN1 emerged as a potential key player. Overexpressed in KRAS-mutant tumors ($log2FC = 1.16$; $p = 0.026$), EDN1 was the gene most negatively correlated with CD8+ T cell infiltration and has known roles in ROS metabolism and TGFβ-mediated immunosuppression.

Conclusions: Our data suggest that KRAS mutations shape a metabolically reprogrammed and immunosuppressive TME that may drive resistance to CIT. Targeting oxidative stress and immunomodulatory pathways—such as those involving EDN1—may represent promising therapeutic strategies to overcome resistance and improve outcomes in KRAS-driven NSCLC.

P3.03.46 Phenotyping Double Negative B Cells in Non-Small Cell Lung Cancer

L.A. Neilson, L. Mathieson, L. Koppensteiner, A.L. Russell, H. Deckers, A.S. Hunt, A.R. Akram
University of Edinburgh, Edinburgh/GB

Introduction: The tumour microenvironment (TME) of NSCLC is complex, containing a variety of tumour infiltrating lymphocytes (TILs) including TIL-B cells which have been associated with favourable treatment responses. However, a subset of B cells characterised by the absence of IgD (naivety marker) and CD27 (activation marker), known as double negative (DN) B cells, have been associated with progression and adverse outcome in non-cancer diseases. We sought to characterise this DN population in NSCLC, including a sub-population (CD11c+, CD21-,CXCR5- DN cells) that may be precursors to short lived pathogenic auto-antibody secreting plasmablasts (PB).

Methods: Tumour, adjacent non-cancerous lung (NCL) and PBMCs from treatment naïve early-stage NSCLC patients were dissociated to single cells and stained with a 32-colour multispectral flow cytometry panel (Figure 1A). B cells were gated, concatenated and a clustering algorithm explored DN populations (IgD-,CD27-); including the DN2 sub-population (IgD-,CD27-,CXCR5-,CD21-,CD38-,CD11c+) and a PB population (IgD-,CD27-/+,CXCR5-/+,CD21-,CD38 high,CD11c low) (1A).

Results: Using key markers (CD19,CD138,CD20,CD38,CD24,CD27,IgD/M/A/G and IL-10) we identified conventional B cell populations (plasma, memory, naïve, regulatory, etc.) across the NSCLC patient cohort. Focusing on DN B cells we observed 3 relevant populations: DN B cells, DN2 B cells and a subpopulation of DN2 PB expressing CD11c and highly expressing CD38, likely arising from the DN2 cells. DN B cells were more prevalent in both the tumour and NCL than in matched PBMC samples (20.5%,15.6%,10.8% respectively, n=5). Of the DN population, DN2 were significantly more prevalent in the tumour than in the NCL or the PBMCs (30%,13.5%, 4.7%, n=5) (1B). Interestingly, the CD11c+ PB population express FOX-P3 in flow cytometry data, indicating a regulatory phenotype (PCREG). As DN2 B cells can progress to autoreactive ASCs identifying the B cell receptor repertoire, and thus the antigen target, of the population we describe could provide insight to new therapeutic targets to exploit and improve NSCLC patient treatment response.

Conclusions: We found two TIL-B cell populations, previously undescribed in NSCLC. In non-cancerous pathologies these influence disease trajectory. Further work will integrate the flow data with sc-RNAseq data sets and tissue validation through a multiplex IFF panel on a tissue microarray set (>160 patients), linked to clinical outcome.

P3.03.47 Study of Genomic Intra-Tumor Heterogeneity and Acquired Resistance to Tyrosine Kinase Inhibitors in Lung Cancer

P. Navajas-Chocarro[1], E. Pros[1], M. Saigi[2], A. Gomez[3], M. Sanchez-Cespedes[1]
[1]Josep Carreras Leukaemia Research Institute, Badalona/ES ,[2]ICO, Badalona/ES ,[3]Departament de Biociencies, Facultat de Ciencies I Tecnologia (FCT), Universitat de Vic-Universitat Central de Catalunya (UVIC-UCC), Badalona/ES

Introduction: Precision-targeted therapies have been developed for lung cancer (LC) patients, focusing on specific tyrosine kinase inhibitors (TKIs) against membrane receptors with tyrosine kinase activity that are genetically activated in these tumors. However, despite an initial favorable response, tumors often develop resistance, leading to patient relapse. In LC, acquired resistance is associated with various molecular and genetic mechanisms, some of which have been studied and characterized. Here, we investigated the role and evolution of intratumoral genomic heterogeneity in acquired resistance to TKIs in LC cells.

Methods: We use the following LC cell models: 1) EGFR-mutant patient-derived cancer cells obtained before and after resistance to TKIs; 2) MET-activated cancer cells that developed resistance to TKIs following exposure to increasing drug concentrations; 3) RET-rearranged cancer cells that similarly acquired resistance through escalating TKI exposure. Comprehensive genetic (whole exome sequencing) and gene expression (bulk RNA sequencing) data from these cells were available from our previous studies. Single-cell analyses were performed at both RNA (scRNAseq) and DNA (scDNAseq) levels using the 10x Genomics and Tapestri (Mission Bio) platforms, respectively.

Results: Through whole exome sequencing and bulk RNA sequencing, we identified tumor-specific gene rearrangements (such as amplifications, deletions, fusions, and loss of heterozygosity [LOH]), as well as mutations and alterations in gene expression, some of them associated with resistance. These include, among others, alterations at MDM2, KRAS, FGFR3, and NF2. Using this information, we performed scDNA-seq and scRNA-seq to investigate cancer cell subpopulations before and after the development of acquired resistance. Our analysis revealed that some of these alterations were already present in the parental cells and expanded during treatment. Additionally, we observed the selection of distinct alterations among different resistant cancer cell populations. This highlights that intrinsic heterogeneity can drive clonal selection under the pressure of TKIs. Notably, however, the acquired alterations linked to TKI resistance were not always present in the parental cancer cells.

Conclusions: We have identified tumor heterogeneity present at both the DNA and RNA levels. The identification of tumor-specific gene rearrangements and mutations, some of which pre-existed in parental cells, suggests that intrinsic tumor heterogeneity plays a significant role in the emergence of resistance. These findings highlight the complexity of the drug resistance process and emphasize the need for more comprehensive approaches to target both pre-existing and emerging resistant subpopulations in order to improve cancer therapeutics. DeepL has been used to translate and modify the text formatting.

P3.03.48 Fluorescence Lifetime Imaging in Fixed NSCLC Samples Demonstrate Differences Between Tissue Compartments

A.S. Hunt, A.L. Russell, L.A. Neilson, L. Koppensteiner, Z. Zang Zang, Q. Wang, A.R. Akram
University of Edinburgh, Edinburgh/GB

Introduction: Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related mortality worldwide. Fluorescence Lifetime Imaging (FLIM) measures the time-dependent decay from autofluorescent endogenous molecules. FLIM in formalin-fixed paraffin-embedded (FFPE) NSCLC has generated virtual H&E staining[1] and accurately predicts TTF-1 and P40 status[2]. Therefore, we characterised FLIM signals within FFPE cores across NSCLC tissue compartments.

[1] doi.org/10.1038/s44303-024-00021-7 [2] doi.org/10.48550/arXiv.2503.20817

Methods: Unstained TMA cores from NSCLC patients were FLIM imaged to capture lifetime using a Leica Falcon X microscope. FLIM images were reconstructed by exponential fitting to calculate lifetime values [A] and exported with a 0-5 nanosecond threshold. The same cores were stained in a multiplex Immunofluorescence assay using Akoya Opal dyes targeting CD3, CD20, PanCK, aSMA, and DAPI and imaged on an Akoya Vectra Polaris [B]. Regions for Tumour, tertiary lymphoid structures (TLS), and Stroma were determined within QuPath, and cell segmentation was performed [C]. These regions were exported to calculate the FLIM lifetime on a per-cell level, which was then averaged over each region for an individual patient core.

Results: We analysed 58 patient cores, calculating 652630 cells for tumour, stroma and TLS across the entire dataset. Using the average FLIM lifetimes for each core region, we found that tumour areas had significantly shorter lifetime values than stromal areas (p=0.0002). Stroma regions were also shorter than TLS regions (p=0.0001) and Tumour/TLS was non-significant [D]. No significant differences were found between adenocarcinoma and squamous cell carcinoma when comparing the compartments between cancer subtypes [E & F]. Similarly, FLIM was not different when stratified by smoking status (smoker vs ex or non-smoker) or Stage (I+II vs III+IV) across all compartments (all p>0.05). There was a trend to a poorer survival outcome in patients with lower tumour FLIM signal [G] and a significantly poorer outcome for recurrence-free survival (p=0.0461) [H]. This was not seen when assessing stromal compartments, suggesting this is tumour-cell driven [I & J].

Conclusions: We demonstrate that FLIM can distinguish between stroma and tumour compartments in NSCLC. While no significant differences were observed between cancer types, stages, or smoking status, lower FLIM lifetimes in tumour regions showed a significant correlation with poorer regression-free survival outcomes. This suggests FLIM has the potential as a prognostic tool in FFPE NSCLC, particularly in identifying more aggressive tumours by their characteristic fluorescence lifetimes. We plan to assess this within a broader cohort and more granular assessment of cell specific FLIM values.

P3.03.49 Mechanisms of Resistance to Tyrosine Kinase Inhibitors in Lung Cancer Cells Harbouring RET Fusions

E. Pros[1], P. Navajas-Chocarro[1], I. Bartolessis[1], M. Cucurull[2,3], O.A. Romero[1], J.M. Morillas[1], C.A. Diaz[1], M. Saigi[2,3], R. Tonda[4,5], J. Morata[4,5], A. Esteve-Codina[4,5], M. Sanchez-Cespedes[1]
[1]Josep Carreras Leukaemia Research Institute (IJC), Badalona/ES ,[2]Catalan Institute of Oncology, ICO-Badalona, Badalona/ES ,[3]BARGO, Germans Trias i Pujol Research Institute (IGTP), Badalona/ES ,[4]Centro Nacional de Análisis Genómico (CNAG), Barcelona/ES ,[5]Universitat de Barcelona (UB), Barcelona/ES

Introduction: RET fusions are present in 1-2% of non-small cell lung cancer (NSCLC), with KIF5B-RET and CCDC6-RET being the most common. In recent years, two selective RET tyrosine kinase inhibitors (TKIs) have been approved by the Food and Drug Administration (FDA), selpercatinib and pralsetinib. However, the emergence of resistance limits the long-term effectiveness of these treatments. The aim of this study was to elucidate the mechanisms of resistance to these RET inhibitors in NSCLC cells and to identify new therapeutic targets to overcome the resistance.

Methods: Two lung cancer cell models harbouring RET fusions, LC-2/ad (CCDC6-RET) and PDC6 (KIF5B-RET), a patient-derived cell line established by our group, were used to generate resistant cell lines to selpercatinib and pralsetinib. We characterize these cells, at genetic and molecular level, by whole exome sequencing (WES), RNA-sequencing and analysis of signaling pathways.

Results: Resistance to both RET-TKIs involved morphological changes and differences in gene expression in all the resistant cells, along with a de novo activation or reactivation of AKT, ERK and mTOR in most of them. No on-target mutations were detected. In the LC-2/ad-resistant cells, different alterations of unknown significance were identified. In the PDC6-resistant cells, KRAS (p.Gly12Asp) and NRAS (p.Gln61Lys) mutations were found in two of the resistant cells, to selpercatinib and pralsetinib, respectively. As a potential resistance mechanism of three of the resistant cell lines, we observed the clonal expansion of a pre-existing novel gene fusion, associated to high expression of one of the fusion partners at both RNA and protein levels.

Conclusions: Here, we show that resistance to RET-TKIs frequently involves activation of the RAS/MAPK pathway through mutations in KRAS and NRAS and activation of ERK. In addition, the activation of AKT and the clonal expansion of a new gene fusion suggest the existence of multiple simultaneous resistance mechanisms to RET-TKIs. Altogether, these observations can help us to better understand the resistance processes in order to design future strategies for the treatment of these patients

P3.03.50 cIRCCAMSAP1 Induce Osimertinib Resistance in Lung Adenocarcinoma by Downregulating the Degradation Level of HSPA1A

H. Ye[1], M. Yin[1], Y. Chen[1], X. Huang[1], W. Su[1], Z. Yang[1]
[1]Affiliated Hospital of Guangdong Medical University, Zhanjiang/CN

Introduction: Circular RNA (circRNA) is a special class of non-coding RNA with a covalently closed circular structure that exerts its biological function in the progression of a variety of cancers.The high expression of circCAMSAP1 in the osimertinib resistant NSCLC cell line was determined by RNA-seq sequencing analysis of the sensitive and resistant cell lines of lung adenocarcinoma, and the research mechanism of circCAMSAP1 in lung adenocarcinoma and osimertinib resistance is still unclear.

Methods: This study is the first to discuss the mechanism of osimertinib resistance of circCAMSAP1 in non-small cell lung cancer, and circCAMSAP1 exerts its biological role by inducing osimertinib resistance in non-small cell lung cancer by destabilizing HSPA1A.

Results: The stable expression of osimertinib-resistant lung adenocarcinoma cell lines PC9/OR and H1975/OR was successfully constructed by measuring IC50 values. The target gene circCAMSAP1 was screened by transcriptome sequencing analysis, and the cyclic structure and resistance to RNase R treatment of circCMSAP1 were further verified by characterization experiments. circCAMSAP1 was clearly distributed in the cytoplasm and nucleus of PC9/OR and H1975/OR cells by cytoplasmic and nuclear isolation experiments. The results of qRT-PCR assay showed that circCAMSAP1 expression was significantly increased in the more sensitive strains (PC9 and H1975) in lung adenocarcinoma osimertinib-resistant cell lines (PC9/OR and 1975/OR). The RNA pull-down assay based on the biotinylated circCAMSAP1 probe (nonsense sequence as a negative control) was used to screen out HSPA1A protein by mass spectrometry analysis, and its expression was verified to be significantly up-regulated in the more susceptible strains of lung adenocarcinoma osimertinib resistant cell lines (PC9/OR and H1975/OR). In vitro experiments showed that silencing of circCAMSAP1 inhibited cell proliferation, invasion, migration and cell clonal formation of osimertinib-resistant cell lines in lung adenocarcinoma, and silencing of circCAMSAP1 reversed osimertinib resistance by inhibiting autophagy. In vivo experiments showed that compared with the control group, the circCAMSAP1 silencing group significantly increased the sensitivity of nude mouse xenograft tumors to osimertinib and inhibited the tumor growth process. At the mechanistic level, RIP and CO-IP experiments were used to verify the mutual binding of circCAMSAP1 to HSPA1A protein, and the stability of HSPA1A protein was enhanced by inhibiting the E3 ubiquitin ligase SMURF1, and its ubiquitination degradation process was inhibited.

Conclusions: CircCAMSAP1 is associated with poor prognosis in lung adenocarcinoma and promotes osimertinib resistance in lung adenocarcinoma by inhibiting SMURF1-mediated HSPA1A ubiquitination.

P3.03.51 FLT3LG Improve Therapeutic Sensitivity to Anti-PD-1 Therapy by Modulating Immune Cell Infiltration in NSCLC

F. Zhao, H. Bai, Y. Liu, S. Gao, C. Yang, X. Zhao, S. Qin
The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an/CN

Introduction: Immunotherapy, particularly anti-PD-1 therapy, has assumed a progressively significant position in the management of non-small cell lung cancer (NSCLC). Nevertheless, a subset of patients exhibit resistance to anti-PD-1 therapy, and the exploration of biomarkers for evaluating the responsiveness to anti-PD-1 therapy necessitates further investigation. FLT3LG is regarded as being associated with tumor diagnosis and immunotherapy in a variety of tumor types, but its function in NSCLC is uncertain.

Methods: Bioinformatics analysis was conducted to evaluate the clinical value, functional enrichment, genetic correlation, and immune infiltration of FLT3LG in NSCLC. We then used a mouse model to detect immune cell infiltration and relevant protein expression by flow cytometry and immunohistochemistry under anti-PD-1 treatment after overexpression of FLT3LG.

Results: In NSCLC patients, a better prognosis is linked to elevated FLT3LG expression. Among the genes strongly associated with FLT3LG, the majority were involved in immune-related processes and were predominantly enriched in immune-related pathways. Moreover, high expression of FLT3LG was significantly positively correlated with increased infiltration of multiple immune cells, including T cells and natural killer (NK) cells, in lung adenocarcinomas, as well with the expression of several immune cell markers, such as CD4 and CD8a. In a mouse model, overexpression of FLT3LG in mice xenograft elicited a pronounced immune response, thus leading to improved therapeutic efficacy following anti-PD-1 therapy.

Conclusions: FLT3LG could be considered as a diagnostic and prognostic marker for NSCLC and might play a role in enhancing the therapeutic response to immunotherapy in patients with NSCLC.

P3.03.52 XPO1 Inhibition Reduces Tumor Growth Potential by Inhibiting Wnt Signaling Pathway in Lung Squamous Cell Carcinoma

v. durani, R. Caeser, H. Sridhar, P. Manoj, E. Redin, C. Rudin, A. Quintanal-Villalonga
MSKCC, new york/NY/USA

Introduction: Squamous cell carcinoma (LUSC) is the second most common histology of lung cancer after adenocarcinomas (LUADs). Molecular characterization of LUADs has defined distinct tumor subsets characterized by the presence of discrete driver alterations that predict sensitive to targeted inhibitors, leading to significant improvement in patient survival. However, for LUSCs, to date no specific drivers have been identified that are amenable for pharmacological targeting, and no targeted therapies are approved for treatment. Thus, identification of targetable vulnerabilities in this histological setting remains a critical unmet clinical need. Preliminary data from our lab has identified the nuclear exporter exportin 1 (XPO1) as a therapeutic vulnerability in small cell lung carcinomas. Importantly, XPO1 can be inhibited with selinexor, an FDA-approved drug for clinical use in hematological malignancies. Pharmacological inhibition of XPO1 with selinexor has shown promising results in several preclinical tumor solid models with negligible toxicity. Here, we explored the role of XPO1 as a therapeutic target in LUSC and the mechanism through which XPO1 inhibition induces tumor cell death in LUSC.

Methods: We performed a comprehensive histological and multi-omics analysis by Immunohistochemistry (IHC), targeted mutational profiling (MSK-IMPACT), methylation array, RNAseq and DIA- Mass spec characterization of a library of LUSC patient-derived xenografts (PDXs) (N=28) and matched clinical specimens (N=17)). To examine the potential of XPO1 inhibition as a therapeutic target in LUSC, we performed genetic and pharmacological inhibition experiments in LUSC cell lines and PDXs and functional in vitro experiments to study XPO1 as a druggable vulnerability in LUSC.

Results: Genomic characterization of our LUSC PDX platform identified frequent XPO1 gene gains (~30%) and amplifications (~4%). Other high prevalent genomic alterations included⋯ This observation was confirmed in the TCGA LUSC dataset with a 10.7% frequency for XPO1 amplification, which correlated with high XPO1 mRNA expression. XPO1 protein assessment by IHC revealed x% of PDXs exhibiting high expression of XPO1 and x% of LUSC clinical specimens in an in-house independent cohort. XPO1 genetic knockdown reduced the tumorigenic potential of LUSC cell lines, including proliferation and anchorage-independent growth. XPO1 inhibition with selinexor strongly synergized with the chemotherapeutic agent irinotecan in vitro. Similarly, selinexor induced a prominent tumor growth delay in LUSC PDXs (n=6) as monotherapy, which was further increased by the addition of irinotecan. Interestingly, squamous/ adenocarcinoma transformed PDXs showed the strongest response to XPO1 pharmacological inhibition across all models evaluated. Mechanistically, genetic and pharmacological inhibition of XPO1 downregulated WNT signaling pathway by disrupting the export of key players from nucleus to cytoplasm.

Conclusions: Our data suggest that XPO1 may exert a pro-oncogenic role in LUSC, and that its inhibition may represent a promising therapeutic approach for LUSC tumors, both as monotherapy or in combination with irinotecan. The clinical availability of selinexor will allow immediate clinical translation of the results generated in this project in a setting where no targeted therapies are available.

P3.03.53 WISP3 Drives NSCLC Progression by Upregulating SDCBP via the TGF-? Signaling Pathway

G. Gao, X. Zhang, T. Jiang, L. Ye, L. Wang, F. Wu, S. Ren
Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Non-small cell lung cancer (NSCLC) represents approximately 85% of all lung cancer cases, constituting a significant global health challenge. Our previous research demonstrated that fibronectin promotes NSCLC angiogenesis and progression through upregulation of Wnt-inducible signaling pathway protein 3 (WISP3) and subsequent activation of Wnt signaling. The current study investigates the functional role and underlying molecular mechanisms of WISP3 in NSCLC progression.

Methods: We employed plasmid-mediated gene transfection to establish WISP3 overexpression and knockdown cell models. Functional characterization included tube formation assays, sphere formation assays, immunohistochemistry, western blot analysis, Transwell migration assays, and MTT viability assays. Proteomic profiling via mass spectrometry coupled with bioinformatics analysis identified differentially expressed proteins and associated signaling pathways in NSCLC cells. Furthermore, we established an NSCLC xenograft tumor model for in vivo validation.

Results: Clinical data analysis revealed that elevated WISP3 expression correlates with poor prognosis in NSCLC patients. Functional studies demonstrated that WISP3 enhances both angiogenic capacity and tumorigenic potential in NSCLC cells, findings that were corroborated in our xenograft tumor model. Mechanistically, WISP3 promotes NSCLC progression through activation of the TGF-β signaling pathway, as evidenced by increased phosphorylation of Smad2/3 (p-Smad2/3). Notably, WISP3 overexpression upregulated syntenin binding protein (SDCBP) expression both in vitro and in vivo. We identified a functional interaction between WISP3 and SDCBP that potentiates angiogenic and tumorigenic properties in NSCLC, effects that were reversible upon SDCBP silencing. These findings underscore the critical role of the WISP3-SDCBP axis in NSCLC progression.

Conclusions: Our study provides novel mechanistic insights into WISP3-mediated NSCLC progression, revealing its dual role in SDCBP upregulation and TGF-β pathway activation. These findings advance our understanding of NSCLC pathophysiology and highlight potential therapeutic targets for clinical intervention.

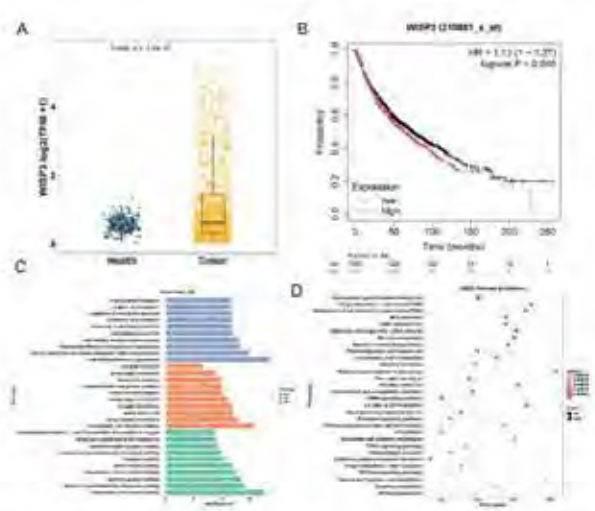

Figure 1. Analysis of WISP3 expression and its clinical significance in NSCLC. (A) A box plot showed WISP3 expression in 1025 LUAD vs. 108 normal tissues (TCGA data), with IQR and median indicated. (B) Kaplan-Meier analysis of 2167 lung cancer cases (stratified by median WISP3) revealed survival differences. (C-D) GO and KEGG analyses compared DEGs between high/low WISP3 groups in NSCLC.

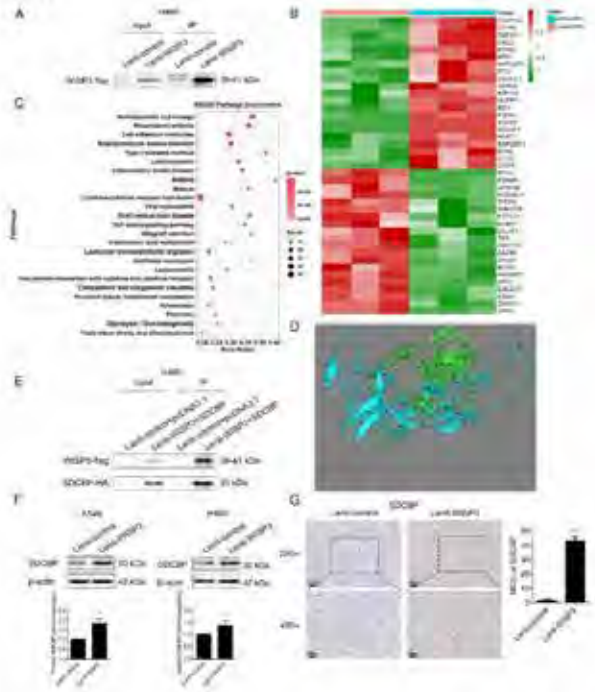

Figure 2. Comprehensive analysis of WISP3-associated proteins and their interactions in NSCLC. Panel A shows the IP assay enriching Flag-tagged WISP3 in overexpressing H460 cells. Purified proteins from WISP3-overexpressing and control cells were analyzed by mass spectrometry (B), followed by KEGG enrichment of WISP3-associated proteins in NSCLC (C). D displays protein docking between SDCBP (yellow) and WISP3 (blue), with hydrogen bonds (red) marking binding sites. E confirms their interaction via co-IP/WB in co-transfected H460 cells using Flag-WISP3 and HA-SDCBP antibodies. F shows upregulated SDCBP in WISP3-overexpressing H460/A549 cells (WB; *p<0.05, **p<0.01). G verifies elevated SDCBP in WISP3-driven tumors (IHC; 200×/400×; scale bars: 20/50 μm; **p<0.01).

P3.03.54 Influenza'S Silent Warriors: Unveiling Lung Tumor Cell Assassination Through Macrophage Reprogramming via SAA4-MLKL Axis

Ö. Cetin[1,2], U. Matt[3], K. Turkowski[1,2], A. Karger[1,2], I. Vazquez Armendariz[3], S. Mansouri[1,2], J. Graumann[2], S. Günther[2], H. Winter[4], F. Grimminger[1,3], W. Seeger[1,3], S. Savai Pullamsetti[1,3], S. Herold[1,3], R. Savai[1,2,3]
[1]Institute for Lung Health, Giessen/DE ,[2]Max Planck Institute for Heart and Lung Research, Bad Nauheim/DE ,[3]Justus-Liebig University Giessen, Giessen/DE ,[4]University Hospital Heidelberg, Heidelberg/DE

Introduction: Macrophages play a crucial role in maintaining balance in the body that goes beyond their known function in innate immunity. In particular, pro-inflammatory macrophages have anti-tumor properties, while anti-inflammatory macrophages tend to promote tumor growth. In diseases such as lung cancer or infections, the alveolar niche plays a crucial role in determining the macrophage phenotype. Since the mechanisms regulating this phenotype imbalance are still unclear, we hypothesized that tumor-inhibitory macrophage phenotypes and functions may be induced by infection stimuli. Our study aims to shed light on macrophage plasticity within a tumor-infection niche.

Methods: After exposure of pro-tumor macrophages to influenza A infection (IAV) bronchoalveolar lavage fluid (BALF), we observed an effective reprogramming of tumor-promoting macrophages to an anti-tumor state. Therefore, mass spectrometric analysis of IAV BALF was performed to identify the secretory factors responsible for this reprogramming. To decipher the transcriptomic signature of the reprogrammed macrophages, we performed RNA sequencing. In addition, we used lung organoids and precisely cut lung sections from tumors to mimic the niche of tumor and infection and demonstrate the inhibition of tumor cells by the regulated macrophage phenotype.

Results: Secretome analysis of IAV BALF revealed a significant upregulation of the SAA4 protein. Subsequent incubation of pro-tumor macrophages with recombinant SAA4 protein confirmed its ability to induce a tumor-inhibitory phenotype. RNA sequencing revealed an upregulation of the Mlkl gene in these reprogrammed macrophages. Silencing of the Mlkl gene resulted in a reduction of the pro-inflammatory and tumor-inhibitory macrophage phenotype, suggesting a regulatory role of MLKL in the reprogramming process.

Conclusions: Our results highlight that influenza A virus infection modulates macrophage plasticity and activates tumor-inhibitory responses through the SAA4-MLKL axis in the context of lung cancer.

P3.09.01 Validation of Lung Specific-Graded Prognostic Assessment Score in NSCLC With Brain Metastases From India

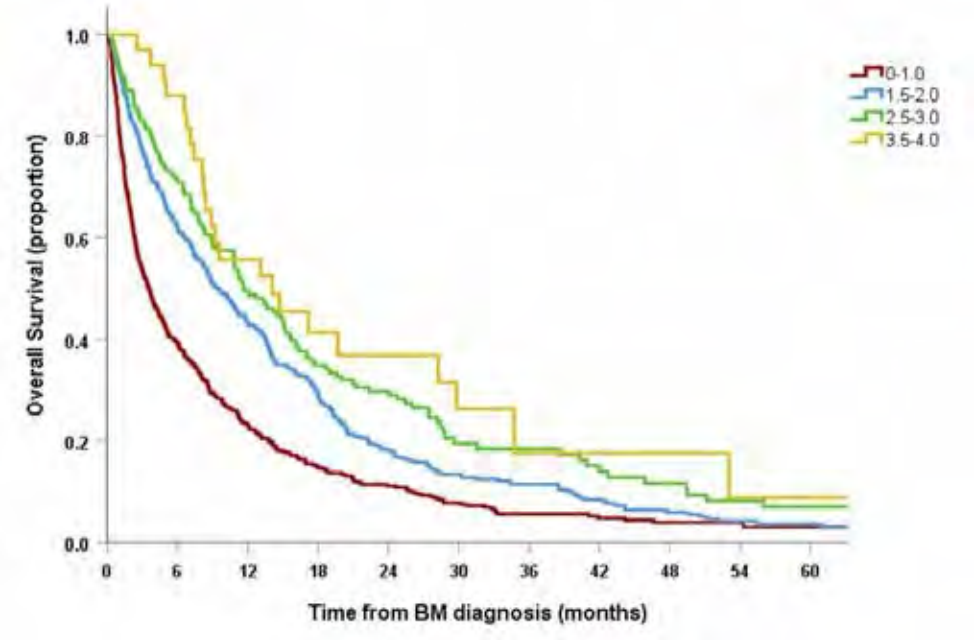
S.M. S, A.R. Tibdewal, G. Maheshwari, G.R. Khatavkar, S.R. Pedapathi, S.B. Yewle, K. Prabhash, V. Noronha, J.P. Agarwal
Tata Memorial Hospital, Homi Bhabha National Institute, Mumbai/IN

Introduction: Prognostication of brain metastasis (BM) aids in patient selection and optimal resource utilisation. We aim to validate the Lung Specific-Graded Prognostic Assessment (GPA) in patients with BM from Non-small cell lung cancer (NSCLC) at a tertiary cancer centre in India.

Methods: An ambispective analysis of 1197 NSCLC patients treated between May 2015 and May 2024 was performed. The GPA scores were calculated using age, Karnofsky Performance Status (KPS), number of BMs and extracranial metastasis status, and the log-rank test compared intergroup differences. Overall survival (OS) was estimated from the date of BM diagnosis till death or last known follow-up. The time-to-event analysis was performed by the Kaplan-Meier method, and a p-value of <0.05 was considered statistically significant. The study has been approved by the Ethics Committee and registered with the Clinical Trials Registry of India.

Results: The median age was 53 years (range, 19-86), and the majority were males (63%) with active tobacco use. Adenocarcinoma was 84% and squamous cell carcinoma (7%). EGFR mutation was seen in 37%, and ALK mutations in 16%. The majority received brain radiotherapy (RT) either in the form of whole brain RT (88%) or stereotactic radiosurgery (8%). The rest were offered observation or optimal supportive care. Systemic therapy was administered to 90% of the patients, which included chemotherapy (35%), TKI (41%), immunotherapy (2%), or a combination thereof. The median OS was 7.3 months (range, 0-78). The median follow-up of surviving patients was 42.1 months (range, 0.5-78). The median OS of various GPA subgroups are detailed in the table and represented in the figure.

Lung specific GPA [N (%)]	Median OS (months)	95% CI (months)
0 – 1 [482 (40.3)]	3.5	2.8 – 4.2
1.5 – 2 [509 (42.5)]	9.4	8.0 – 10.8
2.5 – 3 [172 (14.4)]	11.7	9.1 – 14.4
3.5 – 4 [34 (2.8)]	14.1	4.7 – 23.4
p-value	<0.001	



Conclusions: This is the largest study from India to validate lung specific-GPA in NSCLC patients with BM. Our study has shown the usefulness of lung specific-GPA in prognosticating, which helps in delivering tailored treatment and appropriate resource utilisation.

Keywords: Brain Metastasis, GPA, NSCLC

P3.09.02 Stereotactic Mr-Guided Adaptive Radiotherapy (SMART) for Ultracentral Non-Small Cell Lung Cancer (NSCLC)

E. Moreno-Olmedo[1], B. George[2], K. Owczarczyk[2], D. Woolf[2], J. Conibear[2], A. Gaya[2], J. Adams[2], L. Aznar-Garcia[2], T. Sevitt[2], P. Dickinson[2], K. Franks[2], A. Martin[2], V. Ezhil[2], P. Camilleri[2], J. Good[2], C. Hiley[2]
[1]Genesiscare Uk, Littlemore, Oxford/GB ,[2]Genesiscare UK, Oxford/GB

Introduction: Stereotactic-ablative body radiotherapy (SABR) is a standard of care for early-stage lung cancer and thoracic oligometastatic and oligoprogressive disease. However, ultracentral lesions pose a challenge due to the safety concerns. Stereotactic MR-guided Adaptive Radiotherapy (SMART) permits daily adaptation, real-time tracking and automated-gating, allowing for sparing critical organs while potentially enhancing target coverage.

Methods: This retrospective analysis included SMART-based SABR for ultracentral located primary or metastatic lesions from histologically proven non-small cell lung cancer (NSCLC). Ultracentral location was defined as planning target volume (PTV) overlapping the proximal bronchial tree (PBT), oesophagus or pulmonary vessels. Endpoints included grade ≥3 SMART-related toxicity, freedom from local progression (FFLP), progression-free survival (PFS) and overall survival (OS). Additionally, the reduction in PTV volume and overlap with ultracentral OARs was estimated by comparing the SMART PTV to a simulated non-adaptive 4DCT SABR PTV.

Results: Between 2020 and 2023, twelve patients with 19 ultracentral NSCLC lesions underwent SMART. The median dose was 40Gy (30-60Gy) in 5-8 fractions. Online plan adaptation was performed in 100% of delivered fractions (86 fractions). No severe toxicity (grade 3+) was observed and G1-2 acute and late toxicity rates were 50% and 16.7%, respectively (Figure 1). Over a median follow-up of 15 months (range 4-38), one lesion recurred within the SMART field. FFLP at 1 year was 93%. Median-PFS was 6.15 months (1-38 months). Median and 1-year OS were not reached (range 4-38 months) and 92%, respectively. Median simulated conventional-SABR PTV was significantly larger than the SMART PTV (31.2cc vs 9.3cc, p< 0.001), with a significant increase in the median overlap with ultracentral OARs (4.6cc vs 0.75cc p < 0.001).

Conclusions: SMART, with daily online adaptation, achieved comparable LC to conventional non-adaptive SABR in ultracentral NSCLC, without severe toxicity. tumors.

P3.09.03 Efficacy of Radiotherapy in Patients With Oligo-Progressive Non-Small Cell Cancer - a Retrospective Analysis

T. Barkan[1], N. Israeli Weller[1], M. Moskovitz[1], O. Rotem[1], O. Icht[1], E. Hanovich[1], D. Reinhorn[1], I. Averbuch[1]
[1]Rabin Medical Center – Beilinson Hospital, Petah Tikva/IL

Introduction: Radiotherapy (RT) is well-established for treating oligometastatic non-small cell lung cancer (NSCLC), but its role in oligoprogression remains less defined. This study evaluates RT efficacy in oligoprogressive NSCLC and identifies factors associated with improved outcomes.

Methods: We retrospectively screened all patients with metastatic NSCLC at the Davidoff Cancer Center who were treated with first line systemic therapy (2018-2024) and identified patients who received RT to all progressing sites during first-line therapy. Primary endpoints included progression-free survival (PFS), time to next treatment (TTNT), and overall survival (OS) from RT initiation. We assessed the impact of various factors, such as treatment type, initial disease state and RT sites.

Results: We identified 81 patients who received radiotherapy (RT) for oligoprogressive NSCLC, including 50 treated with immunotherapy with or without chemotherapy (immunotherapy cohort) and 31 treated with tyrosine kinase inhibitors (TKIs) (TKI cohort). The median age in both cohorts was 66 years, 67% had a history of smoking, and adenocarcinoma was the predominant histology (70%), followed by squamous cell carcinoma (16%). In the TKI cohort, EGFR common mutations were the most frequent driver alteration (77%), followed by ALK (13%), KRAS G12C (3%), ROS1 (3%), and BRAF V600E (3%). Overall, driver mutations were detected in 53% of cases, most commonly EGFR (30%). In the immunotherapy cohort, PD-L1 expression was positive (>1%) in 68% of patients. Oligoprogression was most frequently observed at new disease sites (53%), predominantly in the lungs (51%), but also in the primary tumor and pre-existing metastases. The median progression-free survival (PFS) and overall survival (OS) from RT initiation were 9 months and 34 months, respectively, with a median time to next treatment (TTNT) of 21 months. At 6 and 12 months, 81% and 63% of patients, respectively, remained on first-line therapy. PFS rates at 6 and 12 months were 62% and 50% in the immunotherapy cohort, compared to 52% and 29% in the TKI cohort (HR 0.8, 95% CI 0.48-1.35). Patients with oligometastatic disease at diagnosis (≤5 metastases) had longer PFS and OS at 6 and 12 months, although statistical significance was not reached (HR 0.77, 95% CI 0.45-1.32). RT to liver or bone metastases was associated with shorter PFS compared to RT to other sites such as the lungs and brain (HR 3.1, 95% CI 1.1-8.8 for liver; HR 2.2, 95% CI 1.01-4.7 for bone).

Conclusions: RT for oligoprogressive NSCLC demonstrates potential for prolonged disease control, with the potential of lengthening time on first line treatment. RT to bone and liver metastases were associated with shorter disease control compared to other sites. These findings suggest that patient selection is needed to optimize the therapeutic benefit of RT in oligoprogressive NSCLC.

P3.09.04 Macrophage CD38 Expression as a Predictive Biomarker for the Abscopal Effect in Lung Cancer Undergoing Radiotherapy-Immune Therapy

Y. Wu[1], J. Xue[1], R. Zhang[2], N. Yin[1]
[1]West China hospital, Sichuan University, Chengdu/CN ,[2]West China Hospial, Sichuan Univerity, Chengdu/CN

Introduction: The abscopal effect, where tumors outside the radiation field regress after radiotherapy, remains rare in lung cancer. Increasing the incidence of the abscopal effect and identifying its biomarkers are crucial. Bulk RNA sequencing and flow cytometry of distant tumors revealed significant CD38 upregulation in macrophages. We investigated its impact on the abscopal effect and its potential as a biomarker.

Methods: CD38 expression in distant tumors was analyzed by RNA sequencing and flow cytometry. For functional evaluation, we utilized a dual-tumor Lewis lung carcinoma (LLC) mouse model to assess the effects of CD38 inhibition and NAD+ supplementation on tumor regression. To investigate the underlying mechanism, EVs from irradiated tumors were isolated, characterized, and co-cultured with macrophages. TEM confirmed the presence of mitochondrial structures within EVs, while Western blot analysis evaluated signaling pathway activation in macrophages. For clinical validation, peripheral blood samples from lung cancer patients receiving radiotherapy were analyzed. CD38 expression on macrophages was assessed by flow cytometry and correlated with treatment response.

Results: Radiotherapy significantly increased CD38+ macrophages in distant tumors (34.3%, $P < 0.05$). CD38 inhibition enhanced T-cell infiltration (2.83.8-fold increase in GZMB T cells, $p < 0.01$) and tumor regression ($P < 0.05$).EVs from irradiated tumors induced CD38 expression in macrophages, with mitochondrial structures observed via transmission electron microscopy. EV uptake activated the stimulator of interferon genes (STING) pathway and induced macrophage senescence. Nicotinamide supplementation reversed CD38-mediated immunosuppression, restoring anti-tumor immunity ($p < 0.0001$). Clinically, radiotherapy increased macrophage CD38 MFI by 65.5% ($p < 0.05$), with CD38+ macrophages doubling ($p < 0.01$). CD38 MFI changes correlated with treatment response: in partial responders (PR), CD38 MFI decreased by ~40% ($p < 0.01$), while in stable/progressive disease (SD/PD), it increased by ~100% ($p < 0.01$). The percentage increase was significantly higher in SD/PD vs. PR ($p < 0.01$).

Conclusions: High macrophage CD38 expression correlates with poor response to radiotherapy and immunotherapy. Patients with disease progression showed increased CD38 expression on macrophages, while responders showed a decline. Irradiated tumor-derived EVs induced macrophage CD38 expression and senescence, highlighting CD38 as a predictive biomarker and therapeutic target.

P3.09.05 Prognostic Value of TNM 9Th Lymph Node Classification and Pathological Node Count in NSCLC Patients

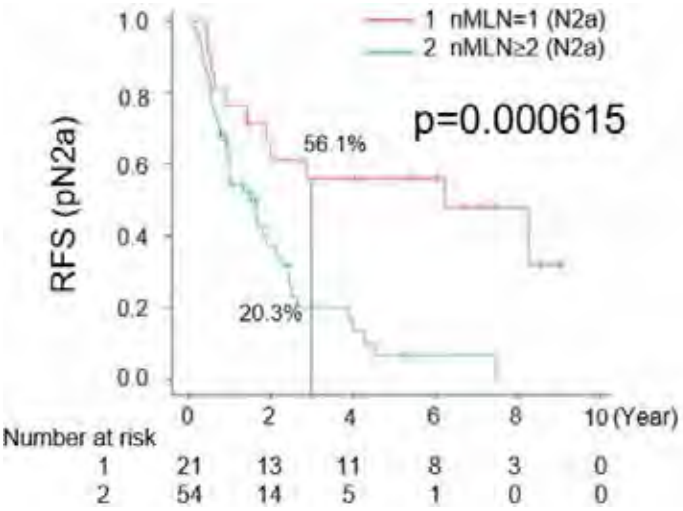
Y. SAKATA[1], J. Soh[1,2], M. Kojima[1], Y. Nakamura[1], T. Fukami[1], H. Oiki[1], S. Fukuda[1], S. Ohara[1], A. Hamada[1], M. Chiba[1], M. Ito[1], M. Shimoji[1], K. Suda[1], T. Mitsudomi[1], Y. Tsutani[1]
[1]KINDAI UNIVERCITY Faculty of Medicine, [377-2] Ohno- Higashi, Osaka-Sayama [589-8511]/JP ,[2]Osaka Metropolitan Univercity Graduate School of Medicine, Professor of respiratory Surgery, [1-4-3] Asahi-cho, abeno-ku, Osaka/JP

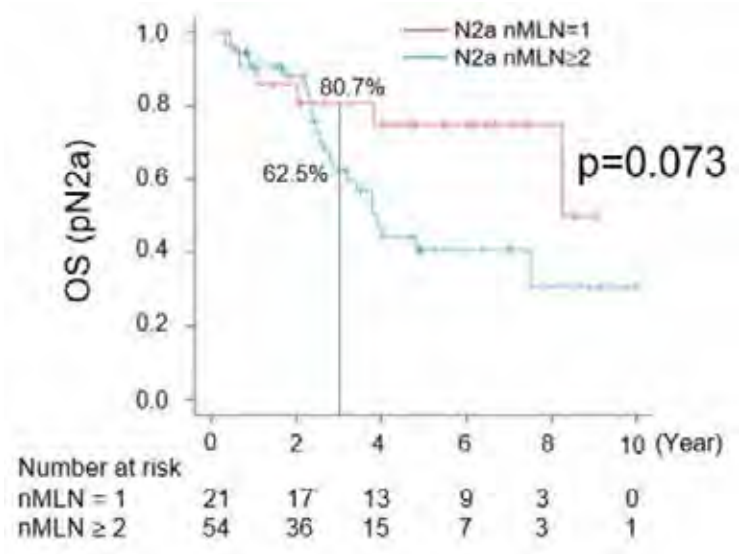
Introduction: The new TNM9th classification for non-small cell lung cancer (NSCLC) subdivided pN2 into pN2a (single) and N2b (multiple) based on the number of metastatic mediastinal lymph node (LN) stations. The number of metastatic LN (nMLN) has also been reported as a prognostic factor in NSCLC patients who underwent radical resection. However, their combined impact remains unexplored.

Methods: We investigated the clinical implication of pN status in NSCLC patients who underwent anatomical resection with systematic mediastinal nodal dissection and had N1/N2 disease from March 2012 to December 2022. Cox regression models were used for univariable and multivariable analyses.

Results: Among 216 patients enrolled, 101, 75, and 40 were classified as pN1, pN2a, and pN2b, respectively. The median nMLN was 2 (range, 1-30), and the patients were divided into two groups: 82 nMLN=1 or 134 nMLN≥2. Univariable analysis indicated that pN9th predicted recurrence-free survival (RFS) but not overall survival (OS), while nMLN predicted both RFS and OS. Multivariable analysis showed that nMLN, but not pN9th, was an independent factor for both RFS [hazard ratio (HR) of 2.283; 95% confidential interval (CI) of 1.513-3.446) and OS (HR of 2.165; 95%CI of 1.310-3.577). Subset analysis demonstrated that pN2a patients with nMLN≥2 had a worse prognosis than those with nMLN=1(Figures). Skip metastasis was present in 34% of pN2 disease while nMLN might impact prognosis more than skip metastasis.

Conclusions: The inclusion of nMLN, along with the pN9th factor, may be recommended for the upcoming TNM classification. Further research is needed to validate this finding.





Keywords: the TNM 9th lymph node classification, the number of pathological lymph node, skip metastasis

P3.09.06 Primary Tumor Resection Confers Survival Benefit in cM0sM1a Lung Adenocarcinoma

J. Tian, S. Liang
Sun Yat-sen University Cancer Center, GuangZhou/CN

Introduction: The surgical management of lung adenocarcinoma (LUAD) with incidentally detected intraoperative pleural metastasis (cM0sM1a) remains a contentious dilemma. Current guidelines recommend aborting radical resection upon identification of pleural dissemination, prioritizing systemic therapy over locoregional intervention. The study aims to assess the prognostic impact of primary tumor resection (PTR), potentially providing evidence for intraoperative decision-making for cM0sM1a LUAD patients.

Methods: This retrospective study analyzed consecutive cM0sM1a LUAD patients without neoadjuvant therapy (November 2008 to December 2023) from Sun Yat-sen University Cancer Center. Clinicopathological characteristics, treatment patterns, and survival outcomes were extracted from electronic medical records. Overall survival (OS) was estimated using Kaplan-Meier analysis. Univariate Cox regression was applied to determine the prognostic factors, while multivariate Cox regression and propensity score matching (PSM) were used to address confounding. Subgroup analyses were performed to further explore the survival impact of PTR in various settings.

Results: The study included 310 cM1a LUAD patients (161 underwent PTR, 149 biopsy only). Multivariate Cox analysis revealed PTR (HR=0.68, p=0.021), adjuvant targeted therapy (HR=0.30, p<0.001), and adjuvant chemotherapy (HR=0.60, p=0.008) as independent protective factors, contrasting with smoking (HR=1.50, p=0.023) and intraoperative pleural effusion (HR=2.11, p<0.001) which demonstrated adverse prognostic significance. Notably, PTR demonstrated consistent survival benefits before (HR=0.57, p<0.001) and after PSM (HR=0.53, p=0.019), with marked survival advantage observed in cT1-2 subgroups (HR=0.56,p=0.001) and among patients without adjuvant targeted therapy (HR=0.47,p=0.007). Conversely, no significant survival advantages of PTR were observed in cT3-4 disease (HR=0.70,p=0.38) or among patients receiving adjuvant targeted therapy(HR=0.69,p=0.06). In terms of surgical resection extent, similar survival outcomes were maintained between sublobar resection and lobectomy (HR=1.00,p=0.99), while lymph node dissection demonstrated no significant impact on survival outcomes in patients with PTR(HR=0.70,p=0.19).

Conclusions: PTR significantly improved survival in cM0sM1a LUAD patients, emphasizing its pivotal role in the multidisciplinary framework. However, a broader resection did not confer survival benefits. This study provides high-quality evidence for optimizing decision-making and refining guidelines in the cM0sM1a LUAD management.

P3.09.07 Local MDT Improve the Survival of Leptomeningeal Metastasis in NSCLC With EGFR Mutation From the CLM-Tree Registry

F. Wang[1], H. Yang[2], W. Hong[3]
[1]Department of Thoracic Oncology, the First Affiliated Hospital of Guangzhou Medical University,, Guangzhou/CN ,[2]Department of Thoracic Oncology, State Key Laboratory of Respiratory Diseases, National Clinical Research Center of Respiratory Disease, The First Affiliated Hospital of Guangzhou Medical University, [151] Yanjiang Road, Guangzhou [510120], China,, Guangzhou/CN ,[3]Department of Oncology, Guangdong Sanjiu Brain Hospital, Guangzhou [510000], China., Guangzhou/CN

Introduction: Leptomeningeal metastasis (LM) in EGFR-mutant NSCLC has poor prognosis, even with TKI dose escalation. Recently, local multidisciplinary treatment (L-MDT) has been applied in China. This study analyzes survival outcomes using CLM-tree registry data (NCT06718972).

Methods: EGFR-mutant NSCLC patients with LM since 2018 were analyzed for clinical characteristics and survival based on CLM-tree registry data.

Results: Among 123 LM patients, 98.3% had adenocarcinoma, and 73.2% were diagnosed during treatment. Poor prognosis (NCCN-LM criteria) was observed in 55.3%. A total of 84.6% received L-MDT plus systemic treatment, including VP-shunt, intracranial chemotherapy, or cranial radiation. Dose escalation of third-generation TKIs was common (79.7%), including Osimertinib 160 mg (56.1%), Almonertinib 165/220 mg (27.6%), and Firmonertinib 160/240 mg (16.3%).Among 120 patients analyzed, median OS from LM diagnosis was 13 months, with a 1-year survival rate of 51.8%. Patients with good prognosis and primary LM had significantly longer OS (20.0 vs. 11.0 months, P<0.001; 20.3 vs. 11.3 months, P=0.004) (Figure). Firmonertinib showed a trend toward better survival (P=0.16). Multivariate analysis identified good prognosis (HR=0.39, P<0.001) and primary LM (HR=0.50, P=0.009) as significant prognostic factors.Due to widespread L-MDT application, OS improvement may be attributed to local treatment combined with TKI escalation. Median OS from LM diagnosis and L-MDT initiation was 12.1 and 10.0 months, respectively. Among 37 L-MDT patients with LM deterioration and neurological symptoms after systemic treatment failure, median OS from L-MDT was 11.0 months, with a 1-year survival rate of 33.8%. Neurological symptoms improved significantly (RANO-LM score: 5.3±0.5 vs. 2.0±0.4, P<0.001). No significant survival difference was observed between non-severe (LM≤4) and severe (LM score >4)) groups (12 vs. 10 months, P=0.19).

Conclusions: L-MDT combined with TKI escalation may improve survival in EGFR-mutant NSCLC patients with LM, especially those with severe neurological symptoms.

P3.09.08 Tumor Treating Fields for Patients With Metastatic Non-Small Cell Lung Cancer: Real World First Experience

[1]Miami Cancer Institute, Miami/FL/USA ,[2]Rutgers Cancer Institute of New Jersey, New Brunswick/NJ/USA ,[3]Mon Health Cancer Center, Morgantown/WV/USA ,[4]Hoag Memorial Hospital Presbyterian, Newport Beach/CA/USA ,[5]Illinois CancerCare, Bloomington/IL/USA

Introduction: Tumor Treating Fields (TTFields) are frequency-specific alternating electric fields that disrupt mitosis of cancer cells and may elicit an antitumor immune effect. TTFields concurrent with docetaxel or a PD-(L)1 inhibitor were FDA-approved in 10/2024 for the treatment of metastatic non-small cell lung cancer (mNSCLC) progressing on or after platinum-based therapy based on the overall survival benefit reported in the phase III LUNAR study. The objective of this analysis was to report demographics, treatment characteristics, and usage for patients treated in the United States post-FDA approval.

Methods: De-identified data from patients with mNSCLC that progressed on or after platinum-based therapy, and who were prescribed TTFields by a certified prescriber were collected from the device-manufacturer database. Baseline patient characteristics and treatment details were collated; usage was calculated for those who had used the device for at least one month, based on device-captured treatment time.

Results: 91 patients were prescribed TTFields and 62 patients (68%) were able to start the treatment within the data cutoff window for this analysis (March 7, 2025). The number of patients per month prescribed TTFields increased from 13 to 23 over the analyzed period (10/24-3/2025). Prescribing providers were medical oncologists for 67 patients (74%), radiation oncologists for 19 patients (21%), and other disciplines for 5 patients (5%). 70 patients (77%) were prescribed in a community hospital vs. 21 patients (23%) in an academic setting. For treated patients, the median age was 66 years (interquartile range [IQR]: 60-72) and 55% were female; 69% and 26% had adenocarcinoma and squamous cell carcinoma histology, respectively. Of 60 patients with available systemic therapy data, 33 (55%) were treated in the second-line setting, 15 (25%) in the third-line setting, and 12 (20%) in the fourth line and beyond. Concurrent systemic therapy consisted of docetaxel-based cytotoxic chemotherapy in 27 (44%), 32 (52%) with an immune-checkpoint inhibitor (ICI), and 3 (5%) with both; an ICI was included in at least one of previous lines of therapy for 94% of patients. Among 32 patients who used TTFields for at least 1 month, the median usage was 12 hours per day (IQR: 9.1-16.3).

Conclusions: Growth in TTFields uptake was observed after FDA-approval for patients with mNSCLC with the majority of patients being treated with an ICI. Usage patterns appear similar to those observed in the phase III LUNAR study. Further outcomes and toxicity data will be important to assess utility and benefit of TTFields with contemporary systemic therapies of mNSCLC in real life clinical practice.

P3.09.09 Frequency and Prognostic Impact of Local Ablation Therapy for Oligoprogression in Non-Small Cell Lung Cancery

D. Morinaga, J. Sakakibara-Konishi, K. Tsuji, S. Ito, M. Furuta, T. Shoji, Y. Takashima, H. Kitai, Y. Ikezawa, H. Taguchi, T. Kato, Y. Shinomiya, K. Hatanaka. C, Y. Hatanaka, S. Konno
Hokkaido University, Sapporo/JP

Introduction: During systemic treatment for patients with non-small cell lung cancer (NSCLC), oligoprogression (OP), a condition in which most lesions remain controlled while a few progress or develop, has recently attracted attention. Previous reports suggest that OP occurs in 20-40% of cases, with frequencies influenced by factors such as the presence of driver genes and the type of treatment. OP lesions are thought to represent populations resistance to systemic treatment. Eliminating these lesions by local ablation treatment (LAT) may prolong survival or the duration of systemic treatment. This rationale supports the application of LAT in managing OP. In fact, advancements in LAT, such as radiotherapy and surgery, have demonstrated clinical efficacy in some patients with OP. However, the characteristics of patients who may benefit from LAT or their genetic backgrounds remain unclear. This study evaluated the frequency of OP, clinicopathological characteristics, and efficacy of LAT as a treatment for OP.

Methods: This retrospective observational study was conducted at Hokkaido University Hospital. The inclusion criterion was patients aged 20 years or older who were diagnosed with NSCLC, experienced relapse after systemic treatment, and were diagnosed with OP between January 2015 and February 2024. OP was defined as those with three or fewer new or exacerbating lesions. LAT was defined as surgery or radiation therapy targeting OP lesions, whether performed for curative or palliative purposes. LAT did not require treatment of all OP lesions. Furthermore, we defined repeat OP as patients with recurrence of OP after treatment for OP and examined its frequency.The primary endpoint was to determine the proportion of patients with NSCLC who developed OP during systemic treatment. We also performed RNA sequencing (RNA-seq) to identify the genetic characteristics of OP.

Results: Overall, 106/510 (23.6%) patients exhibited OP; among these, six patients who received only the best supportive care after OP were excluded. Systemic treatment alone was administered to 79 patients (79.0%), whereas 21 patients (21.0%) received LAT. Median local progression-free survival (LPFS) was numerically longer in the LAT group than in the systemic treatment-only group (8.3 months and 6.7 months, respectively; p=0.38) without significance. In addition, overall survival (OS) was also numerically longer in the LAT group than in the systemic treatment-only group (78.1 months and 55.1 months, respectively; p=0.57) without significance. Next, of all progression events, 36 (45.0%) patients had repeat OP. When comparing the OP-OS between the repeat OP group and the non-repeat OP group, a numerically better trend was observed in the repeat OP group (HR 0.55, 95% CI: 0.29-1.04), with a median OP-OS of 64.1 months for the repeat OP group and 24.6 months for the non-repeat OP group (p = 0.06). RNA-seq showed an increase in extracellular matrix- and external encapsulating structure related gene expression after OP, suggesting potential molecular insights.

Conclusions: LAT showed better trend for LPFS and OS, but no significant prognostic benefit for patients with OP. Future research integrating clinical and molecular data may identify patients most likely to benefit from LAT.

Keywords: Oligometastasis, Oligoprogression, Local ablation therapy

P3.09.10 Safety and Efficacy of Co-Ablation System Therapy in Patients With Lung Cancer: A Single Arm Cohort Study

S. Ren[1], B. Chen[1], L. Zhang[2], S. Yang[1], J. Yin[1]
[1]Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai/CN ,[2]Chengdu Third People's Hospital, Chengdu/CN

Introduction: Co-ablation therapy, an emerging local treatment modality that integrates combined thermal and cryoablation techniques, has attracted growing clinical interest. However, its safety profile and therapeutic efficacy in lung cancer remain largely unknown.

Methods: From Feb 2023 to May 2024, the clinical data of 205 patients (212 lesions) treated with percutaneous co-ablation at Shanghai Pulmonary Hospital were prospectively collected and analyzed.

Results: Adverse events (grade ≥2) occurred in 26.83% (55/205) of patients, with pneumothorax (21.46%), pleural effusion (10.73%), and hemoptysis (6.34%). Grade 3 complications were rare (3.41%) with no procedure-related mortality. Multivariate analyses showed that severe emphysema (OR=3.14), tumor size (OR=1.09), and multiplicity (OR=4.60) as predictors of adverse events. Procedural success was achieved in 100% sessions, with complete ablation rates as 97.56% (200/205). With median follow-up of 6 months, local tumor control rates at 3, 6, and 12 months demonstrated significant advantage for smaller tumors (median diameter 13 mm). Progression-free survival (PFS) was markedly longer in tumors ≤3 cm versus >3 cm [NR vs. 6 months, 95%CI:4.1-7.9, P=0.004].

Conclusions: Co-ablation demonstrates high complete ablation rates (97.56%) and acceptable safety in patients with lung cancer. Tumor size less than 3 cm associated with long-term outcomes, suggesting co-ablation as a promising novel ablation strategy in patients with lung cancer.

P3.12.01 Phase II Trial of First-Line Double-Dose Firmonertinib in Locally Advanced or Metastatic NSCLC With EGFR L858R (FIRM Study)

M. Shi[1], B. Shen[1], C. Wang[2], L. Zhang[3], Y. Zhu[4], X. Zhang[5], X. Wang[5], Z. Guo[1], L. Wang[1], L. Zhu[2], Y. Zhou[6], D. Liao[6]
[1]Affiliated Cancer Hospital of Nanjing Medical University & Jiangsu Cancer Hospital & Jiangsu Institute of Cancer Research, Nanjing/CN ,[2]Liyang People's Hospital, Liyang/CN ,[3]First Affiliated Hospital of Wannan Medical College, Wuhu/CN ,[4]The First Affiliated Hospital of Anhui Medical University, Hefei/CN ,[5]Jiangsu Simcere Diagnostics Co.,Ltd., Nanjing Simcere Medical Laboratory Science Co., Ltd., Nanjing/CN ,[6]China Pharmaceutical University, Nanjing/CN

Introduction: Advanced non-small-cell lung cancer (NSCLC) with EGFR-L858R mutation had a shorter progression-free survival (PFS) compared to those with exon 19 deletions. This efficacy gap, compounded by the considerable toxicity, clinical complexity, and economic burden of current combination regimens, highlights the critical need for novel therapies. The FIRM study (ChiCTR2200060897) investigated double-dose firmonertinib as a therapeutic alternative.

Methods: This single-arm, multicenter phase II trial enrolled treatment-naïve adults (≥ 18 years) with locally advanced or metastatic NSCLC harboring EGFR-L858R mutation. Patients received firmonertinib 160 mg orally once daily in 21-day cycles until disease progression, death, intolerable toxicities, or withdrawal from the study. Circulating tumor DNA (ctDNA) was analyzed using a 158-gene panel at baseline, cycle 3 day 1 (C3D1), and upon disease progression. Primary endpoint was PFS. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), 18-month PFS rate, overall survival (OS), and safety. Exploratory endpoint assessed kinetics of the ctDNA profiles.

Results: As of February 2025, 33 patients received firmonertinib and were enrolled in efficacy and safety analyses with a median follow-up of 18.1 (range, 0.8-29.3) months. The median PFS (mPFS) reached 21.1 (95% confidence interval [CI], 17.5-not reached) months, with an 18-month PFS rate of 59.7% (95% CI, 44.1%-80.8%). Median OS was not reached with a 12-month OS rate of 96.6% (95% CI, 90.1%-100%). The ORR was 75.8% (95% CI, 57.7%-88.9%) with a median DoR of 18.5 (95% CI, 18.3-not reached) months, and DCR reached 90.9% (95% CI, 75.7%-98.1%). In the subgroup of patients with baseline brain metastases, ORR and DCR were 83.3% and 100%, respectively. Treatment was well-tolerated with only 6.1% grade ≥ 3 adverse events (anemia and hyponatremia), and no patients experienced dose reduction, discontinuation, or death. ctDNA dynamics revealed significant decreases in mean variant allele frequency (VAF) at C3D1 compared to baseline ($p<0.0001$), especially in the responders. Patients achieving ctDNA clearance at C3D1 showed significantly improved PFS (20.2m vs. 9.9m, P=0.014). Interestingly, baseline EGFR VAF, which was associated with total tumor diameter (R=0.426, P=0.042), emerged as a predictive biomarker for ctDNA clearance at C3D1 (Cut-off=1.5%, AUC=0.683).

Conclusions: Double-dose firmonertinib exhibited promising efficacy and safety in this trial, supporting its use as a first-line option for patients with EGFR-L858R mutation. ctDNA analysis demonstrates its significant clinical value for efficacy monitoring in FIRM and provides new insights for precise treatment strategies based on biomarker-driven stratification.

Figure 1. The efficacy estimation and biomarker exploration of FIRM study

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.02 Real-World Outcomes in Patients With NSCLC and Leptomeningeal Disease

M. Agarwal, N. Kataria, S. Pandey, A. Alkrekshi, C. Kim
MedStar Georgetown University Hospital, Washington/DC/USA

Introduction: Historically, leptomeningeal disease (LMD) has had poor outcomes, but newer therapies may improve overall survival (OS). We examined factors affecting OS in a contemporary population of patients with NSCLC and LMD.

Methods: We retrospectively analyzed data from patients at MedStar Health who were diagnosed with NSCLC after December 1, 2017, and developed LMD at any point during their clinical course.

Results: Seventy-three patients met the inclusion criteria. LMD was diagnosed via: MRI alone (n=56, 78%), MRI and lumbar puncture (LP) (n=13, 18%), LP alone (n=2, 2%), and leptomeningeal involvement on pathology of a resected CNS metastasis (n=2, 2%). Twenty-two patients (30%) had LMD at their NSCLC diagnosis. Ten patients (14%) had no neurological symptoms at LMD diagnosis, and 16 patients (22%) had isolated LMD without parenchymal brain metastases. Median OS (mOS) following LMD diagnosis was 1.5 months (range: 1 day-43 months). Patients without neurological symptoms at LMD diagnosis had a mOS of 10 months (range: 1 day-32 months), compared to 1.2 months for those with symptoms (range: 6 days-44 months). Systemic treatment-naïve patients had a longer mOS (6.5 months, range: 1 day-43.8 months) than those with prior systemic therapy (1.3 months, range: 2 days-36 months, p=0.02). Patients who received treatment for LMD (n=48, 66%), such as radiation, intrathecal chemotherapy, or systemic therapy, had a longer mOS of 6.8 months (range: 11 days-43 months), compared to <1 month (n= 25, 34%, range: 1 day-5 months, p<.01) for those who did not. Similarly, patients with targetable mutations who received targeted therapy had a longer mOS of 8 months (n=23, range: 1-43 months) compared to those who did not (n= 21, mOS <1 month, range: 1 day-5 months, p<.01). Among patients who received 1 targeted therapy prior to LMD (n=23) diagnosis, those who received further targeted therapy (n=12) had improved OS (mOS 8 months, range 1-32 months), compared to those who did not (n=11, mOS <1 month, range 3 days-16 months, p <.01). Patients with PD-L1 ≥50% treated with immunotherapy had a mOS of 13 months (n=5, range: 1 day-35 months).

Conclusions: Treatment of LMD improves OS and can extend life by several years in a subset of patients, particularly those who are asymptomatic or treatment-naive. Targeted therapy was associated with improved OS in those with targetable mutations, regardless of prior exposure. High PD-L1 expression was linked to notable benefit from immunotherapy. Further investigation in a larger cohort is needed.

	N (%)	Median OS (months)	Minimum OS (months)	Maximum OS (months)
All patients	73 (100)	1.5	<1	44
Any Treatment for LMD	48 (66)	7	<1	44
Targetable mutation & LMD Treated with Targeted Therapy	23 (52)	8	1	44
PD-L1 ≥50% & LMD Treated with Immunotherapy	5 (7)	13	8	35

P3.12.03 Retrospective Analysis of Age, EGFR Mutation Type, and TP53 Co-Mutation on Survival Outcomes in EGFR-Mutant Non-Small Cell Lung Cancer

E.K. Singhi[1], N. Gandhi[2], A. Elliott[2], A. Vanderwalde[2], B. Halmos[3], Z. Hao[4]
[1]The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[2]Caris Life Sciences, Phoenix/AZ/USA ,[3]Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA ,[4]University of Kentucky College of Medicine, Division of Medical Oncology/KY/USA

Introduction: Young adults with non-small cell lung cancer (NSCLC) often have distinct clinico-genomic features compared to older adults. While targeted therapies for EGFR-mutant NSCLC primarily focus on 'classical' EGFR mutations, atypical EGFR mutations and TP53 co-mutations can negatively impact therapy response but remain understudied. This retrospective study evaluates the impact of patient age, EGFR mutation type (classical vs atypical), and TP53 co-mutation status on overall (OS) and survival from the initiation of osimertinib (Osi-OS) in patients with EGFR-mutant NSCLC.

Methods: 5,753 patients with EGFR-mutant NSCLC specimens were molecularly profiled at Caris Life Sciences (Phoenix, AZ) and distributed into two cohorts based on age at specimen collection: older adults (OA, >50 years, n=5404) and young adults (YA, ≤50 years, n=349). Classical mutations in EGFR include L858R, T790M and exon19 deletions, while all non-classical mutations were considered 'atypical'. Only pathogenic and likely pathogenic mutations were considered when determining TP53 mutation status. OS and Osi-OS were calculated using insurance claims data, with survival times measured from the date of specimen collection or osimertinib initiation to the date of last clinical contact using Kaplan-Meier estimates. Hazard ratio (HR) was calculated using the Cox proportional hazards model, and p values were calculated using the log-rank test. To keep OS and Osi-OS distinct, patients treated with osimertinib were removed from OS calculations. Where applicable, p-values were corrected for multiple hypothesis testing with $q<0.05$ denoting statistical significance.

Results: Gender distribution and smoking history were comparable between the two groups. OA had a higher proportion of White and Non-Hispanic/Latino individuals (58 & 71%, respectively, vs 36 & 54% in YA; $q<0.05$); however, race and ethnicity were unknown for a greater proportion of YA. The distribution of classical/atypical EGFR mutations were similar between the two cohorts, while TP53 mutations were enriched in YA (76 vs 62%, $q<0.05$).Compared to OA with atypical EGFR mutations (OA-A), OA with classical mutations (OA-C) had a longer OS only in the absence of concurrent TP53 mutations (median OS: 39 vs 28m, HR=0.735, $p<0.0001$). However, OA-C (vs OA-A) had a longer Osi-OS only when co-mutated with TP53 (29 vs17m, HR=0.631, $p<0.001$). Additionally, YA with classical mutations (YA-C) had a longer median Osi-OS than both OA-C (40 vs 32m, HR=0.692, $p<0.01$) and OA-A (40 vs 21m, HR=0.47, $p<0.0001$), independent of TP53 mutation status.

Conclusions: In our study cohort, YA-C had the longest median Osi-OS, while OA-A had the shortest median Osi-OS. Our results highlight a significant role of TP53 mutation status, EGFR mutation subtype, and age in determining both OS and Osi-OS, particularly in OA. Further investigation is needed to explore the role of these factors in YA, where cohort sizes may limit conclusions.

P3.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY
TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.04 Taletrectinib, a Next Generation Selective ROS1 Inhibitor, Exhibits a Differentiated Profile in ROS1 Fusion Models

H. PATEL, L. Heller, K. Bowman, Z. Hu, Y. Zhang, I.M. Grossi, M. Pan, G. Hattersley
Nuvation Bio Inc., New York/NY/USA

Introduction: ROS1 fusions, present in approximately 2% of non-small cell lung cancer (NSCLC) patients, drive cancer cell growth and survival. While FDA approved ROS1 inhibitors include crizotinib, entrectinib, and repotrectinib, patients are still in need of better treatment options that provide durable responses and prolonged progression-free survival (PFS), coupled with limited side effects. Taletrectinib is an oral, potent, central nervous system (CNS) active, selective, next-generation ROS1 inhibitor specifically designed for the treatment of patients with ROS1-positive NSCLC. Taletrectinib is being evaluated in patients with advanced ROS1-positive NSCLC, including tyrosine kinase inhibitor (TKI) naïve and TKI pretreated patients, in two Phase 2 single-arm pivotal studies: TRUST-I (NCT04395677) and TRUST-II (NCT04919811). Pooled results from the TRUST-I and TRUST-II studies of taletrectinib demonstrated a confirmed objective response rate (cORR) of 89%, an intracranial cORR of 77%, and a PFS of 46 months in patients with advanced ROS1-positive NSCLC that have not previously received a ROS1 TKI.

Methods: The kinase selectivity of taletrectinib was evaluated in comparison to approved ROS1 inhibitors. The in vitro and in vivo antitumor activity of taletrectinib was assessed against multiple ROS1 fusion models, including models with ROS1-G2032R fusions. Since ROS1 positive lung cancers have a high incidence of brain metastases, the intracranial activity and safety of taletrectinib was also compared to approved ROS1 inhibitors.

Results: Taletrectinib exhibits selectivity for ROS1 over tropomyosin receptor kinase (TRKB), the latter being associated with CNS-related side effects. At clinically relevant concentrations, taletrectinib inhibited growth of cell lines harboring various ROS1 wild type and ROS1-G2032R fusions. Taletrectinib treatment caused tumor regressions in several ROS1 fusion models regardless of fusion partner, including models resistant to crizotinib and entrectinib. Additionally, taletrectinib demonstrated CNS activity and a favorable toxicological profile in nonclinical safety studies.

Conclusions: In summary, our nonclinical data demonstrate that, at clinically relevant concentrations, taletrectinib exhibits activity in ROS1 wild-type- and mutant-driven cancers, including intracranial models, while maintaining selectivity against TRKB, resulting in an overall favorable profile. An NDA, based on the results from the pivotal TRUST-I and TRUST-II studies, has been accepted with Priority Review by the U.S. FDA for the treatment of patients with advanced ROS1-positive NSCLC.

[1]MOC Cancer Care & Research Centre, Mumbai/IN ,[2]MOC Cancer Care & Research Centre, Indore/IN ,[3]MOC Cancer Care & Research Centre, Pune/IN ,[4]MOC Cancer Care & Research Centre, Nagpur/IN ,[5]MOC Cancer Care & Research Centre, Nashik/IN ,[6]MOC Cancer Care & Research Centre, Kolhapur/IN ,[7]MOC Cancer Care & Research Centre, Chh. Sambhajinagar/IN

Introduction: Epidermal Growth Factor Receptor (EGFR) mutations, the most commonly targeted mutations in lung cancer, have led to expanded treatment options in metastatic settings due to their heterogeneity. This study comprehensively summarizes the spectrum of EGFR mutations and co-mutations, clinical characteristics, treatment patterns, and survival outcomes in a real-world community oncology practice

Methods: This retrospective study included consecutive patients from community oncology centres diagnosed with EGFR mutant Non-small cell lung carcinoma (NSCLC) between March 2018 and September 2024

Results: Out of 2281 patients with Non-small cell lung carcinoma (NSCLC), 1592 were identified as adenocarcinomas, with EGFR mutations detected in 560/1592 (35.2%). The median age of the cohort was 64 years (IQR 55-72) with 17 patients presenting at less than 40 years of age and the M:F ratio being 1:1.07. The ECOG performance status scores were 0 in 54.4%, 1 in 38.6%, and ≥2 in 6.1% of patients, with the majority (80.5%) diagnosed with Stage IV disease most commonly metastasizing to the bone (270/451), brain (148/451), and lymph nodes (100/451). The prevalence of EGFR was higher in females compared to males (51.6% v/s 48.4 %, p=0.28).Detailed EGFR mutational testing records were available for 466 out of which comprehensive Next-generation sequencing (NGS) was done in 297/466 patients wherein 57.3% were tissue-based NGS, and 8.9% were liquid biopsy-based NGS while 281/466 patients were tested by Polymerase chain reaction (PCR). The frequency of co-mutations with EGFR was seen in 122/560 (21.8%) shown in Table 1. The majority of patients received tyrosinekinase inhibitors (TKIs) in the first-line (406/504, 80.6%) of which Gefitinib, Erlotinib, Afatinib, and Osimertinib were used in 32%, 7.8%, 13.3%, and 16.25% respectively while 21.67% received TKI in combination with chemotherapy. The TKI plus chemotherapy subgroup had a median age of 59 years (IQR: 52-67), with an ECOG PS of 0-1 in 97% and ≥2 in 3.3% of patients and 30.7% had brain metastases. Median overall survival m(OS) was 33 months (95% CI 29.3-36.7), with a median follow-up time being 29 months (95% CI 25.7-32.3). mOS was 33 months for Gefitinib/Erlotinib/Afatinib, 58 months for CT combined with TKIs, 38 months for Osimertinib, while moS for CT plus Osimertinib was not reached (P=0.078)

Conclusions: EGFR mutation testing is vital for optimizing NSCLC treatment outcomes, particularly in community oncology settings and developing countries, where access to targeted therapies and personalized treatment approaches can significantly improve patient care

P3.12.06 Pralsetinib (Phase 1/2 ARROW Trial) Compared With Best Available Therapy (External Control) in Pretreated RET Fusion+ NSCLC

A. Drilon[1], D. Galetta[2], J. Mazieres[3], P. Bobbili[4], A. Lax[4], A. Muthukumar[5], M.S. Duh[4], A.D. Sheppard[6], A. Thomassen[6], O. Gautschi[7]
[1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]IRCCS Istituto Tumori "Giovanni Paolo II", Bari/IT ,[3]University Hospital Center of Toulouse, Toulouse/FR ,[4]Analysis Group, Inc., Boston/MA/USA ,[5]Analysis Group, Inc., Menlo Park/CA/USA ,[6]Rigel Pharmaceuticals, Inc., South San Francisco/CA/USA ,[7]Cantonal Hospital Lucerne and University of Berne, Lucerne/CH

Introduction: Pralsetinib, a highly potent, oral, selective inhibitor of rearranged during transfection (RET) receptor tyrosine kinase, received FDA approval in September 2020 for metastatic RET fusion-positive non-small cell lung cancer (NSCLC). Understanding pralsetinib's efficacy following front-line chemotherapy is key to optimizing treatment strategies and patient outcomes. This analysis used real-world (RW) data as an external control arm to compare outcomes of the subset of patients treated with pralsetinib as second-line or later (2L+) treatment in the Phase 1/2 trial ARROW (NCT03037385) vs best available therapy (BAT).

Methods: RW data on advanced RET fusion-positive NSCLC patients (2010-2020) were collected via retrospective medical chart review from 4 centers located in the US, France, Switzerland, and Italy. Eligibility criteria similar to ARROW were applied to obtain a comparable RW sample; the RW sample was limited to treatments initiated after RET fusion identification (i.e., "post-RET") to match trial patients. Objective response rate (ORR) was assessed using proportions. Average treatment effect of the treated (ATT) weights were calculated to balance baseline characteristics between ARROW and RW samples. Overall survival (OS) and progression-free survival (PFS) were evaluated using Kaplan-Meier methods and weighted Cox regression models, including variables that remained unbalanced after ATT-weighting (>10% standardized mean difference).

Results: The 2L+ post-RET analytical sample included 22 RW patients treated with BAT and 159 ARROW patients treated with pralsetinib in 2L+ (trial data cutoff Nov 18, 2019). Mean age was 58.3 and 59.1 years and 56.0% and 51.9% were female, among ARROW and the RW, respectively; 49.7% of ARROW and 37.0% of RW patients had received >1 prior lines of therapy. Most frequently received BAT were tyrosine kinase inhibitors (66.7%; 29.6% investigational agents, 25.9% cabozantinib, 7.4% vandetanib, 3.7% alectinib) and chemotherapy (25.9%). ORR (95% confidence interval [CI]) in ARROW was 61.4% (53.7, 69.2) and in the RW was 25.9% (9.4, 42.5). Median PFS was 16.8 and 3.5 months in ARROW and the RW, respectively. Median OS was not reached in ARROW and was 9.1 months in the RW. After adjustment, compared to BAT, patients treated with pralsetinib had significantly longer PFS and OS, with adjusted hazard ratios (95% CIs) of 0.13 (0.09, 0.20), p<0.001 and 0.28 (0.17, 0.46), p<0.001, respectively.

Conclusions: This RW, multi-center study found that 2L+ treatment with pralsetinib in advanced RET fusion-positive NSCLC was associated with higher ORR and significantly improved OS and PFS compared to BAT, even after adjusting for population differences. Limitations of RW data include missing data and potential unmeasured confounding, which this study aimed to mitigate through rigorous analytical methods.

Introduction: The RAZOR study (NCT03866499) randomized 369 treatment-naïve patients with EGFR-mutated (Ex19del or L858R) locally advanced or metastatic non-small cell lung cancer (NSCLC) into two double-blind groups at a 1:1 ratio, to receive either rezivertinib (180mg po QD) or gefitinib (250mg po QD). Previous results demonstrated that rezivertinib significantly prolonged progression-free survival (PFS) compared to gefitinib, with a favorable safety profile. This analysis updates the central nervous system (CNS) outcomes in patients with baseline CNS metastases.

Methods: In the RAZOR study, all patients received CT or MRI scans and brain MRI scan at baseline, and the following-up status until radiological disease progression. EGFR mutation testing was done on tissue or plasma samples. Patients with stable, asymptomatic CNS metastases were eligible for inclusion. The CNS full analysis set (cFAS) comprised patients with baseline CNS metastases by MRI scan, which was evaluated by blinded independent central review (BICR) per RECIST v1.1. Among them, those with measurable CNS target lesions formed the CNS evaluable-for-response set (cEFR). CNS efficacy was further assessed by BICR using RANO-BM criteria.

Results: By the data cut-off date on Nov 30, 2023, 159 patients with baseline CNS metastases were included in cFAS (rezivertinib: 81; gefitinib: 78) and 25 were included in cEFR (rezivertinib: 12; gefitinib: 13) assessed by BICR. In the cFAS, 59 CNS PFS events occurred (rezivertinib: 30; gefitinib: 29), and the median CNS PFS was significantly prolonged with 24.9 (95% CI, 16.5-NC) month in the rezivertinib group over 15.2 (95% CI, 10.5-NC) months in the gefitinib group (HR=0.58; 95% CI, 0.34-0.99; P=0.0473). Estimated CNS PFS rates at 12 and 18 months were 71.7% (95% CI, 59.2-81.0) and 60.3% (95% CI, 46.4-71.7) for the rezivertinib group, respectively, versus 60.4% (95% CI, 46.9-71.5) and 41.3% (95% CI, 24.1-57.8) for the gefitinib group. For 116 patients with baseline tissue EGFR mutation positivity in the cFAS (rezivertinib: 57; gefitinib: 59), the CNS PFS was 24.9 (95%CI, 16.0-NA) months for the rezivertinib group and 16.6 (95%CI, 12.6-NA) months for the gefitinib group, respectively (HR = 0.80; 95% CI, 0.40-1.58; P=0.5182); for 58 patients with baseline plasma EGFR mutation positivity in the cFAS (rezivertinib: 32; gefitinib: 26), the CNS PFS was NA (95%CI, 15.4-NA) months for the rezivertinib group and 8.5 (95%CI, 5.7-NA) months for the gefitinib group, respectively (HR = 0.34; 95% CI, 0.14-0.81; P=0.0142). In the cEFR, the confirmed CNS objective response rates (ORR) were 83.3% for the rezivertinib group and 76.9% for the gefitinib group (odds ratio=1.50; 95% CI, 0.220-11.0; P=0.6900). Estimated CNS PFS rates at 12 and 18 months were 73.3% (95% CI, 37.9-90.6) and 73.3% (95% CI, 37.9-90.6) for the rezivertinib group, respectively, versus 51.9% (95% CI, 22.5-75.0) and 41.5% (95% CI, 14.4-67.2) for the gefitinib group. No new safety findings were identified.

Conclusions: Rezivertinib exhibited superior CNS efficacy compared to gefitinib as a first-line treatment for EGFR-mutated advanced NSCLC with baseline CNS metastases. Safety profile was manageable.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.08 Weight Gain Induced by Tyrosine Kinase Inhibitors in Oncogene-Addicted Non-Small Cell Lung Cancer: A Meta-Analysis and a Meta-Regression Study

L. Belluomini[1], A. Avancini[1], I.M. Scaglione[1], I. Trestini[1], S. Eccher[1], G. La Cava[2], A. Borsati[1], D. Tregnago[1], M. Sposito[1], J. Insolda[1], L. Pasqualin[1], L. Longo[3], D. Giannarelli[4], M. Milella[1], S. Pilotto[1]
[1]University of Verona, Verona/IT ,[2]Campus Biomedico Rome, Rome/IT ,[3]University of Naples Federico II, Naples/IT ,[4]Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome/IT

Introduction: For patients with oncogene-addicted (OA) non-small cell lung cancer (NSCLC) treated with tyrosine kinase inhibitors (TKIs), weight gain (WG) has recently gained attention as a relevant treatment-related effect. Identifying those TKIs more frequently associated with WG is crucial to characterize body composition-related modifications, deepen their metabolic impact and guide treatment decisions, considering the influence of WG on patients' quality of life (QoL) and long-term outcomes.

Methods: A systematic search was conducted across PubMed, Scopus, Cochrane and meeting resources (ESMO, ASCO, WCLC) using the following string: ("lung cancer" OR "NSCLC") AND ("TKI" OR "tyrosine kinase inhibitor" OR "target therapy") AND ("weight gain"). WG (calculated as the percent change from baseline) incidence and its association with demographic/clinical parameters were analyzed using meta-regression models.

Results: Among 7,596 identified studies (January 2009 - December 2024), 18 pivotal trials reporting WG data (7 randomized and 11 single-arm) were included in the final analysis, encompassing 25 arms. Table 1 reported the incidence of WG in patients receiving TKIs, according to the CTCAE grade. Lorlatinib showed the highest risk for treatment-induced WG [incidence 36%; 95% CI: 26%-46%; I2=92%], followed by alectinib [incidence 15%; 95% CI: 26%-46%; I2=52%] and crizotinib [incidence 5%; 95% CI: 0%-13%; I2=93%] [Figure 1]. Osimertinib and erlotinib showed the lowest incidence of WG. The meta-regression confirmed no significant correlation between WG and patient-specific factors, including gender (p=0.18), age (p=0.99), and ECOG PS (p=0.15), suggesting a drug-specific effect.

Conclusions: Our findings confirmed lorlatinib unique profile regarding WG, independently of patients' demographics or baseline ECOG PS. Considering the impressive prognostic horizons achievable with TKIs in OA NSCLC, adequate reporting of WG in clinical trials, as well as assessment/monitoring of WG, body composition modifications and impact on QoL should be prioritize, together with adequate lifestyle-based strategies for its management.

Table 1. Incidence of weight gain in patients receiving TKIs, according to the severity

P3.12.09 Efficacy of Tepotinib Against Non-Adenocarcinoma MET Exon 14 Skipping NSCLC: A Subanalysis of the REAL-MET Study

A Subanalysis of the REAL-MET Study

R. Saito[1], K. Misawa[2], Y. Kato[3], S. Katakura[4], K. Nishiyama[5], T. Kobayashi[6], K. Shinada[6], N. Furuya[5], T. Okano[3], H. Mizutani[2], Y. Hosomi[6], K. Watanabe[6]

Introduction: The VISION study demonstrated the efficacy of the MET inhibitor, tepotinib against non-small cell lung cancer (NSCLC) harboring MET exon 14 (METex14) skipping variants. However, the clinical efficacy and safety of tepotinib in histological subtypes other than the most common form of adenocarcinoma, such as squamous cell carcinoma and sarcomatoid carcinoma, have not been sufficiently evaluated.

Methods: We conducted herein a multicentric, retrospective study (the REAL-MET study) analyzing data on patient characteristics, treatment details, and the efficacy and safety of tepotinib in patients with METex14 skipping NSCLC diagnosed at any of six, Japanese hospitals between August 2020 and December 2024. Specifically, the clinical efficacy and safety of tepotinib were assessed in patients in this cohort with a histological subtype other than adenocarcinoma.

Results: In total, 79 patients were enrolled. Adenocarcinoma, squamous cell carcinoma, sarcomatoid carcinoma, adenosquamous carcinoma, and other subtypes occurred in 56 (70.9%), eight (10.1%), five (6.3%), four (5.1%), and six (7.6%) patients, respectively. Comparison of the baseline characteristics of the patients with non-adenocarcinoma histology (n=23) and those with adenocarcinoma (n=56) found that the former group had a higher proportion of females (47.8% vs. 35.7%), never-smokers (47.8% vs. 37.5%), and cases of high PD-L1 expression (60.9% vs. 37.5%). Median progression-free survival (PFS) and median overall survival (OS) after tepotinib therapy were superior in patients with adenocarcinoma than in those with non-adenocarcinoma histology although the difference was not significant (PFS: 10.4 months [95% confidence interval (CI): 8.0-12.8] vs. 5.3 months [95% CI: 3.8-6.8], hazard ratio [HR]: 0.77, 95% CI: 0.45-1.34, P = 0.35; OS: 24.4 months [95% CI: 15.2-33.5] vs. 16.0 months [95% CI: 10.9-21.2], HR: 0.60, 95% CI: 0.31-1.14, P = 0.12). The following were the median PFS and OS for specific, non-adenocarcinoma histological subtypes. Squamous cell carcinoma: PFS 4.7 months (95% CI: 2.7-6.8), OS 16.0 months (95% CI: 0.3-31.7); sarcomatoid carcinoma: PFS 5.3 months (95% CI: 0.0-12.9), OS 5.9 months (95% CI: 5.6-6.1); adenosquamous carcinoma: PFS 8.1 months (95% CI: 0.4-15.9), OS 30.8 months (95% CI: not achieved)(NOS); other subtypes: PFS 3.6 months (95% CI: 1.4-5.8), OS 13.4 months (95% CI: 10.6-16.1). Among the non-adenocarcinoma subtypes, patients with sarcomatoid carcinoma had the shortest, median OS. No significant difference was observed in the objective response rate or the frequency of adverse events among the histological subtypes.

Conclusions: The present, real-world analysis found that non-adenocarcinoma histology accounted for 29.1% of patients with METex14 skipping NSCLC, with squamous cell carcinoma, sarcomatoid carcinoma, and adenosquamous carcinoma being the most common subtypes. Although PFS and OS were shorter in patients with non-adenocarcinoma than in those with adenocarcinoma, tepotinib demonstrated clinical efficacy in the former subgroup, suggesting that the drug is effective against METex14 skipping NSCLC, including cases with a non-adenocarcinoma histology.

Introduction: Biomarker-defined drug-targetable subpopulations of NSCLC may be too small for classical Phase III confirmatory studies. In such cases, a post-authorization real-world cohort efficacy study, with independent tumor activity reads to assess activity endpoints, may be a practical alternative. However, such methodology has not previously been applied to solid tumors. Here we present an approach to independent read methodology, to guide and inform assessments in real-world data analyses for NSCLC. This methodology, modified from RECIST 1.1, was designed to evaluate treatment activity in the real-world NSCLC MOMENT registry, and was informally tested in a biomarker-defined subpopulation of NSCLC.

Methods: Images from the MOMENT registry were segmented into lines of treatment; baseline images for each line were identified. Read processes were developed to align with RECIST 1.1: two independent primary reviewers provide separate blinded assessments, with discrepancies resolved by an adjudicator, as required. Readers are informed of the date of dosing in relation to the dates of supplied images, and any change in the line of treatment. Measurable disease identified in one line of treatment does not determine measurable disease in subsequent treatment lines. Modified RECIST 1.1 criteria (Table 1) were developed. Key read testing refinements of this methodology include retrospective reselection of target lesions, to ensure the best assessment within the potentially incomplete real-world dataset. New lesions observed in previously unimaged areas are not automatically defined as progressive disease (PD). Brain lesions are followed as non-target lesions to avoid any impact from post-radiotherapy necrosis, and fluid collections do not define PD in the absence of other clear indications of progression.

Results: Application of this methodology was tested successfully on preliminary data from the MOMENT cancer registry database. It was also tested and found to be feasible in an informal analysis of data from a subset of clinical trial patients with NSCLC harboring MET exon 14 skipping; on a case-by-case basis, the results were consistent with independent review committee (IRC) assessments performed in the trial.

Conclusions: This methodology replicates the rigor of a clinical trial IRC-approach to tumor assessments using real-world imaging data. It may produce a more accurate estimate of overall response rate in real-world studies with prospective primary data collection, and could be considered an easy-to-implement alternative to classical Phase III confirmatory studies in small biomarker-defined subpopulations of patients with lung cancer. It may also be applicable to other orphan indications when randomized trials are not feasible.

Table 1. Modified RECIST 1.1 criteria

Topic	Read rule modifications
Technical Adequacy Review	All images reviewed for quality. Examples of technical inadequacies include: subject motion, artifacts, poor image quality, missing anatomical regions or entire imaging time points, and poor compliance with imaging guidelines
Measurable, Non-Measurable and New Lesions	Defined as per RECIST 1.1
Baseline	At baseline, independent reviewers will prospectively identify representative sites of disease present at the start of each treatment line, and characterize as target or non-target lesions
Target Lesions	Defined as per RECIST 1.1
Prior Radiation Therapy	Lesions known to have been previously irradiated will only be selected as target lesions if unavoidable
Lesion Measurement Procedures	Defined as per RECIST 1.1
Evaluation of Target Lesions	Defined as per RECIST 1.1
Non-Target Lesions	Defined as per RECIST 1.1
Fluid Collections	Pleural effusions, pericardial effusions and ascites may be considered, if felt to be a manifestation of malignant disease. If selected, they will be followed as a non-target lesion. A significant increase in existing effusions or ascites alone will not be considered sufficient evidence of progression
Evaluation of Non-Target Lesions	All non-target lesions to be considered together as either CR, non-CR/PD, unequivocal progression, or NE
Evaluation of New Lesions	Unequivocal appearance of new lesion(s) on CT/MRI will be considered PD. Ultrasound reports from the sites can be considered, but new lesions must show sequential enlargement to be considered PD if lacking CT/MRI confirmation
Pseudoprogression / pseudopseudoprogression	If tumor enlargement results in PD, but subsequent determinations result in a decrease in size, the initial tumor increase may be pseudoprogression or pseudopseudoprogression. Therefore, lesions will continue to be followed after PD so that this is noted
Re-Baselining Assessments for Subjects that Undergo Multiple Lines of Treatment	The time point closest to the new treatment date will be considered the new baseline by applying the following order of preference: 1) ≤4 weeks prior to the start of a new line of therapy; 2) ≤2 weeks after starting a new line of therapy; 3) 4–8 weeks prior to the start of a new line of therapy. If no images are available from any of these periods, then the line of therapy is not evaluable due to a lack of baseline
CR, complete response; CT, computed tomography; MRI, magnetic resonance imaging; NE, not evaluable; PD, progressive disease; RECIST, Response Evaluation Criteria in Solid Tumors; SD, stable disease.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.11 Aumolertinib Plus Chemotherapy as First - Line for Ps 2 - 3 Advanced NSCLC With EGFR Mutations: A Phase 2 Subgroup Analysis

Y.W. Li
Tianjin medical university cancer institute & hospital, Tianjin/CN

Introduction: The ECOG performance status (PS) score rates from 2 to 3 with worse prognosis and tolerance, defined as advanced severe lung cancer. However, PS 2-3 patients(pts) were not included in most clinical trials and the efficacy of EGFR-TKIs for PS 2-3 pts were still unknown in the real world. Here, we report pre-specified, exploratory subgroup analyses of the efficacy and safety of aumolertinib combined with pemetrexed and carboplatin in the aforementioned PS 2-3 population.

Methods: In this phase 2 trial (NCT04646824), pts received aumolertinib 110 mg once daily plus pemetrexed (500 mg/m2) and carboplatin (area under curve=5) once every 3 weeks for 4 cycles, followed by maintenance aumolertinib (110 mg once daily) and pemetrexed (500 mg/m2 once every 4 weeks).The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety. Of the 34 patients involved in this prospective phase 2 study, 17 patients had a PS score of 2-3.

Results: From November 2020 to October 2021, 34 pts with EGFR Mutations were enrolled for overall analysis. The median PFS was 28.0 months (95% CI, 18.7 to 36.9) and the ORR was 91.2%. Of these 17 pts, 14 had a PS score of 2 and 3 had a PS score of 3. Among them, there were 8 male patients and 9 female patients. Nine had the 19del mutation, five had the L858R mutation, and three had other rare mutation types. The median PFS was 24.0 months(95% CI, 17.0 to 26.0). The ORR was 94.1% (16/17), and the DCR was 100%. The median OS was not reached. Among the 17 pts who underwent circulating tumor DNA (ctDNA) testing, 15pts (88.2%) demonstrated clearance of EGFR mutations after 2 or 4 cycles of treatment. Two pts had disease progression soon after ctDNA re-examination revealed EGFR-positive, with PFS 10 and 11 months respectively. The most common grade ≥ 3 treatment-related adverse event was decreased neutrophil count.

Conclusions: Aumolertinib plus chemotherapy shows benefits as first-line treatment for patients with PS 2-3 and EGFR-mutant NSCLC, which may be associated with a higher clearance rate of ctDNA.

Keywords: aumolertinib plus chemotherapy, PS 2-3, ctDNA clearance

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.12 Clinical Pharmacologic Characteristics of Taletrectinib

M. Perol[1], N.A. Pennell[2], L. Bazhenova[3], C. Li[4], J. Guo[4], F. Ran[4], W. Chen[4], W. Wang[4], C. Zhou[5,6]
[1]Department of Medical Oncology, Léon Bérard Cancer Center, Lyon/FR ,[2]Cleveland Clinic Taussig Cancer Institute, Cleveland/OH/USA ,[3]University of California San Diego Moores Cancer Center, San Diego/CA/USA ,[4]Nuvation Bio, New York/NY/USA ,[5]Department of Medical Oncology, Shanghai Pulmonary Hospital and Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai/CN ,[6]Department of Medical Oncology, East Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Taletrectinib is an oral, potent, central nervous system-active, selective, next-generation ROS1 inhibitor. In December 2024, the US FDA granted Priority Review of the New Drug Application for taletrectinib for advanced ROS1+ non-small cell lung cancer (NSCLC; Prescription Drug User Fee Act goal date, June 23, 2025). In a pooled analysis from TRUST-I and TRUST-II, taletrectinib demonstrated robust, durable efficacy and tolerable safety in patients with ROS1+ NSCLC. Here, we report key clinical pharmacologic findings of taletrectinib.

Methods: An integrated analysis from 10 phase 1 or 2 clinical trials was performed. Clinical pharmacology of taletrectinib (pharmacokinetics [PK], metabolism/elimination, and drug-drug interactions) was assessed as well as PK across populations to characterize exposure across patient groups.

Results: Taletrectinib PK exposure increases were roughly proportionate for 50-1200- mg doses once daily (QD). A steady state was reached by day 8 following 7-day QD dosing, with an accumulation ratio of 3.3-4.5 at 600 mg QD. Following oral administration, tmax was reached after ~2-6 hours. Taletrectinib had a terminal half-life (t1/2) of ~80-100 hours; effective t1/2 was ~66 hours, supporting QD dosing. Taletrectinib exhibited concentration-dependent protein binding; the estimated binding percentage in human plasma was 92.6%-96.5% for concentration levels 100-10,000 ng/mL. In vitro studies indicated that CYP P450 3A4 was the primary enzyme responsible for metabolizing taletrectinib. Per a clinical mass balance study, taletrectinib was eliminated primarily through hepatic metabolism (renal elimination, <5% of the total dose); 75.1% was excreted in feces, and 11.1% in urine. Plasma taletrectinib Cmax/AUCinf were increased by 76%/228% with administration of a strong CYP3A4 inhibitor and decreased by 42%/86% with administration of a strong CYP3A4 inducer; Cmax/AUCinf were decreased by 65%/40% with administration of a proton pump inhibitor (PPI). Pooled PK data from healthy participants (n=110) and patients with NSCLC (n=405) showed no clinically significant differences in PK based on age (≥65 years, 21%), sex (male, 55%), weight (median, 66 kg), hepatic impairment (mild impairment, 18%; not studied in patients with moderate or severe impairment), or renal impairment (mild impairment, 11%; moderate impairment, 1.4%; not studied in patients with severe impairment).

Conclusions: Taletrectinib demonstrated dose-proportional PK with a long terminal t1/2, enabling QD dosing. Metabolism primarily occurred through CYP3A4. Drug-drug interactions should be considered with CYP3A modulators and PPIs. No clinically significant PK changes were observed across demographics or with mild hepatic impairment or mild-to-moderate renal impairment.

P3.12.13 Long-Term Real-World Outcomes of Sotorasib in Second-Line and Beyond Treatment of KRAS G12C-Mutated Advanced NSCLC

E. Felip[1], G. Riely[2], A. Spira[3], F. Griesinger[4], G. Mountzios[5], C-C. Ho[6], T. Yoshida[7], J. Lee[8], R. Jassim[8], M. Mesa-Frias[8], M. Johnson[9]
[1]Vall d'Hebron Hospital Campus, Vall d'Hebron Institute of Oncology, Barcelona/ES ,[2]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[3]Virginia Cancer Specialists Research Institute and Next Oncology, Fairfax/VA/USA ,[4]Pius-Hospital, University Medicine Oldenburg, Oldenburg/DE ,[5]University of Athens Medical School, Athens/GR ,[6]National Taiwan University Hospital, Taipei/TW ,[7]National Cancer Center Hospital, Tokyo/JP ,[8]Amgen Inc., Thousand Oaks/CA/USA ,[9]Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville/TN/USA

Introduction: In a previous study, the survival benefit of sotorasib was demonstrated in the second-line and beyond (2L+) real-world setting over a 1-year period in patients with KRAS G12C-mutated advanced non-small cell lung cancer (NSCLC; Johnson et al, Lung Cancer, 2024:197;107960). In the present study, we evaluate real-world clinicopathological characteristics and median overall survival (OS) of sotorasib in 2L and 2L+ settings from additional patients with a more recent data cutoff date thereby allowing for assessment of longer-term survival.

Methods: Patients from a US-based electronic health record-derived de-identified Flatiron Health Enhanced Datamart treated with 2L and 2L+ sotorasib between May 28, 2021, and September 30, 2023, and with a confirmed KRAS G12C mutation, were included in this analysis. The data cutoff date was September 30, 2024, allowing for a minimum of 12 months and up to 28 months opportunity for follow-up for outcomes from the initiation of treatment. Patient demographic and clinical characteristics were described. Median OS was the primary endpoint. Median OS and corresponding 95% confidence intervals (CIs) were calculated by line of therapy (2L and 2L+) using Kaplan-Meier estimates.

Results: A total of 210 patients received 2L sotorasib and 338 received 2L+ sotorasib. Overall, baseline demographics and disease characteristics of patients were similar across 2L and 2L+ analysis sets. Most patients included in the 2L and 2L+ analysis sets were female (56.7%; 57.4%); ≥65 years old (73.8%; 68.9%); White (73.3%; 73.7%); were from the community practice setting (74.8%; 73.7%); had a history of smoking (96.2%; 97.3%); an initial diagnosis of advanced disease (72.9%; 72.5%); with a histology of non-squamous cell carcinoma (96.2%; 95.9%); and had prior anti-PD-(L)1 treatment (75.2%; 78.4%). Most patients in the 2L and 2L+ analysis sets had an Eastern Cooperative Oncology Group performance status (ECOG PS) 0-1 (53.8%; 55.6%). Of note, 19.0% and 17.8% of patients had ECOG PS 2 and 3.8% each had ECOG PS ≥ 3 in 2L and 2L+ analysis sets, respectively; ECOG PS data were not available for 23.3% and 22.8% of patients. The median OS (95% CI) for 2L and 2L+ sotorasib was 11.0 months (8.8-12.5) and 10.8 months (8.8-11.7), respectively (Figure).

Conclusions: Sotorasib in 2L and 2L+ settings demonstrated long-term survival in a real-world population of patients with KRAS G12C-mutated advanced NSCLC, including those with poor ECOG PS.

Introduction: MET exon 14 (METex14) skipping is a primary oncogenic driver observed in 2% (range: 0.5% to 6.8%) of patients with non-small cell lung cancer (NSCLC). Tepotinib, a highly selective MET tyrosine kinase inhibitor (TKI), is approved to treat METex14 skipping NSCLC in multiple countries/regions, including the EU, where it was approved for use after immunotherapy and/or chemotherapy in February 2022. We report clinical effectiveness and safety outcomes from a cohort of patients with METex14 skipping NSCLC in Germany, who gained early access to tepotinib via compassionate use requests prior to its EU approval.

Methods: Patients received tepotinib 500 mg (450 mg active moiety) once daily in clinical practice in Germany. Physicians provided data on patient characteristics, response (per the treating physician's assessment), and tepotinib-related adverse events (AEs) as of November 2024.

Results: The cohort included 25 patients with stage IIIA-IVB NSCLC, who initiated tepotinib between January 2021 and February 2022. Patients were aged 58-91 years, 14 were female, 15 had a smoking history, and 18 had adenocarcinoma histology. ECOG PS was 0 in seven patients, 1 in 15 patients, and 2 in three patients. METex14 skipping was detected in tissue biopsies by next-generation sequencing in 24 patients and polymerase chain reaction in one patient. Programmed death-ligand 1 status was positive in 18 patients. Twelve patients received tepotinib as first-line, eight as second-line, four as third-line, and one as fourth-line treatment. Tepotinib treatment duration was 0.8-34.4 months. At the time of data collection, treatment was ongoing in one patient. Per the treating physician's assessment in patients with available data, 12/23 patients had a partial response, and duration of response was 3-32.9 months. Detailed outcomes will be presented during the meeting. The most common tepotinib-related AE was edema, which was reported in 17/25 patients (Grade 1/2, n=14; Grade 3, n=3), followed by pleural effusion (n=4), and fatigue (n=2). AEs led to dose reduction in three patients and discontinuation in six patients (mostly due to edema). Conservative management of edema included compression stockings, diuretics, and fluid restriction.

Conclusions: In this case series from Germany, tepotinib demonstrated clinical effectiveness and manageable safety in patients with METex14 skipping NSCLC in real-world practice.

Introduction: Capmatinib and tepotinib have been incorporated into the treatment algorithm for patients with advanced non-small cell lung cancer (NSCLC) with MET exon 14 skipping mutations (METex14). Here, we report updated data on disease and patient characteristics, as well as on efficacy and tolerability of MET tyrosine kinase inhibitors (TKIs) in advanced METex14 mutated NSCLC patients from the Italian real-world registry ATLAS.1

Methods: Clinical data, treatment efficacy and tolerability were retrospectively collected from patients' medical and electronic healthcare records. Treatment-related adverse events (TRAEs) were classified according to the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0.

Results: From July 2020 to February 2025, a total of 185 patients with advanced METex14 NSCLC were included across 45 Italian centers. The median age was 74 years, most patients were female (53.5%), with an Eastern Cooperative Oncology Group performance status < 2 (83.8%). Most patients were current or former smokers (53%) with adenocarcinoma histology (82.7%). 166 (89.7%) received at least one line of systemic anticancer therapy. 130 patients (70.3%) received targeted treatment, 78 (42.2%) were treated with capmatinib and 52 (28.1%) with tepotinib. Among patients treated with MET TKIs, the response rate (RR) was 54.8% in 42 treatment-naïve patients and 40.9% in 88 patients who had received one or more lines of therapy previously. With a median follow-up of 18 months, median progression-free survival (mPFS) was 8.1 months (95% confidence interval [CI] 6.5-9) and median overall survival (mOS) of 13.1 months (95% CI, 9.9-16.2). In patients with measurable brain metastases (17 cases), the intracranial RR was 41.1%. In the cohort of 78 patients treated with capmatinib, the RR was 62.5% among the 24 patients who received capmatinib as first-line therapy and 38.9% among the 54 patients treated with capmatinib in second or further treatment line. mPFS was 7.5 months(95% CI, 5.8-9.2) and mOS was 14.8 months (95% CI, 10.6-19.0). Grade > 3 TRAEs were reported in 16.7% of the patients, including peripheral edema in 10.3%. A fatal adverse reaction occurred in one patient due to pneumonitis. Adverse events led to dose reduction in 30.8% of patients and to permanent discontinuation in 1.3%. In the cohort of 52 patients treated with tepotinib, the RR was 44.4% among the 18 patients who received tepotinib as first line and 44.1% among 34 patients treated with tepotinib in second or later lines. mPFS was 8.7 months (95% CI, 5.5-11.9) and mOS 11.5 months (95% CI, 8.1-14.8). Grade > 3 TRAEs were reported

in 25% of patients, including peripheral edema in 19.2%. A fatal adverse reaction occurred in one patient, also in tepotinib cohort, due to pneumonitis. Adverse events led to dose reduction in 21.2% of patients and to permanent discontinuation in 7.7%.

Conclusions: Conclusion: This updated real-world analysis confirmed the good clinical activity of MET TKIs, particularly in the treatment-naive setting, supporting the implementation of this therapeutic approach in a challenging patient population.1 Reale ML, et al. ESMO Open. 2024 Sep;9(9):103680.

P3.12.16 Reduced Survival in Black Patients With EGFR-Mutant NSCLC

B. Waissengrin[1], R. Gutta[2], S.Y. Choi[1], E. Vail[1], K. Sankar[1], H. Ramakrishnan[3], K. Sharma[3], J. Sherwood[2], J. Ethakota[2], A. Mckheen[4], J. Figueiredo[1], F. Abu Rous[2], K. Reckamp[1]
[1]Cedars Sinai Medical Center, Los Angeles/CA/USA ,[2]Henry Ford Health System, Detroit/MI/USA ,[3]Wayne State University, Detroit/MI/USA ,[4]Michigan State University, Detroit/MI/USA

Introduction: Despite improvements in survival for patients with non-small cell lung cancer (NSCLC), disparities persist in outcomes of patients with EGFR-mutant disease. Lack of representation across racial and ethnic groups in clinical trials limits the understanding of treatment effectiveness and safety across populations. This study aims to investigate the impact of race on the efficacy of first-line osimertinib in treating EGFR-mutant NSCLC within two large metropolitan hospitals in the United States.

Methods: In this observational study, data from the electronic medical records of consecutive patients with EGFR-mutant NSCLC from Cedars-Sinai Medical Center (Los Angeles, CA) and Henry Ford Hospital (Detroit, MI) were evaluated. The cohort included patients with metastatic diease at the time of diagnosis who received single-agent osimertinib as first-line therapy. Patient characteristics were compared by race using Fisher's exact test or the Kruskal-Wallis test. Progression-free survival (PFS), time on osimertinib treatment (TOT), and overall survival (OS) were analyzed across racial groups using Kaplan-Meier curves and the log-rank test. Multivariable logistic regression models were applied to assess factors associated with PFS exceeding 18 months.

Results: A total of 337 patients met the inclusion criteria across both sites: 204 (60.5%) White, 71 (21%) Asian, and 62 (18.5%) Black. The groups were balanced for gender and EGFR mutation type. However, Black patients were younger (p<0.01), and Asian patients had lower smoking rates (p<0.001) and higher TP53 co-mutation (p-0.002). The median PFS was significantly lower among Black patients compared to Asian and White patients (p<0.0001), as was the TOT (p<0.0001). OS was also lower in Black patients and highest among Asian patients (p=0.013) (Table 1). In a multivariable logistic regression model assessing PFS>18 months, Asian patients had 16.6 times the odds of remaining progression-free >18 months compared to Black patients (p<0.001), and White patients had 14.5 times the odds (p<0.001).

Conclusions: This study presents survival outcomes in the largest cohort of Black patients with EGFR-mutant NSCLC to date. Black patients exhibited poorer PFS, TOT, and OS compared to Asian and White patients. These findings underscore the urgent need to address inequalities in care to ensure high quality treatment access and outcomes across all racial groups. Further research is necessary to better understand the underlying factors contributing to these results, identify modifiable challenges, and implement targeted interventions to optimize therapeutic strategies in first line treatment to improve outcomes for all patients with EGFR-mutant NSCLC.

Table 1:

	Black (months)	Asian (months)	White (months)	P value
PFS	7.8	21.6	24.2	<0.0001
TOT	13.3	25.3	35.1	<0.0001
OS	31.4	68.4	59.5	0.013

PFS – Progression free survival, TOT – Time on treatment, OS – Overall survival

P3.12.17 A Phase II Study of Firmonertinib Combined With Apatinib as First-Line Therapy in NSCLC Patients With EGFR Uncommon Mutations

H-Y. Xu, Y. Wang, R. Sun, H. Shi, L. Tian, F. Wei
National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Firmonertinib is an oral, highly CNS-penetrant epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI). Although afatinib or osimertinib as preferred first-line therapy options have been recommended for the treatment of non-small cell lung cancer (NSCLC) with EGFR uncommon mutations, patients' therapeutic demands are far from being met. The purpose of this study is to investigate the efficacy and safety of the combination of firmonertinib and apatinib as firs-line therapy for metastatic NSCLC with EGFR uncommon mutations.

Methods: Metastatic NSCLC patients with EGFR uncommon mutations received oral firmonertinib 80 mg plus apatinib 250 mg once daily until disease progression, intolerable toxicity, or death. The primary endpoint was the investigator-assessed objective response rate (ORR).

Results: Between June, 5, 2023 and April, 1, 2025, 18 patients were enrolled. 8 (44.4%) presented brain metastases, and 8 (44.4%) had ECOG scores of 1 or 2. EGFR uncommon mutations included EGFR 18 exon G719X (12/18,66.7%), followed by EGFR 21 exon L861Q (4/18,22.2%) and EGFR 20 exon S768I (2/18,11.1%). As of April, 1, 2025, the median follow-up was 8.2 (range, 2.2-22.2) months. The investigator-assessed ORR was 61.1% (11/18), and the disease control rate (DCR) was 100% (18/18). The median progression-free survival (PFS) was 13.5 (95% CI, 8.7 to 18.3) months, and overall survival was not reached. The most frequent grade 1 or 2 treatment-related adverse events included rash (29.4%), oral ulcers (17.6%) and diarrhea (11.7%), with one patient presenting with a grade 3 rash. No treatment-related deaths were reported.

Conclusions: Firmonertinib combined with apatinib demonstrated promising antitumor activity and a manageable safety profile for metastatic non-small cell lung cancer with EGFR uncommon mutations.

Keywords: NSCLC, EGFR uncommon mutations

P3.12.18 Vebreltinib Plus EGFR-TKI in EGFR-Mutated NSCLC With MET Amplification And/Or Overexpression After Failure on EGFR-TKI: A Retrospective Study

H. Wang, Z. Huang, K. Jiang, W. Zou, Y. Huang, W. Zhuang
Clinical Oncology School of Fujian Medical University,Fujian Cancer Hospital, Fuzhou/CN

Introduction: Combination therapy with MET inhibitors and EGFR tyrosine kinase inhibitors (EGFR-TKIs) can overcome acquired MET-mediated resistance to EGFR-TKIs. Vebreltinib is a potent and highly selective c-MET inhibitor. This retrospective study investigates the efficacy and safety of the combination of Vebreltinib and EGFR-TKI, and explores criteria to identify patients most likely to respond.

Methods: Between November 2023 and January 2025 in our center, we reviewed data from patients(pts) with EGFR-mutant NSCLC and MET driven who had received Vebreltinib plus EGFR-TKI combination therapy. Eligibility criteria included advanced NSCLC, initial treatment with EGFR-TKI, MET overexpression was detected by IHC (3+ in ≥50% of tumor cells [IHC50+]) or MET amplification was detected by NGS(regardless of copy number value). The primary endpoint was objective response rate (ORR), secondary endpoints included disease control rate (DCR), progression-free survival (PFS), and safety profile.

Results: As of the data cut-off (March 20, 2025), a total of 26 patients were retrospectively enrolled and evaluated. Median age 56 years; 62% female; 23% brain metastases. Regarding treatment, 100% pts received third-generation EGFR-TKI as first-line (1L) treatment,58% received dual-target therapy in the 3L-7L treatment, while 42% received it as 2L treatment. The most common dual-target regimen was Furmonertinib plus Vebreltinib (54%), followed by Osimertinib plus Vebreltinib (31%) at study entry. The ORR was 50.0 % (95%CI, 32.0,68.0). The DCR was 92.3% (95%CI, 75.9,97.9). The median PFS was 6.2 months (95%CI, 4.7,8.0). The efficacy was particularly impressive in the MET amplified population. The ORR was 57.1 % (95%CI, 32.6,78.6). The DCR was 92.9% (95%CI, 68.5,98.7). The median PFS was 8.3 months (95%CI, 5.3,11.0)(Table). Overall, treatment was well tolerated and no severe adverse reactions (SAEs) were observed.

Conclusions: Vebreltinib combined with EGFR-TKI is a promising treatment for EGFR-mutated advanced NSCLC pts with MET amplification and/or overexpression after EGFR-TKI failure, especially in MET-amplified pts. In our study, pts were eligible if MET gene amplification was detected by NGS, without a threshold limit. The manageable adverse events further support its use in clinical practice.

Table

	All Pts; MET IHC 3+/≥50% or MET amplification by NGS	Pts with MET amplification by NGS
Endpoint	Tatal(N=26)	Tatal(N=14)
ORR,%(95%CI)	50.0 % (95%CI, 32.0，68.0)	57.1 % (95%CI, 32.6，78.6)
DCR,%(95%CI)	92.3% (95%CI, 75.9，97.9)	92.9% (95%CI, 68.5，98.7)
Median PFS, months(95%CI)	6.2 months (95%CI, 4.7，8.0)	8.3 months (95%CI, 5.3，11.0)

CI, confidence interval; IHC, immunohistochemistry; NGS, Next-generation sequencing ; ORR, objective response rate; DCR, disease control rate; PFS, progression free survival.

P3.12.19 Optimizing Treatment Sequencing to Maximize Survival in ALK+ Advanced Non-Small Cell Lung Cancer: A Modeling Study

H. Le[1], N. Rifi[2], T. Williams[3], L. Bloudek[4], S. Ramsey[4]
[1]Pfizer Inc, New York/NY/USA ,[2]Pfizer Inc, Paris/FR ,[3]Curta Inc, Seattle/WA/USA ,[4]Curta Inc, Seatle/WA/USA

Introduction: The European Society for Medical Oncology and National Comprehensive Cancer Network 2024 guidelines recommend either alectinib, brigatinib or lorlatinib anaplastic lymphoma kinase inhibitors (ALKis) as first-line (1L) treatment options for ALK-positive advanced non-small-cell lung cancer (aNSCLC). Second-line (2L) recommendations include lorlatinib or chemotherapy. Additional ALKis, such as NVL-655 is under investigation. Currently there are no head-to-head comparisons to aid in selection of different sequences of ALKis. Moreover, real-world evidence comparing observed treatment sequences has not had sufficient follow-up time to interpret findings. This study uses modeling methods to identify the longest likely progression-free survival (PFS) and overall survival (OS) across sequencing strategies for recommended ALKis.

Methods: Disease state models were informed from clinical trials of recommended therapies for ALK+ aNSCLC by line of therapy (LoT). Parametric survival curves for PFS and OS were fit to published Kaplan-Meier curves. Patients experiencing disease progression on a treatment were assumed to initiate the next treatment in the sequence, up to 2 ALKis then chemotherapy. An area under the curve (AUC) approach was used to account the long "tails" of observed PFS to estimate cumulative progression-free life years across all LoTs.

Results: 1L lorlatinib sequences yielded the longest PFS overall, with ~5 years of additional PFS vs 1L therapy with alectinib or brigatinib (Table and Figure). Results were sensitive to assumptions around long-term extrapolation of PFS. An important limitation is that due to the prolonged PFS observed for patients treated with 1L lorlatinib, minimal information is available to characterize PFS on 2L therapy. OS analyses are ongoing.

Conclusions: Based on current evidence and modeling assumptions, initial treatment with 1L lorlatinib may yield the longest PFS vs 2nd gen TKIs, regardless of types of subsequent treatments. This highlights the importance of initiation of 1L treatment with the longest demonstrated PFS upfront.

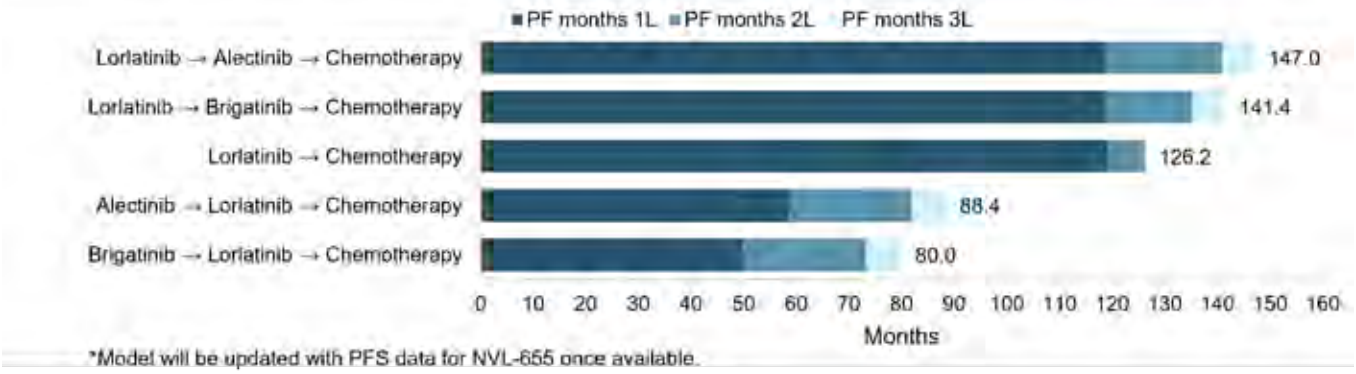
Comparison of Sequences*

Sequence	1L Median PFS, Months (Source)	2L Median PFS, Months (Source)	3L Median PFS, Months (Source)	Cumulative Progression-Free Years Across LoTs Based on AUC Approach
Lorlatinib → alectinib → chemotherapy	93.6 (CROWN)	10.9 (ALUR)	4.3 (Lin 2020)	12.3 years
Lorlatinib → brigatinib → chemotherapy		12.9 (ALTA)		11.8 years
Lorlatinib → chemotherapy		4.3 (Lin 2020)	N/A	10.5 years
Alectinib → lorlatinib → chemotherapy	34.8 (ALEX)	12.2 (NCT01970865 [1027 Study] EXP2-3A)	4.3 (Lin 2020)	7.4 years
Brigatinib → lorlatinib → chemotherapy	30.8 (ALTA-1L)			6.7 years

†Model will be updated with PFS data for NVL-655 once available.

*Median estimated based on extrapolation of PFS curve fitted to patient-level data, as median PFS for lorlatinib had not yet been met at time of analysis.

PFS Months (Estimated Based on AUC Approach) Across LoTs*



*Model will be updated with PFS data for NVL-655 once available.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.20 VAF of EGFR Mutations in Relation to Early Tumor Shrinkage or Deepness of Response During Osimertinib in NSCLC Patients

G. Bronte[1], A. Carnevale[1], A. Ciancetta[1], D.M. Cosi[1], C. Fragale[1], S. Ciarrocchi[1], M.L. Di Guglielmo[1], G. Tinelli[1], N. Mindicini[1], L. Battara[1], L. D'Abundo[1], E. Callegari[1], D. Gabriele[2], R. Gafà[1], A. Santini[2], M. Negrini[1], L. Calabrò[1]
[1]University of Ferrara, Ferrara/IT ,[2]University Hospital of Ferrara, Ferrara/IT

Introduction: This study investigates the impact of variant allele frequency (VAF) of EGFR mutations on osimertinib effectiveness in mNSCLC. Despite NGS provides extensive genomic data, VAF is poorly used in clinical practice. This research explores the relationship between VAF and ETS or DpR.

Methods: We retrospectively analyzed mNSCLC patients treated with an EGFR-TKI; VAF was determined by NGS. The primary goal was to explore the relationship between VAF and ETS or DpR, according to RECIST-1.1 criteria. Secondary objectives included assessing associations between VAF and best tumor response (BTR), progression-free survival (PFS), and overall survival (OS). Molecular modeling was performed for compound uncommon mutations, never described before in literature. Statistical analyses included Spearman correlation, chi-squared test, and log-rank test.

Results: Sixteen patients were included. No significant correlation between VAF and ETS (r = 0.11, p = 0.69) (Figure 1A) or DpR (r = 0.06, p = 0.83) (Figure 1B) were found. A VAF percentage equal to or greater than the median (33%) showed a trend toward longer median PFS (29 months vs. 9 months; HR: 0.55, p = 0.42) and OS (36 months vs. 26 months; HR: 0.29, p = 0.11), though not statistically significant. We found undescribed compound uncommon EGFR mutations: N771Y + L858R and L718V + K713R + L858R. These mutations do not prevent osimertinib binding and function, as suggested by molecular modeling (Figure 2).

Conclusions: VAF of EGFR mutations does not significantly influence tumor size reduction (ETS/DpR) in osimertinib-treated patients. Higher VAF showed a not statistically significant trend toward improved PFS and OS.

Introduction: Lorlatinib is a brain-penetrant, third-generation anaplastic lymphoma kinase (ALK) and ROS1 tyrosine kinase inhibitor (TKI) approved for patients with ALK-positive advanced non-small cell lung cancer (NSCLC) in the first line as well as in those previously treated with a second-generation ALK TKI. In patients treated with lorlatinib after failure of a second-generation ALK TKI, ALK mutations were identified as a potential marker of response. To identify other correlates, we evaluated ALK fusion subtypes and comutations to predict clinical outcomes with lorlatinib and identify potential resistance mechanisms.

Methods: Plasma samples were prospectively collected at baseline and end of treatment from patients enrolled in the following expansion cohorts (EXPs) in the global phase 2 study (NCT01970865): EXP1 (treatment naive), EXP2-3A (prior crizotinib ± chemotherapy), and EXP3B-5 (≥1 prior ALK TKI ± chemotherapy). Circulating tumor DNA (ctDNA) was analyzed using Guardant360. ALK fusion subtypes and mutation and TP53 mutation status were correlated with clinical outcomes. Tumor tissue samples collected at baseline were also analyzed by next-generation sequencing.

Results: Thirty patients were enrolled in EXP1, 59 in EXP2-3A, and 139 in EXP3B-5. Baseline ctDNA samples were available for 28 patients in EXP1, 55 in EXP2-3A, and 129 in EXP3B-5. In EXP2-3A cohort, patients with short EML4-ALK fusion variant 3 (v3) had shorter overall survival (OS) or lower survival probability at 72 months than those with long variants (v1 and v2), while similar OS benefit was observed regardless of the variant type in EXP1 and EXP3B-5 (Table). Presence of TP53 mutation led to shorter OS or lower survival probability at 72 months in EXP1, EXP2-3A, and EXP3B-5 cohorts. Confirmation of these results in tumor tissue is ongoing. In patients with matched paired ctDNA samples, none had acquired ALK single or compound mutations in EXP1; however, these mutations were detected in patients in EXP2-3A and EXP3B-5 cohorts.

Conclusions: After a minimum follow-up of 5 years, final analyses from this phase 2 study confirmed substantial activity and prolonged OS with lorlatinib in treatment-naive and previously treated patients with ALK-positive advanced NSCLC, regardless of the ctDNA-based biomarker groups. Resistance mechanisms in treatment-naive patients did not include emergence of ALK mutations, while new single and compound mutations emerged in a small number of patients who previously received an ALK TKI.

Survival probability at 72 months and median OS by ctDNA-based molecular biomarker subgroups

Biomarker subgroup	EXP1 (n=28)		EXP2-3A (n=55)		EXP3B-5 (n=129)	
	n	Probability (%) or median OS (months) (95% CI)	n	Probability (%) or median OS (months) (95% CI)	n	Probability (%) or median OS (months) (95% CI)

P3.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY
TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.22 A Phase II Study of Sunvozertinib Combined With Anlotinib in Treatment-Naïve NSCLC With EGFR Sensitive Mutations and Co-Mutations (WU-KONG32)

Y. Zhang, L. Zeng, W. Jiang
Hunan Cancer Hospital, Changsha/CN

Introduction: EGFR mutations are key drivers in non-small cell lung cancer (NSCLC), but when accompanied by co-mutations such as TP53, the efficacy of EGFR-tyrosine kinase inhibitors (TKIs) is significantly reduced, leading to shorter survival.The molecular mechanism of vascular endothelial growth factor (VEGF) inhibitors combined with EGFR inhibitors in the treatment of NSCLC suggests synergistic anti-tumor effects and drug resistance alleviation. Sunvozertinib is a novel EGFR-TKI targeting EGFR-sensitive mutations (e.g., 19del, L858R, T790M), while Anlotinib is a multi-target TKI with anti-angiogenic effects. This combination may enhance efficacy in NSCLC patients with EGFR mutations and co-mutations.

Methods: This phase II, single-arm, open-label study evaluated Sunvozertinib (300 mg or 200 mg once daily) plus Anlotinib (8 mg once daily, days 1-14 of a 21-day cycle) in treatment-naïve patients with advanced NSCLC harboring EGFR-sensitive mutations (19del, L858R, T790M) and co-mutations (e.g., TP53, CTNNB1,PIK3CA). In the safety un-in phase, the first 10 patients received 300 mg of Sunvozertinib to observe dose-limiting toxicities (DLTs). If more than 3 DLTs are observed in these patients, the dose for subsequent patients will be reduced to 200 mg. Treatment continued until disease progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS) per RECIST 1.1. Secondary endpoints included objective response rate (ORR), duration of response (DoR), disease control rate (DCR), overall survival (OS), and safety. Planned enrollment was 52 patients.

Results: Sixteen EGFR-sensitive mutation patients were enrolled and 9 with TP53 mutations. In the safety run-in, 1 DLT (grade 2 interstitial lung disease) occurred among the first 10 patients, leading to 300 mg p.o. daily Sunvozertinib in combination with Anlotinib 8 mg p.o. daily from day 1 to day 14 (21 days per cycle) for subsequent patients. Of 9 evaluable patients, 7 achieved partial response (PR) and 2 had stable disease (SD), yielding an ORR of 77.8% (95% CI: 40.0-97.2) and DCR of 100% (95% CI: 66.4-100). The common (≥30%) TEAEs were diarrhea, rash, and anorexia. Grade ≥3 TEAEs occurred in 5 patients (31.3%), with no discontinuations or treatment related deaths.

Conclusions: Sunvozertinib combined with Anlotinib demonstrated promising efficacy and manageable safety in treatment-naïve NSCLC patients with EGFR mutations and co-mutations. This combination therapy holds promise to meet the unmet clinical needs of this population, offering new regimen for patients and warranting further investigation.

P3.12.23 Tepotinib Efficacy in Poor Performance Status and Elderly Patients With MET Exon 14 Skipping NSCLC: A RELA-MET Subanalysis

K. Nishiyama[1], K. Misawa[2], Y. Kato[3], S. Katakura[4], T. Kobayashi[5], K. Shinada[5], R. Saito[6], N. Furuya[1], T. Okano[3], H. Mizutani[2], Y. Hosomi[5], K. Watanabe[5]
[1]St. Marianna University School of Medicine, Kanagawa/JP ,[2]Saitama Cancer Center, Saitama/JP ,[3]Nippon Medical School Chiba Hokusoh Hospital, Chiba/JP ,[4]Kanagawa Cancer Center, Kanagawa/JP ,[5]Tokyo Metropolitan Cancer and Infectious Diseases Center, Komagome Hospital, Tokyo/JP ,[6]Yamanashi Prefectural Central Hospital, Yamanashi/JP

Introduction: While the VISION study demonstrated tepotinib's efficacy against MET exon 14 (METex14) skipping non-small cell lung cancer (NSCLC), the data on its clinical effectiveness and safety in subgroups frequently managed outside the clinical trial setting are scarce. Specifically, the utility of tepotinib in patients with poor performance status (PS) and in the elderly population warrants further investigation.

Methods: We conducted a multicenter retrospective study (REAL-MET) using data on patient characteristics and treatment details, including its efficacy and safety, in patients with METex14 skipping NSCLC receiving tepotinib therapy at six Japanese hospitals between August 2020 and December 2024. The analysis focused on evaluating the clinical efficacy and safety of tepotinib in patients in the cohort with a poor PS or advanced age. Poor PS was defined as Eastern Cooperative Oncology Group (ECOG) PS 2 or 3, and advanced age was defined as age ≥ 75 years.

Results: In total, 79 patients were enrolled. Their median age was 75 years (range: 55-90), 53.2% were aged ≥75 years, and 24.1% (n=19; PS 2: n = 14; PS 3: n = 5) had a poor PS. Compared to patients with a good PS (PS 0-1; n=60), those with a poor PS were more often aged < 75 years (57.9% vs 43.3%) and had programmed death ligand-1 ≥ 50% (26.3% vs 50.0%). The characteristics of the elderly patients resembled those of the overall cohort. The median PFS and OS were significantly shorter for patients with poor PS (PFS: 7.6 months [95% CI: 2.5-12.7] vs. 10.8 months [95% CI: 5.6-16.0], hazard ratio [HR]: 2.26, 95% CI: 1.27 to 4.02, P = 0.01; OS: 13.4 months [95% CI: 6.6-20.1] vs. 25.8 months [95% CI: 19.7-31.8], HR: 2.30, 95% CI: 1.13 to 4.70, P = 0.02). Within the poor PS group, the median PFS and OS was 8.5 months [95% CI: 5.6-11.4] and 16.4 months [95% CI: 11.8-21.0] for patients with PS 2, respectively. The outcomes were notably poor for patients with PS 3 (PFS: 1.8 months [95% CI: 0.01-3.5]; OS: 3.2 months [95% CI: 0.0-7.8]). After stratification by age, the median PFS and OS were shorter for elderly (≥ 75 years) patients than for younger (< 75 years) patients, but the difference was not significant (PFS: 8.1 months [95% CI: 6.9-9.3] vs. 10.4 months [95% CI: 8.0-12.8], HR: 1.14, 95% CI: 0.69 to 1.90, P = 0.6; OS: 16.4 months [95% CI: 14.2-18.5] vs. 25.8 months [95% CI: 18.7-32.8], HR: 1.66, 95% CI: 0.87 to 3.16, P = 0.13) Among patients with a poor PS (n=19), treatment discontinuation was mainly due to progressive disease (57.9%), adverse events (21.1%), and PS deterioration (10.5%). The frequency of adverse events was comparable across PS and age groups.

Conclusions: This real-world analysis included a substantial cohort of elderly (53.2%) patients and those with a poor PS (24.1%). While age had minimal impact, poor PS significantly limited the efficacy of tepotinib. Nonetheless, the discernible benefit to patients with PS 2 supports the use of this drug for this subgroup.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.24 Real-World Treatment of Osimertinib Monotherapy Versus Combination Therapy in Stage IV Non-Small Cell Lung Cancer Patients

E.S. Santos, MD[1], T. Patel, MD[2], S.". Divers, MD[3], D.P. Petro, MD[4], B. Mulherin, MD[5], R. Choksi, MD[4], M. Gart, MBA[6], P. Dave, MHA[6], B. Wang, MBA[6], P. Varughese, PharmD, MBA[6], R. Geller, MD[6], J. Scott, MD[6]
[1]The Oncology Institute of Hope and Innovation, Fort Lauderdale/FL/USA ,[2]Zangmeister Cancer Center, Columbus/OH/USA ,[3]Genesis Cancer and Blood Institute/AON, Hot Springs/AZ/USA ,[4]University of Pittsburgh Medical Center (UPMC), Pittsburgh/PA/USA ,[5]Hematology Oncology of Indiana, Indianapolis/IN/USA ,[6]Integra Connect, West Palm Beach/FL/USA

Introduction: In February 2024, the Food and Drug Administration approved osimertinib in combination with chemotherapy given the results of the FLAURA-2 trial showing a progression-free survival benefit. We evaluated stage IV non-small cell lung cancer (NSCLC) pts who received osimertinib in the real world, and what clinical and demographic factors may impact the choice of osimertinib monotherapy (osi-mono) versus osimertinib plus chemotherapy (osi+chemo).

Methods: Using the Integra Connect PrecisionQ's de-identified database, pts were identified with an ICD-10 diagnosis of C34, age >=18, who were stage IV and started first treatment on or after February 19, 2024 to December 31, 2024, with osi-mono or osi+chemo. Pts were assessed as to whether age, gender, race, Eastern Cooperative Oncology Group (ECOG) performance status, provider volume based on attributed NSCLC pts, stage, treatment with radiation, or brain/central nervous system (CNS) metastases (mets) may have impacted treatment with monotherapy versus combination therapy. Descriptive statistics were used for proportions and chi-squared analyses to assess for significance.

Results: A total of 235 pts were identified for the analysis, median age 71 (IQR 62 - 79), 67% were female. Among 235 pts, the use of osi+chemo was 29%. In Q1 2024, the use of osi+chemo was 21% (N = 28) to a high of 37% in Q2 2024 (N = 71) that decreased to 18% (N = 65) in Q4 2024. There were no differences in treatment by gender with 29% of both male and female pts receiving osi+chemo. Osi+chemo was higher in pts <65 years of age at 42% (N = 71) compared to pts >=65 at 23% (N = 164) (p <0.01). Osi+chemo by ECOG performance status was as follows: 0 at 33% (N = 87), 1 at 30% (N = 83), >=2 at 23% (N = 39). Osi+chemo by race was as follows: White at 23% (N = 110), Black/African American at 24% (N = 21), Asian at 17% (N = 12), and all other at 38% (N = 92). Based on stage, use of osi+chemo was 20% in Stage IVA (N = 94) and 34% in stage IVB (N = 127) (P <0.05). Among pts with CNS/Brain mets the use of osi+chemo was 37% (N = 38). Among pts who receive radiation therapy the use of osi+chemo was 32% (N = 34). For physicians who had <200 NSCLC attributed pts, the use of osi+chemo was 24% (N = 94) vs. 31% (N = 141) for those who had treated >=200 attributed NSCLC pts.

Conclusions: Since the approval of FLAURA-2, real-world data suggests that among pts who received osimertinib, only 29% of pts are being treated with osi+chemo. The data also suggest pts who are younger and have a more advanced stage are more likely to receive osi+chemo compared to the osi-mono and other factors such as race, gender, performance status, and provider volume of pts managed with NSCLC did not seem to play as much of a factor.

P3.12.25 First-Line HLX07 Plus Serplulimab With or Without Chemotherapy in Squamous Non-Small Cell Lung Cancer: A Phase 2 Study

Y. Wu[1], Z. Wang[1], X. Dong[2], J. Li[3], L. Wu[4], L. Han[5], X. Li[6], A. Zang[7], W. Li[8], G. Wen[9], W. Lin[10], X. Hu[11], F. Yang[11], H. Yu[11], J. Li[11], Q. Wang[11], J. Zhu[11]
[1]Guangdong Provincial People's Hospital, Guangzhou/CN ,[2]Union Hospital Tongji Medical College Huazhong University of Science and Technology, Wuhan/CN ,[3]Liuzhou people's Hospital, Liuzhou/CN ,[4]Hunan Cancer Hospital, The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha/CN ,[5]Xuzhou Central Hospital, Xuzhou/CN ,[6]The First Affiliated Hospital of Zhengzhou University, Zhengzhou/CN ,[7]Affiliated Hospital of Hebei University, Baoding/CN ,[8]The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN ,[9]The First Affiliated Hospital of Nanchang University, Nanchang/CN ,[10]Cancer Hospital Affiliated to Shantou University Medical School, Shantou/CN ,[11]Shanghai Henlius Biotech, Inc., Shanghai/CN

Introduction: This was a randomized, multicenter phase 2 study comparing the efficacy and safety of HLX07, a novel humanized anti-EGFR antibody, plus serplulimab (anti-PD-1 antibody) ± chemo versus serplulimab plus chemo as first-line option for advanced sqNSCLC.

Methods: This study consisted of 4 parts that assessed varied combinations of HLX07 (at different doses), serplulimab, and chemotherapy. Part 3 evaluated the preliminary efficacy of the three-drug combination and is presented below. Patients with stage IIIB/IIIC or IV sqNSCLC that was not amenable to surgery or radiation therapy and high tumor expression of epidermal growth factor receptor (H score≥150) and no prior systemic therapy were randomized 1:1 to receive intravenous HLX07 at 800 mg (group A) or 1000 mg (group B), in combination with serplulimab (300 mg) and chemotherapy (carboplatin and nab-paclitaxel), once every three weeks. The primary endpoints were the independent radiological review committee (IRRC)-assessed objective response rate (ORR) and progression-free survival (PFS) per RECIST 1.1.

Results: As of 05 March 2025, 27 patients were enrolled and randomly assigned to group A (n=13) and group B (n=14) in part 3. 15 (55.6%) patients had metastatic disease. With a median follow-up of 18.6 months (95% CI 17.2-23.4), IRRC-assessed confirmed ORR per RECIST 1.1 was 69.2% (95% CI 38.6-90.9) in group A and 71.4% (95% CI 41.9-91.6) in group B. Disease control rate was 92.3% (95% CI 64.0-99.8), and 100% (95% CI 76.8-100.0), respectively. Median PFS was not reached (95% CI 4.1-not evaluable [NE]) in group A and 17.4 months (95% CI 8.1-NE) in group B. The median overall survival and duration of response were still not reached in either group. All the patients in both groups reported treatment-emergent adverse events (TEAEs); most common TEAEs of any grade included neutrophil count decreased (92.3% vs. 71.4%), white blood cell count decreased (84.6% vs. 85.7%), anemia (84.6% vs. 78.6%), platelet count decreased (76.9% vs. 71.4%), hypokalemia (53.8% vs. 64.3%), rash (46.2% vs. 57.1%), alopecia (46.2% vs. 50.0%) and hypocalcemia (53.8% vs. 50.0%). 6 (46.2%) patients, and 8 (57.1%) in group A, and B reported immune-related adverse events, respectively.

Conclusions: First-line HLX07 plus serplulimab and chemotherapy showed promising preliminary efficacy with a manageable safety profile in patients with advanced sqNSCLC which warrants further investigation.

P3.12.26 Adding Gefitinib to Target Acquired C797S Mutation After Progression on First-Line Osimertinib in EGFR-Mutant Advanced NSCLC

Z-J. Mao, X-H. Guan, C-D. Weng, Q-Q. Tan, J-W. Liu, J-J. Yan, A. Li, H-J. Chen, J-J. Yang
Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN

Introduction: Acquired epidermal growth factor receptor (EGFR) C797S mutation accounts for approximately 7% of resistance mechanism after first-line osimertinib. Few data reported that the first-generation EGFR tyrosine kinase inhibitors (EGFR-TKIs) showed efficacy in overcoming such resistance. This study aims to investigate the efficacy of gefitinib for non-small-cell lung cancer (NSCLC) patients with acquired C797S mutation after first-line osimertinib.

Methods: Totally 14 patients with acquired C797S mutation were included in the study. A retrospective review of medical records was performed in Guangdong Provincial People's Hospital to analyze EGFR-mutant advanced NSCLC patients who developed acquired C797S mutation after first-line osimertinib. Objective response rate (ORR) and progression-free survival (PFS) were assessed. Clinical characteristics and adverse events (AEs) were documented. Next-generation sequencing (NGS) was performed upon progression to gefitinib plus osimertinib.

Results: Up to Jan 10, 2025, 13 (92.9%, 13/14) patients had progressed or died, and one (7.1%, 1/14) patient was still on treatment. Following gefitinib plus osimertinib/savolitinib therapy, the ORR and disease control rate (DCR) was 42.9% and 78.6%. The median PFS was 5.2 months (95% CI: 3.9-6.5) . One patient with cellular mesenchymal-epithelial transition factor (c-MET) amplification and EGFR C797S subsequently received gefitinib plus savolitinib and the other 13 patients received gefitinib plus osimertinib. One patient stopped osimertinib due to Grade 2 diarrhea(CTCAE 5.0). Other patients did not discontinue the treatment due to serious AEs, and all other AEs observed were mild and manageable. Resistance mechanisms of the gefitinib plus osimertinib have been analyzed in 5 patients, including T790M/C797S in-cis, EGFR C797S disappearance, no change and new unknown mutations.

Conclusions: Gefitinib therapy may be an optional strategy to overcome resistance of acquired C797S mutation in EGFR-mutant advanced NSCLC treated with first-line osimertinib.

P3.12.27 Resistance Mechanisms of Novel Targeted Therapies to EGFR Exon 20 Insertion Mutation-Positive Non-Small Cell Lung Cancer

B-C. Liao[1], N-J. Chiang[2], C-L. Lai[3], W-Y. Liao[4], S-G. Wu[1], C-J. Yang[5], M-H. Lee[5], I-W. Chong[5], C-I. Shen[2], Y-H. Luo[2], W-H. Hsu[4], C-L. Hsu[4], Y-T. Lin[1], C-F. Hsiao[6], C-C. Ho[4], J-Y. Shih[4], J.C-H. Yang[1]
[1]National Taiwan University Cancer Center, Taipei City/TW ,[2]Taipei Veterans General Hospital, Taipei City/TW ,[3]Dalin Tzu Chi Hospital, Chiayi/TW ,[4]National Taiwan University Hospital, Taipei City/TW ,[5]Kaohsiung Medical University Hospital, Kaohsiung/TW ,[6]National Health Research Institutes, Miaoli/TW

Introduction: Amivantamab is the only approved targeted therapy for metastatic EGFR exon 20 insertion mutation-positive (EGFR exon 20+) NSCLC. Many novel oral EGFR inhibitors are under clinical development for this patient population. The resistance mechanisms of these drugs are not known.

Methods: We enrolled patients with metastatic EGFR exon 20+ NSCLC who received amivantamab, mobocertinib or other novel EGFR inhibitors targeted on EGFR exon 20 insertion mutation. We also enrolled patients with tumor harboring EGFR p.A763_Y764insFQEA mutation who received first- or second-generation EGFR tyrosine kinase inhibitors. We collected tissue samples before and after treatment. We conducted comprehensive tissue-based next-generation sequencing (NGS) testing (ACTOnco+).

Results: We enrolled eighteen patients with various types of EGFR exon 20 insertion mutations. Ten (56%) patients had paired tumor tissue samples. Two patients with p.A763_Y764insFQEA who received afatinib therapy developed EGFR T790M as the resistance mechanism. Among 10 patients who received mobocertinib (n = 7), sunvozertinib (n = 2) or furmonertinib (n = 1), baseline EGFR mutations preserved in post-treatment tissue samples in 9 (90%) patients, EGFR amplification was detected in 5 (50%) patients. One patient who received sunvozertinib and another one who received furmonertinib developed MET and MYC amplification, respectively. Two patients who received mobocertinib developed MDM2 and CDK4 amplifications. Three patients received amivantamab monotherapy in this cohort, but NGS analysis did not disclose potentially actionable resistance mechanisms.

Conclusions: EGFR amplification is the most common resistance mechanism of novel EGFR inhibitors targeted on EGFR exon 20 insertion mutation. The resistance mechanisms of amivantamab therapy warrant further study.

Keywords: EGFR exon 20 insertion, resistance mechanism, mobocertinib

P3.12.28 Association of PD-L1 Expression With Clinical Outcome in Advanced NSCLC With ALK Rearrangement

N. Suriyaphan[1], A. Jinawath[2,3], N. Trachu[4], T. Reungwetwattana[1,3], T. Thamrongjirapat[1,3]
[1]Division of Medical Oncology, Department of Medicine, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok/TH ,[2]Department of Pathology, Faculty of Medicine Ramathibodi hospital, Mahidol University, Bangkok/TH ,[3]Ramathibodi Lung Cancer Consortium (RLC), Faculty of Medicine Ramathibodi Hospital, Bangkok/TH ,[4]Research Center, Faculty of Medicine Ramathibodi hospital, Mahidol University, Bangkok/TH

Introduction: ALK-rearrangement is the second common oncogenic-driver (7-10%) in Thailand. ALK-inhibitors accessibility in Thailand is limited. We conducted this study to evaluate clinical outcomes and the correlation between PD-L1 expression and survival in ALK-rearranged patients.

Methods: Patients with ALK-rearranged advanced-NSCLC, identified by either D5F3-IHC or FISH between January 2019 and October 2024 at Ramathibodi Hospital were enrolled. PD-L1 expression by tumor proportion score was tested using 22C3-IHC. Categorical variables were compared using the chi-square test and Fisher's exact test. Survival analysis was performed using the Cox regression method.

Results: Eighty-seven patients were enrolled, of whom 82 received ALK-inhibitors. Majority of patients were female (57%), non-smokers (47%), had M1b disease (39%), and 16% had intracranial metastases. Sixty-six patients had adequate tissue for PD-L1 testing with positive expression of 77% (51 out of 66). CNS metastases were found in 14 out of 87 patients and majority of them (9 patient) were PD-L1-positive expression. Among the 87 patients, 65 received ALK-inhibitor as first-line (1L) treatment (Crizotinib: 6; Ceritinib: 37; others 2nd/3rd generation ALK-inhibitors: 22), 17 patients received chemotherapy. Sixty percent of patients received only one line of ALK-inhibitor. The overall response rate was 80-85% across all generations of ALK-inhibitors. The 5-year overall survival (OS) rate and progression-free survival (PFS) rates in 87 patients were 52% and 16%. The 5-year PFS rate was extremely high (38.5%) in patients whom taking 2nd/3rd generation ALK-inhibitors as the first-line treatment compared to other types of first-line treatment (Table 1). Univariate analysis showed that de novo metastasis, extra-thoracic metastasis, and PD-L1 positivity tended to be associated with poorer prognosis, although the results were not statistically significant. Patients receiving ALK-inhibitors (65 patients) as first-line treatment had significantly higher PFS compared to those receiving chemotherapy (median PFS: 1.8 VS 0.3 years, HR: 0.24, P < 0.01). The median chemotherapy-free survival was 2.1 years. Patients whom receiving ≥ one line of ALK-inhibitors (17 patients) had significantly longer chemotherapy-free survival (3.8 vs 1.6 year, HR: 0.33, P = 0.001) and tend to have longer OS (5.4 vs 3.1 year, HR: 0.66, P = 0.35), compared to whom received only one ALK-inhibitor (48 patients).

Conclusions: ALK-inhibitors demonstrated a certain benefit in survival outcomes, especially with the use of higher-generation drugs. High PD-L1 co-expression was found in ALK-positive patients and tended to be associated with a poorer prognosis. Treating patients with first-line and with more than one ALK-inhibitor demonstrated the significant longer survival.

First-line treatment	Median PFS (Years)	Hazard ratio	3-years PFS rate (%)	5-years PFS rate (%)
Chemotherapy without pemetrexed	0.3	Ref.	8.3	0
Chemotherapy with pemetrexed	1.35	0.55 (95% CI 0.19, 1.60) *P* = 0.27	0	0
Crizotinib	0.63	0.44 (95% CI 0.26, 1.21) *P* = 0.11	16.7	0
Ceritinib	1.87	0.21 (95% CI 0.10, 0.44) *P* = < 0.01	34.5	0
Others 2nd-3rd generation ALK-TKIs	1.91	0.13 (95% CI 0.05, 0.33) *P* = < 0.01	48.1	38.5

P3.12.29 Effectiveness and Treatment Patterns in Patients With First-Line 2G ALK TKI Across the Esme French Real-World Cohort

G. Nicolas[1], S. Eltaief[2], D. Debieuvre[3], Y. Le Guen[4], H.H. Le[5], N. Rifi[6], C. Audigier Valette[7], J. Remon-Masip[8], L. Bosquet[2], C. Chouaid[9], M. Pérol[10]
[1]Institut Curie, Paris/FR ,[2]Unicancer, Paris/FR ,[3]GHR Mulhouse Sud Alsace, Mulhouse/FR ,[4]CHU Pontchaillou, Rennes/FR ,[5]Pfizer Inc, New York/NY/USA ,[6]Pfizer Inc, Paris/FR ,[7]CH Sainte Musse, Toulon/FR ,[8]Gustave Roussy, Villejuif/FR ,[9]CHI Créteil, Créteil/FR ,[10]Centre Léon Bérard, Lyon/FR

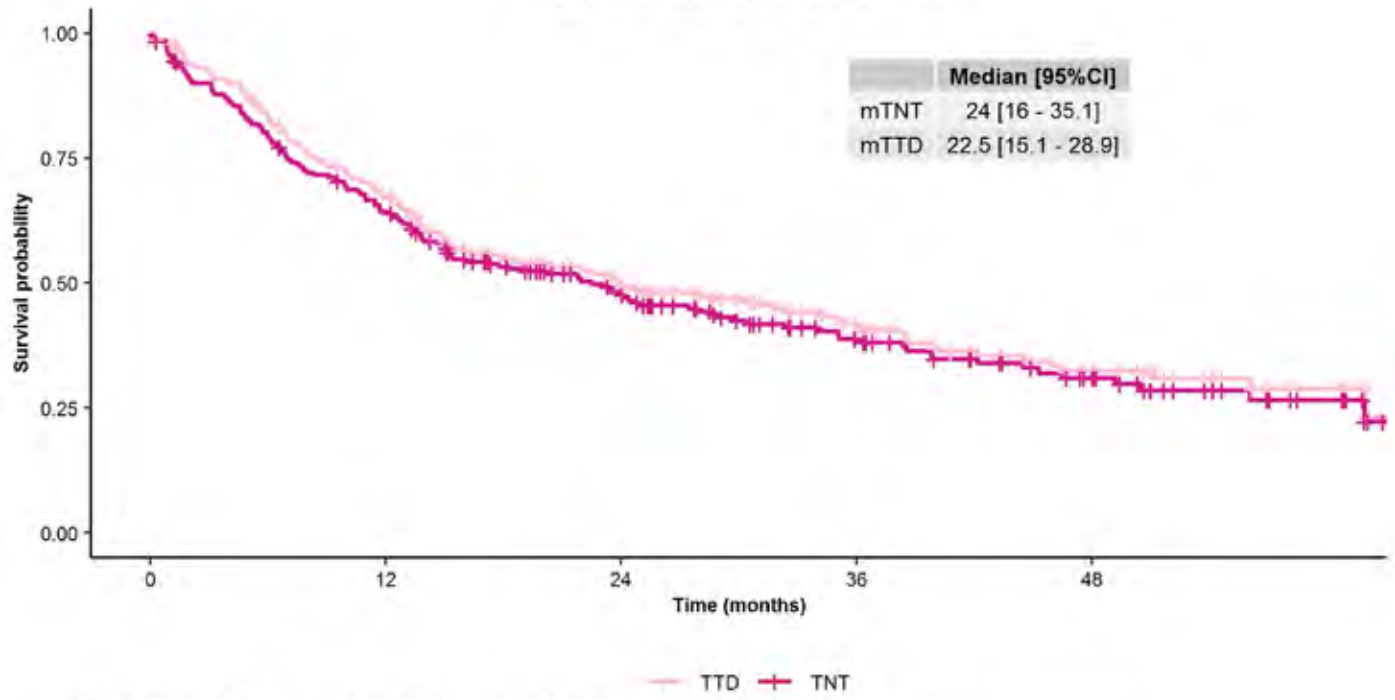
Introduction: The ESMO guidelines recommend alectinib, brigatinib (second-generation [2G]) or lorlatinib (third-generation [3G]) anaplastic lymphoma kinase inhibitors (ALKis) as the preferred first-line (1L) treatments for ALK+ advanced non-small-cell lung cancer (aNSCLC). As around 35% of patients in this population have baseline brain metastases (BM) and additional 20% on 2G ALK tyrosine kinase inhibitors (TKI) will develop new BM within 5 years, intracranial efficacy is also of interest. Since ALK+ aNSCLC is rare, real-world evidence of 1L ALK TKIs are limited. This study aims to describe treatment patterns and real-world outcomes in patients initiated with 1L 2G ALK TKIs for aNSCLC in France.

Methods: This retrospective chart review study utilized the ESME LC Database, encompassing a group of 38 oncology centers in France. The study included adults (aged ≥18 years) with a histologically confirmed diagnosis of ALK+ aNSCLC treated with 2G ALK TKIs in 1L between June 2017 and March 2023, followed until September 2024. The primary outcomes were effectiveness by BM status.

Results: 239 patients who received 1L 2G ALK TKIs were included in this study; 92 (38%) of them had baseline BM. Patients had median age of 63 years (52-73), 46% were male and 82% had ECOG score of 0-1. Most patients (83%) received alectinib in 1L, 12% received brigatinib. With the median follow-up time of 41 months (95%CI 35.3-45.6), treatment discontinuation during 1L was 53.6% (n=128), majority due to progression (73.4%) and 112 patients (47%) went on to receive 2L, with majority (78.6%) receiving ALK TKI. For patients with progression during 1L (n=141), 32 (23%) did not receive 2L. Median time to discontinuation (mTTD) and median time to next treatment (mTNT) were about 2 years (Fig1). mTTD in patients with/without baseline BM were similar, 21.8 [12.9-34.0] vs 22.5 [14.8-35.1] months. Same trend was observed with mTNT, 23.4 [13.9-36.1] vs 25.1 [15.3-38.5] months respectively. Median OS was 55.8 months [44.5-NR], and was 46.1 [32.7-NR] vs 65.1 [46.4-NR] months respectively in patients with/without baseline BM. BM incidence in overall cohort were 7.4% within 1 year, 13.6% within 2 years, 15.1% within 3 years and 18.8% within 4 years from 1L start date among patients who were alive.

Conclusions: Results of this study are consistent with previous results, highlighting the unmet need with 2G ALK TKIs. This supports thoughtful consideration of 1L treatment with the longest systemic and intracranial efficacy upfront to provide the greatest benefit for patients with ALK+ aNCSLC.

Figure 1: TNT and TTD - 2G ALK TKi cohort



TNT is the time from the 1L start date to the start date of subsequent line of therapy (2L)
TTD is the time from the date of initiation of 1L ALK TKI to the stop date of ALK TKI received as per the first-line treatment or date of death wichever occured first.
mTNT and mTTD are proxies of mrwPFS.

Introduction: Histological transformation (HT) is recognized as a resistance mechanism to systemic therapies in non-small cell lung cancer (NSCLC). However, the clinico-pathological and molecular determinants driving this shift remain poorly characterized.

Methods: We conducted an international, retrospective, multicenter study across 15 European centers. Clinical, pathological, treatment response and molecular data at diagnosis and at the time of HT were collected for patients with proven HT. Here we present the preliminary results based on the clinico-pathological and the available molecular data.

Results: A total of 75 patients were enrolled, with median age 59.5 years (17-88). The majority (69.3%) were women and 54.7% never-smokers. Among former-smokers (26.7%), median time since smoking cessation was 10 years. The majority (82.7%) of patients presented with stage IV disease and 34.7% had central nervous system (CNS) metastases at diagnosis. Molecular profiling revealed: 70.7% of tumors harbored EGFR mutations (EGFRdel19 or EGFRex21), 9.3% ALK rearrangements, and 1.3% each an EGFR ex20ins, a RET/ROS1 translocation or BRAF V600E and KRAS G12C mutation. An actionable genomic alteration lacked in 10.7% of cases.At the time HT was demonstrated, 73.3% of patients were receiving targeted therapy, 8% chemotherapy, 6.7% chemo-immunotherapy, 5.3% immunotherapy, and 2.7% an antibody-drug conjugate. The median number of lines of therapy before HT was 1 (0-6). At HT, 62.7% of tumors had transformed into SCLC, while 16% showed squamous histology. In few cases, we observed a shift towards large cell neuroendocrine carcinoma (8%), sarcomatoid (2.7%), pleomorphic (2.7%), neuroendocrine carcinoma (2.7%), carcinosarcoma (1.3%), and combined histologies (4%). CNS metastases were present in 42.7% of patients after HT. Among patients with available matched NGS (before and after HT, n=30), all retained their original driver mutations. After HT, 14.7% of patients received targeted therapy, while 68% of patients received chemotherapy, either alone (34.7%) or combined (with target therapy 9.3%, with immunotherapy 24%). The median time from diagnosis to HT was 30.8 months (3.0-134.3), while median survival after HT was 10.8 months (0.3-60.1).

Conclusions: This work represents the largest reported cohort of HT, beyond EGFR-mutated NSCLC and SCLC transformations. HT is an underexplored phenomenon that may occur more commonly and more heterogeneously than previously recognized. Further molecular analyses are needed to uncover potential biomarkers that may predict or better characterize this phenomenon.

Introduction: Rezivertinib (BPI-7711) is a novel third-generation EGFR-TKI. During the phase I and phase IIb studies, patients were allowed to detect with tissue or plasma samples for EGFR mutations status at screening. The results revealed that patients with tissue positive sampling at baseline showed higher ORR, DCR and prolonged median PFS over those with plasma EGFR T790M positive sampling, while patients with both positive tissue and plasma EGFR T790M mutation were associated with the worst efficacy. Here we further analyzed the efficacy and safety results of rezivertinib, at the dosage of 180 mg orally once daily, for advanced NSCLC patients with EGFR T790M mutation detected with both tissue and plasma samples at baseline.

Methods: Eligible patients were included from rezivertinib phase I and IIb studies. Patients with EGFR T790M detected in both tissue and plasma samples (at least one positive result) after progressing on first- or second-generation EGFR-TKIs and treated with rezivertinib 180mg once daily were included in full analysis set (FAS). Patients with stable, asymptomatic baseline CNS lesions (measurable/non-measurable) formed the CNS full analysis set (cFAS). Blinded independent central review (BICR) assessed ORR, DCR, PFS, OS, and CNS-PFS.

Results: 89 patients were included in the FAS, while 32 patients in the cFAS. The ORR was 55.0% (95% CI: 34.2-74.2%) and 78.3% (95% CI: 67.2-86.4%) for patients detected with both positive tissue and plasma EGFR T790M sampling (group A) and for patients with only tissue-positive but plasma-negative EGFR T790M sampling (group B). The DCR was 90.0% (95% CI: 69.9-97.2%) and 100.0% (95% CI: 94.7-100.0%) for group A and group B (P=0.0485). The BICR-assessed median PFS was 6.5 (95% CI: 3.8-12.4) months in group A and 16.7 (95% CI: 13.9-27.7) months in group B (hazard ratio [HR]=0.26, 95% CI: 0.13-0.50, P<0.0001; Figure 1). The BICR-assessed median CNS-PFS was 18.3 (95% CI: 1.3-NC) months in group A months versus 16.7 (95% CI: 8.3-NC) months in group B. 84.3% (75/89) patients in the FAS experienced TRAEs.

Conclusions: Rezivertinib demonstrated encouraging systematic and CNS efficacy among EGFR T790M-mutated advanced NSCLC patients detected with both tissue and plasma samples. Patients with tissue-positive but plasma-negative EGFR T790M mutation showed better efficacy than those with both tissue and plasma EGFR T790M positivity. Plasma EGFR T790M positivity at baseline might predict the worse treatment outcome for rezivertinib in this patient population.

P3.12.32 Long-Term Survival Outcome After First-Line Osimertinib Monotherapy in Advanced/Metastatic NSCLC: Results From LC-SCRUM-Asia

H. Izumi[1], S. He[2], M. Hiraoka[3], Y. Wan[2], B. Wu[2], K. Shiga[3], S. Kitazono[3], H. Tsuchiya[3], K. Goto[1]
[1]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa/JP ,[2]Janssen Global Services LLC, Raritan/NJ/USA ,[3]Janssen Pharmaceutical K.K., Tokyo/JP

Introduction: Osimertinib, a 3rd-generation EGFR tyrosine kinase inhibitor, is the common first-line treatment for EGFR-mutated advanced non-small cell lung cancer (NSCLC). However, few real-world studies have investigated long-term survival outcome with osimertinib in Japan. We assessed overall survival (OS) following first-line osimertinib using a large-scale clinico-genomic database of LC-SCRUM-Asia.

Methods: LC-SCRUM-Asia was a real-world patient registry established in Feb 2013 as a nationwide genomic screening project for developing individualized medicine of lung cancer in Japan. It enrolled NSCLC patients with stage II or higher, ECOG<2, with adequate organ functions, without serious complications, and have >3 months life expectancy. This retrospective, observational cohort study included patients who met additional eligibility criteria: i) age≥18 years at enrollment; ii) diagnosed with EGFR-mutated (exon19 deletions or exon21 L858R) advanced/metastatic NSCLC, and iii) initiated first-line osimertinib monotherapy on or after 21-August-2018 (osimertinib approval date in Japan). Index date was first osimertinib initiation date. The latest enrollment date available was 31-March-2022. Patients were followed-up until death, loss to follow-up, or data cut-off. OS and 95% confidence intervals (CIs) were estimated using Kaplan-Meier method. Real-world overall response rate (rwORR) was reported.

Results: A total of 809 patients were included. At enrollment, the median age was 71 years (IQR: 63, 77), 65% were female and 59% having never smoked. ECOG performance status was 0 in 42% of patients, 95% were stage IV, 97% had adenocarcinoma and 52% had exon19 deletions. Baseline metastases were noted in 31% of patients for brain, 11% for liver, and 40% for bone. The median OS following first-line osimertinib was 33.4 months (95% CI: 30.8, 37.3), with a rwORR of 65%. Of 608 patients who discontinued osimertinib, 203 (33%) did not receive subsequent treatments. Among patients who received second-line treatments (n=405), 34% received chemotherapy, 24% received EGFR TKIs, 19% received combination of chemotherapy and immune-oncology agents, and 12% received combination of chemotherapy and VEGF inhibitors. Older age (≥75 years), brain metastases, liver metastases, bone metastases and exon21 L858R were associated with significantly shorter median OS (P<0.01; Table).

Conclusions: First-line osimertinib was found to have a lower median OS (33.4 months) from LC-SCRUM-Asia database, when compared to that reported in pivotal trials (median OS of 38.6 months in FLAURA trial). Majority of patients (86%) had risk factors associated with poor survival. Approximately one-third of patients who discontinued osimertinib did not receive second-line therapy. These results highlight the pressing need to improve outcomes in first-line treatment.

Table Prevalence of risk factors for poor survival

Risk factors	Prevalence (%)	Median OS (95% CI) with vs. without risk factors	P-value*
≥75 years of age	35%	29.2 (26.3, 33.1) vs. 36.8 (31.2, 45.3)	0.0022
Brain metastases	31%	30.1 (27.3, 35.4) vs. 36.9 (31.9, 41.5)	0.0095
Liver metastases	11%	22.4 (18.6, 29.2) vs. 36.2 (32.8, 39.4)	<0.0001
Bone metastases	40%	29.8 (25.9, 33.1) vs. 37.3 (33.4, 42.3)	<0.0001
EGFR exon21 L858R	48%	29.1 (27.2, 33.1) vs. 38.2 (34.0, 46.1)	<0.0001
Patients who had ≥1 risk factors above	86%	31.9 (29.8, 35.4) vs. 46.1 (41.5, NA)	0.0003

*P-values are obtained from the log-rank test.

Introduction: The treatment efficacy of patients with EGFR-mutated non-small cell lung cancer (NSCLC) and malignant pleural effusion (MPE) is considered poor. Efficacy of ramucirumab plus erlotinib in EGFR-mutated non-squamous (non-Sq) NSCLC with MPE has not been investigated.

Methods: In this single-arm, phase II study, treatment-naïve, advanced non-Sq, NSCLC patients with EGFR common mutation and MPE were enrolled. Participants were treated with ramucirumab 10 mg/kg, intravenously every 2 weeks plus oral erlotinib (150 mg) until disease progression or unacceptable toxicity. The primary end point was investigator-assessed progression-free survival (PFS). The secondary endpoints were overall response rate (ORR), overall survival (OS), drainage-free survival without thoracic drainage, and safety. Regarding statistical consideration, the threshold and the expected PFS were set as 9 and 14 months, respectively with one-sided $\alpha = 0.2$, and $\beta = 0.2$, the required sample size was 38 cases. A total of 40 cases was planned to take into account the possibility of a few dropped or ineligible cases. This study was funded by Eli Lilly and Trial identification no. is jRCT051210138.

Results: Between Dec 2021 and Dec 2023, 40 patients were enrolled from 15 institutions in Japan. All patients were analyzed for safety and efficacy. Of those, median age was 73 (41-85), male/female: 18/22, never-/smoker/unknown: 21/18/1, ECOG performance status: 0/1/2 8/30/2, stage IVa/IVb: 26/14 and EGFR mutation:19del/L858R 23/17. Baseline brain metastases were 10% of the patients. The median duration of follow-up was 24.2 months (6.5-37.7 months). Median PFS of the primary endpoint was 12.9 months (95% CI, 7.3-17.0 months) and PFS rate at 12 months was 55.0%. Median OS was 33.0 months (95% CI, 28.5-NA months) and OS rate at 12 months was 87.5%. Median drainage-free survival was 31.8 months (95% CI, 22.8-NA months). The ORR and disease control rate were 77.5% (95% CI, 61.5-89.2%) and 85.0% (95% CI, 70.2-94.3%), respectively. Any grade and grade 3-4 adverse events (AEs) occurred in 67.5% and 22.5%, respectively. Most common AEs were dermatitis acneiform (47.5%), anorexia (25.0%), elevated AST (25.0%) and anemia (22.5%). Pneumonitis occurred in 5.0% (grade2, n=2). Grade 3-4 AEs were dermatitis acneiform (7.5%), anorexia (5.0%), hypertension (5.0%) and elevated AST and ALT (5.0%), but no treatment-related death occurred. T790M mutation rate at disease progression was 27.8% (5 of 18 patients).

Conclusions: Median PFS of the primary endpoint was 12.9 months in patients with advanced non-Sq NSCLC harboring EGFR mutation and MPE, and it did not exceed the expected PFS of 14 months. MPE control was favorable. The safety profile of ramucirumab plus erlotinib was consistent with the established profiles of the individual agents for patients with MPE.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.34 Real-World Study in Patients With ALK+ Metastatic Non-Small Cell Lung Cancer (mNSCLC) Treated With First-Line (1L) Lorlatinib

S. Gadgeel[1], L. Stansfield[2], P. Ramachandran[3], O. Emidio[4], A. Kotomale[4], N. Rifi[5], L. Alejandro[6], D. Abrahami[2]
[1]Henry Ford Cancer Institute/Henry Ford Health System, Detroit/MI/USA ,[2]Pfizer, New York/NY/USA ,[3]Pfizer, Harrison/NJ/USA ,[4]Cardinal Health, Dublin/OH/USA ,[5]Pfizer, Paris/FR ,[6]Pfizer, San Diego/CA/USA

Introduction: Lorlatinib, a brain-penetrant, third-generation ALK tyrosine kinase inhibitor (TKI), was approved by the FDA for the 1L treatment of ALK+ mNSCLC on March 3, 2021. Evidence for real-world 1L lorlatinib patient and provider experience is limited. We conducted a retrospective pilot study to describe 1L lorlatinib patient and provider characteristics and the real-world starting dose.

Methods: In this multi-site, physician-led chart review, adult patients diagnosed with ALK+ mNSCLC in the US on or after January 1, 2021, and treated with 1L lorlatinib on or after March 3, 2021, were included. Patients who received lorlatinib in a randomized clinical trial (RCT) were excluded. The target sample size was 50, with a maximum of 5 patients recruited per provider. The primary objective was a descriptive assessment of real-world demographics and clinical characteristics of 1L lorlatinib recipients. Data were collected through February 6, 2025.

Results: Fifty patient charts were abstracted by 15 providers. Providers practiced for a median of 17 years and treated a median of 10 patients with ALK+ mNSCLC during the study period. Overall, 12 (80%) practiced in a community setting, 6 (40%) were from the South, 6 (40%) were from the West, and 10 (67%) were from urban settings. Patient characteristics are presented in the Table. The median time between mNSCLC diagnosis and ALK testing date was 2.5 days, and the median time between ALK testing date and 1L lorlatinib initiation was 14 days. Most patients (31 [62%]) initiated 1L lorlatinib in 2024. Overall, 39 (78%) patients had ≥1 comorbidities at treatment initiation, and 20 (40%) had baseline brain metastases. Lorlatinib was initiated at 100 mg in 41 (82%) patients, 75 mg in 8 (16%), and 50 mg in 1 (2%). No patient had a dose increase during a median follow-up period of 7.8 months; 9 (18%) patients had ≥1 dose reduction, and 5 (10%) had ≥1 dose interruption or delay. By the end of follow-up, 41 (82%) patients remained on 1L lorlatinib treatment.

Conclusions: This study characterized the real-world demographics, clinical and provider characteristics, and starting dose in 50 patients with ALK+ mNSCLC treated with 1L lorlatinib. In this pilot study, most patients started lorlatinib at 100 mg, which was the starting dose assessed in the CROWN RCT. A larger real-world study with expanded patient counts and longer-term follow-up is ongoing. A genAI tool (3/05/25; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility.

Table. Patient demographics and clinical characteristics of 50 1L lorlatinib patients in real-world setting	
Patient demographics	
Female, n (%)	24 (48)
Age at mNSCLC diagnosis, median (Q1, Q3), years	59.4 (54.4, 69.0)
Never smoked, n (%)	28 (56)
Race/ethnicity, n (%)	
White	30 (60)
Asian	8 (16)
Black or African-American	6 (12)
Hispanic or Latino	5 (10)
American Indian or Alaska Native	1 (2)
Employment status, n (%)	
Retired	16 (32)
Full-time employed	14 (28)
On disability	6 (12)
Part-time employed	5 (10)
Unemployed	4 (8)
Short/long-term leave	1 (2)
Unknown	4 (8)
BMI at mNSCLC diagnosis, n (%)	
18.5 to 24.99 kg/m² (normal)	20 (40)
25 to 29.99 kg/m² (overweight)	21 (42)
≥30 kg/m² (obese)	8 (16)
Unknown	1 (2)
Clinical characteristics	
Tissue sample used for *ALK* genetic testing, n (%)	48 (96)
Broad next-generation sequencing used for *ALK* genetic testing, n (%)	45 (90)
Adenocarcinoma histology, n (%)	49 (98)
ECOG performance status 0-1, n (%)	40 (80)
Comorbid conditions,[a] n (%)	
Comorbid hypertension	28 (56)
Hyperlipidemia	10 (20)
Diabetes	7 (14)
Myocardial infarction-history	3 (6)
Psychiatric disorders (anxiety, depression, post-traumatic stress disorder, other)	3 (6)
Renal disease	3 (6)
Cerebrovascular disease	0
Concomitant medications,[a] n (%)

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.35 Real-World Clinical Outcomes of Osimertinib in Patients With Recurrent EGFR Mutated Lung Adenocarcinoma: A Multicenter Study

I. Tanaka[1], M. Sato[1], K. Hori[1], J. Koyama[1], Y. Kodama[2], A. Matsui[3], A. Miyazawa[4], S. Miyamatsu[5], S. Asano[5], Y. Hibino[4], M. Morise[1], T. Yokoyama[2], T. Kimura[6], N. Yoshida[3], M. Sato[1], M. Ishii[1]
[1]Nagoya University Graduate School of Medicine, Nagoya/JP ,[2]Japanese Red Cross Aichi Medical Center Nagoya Daiichi Hospital, Nagoya/JP ,[3]Kariya Toyota General Hospital, Kariya/JP ,[4]Konan Kosei Hospital, Konan/JP ,[5]Japan Community Health care Organization Chukyo Hospital, Nagoya/JP ,[6]Tosei General Hospital, Seto/JP

Introduction: The 9th edition of the TNM classification for lung cancer introduced a new subdivision of M1c status into M1c1 (multiple extra-thoracic metastases in a single organ system) and M1c2 (multiple extra-thoracic metastases in multiple organ systems) under the category of stage IVB. This refinement is also reflected in the IASLC staging manual and can more accurately predicts prognosis; however, their clinical implications, especially in relation to the efficacy of molecular targeted therapies, remain unclear. Furthermore, although recurrent lung cancer under the postoperative monitoring can be generally detected with lower tumor burden than those with de novo stage IV, there are no prior studies that have examined whether this distinction influences the clinical efficacy of EGFR-TKIs. To address the therapeutic outcomesbased on the 9th edition of TNM classification, we analyzed that the clinical efficacies of 3rd generation EGFR-TKI,Osimertinib, for patients with recurrent EGFR-mutant lung adenocarcinoma in comparison with those for patients with de novo stage IV in a real-world cohort.

Methods: We retrospectively analyzed clinical data from 275 patients with de novo stage IV or recurrent sensitizing EGFR-mutant lung adenocarcinoma treated with first-line osimertinib from six institutions. Disease stages of de novo stage IV were assigned according to the 9th edition of the TNM classification. Patients with postoperative recurrence were subclassified as follows: r-M1a (recurrence within the thorax), r-M1b (single extra-thoracic metastasis), r-M1c1 (multiple extra-thoracic metastases in a single organ system), and r-M1c2 (multiple extra-thoracic metastases in multiple organ systems) based on recurrence pattern. Progression-free survival (PFS) and overall survival (OS) were compared between these classifications.

Results: Among the 183 patients with de novo stage IV disease, the distribution was as follows: M1a (26.8%), M1b (13.1%), M1c1 (28.4%), and M1c2 (31.7%). In the 92 patients with postoperative recurrence, recurrence patterns were: r-M1a (63.0%), r-M1b (12.0%), r-M1c1 (12.0%), and r-M1c2 (13.0%). Patients with postoperative recurrence had significantly better PFS and OS compared to those with de novo stage IV (PFS: 34.6 vs. 17.9 months, $P < 0.0001$; OS: 53.4 vs. 35.2 months, $P = 0.0030$). In multivariate analysis, recurrence status remained an independent prognostic factor. Furthermore, in the patients with de novo stage IV, patients with M1c2 showed significantly shorter PFS and OS compared to those with M1b and M1c1. A similar trend was observed in the patients with postoperative recurrence, indicating multiple extra-thoracic metastases in multiple organ systems were associated with the poorest outcomes in the cases treated by osimertinib.

Conclusions: Our real-world cohort study demonstrates that postoperative recurrence is associated with more favorable survival compared to de novo stage IV in patients with EGFR-mutant lung adenocarcinoma, who were treated by osimertinib. Moreover, the subclassification of M1c1 and M1c2 in the 9th edition of the TNM classification can reflect clinically meaningful differences in the therapeutic response and prognosis.

P3.12.36 Multicenter Retrospective Study of Selpercatinib Treatment for Advanced or Recurrent RET Fusion-Positive NSCLC in Japan

Y. Mihashi
National Hospital Organization Osaka Toneyama Medical Center, Toyonaka City, Osaka Prefecture/JP

Introduction: Based on the results of the LIBRETTO-431 trial, selpercatinib has become the standard first-line treatment for recurrent or advanced non-small cell lung cancer (NSCLC) with RET fusion gene alterations. However, RET fusion-positive recurrent or advanced NSCLC is rare, accounting for only 1-2% of all lung cancers, and real-world data (RWD) on the use of selpercatinib remain extremely limited, particularly in the Japanese population. Therefore, we conducted a multicenter retrospective study to evaluate the efficacy and safety of selpercatinib in patients with recurrent or advanced RET fusion-positive NSCLC.

Methods: This retrospective multicenter study enrolled 27 patients, who were pathologically diagnosed with advanced or recurrent RET fusion-positive NSCLC and started administration of selpercatinib between September 2021 and June 2024.The median follow-up period was 12.0 months (range 0.5-31.5 months). From the perspective of efficacy, we evaluated the objective response rate (ORR), progression-free survival (PFS), and overall survival (OS) in both previously systemically treated and treatment-naive groups. Additionally, PFS was analyzed based on PD-L1 status, separately in the tumor proportion score (TPS)-high (TPS≥50%) and TPS-low groups. From the perspective of safety, we summarized all reported adverse events of any grade and those of Grade 3 or higher in all 27 cases.

Results: The ORR was 80% (8 of 10 cases) in the previously treated group and 76% (13 of 17 cases) in the treatment-naive group, with no significant difference between the two. The median PFS was not reached (95% confidence interval [CI] 0.5-Not Evaluable [NE]) in the previously treated group and 23.5 months (95% CI 5.7-NE) in the treatment-naive group, no significant difference was observed. Given that a majority of patients have not experienced an event, the median PFS should be interpreted with caution. The median OS was 25.4 months (95% CI 0.5-NE) in the previously treated group and not reached (95% CI NE-NE) in the treatment-naive group, no significant difference was observed. The median PFS was 23.5 months (95% CI 8.0-NE) in the TPS-low group (TPS<50%) and not reached (95% CI 2.9-NE) in the TPS-high group (50%≤TPS), no significant difference was observed. The most frequent Grade3 adverse event (AE) was increased ALT (n=11,41%), followed by increased AST (n=7,26%). Grade 3 hypertension was observed in 5 patients (19%), Grade 3 QT prolongation was observed in 1 patient (4%).

Conclusions: Compared to the LIBRETTO-001 trial, this study showed a trend toward lower ORR and PFS in the treatment-naive group, whereas the previously systemically treated group exhibited a trend toward higher ORR and PFS. Regarding adverse events, this study reported a higher frequency of severe liver dysfunction compared to the LIBRETTO-001 and LIBRETTO-431 trials, while the incidence of hypertension and QT prolongation remained relatively similar. These findings suggest that liver dysfunction may be more severe in the Japanese population, highlighting the need for careful dose management strategies.

Keywords: RET Fusion-Positive NSCLC, Selpercatinib

P3.12.37 First-Line Lazertinib With or Without Local Ablative Radiotherapy in Oligo-Metastatic EGFR-Mutant NSCLC

J.B.(. Lee[1], K.H. Kim[1], S. Yoon[2], S.Y. Song[2], S.S. Lee[3], S. Jo[3], H.K. Ahn[4], H.J. Kim[4], M.H. Hong[1], B.C. Cho[1], H.I. Yoon[1], S.M. Lim[1]
[1]Yonsei Cancer Center, Seoul/KR ,[2]Asan Medical Center, Seoul/KR ,[3]Inje University Haeundae Paik Hospital, Busan/KR ,[4]Gachon University Gil Medical Center, Incheon/KR

Introduction: Lazertinib, a blood-brain barrier penetrant, third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor, has demonstrated significant improvement in progression-free survival (PFS) in treatment-naïve, EGFR-mutant advanced non-small cell lung cancer (NSCLC), as a single-agent or in combination with amivantamab. In this study, we aimed to investigate whether the addition of local ablative therapy (SBRT) to lazertinib would improve PFS in oligo-metastatic, EGFR-mutant NSCLC compared to lazertinib alone (NCT05167851).

Methods: This is a multi-center, randomized, non-comparative, phase II study of patients with oligo-metastatic NSCLC harboring activating EGFR mutations (ex19del or L858R). Synchronous oligo-metastatic disease was defined as metastatic lesion < 5 and involved organs < 3. All lesions were deemed amenable for SBRT at the discretion of radiologist. Patients were stratified by EGFR mutation status (Ex19del vs. L858R), and randomized to receive 240 mg of oral lazertinib monotherapy with or without the addition of SBRT. The primary endpoint was investigator-assessed PFS. Secondary endpoints included overall survival (OS), objective response rate (ORR), duration of response (DoR), and safety.

Results: A total of 67 patients (lazertinib monotherapy, n=34; lazertinib plus SBRT, n=33). were enrolled from 4 centers in Republic of Korea between January 2022 and May 2023. At the data cutoff (December, 2024), the median follow-up duration was 23 months (range 20.3-24.0 months). The median PFS were 24.8 months (90% CI, 15.7-NA months) and 34.0 months (90% CI, 26.6-NA months) for lazertinib and lazertinib plus SBRT groups, respectively. In the lazertinib monotherapy group, the median PFS was 24.8 months (90% CI, 14.5-NA) for Ex19del (n=16) and 20.3 months (90% CI, 10.8-25.7 months) for L858R (n=18). In the lazertinib plus SBRT group, the median PFS was not reached (90% CI, 15.7-NA) and 27.6 months (90% CI, 18.2-NA) for Ex19del (n=17) and L858R (n=16), respectively. OS data remain immature with 3 death events at the time of data cutoff. The ORR was similar between both treatment groups (lazertinib, 62%; lazertinib + SBRT, 58%). Sites of progression were mainly the original sites in lazertinib group (n=11/14, 78%) and new sites in lazertinib plus SBRT group (n=12/13, 92%). In terms of toxicity profile, no new safety signals were seen in lazertinib plus SBRT arm, and no grade 3 or higher radiation pneumonitis was seen. There were no grade 4 or 5 adverse events in both arms. Additionally, whole exome sequencing and bulk RNA sequencing analyses using baseline tissue samples and tissues obtained at the time of progression are ongoing to reveal mechanisms of acquired resistance.

Conclusions: In patients with EGFR-mutant, oligo-metastatic NSCLC, the addition of SBRT to lazertinib is a feasible approach, leading to clinically meaningful improvement in terms of PFS, compared to historical data. The addition of SBRT was well-tolerated with previously reported safety profile.

Introduction: Firmonertinib (also known as furmonertinib) is a once-daily oral, highly brain-penetrant EGFR inhibitor with broad activity and selectivity across EGFR mutations. Firmonertinib has FDA breakthrough therapy designation and is being tested in a global, Phase 3 study in first-line (1L) EGFR ex20ins mutant NSCLC. P-loop and αC-helix compressing (PACC) mutations represent approximately 12% of EGFR mutations and are similar to ex20ins mutations in narrowing the drug-binding pocket of ATP competitive EGFR inhibitors. We report updated FURTHER trial clinical and translational results.

Methods: FURTHER (FURMO-002; NCT05364073) is a global, Phase 1b study. Stage 2, Cohort 4 (PACC cohort) enrolled NSCLC patients with EGFR PACC mutations randomized to two dose levels of firmonertinib (160 mg or 240 mg, QD). Key eligibility criteria include documented EGFR PACC mutation, measurable disease per RECIST 1.1, and no prior EGFR TKI. Patients with untreated but clinically stable brain metastases were eligible. Primary endpoint is confirmed ORR per RECIST 1.1 by BICR. Key secondary endpoints include PFS and duration of response (DoR).

Results: Updated efficacy results for 1L NSCLC patients (n=45 patients) with EGFR PACC mutations include ORR by BICR which was 81.8% (18/22; 95% CI, 59.7% - 94.8%) at 240 mg, and 52.2% (12/23; 95% CI, 30.6% - 73.2%) at 160 mg. Confirmed ORR by BICR were 68.2% (15/22; 95% CI, 45.1% - 86.1%) at 240 mg, and 43.5% (10/23; 95% CI, 23.2% - 65.5%) at 160 mg, and median DoR was 14.6 months at 240 mg and not reached (NR) at 160 mg. Median PFS by BICR was 16.0 months (95% CI, 12.5, NR) at 240 mg QD and 11.1 months at 160 mg (95% CI, 6.6, NR) with a hazard ratio of 0.728 (95% CI, 0.305, 1.736) and a median follow-up of 12.5 months for both dose levels. Antitumor activity was observed in both single PACC mutation (confirmed ORR by BICR of 60% [6/10; 95% CI, 26.2% - 87.8%] at 240 mg and 25% [3/12; 95% CI, 5.5% - 57.2%] at 160 mg) and compound PACC mutation (confirmed ORR by BICR of 75% [9/12; 95% CI, 42.8% - 94.5%] at 240 mg and 63.6% [7/11; 95% CI, 30.8% - 89.1%] at 160 mg) subgroups. In patients with brain metastases, CNS confirmed ORR by BICR was 50% (7/14) per modified RECIST. A rapid decrease in EGFR mutation variant frequency in ctDNA was overall consistent with radiographic responses. The adverse event profile was consistent with prior firmonertinib studies with dose reductions due to TRAEs occurring at 22.7% and 12.0% at 240 mg and 160 mg dose levels, respectively. Treatment discontinuation due to TRAE occurred at 0% and 4.0% at the 240 mg and 160 mg dose levels, respectively. Additional updated efficacy and safety data will be presented at the conference.

Conclusions: Updated FURTHER trial results demonstrate promising antitumor activity in 1L EGFR PACC mutant NSCLC patients treated with firmonertinib including prolonged DoR and PFS with a tolerable and manageable safety profile. Further investigation of firmonertinib in this patient population is planned, including future registrational studies.

P3.12.39 Long-Term Overall Survival in Advanced EGFRm NSCLC Treated With 1L Osimertinib: Results From the US, Japan, Germany and China

J. Nieva[1], P.S. Karia[2], P. Chander[3], M. Cooper[4], D. Doroshow[5], S. Tech[6], W.E. Eberhardt[7], F. Griesinger[8], M. Muto[9]

Introduction: Osimertinib is a third-generation, irreversible, central nervous system-active epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) that selectively targets EGFR-TKI sensitising and EGFR T790M resistance mutations. It is the global preferred first-line (1L) treatment for advanced EGFR-mutated (EGFRm) non-small cell lung cancer (NSCLC). We present data on long-term real-world overall survival (rwOS) from a global retrospective cohort, examining outcomes in patients with advanced EGFRm NSCLC who received 1L osimertinib.

Methods: Adults with stage IIIB-IV EGFRm NSCLC who initiated 1L osimertinib between April 2018 and December 2020 were identified through deidentified electronic health records from country-specific registries and hospitals. Participating countries included the US and Japan (via chart reviews), Germany (CRISP registry), and China (China Precision Medicine Registry). Median rwOS estimates were reported for the overall cohort and a subset of patients meeting the FLAURA trial (NCT02296125) inclusion criteria (ECOG 0/1 with EGFR Ex19Del/L858R, with or without other co-occurring EGFR mutations), referred to as the FLAURA-like cohort.

Results: Baseline patient characteristics are summarised in the Table. The median age at treatment initiation ranged from 62 to 71 years. Most patients were female, diagnosed with stage IV adenocarcinoma, and had classical EGFR mutations (Ex19Del or L858R). The proportion of patients with brain metastases at baseline ranged from 37% to 51%. Median follow-up times were 52.6 months in the US, 41.4 months in Japan, 35.1 months in Germany, and 35.5 months in China. Median rwOS in the overall cohort was 34.1 months (95% CI 25.6, 52.1) in the US, 39.7 months (95% CI 31.6, 51.8) in Japan, 30.1 months (95% CI 23.9, 35.8) in Germany, and 36.5 months (95% CI 27.6, NE) in China. For FLAURA-like patients, median rwOS was 37.2 months (95% CI 28.5, NE) in the US, 42.7 months (95% CI 37.8, NE) in Japan, 34.1 months (95% CI 27.0, NE) in Germany, and 36.5 months (95% CI 24.4, NE) in China.

Conclusions: The outcomes for patients in our study were consistent with the OS findings from the FLAURA trial (NCT02296125). Our results support the rwOS benefits of 1L osimertinib monotherapy in patients with EGFRm advanced NSCLC, including those who may not have qualified for the FLAURA trial.

Introduction: Patients with non-small cell lung cancer (NSCLC) harboring MET exon 14 (METex14) skipping are typically elderly with a poor prognosis, and therefore treatments with a manageable safety profile are especially relevant. Tepotinib is an oral, once-daily, and highly selective MET-tyrosine kinase inhibitor (TKI), approved in multiple countries for the treatment of advanced/metastatic NSCLC with METex14 skipping based on the outcomes from the VISION study. Safety outcomes and health-related quality of life (HRQoL) patient-reported outcomes (PROs) of tepotinib in VISION have previously been reported from earlier data cuts (safety: data cut-off: July 1, 2020 [Clin Lung Cancer 2022;23(4):320-332]; HRQoL PROs: data cut-off: February 20, 2022 [Poster 9060 presented at ASCO 2023]). Here, we report long-term safety outcomes and HRQoL PROs from VISION in patients with ≥3-years follow-up (data cut-off: May 20, 2024).

Methods: Patients with advanced EGFR/ALK wild-type NSCLC and METex14 skipping received tepotinib 500 mg (450 mg active moiety) once daily until disease progression, intolerable toxicity, or withdrawal of consent. Secondary endpoints included safety and HRQoL, which was assessed using the EORTC QLQ-C30 Global Health Score (GHS), EQ-5D-5L visual analog scale (VAS), and EORTC QLQ-LC13 cough, dyspnea, and chest pain scores. Mean change from baseline across all visits was evaluated by linear mixed model regression in patients with baseline and ≥1 post-baseline score.

Results: 313 patients were evaluated for safety. Median age of the patients was 72.0 years (range: 41-94), 50.8% were female, and 73.8% had an Eastern Cooperative Oncology Group performance status of 1. Patients had a median treatment duration of 7.5 months (0.03-83.12). All-cause any grade adverse events (AEs) occurred in 310 (99.0%; Grade ≥3: 68.4%) patients, while any grade treatment-related AEs (TRAEs) occurred in 287 patients (91.7%; Grade ≥3: 36.1%) patients. Any grade serious TRAEs were observed in 50 (16.0%) patients. The most common TRAEs were peripheral edema in 212 patients (67.7%; Grade ≥3: 11.8%), hypoalbuminemia in 79 patients (25.2; Grade ≥3: 3.8%), and nausea in 73 patients (23.3%; Grade ≥3: 0.6%). TRAEs led to permanent discontinuation in 49 (15.7%) patients. At the end of treatment, in patients analyzed for HRQoL, the mean change (±standard deviation) from baseline for EORTC QLQ-C30 GHS was −7.1 (26.66) (n=174) and for EQ-5D-5L VAS was −10 (23.7) (n=172), with positive values indicating an improvement. Mean change (±standard deviation) from baseline in EORTC QLQ-LC13 symptom scores for cough, dyspnea, and chest pain were −6.1 (28.16) (n=175), 7.1 (21.05) (n=175), and −2.3 (28.13) (n=174), respectively, with negative values indicating improvement. Median time to deterioration of EORTC QLQ-LC13 symptom scores was 36.5 months for cough, 30.4 months for chest pain, and 5.5 months for dyspnea. Overall, HRQoL PROs remained stable during treatment with tepotinib.

Conclusions: In patients with ≥3-years follow-up, tepotinib demonstrated a continued manageable safety profile with no new safety signals, as well as stability in HRQoL PROs, consistent with earlier findings. These considerations support maximizing clinical benefits for this elderly patient population while maintaining their quality of life.

Introduction: Mutations in HER2 occur in about 2-4% of patients with non-small cell lung cancer (NSCLC) and are associated with unfavorable outcomes. Sevabertinib is a potent, oral, reversible HER2 tyrosine kinase inhibitor that has demonstrated durable responses and a manageable safety profile in patients with advanced NSCLC having HER2 mutations. Our exploratory analysis assessed the impact of baseline clinical characteristics and molecular alterations on treatment outcomes.

Methods: Patients from expansion Cohort D of the SOHO-01 Phase I/II study (NCT05099172) were included in this analysis. All had advanced NSCLC with a HER2-activating mutation and experienced disease progression after at least one systemic therapy, but were naïve to HER2-targeted therapy, and received treatment with sevabertinib 20 mg twice daily. Plasma ctDNA was assessed using the Thermo Fisher Scientific Oncomine™ Precision Assay. HER2 variant information and co-alteration data were used to assess the correlation with investigator-assessed treatment response and outcomes.

Results: Of the 44 patients treated in expansion Cohort D, 43 patients who had a post-baseline tumor assessment were included. At baseline, median age was 62.0 years, 65.1% were female, 72.1% had never smoked, and 46.5% had received <2 prior lines of therapy. Treatment with <2 vs ≥2 prior lines of therapy was associated with a higher objective response rate (75.0% vs 69.6%), longer median duration of response (DoR: not reached vs 5.2 months), and improved median progression-free survival (PFS: not reached vs 6.7 months). TP53 mutations were the most frequently observed co-alterations, found in 13 out of 37 patients (35.1%) with detectable HER2 ctDNA. The HER2 Y772_A775dup (YVMA) variant appeared to be associated with enhanced treatment efficacy, whereas the presence of a TP53 co-alteration was not. Multivariate analysis indicated that both TP53 and HER2 YVMA provide independent prognostic information. Patients lacking TP53 co-alterations and having the YVMA variant showed favorable responses and outcomes, similar to those who had received only one prior therapy.

Conclusions: This exploratory analysis of clinical and molecular factors in patients with HER2-mutant NSCLC indicates favorable DoR and PFS among those who had received only one prior line of therapy or who had specific molecular characteristics. The findings underscore the importance of integrating clinical and molecular features to identify potential prognostic or predictive markers. As part of an ongoing study, these preliminary results emphasize the need for validation in a larger sample size to confirm these insights and further explore therapeutic strategies for patients with HER2-altered cancers.

P3.12.42 Concurrent KRAS Mutations Render Single-Agent EGFR Inhibitors Futile in Advanced NSCLC

I. Aza[1,2], M. Nagasaka[3], A. Azmi[4], T. Al Baghdadi[5], E. Dib[5], F. Abu-Rous[6], A. Qin[7], R. Shah[2], N. Vojjala[2], K. Goyal[2], G. Li[8], J. Quintanilha[8], J. Altenburg[8], R. Graf[8]

Introduction: Anti-EGFR tyrosine kinase inhibitors (TKI) are transformational drugs for patients with advanced NSCLC and EGFR alterations. Osimertinib, a third generation TKI, is considered first line for metastatic EGFRmut(+) NSCLC, among other TKIs. While rare, some tumors with EGFR alterations have concomitant KRAS mutations, and may have an activated oncogenic pathway not inhibited by current TKIs. We hypothesized that patients with EGFR-mutant NSCLC receiving current generation anti-EGFR targeted therapy will have reduced clinical benefit when there are co-occurring KRAS alterations.

Methods: Following a prespecified analysis plan, this study used the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine NSCLC clinico-genomic database (FH-FMI CGDB), with data originating from approximately 280 US cancer clinics (~800 sites of care). The prevalence cohort included patients with NSCLC treated in the advanced setting with first-line and had both EGFR and KRAS status assessed via tissue NGS obtained prior to treatment initiation. The outcome cohort included patients in the prevalence cohort treated with single-agent anti-EGFR TKIs and were EGFRmut(+). Differences in outcomes between groups were assessed via Kaplan-Meier plots and multivariable Cox PH models additionally adjusting for clinical factors: age, sex, ECOG performance score, pre-therapy [IA1] opioid prescription, presence of brain or bone metastases, socioeconomic status, histology, stage at diagnosis, and specific TKI. We additionally explored similar outcome associations on standard chemotherapy regimens.

Results: Prevalence cohort: among 10,740 1st line treatment decisions, 1359 (12.6%) were EGFRmut(+), and among these, 36 (2.5%) had EGFR and KRAS co-mutations. Outcome cohort: of 859 patients with EGFR-alterations meeting selection criteria, 11 (1.2%) had co-alteration of EGFR and KRAS, with the rest being KRAS wild-type. Among the 11 co-altered, 2 had EGFR exon 19 deletion, 2 had L858R, 6 had other EGFR alterations, and 1 had multiple EGFR alterations. Among co-altered, 4 received afatinib, 1 received getfitinib, and 6 received osimertinib. Compared to those with wild-type KRAS, co-altered patients had shorter median PFS (4.2 vs. 12.4 months, adjusted HR: 2.41, 95%CI: 1.24 - 4.65, p = 0.009) and directionally consistent OS (17.7 vs. 26.2 months, adjusted HR: 1.5, 95%CI: 0.71 - 3.17, p = 0.284). Evaluating patients who received chemotherapy and not anti-EGFR TKIs, we additionally saw less favorable PFS (HR: 2.66, 95%CI: 1.47 - 4.81, p = 0.001) and directionally consistent OS (HR: 1.24, 95%CI: 0.57 - 2.66, p = 0.59). Additional associations of specific concurrent KRAS alterations and prior treatment exposure will be presented at conference.

Conclusions: While rare, co-alteration of EGFR and KRAS appears to be a poor prognostic marker and compromises anti-EGFR treatment efficacy with numerically lower PFS (statistically significant) and OS for current generation TKIs. The results are consistent with our biologically informed hypothesis. We also saw similar associations with standard chemotherapy, underscoring the challenge of treating this subgroup Recently, the FLAURA2 (chemotherapy/Osimertinib) and MARIPOSA: Amivantamab/Lazertinib trials showed improved PFS as compared to osimertinib but with increased toxicity. In the setting of approved treatment-intensification strategies, co-alteration of KRAS should be further evaluated as a biomarker of aggressive disease that may warrant more aggressive frontline treatment.

P3.12.43 A Phase II Study of Sunvozertinib Combined With Anlotinib in NSCLC Patients Harboring EGFR Ex20Ins and Uncommon EGFR Mutations

H-Y. Xu, Y. Wang, R. Sun, H. Shi, L. Tian, F. Wei, Y. Wang
National Cancer Center, National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Sunvozertinib is an oral, potent, highly selective epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) has been approved in China for ≥second-line treatment of advanced NSCLC with EGFR exon 20 insertion mutation (exon20ins). In previous reports, sunvozertinib monotherapy has demonstrated promising and durable anti-tumor activity in EGFR exon20ins and uncommon mutation. Preclinical studies indicated that the combination of an EGFR-TKI plus a VEGF inhibitor (VEGFi) resulted in a synergistic effect. This is the first report about sunvozertinib combination therapy with anti-angiogenic drug in EGFR exon20ins and uncommon EGFR mutations.

Methods: This open-label, single arm, phase II study is planned to enroll 40 patients into two groups. Cohort 1 was defined as previously untreated patients with EGFR exon20ins. Cohort 2 was defined as previously treated patients with uncommon EGFR mutations. This study has two parts. Part A adopted the dose-reduction safety run-in design to assess the tolerability and safety of sunvozertinib combined with anlotinib. The initial dosing of sunvozertinib was 300 mg p.o. daily in combination with anlotinib 8 mg p.o. daily from day 1 to day 14 (21 days per cycle). Part B is an expansion period at the recommended combination dose (RCD). The primary endpoint of this study is objective response rate (ORR). Secondary endpoints include disease control rate (DCR), progression free survival, overall survival and safety profile.

Results: As of the 31th, March 2025 (DCO), 10 patients had successfully passed dose reduction safety run-in part and 2 patients was enrolled in dose expansion part. Sunvozertinib in combination with anlotinib was well tolerated, no DLT event occurred, and the RCD was sunvozertinib 300 mg p.o. daily in combination with anlotinib 8 mg p.o. daily from day 1 to day 14 (21 days per cycle). Overall, 10 patients completed first assessment. The ORR was 100%. These 10 cases include 9 previously untreated patients with EGFR exon20ins and one patient harboring with EGFR uncommon mutation (G719S and L861Q). In this uncommon EGFR mutation case, we also observed complete remission of the intracranial lesions. As of the DCO, all patients remained on treatment. The common (≥10%) TEAEs were diarrhea, rash, hypertension, hepatic dysfunction and oral ulcer. Only one patient required dose reduction of sunvozertinib due to diarrhea. No sunvozertinib-related discontinuations and no treatment related deaths were observed.

Conclusions: Sunvozertinib in combination with anlotinib is well tolerated and has demonstrated encouraging antitumor activity in NSCLC patients with EGFR exon20ins and uncommon EGFR mutations. Enrollment is currently ongoing and results will be updated in the meeting.

Keywords: EGFR ex20ins, uncommon EGFR mutation, sunvozertinib

P3.12.44 A Retrospective Study of the Effect of Cumulative Smoking Dose on Clinical Course in People With EGFR-Mutated NSCLC Treated With Osimertinib

T. Ito, O. Kanai, Y. Okada, S. Toyama, T. Imakita, I. Oi, K. Fujita, K. Tanizawa
NHO Kyoto Medical Center, Kyoto/JP

Introduction: Non-small cell lung cancer (NSCLC) harboring epidermal growth factor receptor (EGFR) mutations are more common in people with non-smoking (NS). In analyzing the impact of smoking history on anticancer therapy, smoking history is usually stratified into two groups, NS versus smokers. However, it is controversial whether it is correct to divide smoking into only these two groups. Previous reports have shown that cumulative smoking dose (CSD) had significant impacts on clinical outcomes in first- and second-generation EGFR-tyrosine kinase inhibitors (TKIs), but there has been no study for osimertinib, which is the most frequently used agent recently. Thus, in this study, we investigated the impact of CSD on progression free survival (PFS), objective response rate (ORR), overall survival (OS), and type of genetic mutation other than EGFR in treatment with osimertinib.

Methods: We retrospectively reviewed people with NSCLC treated with osimertinib at our institution from October 2016 to June 2024. Primary endpoint was designated as PFS, and secondary endpoints were ORR, OS and genetic mutation. CSD was classified into three groups: NS, light-smoking (<20 pack-year (PY), LS) and heavy-smoking (≥20 PY, HS).

Results: There were 109 eligible participants, 64 with NS, 20 with LS, and 25 with HS, respectively. The overall median age was 74 years, with a larger proportion of women overall (64.2%) but a larger proportion of men among LS (60.0%) and HS (80.0%). The proportion of osimertinib administered as the first-line therapy was not significantly different between the groups. Median PFS was 14.3 months (mo.) for NS, 9.0 mo. for LS, and 3.7 mo. for HS, with a statistically significant difference (p=0.031 estimated by the Log-rank test). ORR was 73.4% for NS, 65.0% for LS, and 72.0% for HS (p=0.765). Median OS was 30.8 mo. for NS, 31.9 mo. for LS, and 24.5 mo. for HS (p=0.329). Cox proportional hazard model for PFS showed a trend of decreasing the efficacy of osimertinib with increasing CSD [hazard ratio (HR), 1.17; 95% confidence interval (CI), 0.65-2.09; p=0.596 for LS, HR, 1.93; 95% CI, 1.17-3.18; p=0.010 for HS], but the model for OS showed no significant difference (HR, 0.93; 95% CI, 0.49-1.78; p=0.838 for LS, HR, 1.46; 95% CI, 0.85-2.52; p=0.173 for LS). The frequency of gene mutations other than EGFR was 18.8% in NS, 15.0% in LS, and 20.0% in HS, showing no significant difference (p=0.331).

Conclusions: As with first- and second-generation EGFR-TKIs, PFS of osimertinib shortened significantly with increasing CSD. Osimertinib monotherapy may have insufficient efficacy on EGFR-mutated NSCLC for those with high CSD.

P3.12.45 Aumolertinib for Treatment-Naïve EGFR-Mutant NSCLC Patients With Brain Metastases: Updated Efficacy Data From the ARTISTRY

X. Zhang, C.h. Wei, X.Y. Du, M.n. Zhang, G. Zhang, H. Wang
The affiliated hospital of Zhengzhou university, Henan Cancer Hospital, Zhengzhou/CN

Introduction: Brain metastases (BMs) represent the most prevalent site of distant metastasis in non-small cell lung cancer (NSCLC). Patients with BMs generally have a poor prognosis. Notably, the incidence of BMs is significantly higher, ranging from 44% to 63% in EGFR mutant NSCLC patients. Thus, investigating the optimal treatment for BMs in EGFR mutant NSCLC patients has substantial clinical significance. Results from the FLAURA and AENEAS trials demonstrated that third -generation EGFR-TKIs exhibit superior efficacy and safety compared to first-generation EGFR-TKIs in patients with BMs harboring EGFR mutations. The BLOOM study indicated that high-dose EGFR-TKIs are highly effective in treating leptomeningeal metastases. ARTISTRY (NCT04778800) is an ongoing dose-escalation study. It evaluates the third-generation EGFR-TKI aumolertinib in three cohorts of EGFR-mutated NSCLC patients with brain or leptomeningeal metastases. Here, we report updated efficacy and safety data from cohort 1, which focuses on patients with brain parenchymal metastases.

Methods: Treatment-naïve EGFR-mutant NSCLC patients with brain parenchyma metastases received aumolertinib 110mg orally once daily. The dose was then escalated to 165mg in case of only intracranial progression. Assessments were performed every 4 weeks and then every 8 weeks after 2 consecutive disease control until extracranial progression as per RECIST v1.1. The primary endpoint was progression free survival (PFS), which included PFS1 during the standard-dose phase for all patients and PFS2 during the subsequent dose-escalation phase for patients with intracranial progression as the initial progression. Other endpoints were intracranial objective response rate (iORR), intracranial disease control rate (iDCR), ORR, DCR and safety.

Results: At data cut-off (January, 2025), a total of 30 patients were enrolled. The median age was 59.5 years, and 20% of the patients were male. In the 110mg period, the ORR was 90% and the DCR was 96.7%. The median PFS1 was 17.1 months (95% CI:15.0-26.40). Eight patients achieved intracranial complete remission during the treatment with the standard dose of aumolertinib. The iORR was 86.7% and the iDCR was 96.7%. The median iPFS1 was not reached (95% CI: 19.10-NR). Seven patients had intracranial metastasis as the initial lesion in progression. One withdrew from the study, while the remaining six underwent dose escalation to 165 mg/day of aumolertinib. During 165mg treatment, the iORR and iDCR were 33.3% (2/6) and 100% (6/6), respectively. The iPFS2 was 12.8m (95% CI: 4.40-12.80). The mPFS2 was 8.7 months (95% CI: 2.00-17.10). The most common grade 1-2 adverse events (AEs) in all patients were elevated creatine kinase, alanine aminotransferase increased, glutamic aminotransferase increased.

Conclusions: Aumolertinib showed superior antitumor activity with a manageable safety profile as first-line therapy in EGFR-mutant NSCLC patients with brain metastases, and patients with brain metastases progression still benefit from high dose Aumolertinib. Enrollment for this trial will continue, and further analyses are warranted to determine longer-term outcomes.

Introduction: First-line amivantamab-lazertinib significantly prolonged overall survival (OS) versus osimertinib among participants with EGFR-mutant advanced NSCLC in MARIPOSA (P<0.005). The phase 2 COCOON study (NCT06120140) demonstrated early success (median follow-up: 4.2 months), showing a significant reduction in grade ≥2 dermatologic adverse events (AEs) with enhanced (COCOON) vs standard-of-care (SoC) dermatologic management (P<0.0001). Here, we report results from the fully-enrolled population.

Methods: Eligible participants with previously-untreated, EGFR-mutant (Ex19del/L858R) locally advanced or metastatic NSCLC were randomized 1:1 to receive COCOON dermatologic management (DM), described below, or only SoC DM. All participants received standard-dose IV amivantamab plus oral lazertinib and SoC DM. Prophylactic anticoagulation was mandatory for the first 4 months of anticancer treatment. COCOON DM included oral doxycycline or minocycline 100 mg (twice daily, Weeks 1-12), chlorhexidine 4% on fingernails/toenails daily for 12 months, clindamycin 1% lotion on the scalp (daily, Weeks 13-52), and ceramide-based moisturizer for the face/body for 12 months. Primary endpoint was incidence of grade ≥2 dermatologic AEs of interest in the first 12 weeks of anticancer treatment

Results: As of 12-Mar-25 (median follow-up: 7.1 months), 199 participants received COCOON DM (n=99) or SoC DM (n=100) with amivantamab-lazertinib. Median age was 63 years; 59% were female, and 77% remain on anticancer treatment as of clinical cutoff.

Based on full trial enrollment, the COCOON DM regimen demonstrated a significant reduction in grade ≥2 dermatologic AEs in the first 12 weeks vs SoC DM (41% vs 73%; OR, 0.26 [95% CI, 0.14-0.47]; P<0.0001; Figure 1). By Week 12, the largest benefit with COCOON DM was observed in face/body dermatologic AEs (excludes paronychia; 26% vs 59%; P<0.0001) and scalp dermatologic AEs (10% vs 26%; P=0.005); paronychia incidence was comparable (20% vs 21%). Discontinuations of amivantamab or lazertinib due to any AE were lower with COCOON DM vs SoC DM (16% vs 20%). The COCOON regimen was well-tolerated, with only 2 participants discontinuing doxycycline or minocycline due to treatment-related AEs.

Objective response rate (investigator-assessed) was 81% in the COCOON DM arm and 76% in the SoC DM arm, consistent with prior reports for first-line amivantamab-lazertinib. Additional results will be reported at the meeting.

Conclusions: An easy-to-use, widely available, prophylactic regimen (COCOON DM) reduced the incidence and severity of dermatologic AEs with amivantamab-lazertinib. New approaches focusing on a simplified regimen with early intervention are being investigated. This optimization, along with an OS improvement, further enhances the benefit-risk profile for first-line amivantamab-lazertinib.

P3.12.47 A Phase II Study of Sunvozertinib Combined With Chemotherapy in EGFR-TKIs Resistant EGFRm Advanced NSCLC Patients(WU-KONG36)

F. Na, m. yu, w. xiu, j. li, l. xiang, y. li, s. zeng, x. zhang, l. zhou, y. wang, y. gong, b. zou, m. huang, j. xue, y. lu
west china hospital,Sichuan university, Chengdu/CN

Introduction: Sunvozertinib is a highly selective EGFR tyrosine kinase inhibitor (TKI) targeting various EGFR mutations. In previous reports, Sunvozertinib monotherapy has demonstrated promising and durable anti-tumor activity in EGFR sensitizing mutations (EGFRm), who failed standard EGFR TKI treatment. Preclinical studies also shown that the combination of Sunvozertinib and chemotherapy resulted in a synergistic effect. This is the first report about sunvozertinib in combination with chemotherapy in EGFRm NSCLC.

Methods: Methods: This open-label, single arm, phase II study is planned to enroll 40 patients, which harbored EGFR sensitizing mutations and failed standard EGFR-TKI treatment. This study has two parts. Part A adopted the dose-reduction safety run-in design to assess the tolerability and safety of Sunvozertinib combined with chemotherapy. The initial dosing of Sunvozertinib was 200 mg p.o. daily in combination with pemetrexed plus cisplatin or carboplatin, followed by pemetrexed maintenance and Sunvozertinib 200 mg. Part B is an expansion period at the recommended combination dose (RCD). The primary endpoint of this study is objective response rate (ORR). Secondary endpoints include disease control rate (DCR), progression free survival, overall survival and safety profile. In this study, we also explored the potential resistance mechanisms based on NGS testing.

Results: As of the 23th, March 2025 (DCO), 9 patients had successfully passed dose reduction safety run-in part. Sunvozertinib in combination with chemotherapy was well tolerated, with no DLT event. Overall, 9 patients completed first assessment. The ORR was 33.3%, and DCR was 77.8%. The common (≥30%) TEAEs were anemia, neutrophil count decreased, alanine aminotransferase increased, white blood cell count decreased, platelet count decreased, and aspartate aminotransferase increased. No Sunvozertinib-related discontinuations or reductions and no treatment related deaths were observed.

Conclusions: Sunvozertinib in combination with chemotherapy is well tolerated and has demonstrated encouraging antitumor activity in NSCLC patients with EGFR mutations who failed prior EGFR-TKIs therapies. Enrollment is currently ongoing and results will be updated in the meeting.

Keywords: NSCLC, TKI failure, sunvozertinib

P3.12.48 Efficacy and Safety of Savolitinib in Advanced or Metastatic METex14 NSCLC Patients With or Without Prior Immunotherapy

Introduction: For treatment-naïve, biomarker-driven, gene-positive, advanced or metastatic non-small cell lung cancer (NSCLC), the recommended first-line regimen is gene-targeted therapy with or without chemotherapy; but few patients (pts) would receive immunotherapy (IO). We previously reported the primary results of savolitinib (savo, a highly selective oral MET inhibitor) in advanced or metastatic MET exon 14 mutation (METex14) NSCLC in a phase 3b confirmatory study (data cut-off date: Oct 20, 2023; Shun L, et al. ELCC 2024). Herein, we evaluated whether prior IO potentially impacted the efficacy and safety of savo in this phase 3b study.

Methods: Eligible pts with advanced or metastatic METex14 NSCLC received savo once daily at 600 mg (≥50 kg) or 400 mg (<50 kg). Previously treated (≥2L) pts were included in the post-hoc analysis, which examined baseline characteristics, efficacy, and safety variables, in populations who had been treated with prior IO (prior IO-treated) and had not (prior IO-naïve).

Results: As of Nov 30, 2024, in 79 previously treated pts, 19 pts were prior IO-treated, and 60 were prior IO-naïve. The median follow-up was 21.2mo. No notable differences in baseline characteristics were observed between the two populations. Among the prior IO-treated population (n=19), the Independent Review Committee-assessed objective response rate (ORR), disease control rate (DCR), and median progression-free survival (PFS) were 31.6%, 94.7%, and 9.7mo, respectively; median overall survival (OS) was 18.0mo. A trend toward improved response and survival was observed in prior IO-naïve population (n=60), with corresponding efficacy variables of 45.0%, 91.7%, 13.7mo, and 25.3mo, respectively (Table 1). A more favorable safety profile was also identified in prior IO-naïve population. The incidence of grade ≥3 treatment-related adverse events (TRAEs) was 63.2% vs 51.7%, the incidence of TRAEs leading to dose interruption or reduction was 89.5% vs 60.0%, and the incidence of TRAEs leading to discontinuation was 15.8% vs 5.0%, in prior IO-treated vs prior IO-naïve populations, respectively.

Table 1 Efficacy Summary

	IRC		Investigator	
	Prior IO-treated (N = 19)	Prior IO-naive (N = 60)	Prior IO-treated (N = 19)	Prior IO-naive (N = 60)
ORR (95%CI), %	31.6 (12.6, 56.6)	45.0 (32.1, 58.4)	31.6 (12.6, 56.6)	53.3 (40.0, 66.3)

Ltd, Tokyo/JP

Introduction: The lung cancer genomic screening platform (LC-SCRUM-Asia) started in Japan, which expanded to other Asia-Pacific countries (LC-SCRUM-AP). The objective of this study is to elucidate the clinical significance of genomic screening in Asia-Pacific countries and to compare the current situation of targeted therapies in Asia-Pacific countries with that in Japan.

Methods: 14 institutions in Taiwan, Thailand, Malaysia, and Vietnam are participating in the LC-SCRUM-AP. Samples are analyzed by a rapid multi-gene PCR assay, AmoyDx® Pan Lung Cancer PCR Panel, and a high-spec next-generation sequencing assay, Oncomine™ Precision Assay. Clinical, pathological and genomic data are stocked as a clinical-genomic database in each participating country, which was compared with that of 6753 Japanese-cohort with matched clinical characteristics (LC-SCRUM-Asia data from June 2019 to March 2024).

Results: From January 2023, a total of 345 non-small cell lung cancer (NSCLC) patients has been enrolled from 3 countries (Taiwan/Thailand/Malaysia = 149/102/94 pts). A multi-gene PCR assay data was available in 317 cases. The median turn-around time (TAT) was 5 days, and the genomic analysis successful rate was 99.7%. The frequency of driver alterations in the Taiwan/Thailand/Malaysia cohort (AP-cohort) were shown in Figure 1. The information regarding treatment history was available in 222 cases of the AP-cohort, which was compared with that of the Japanese-cohort. In the AP-cohort, oncogenic driver alteration was detected in 154 patients, of which 117 (76%) received targeted therapies. Proportion of patients received targeted therapies were similar between the AP-cohort and Japanese-cohort in the EGFR mutations excluding ex20ins (AP-cohort vs. Japanese-cohort = 95% vs. 90%), ALK fusions (AP-cohort vs. Japanese-cohort = 100% vs. 91%), and ROS1 fusions (AP-cohort vs. Japanese-cohort = 78% vs. 84%). Meanwhile, proportion of patients received targeted therapies for BRAF V600E tended to be lower in the AP-cohort (AP-cohort vs. Japanese-cohort = 0% vs. 70%). For the patients with EGFR ex20ins, while no patient received targeted therapy in the AP-cohort, 20% of the Japanese-cohort enrolled in the clinical trials for targeted agents.

Conclusions: LC-SCRUM-AP enables the efficient detection of driver alterations in NSCLC with a short TAT. This screening platform highly contributed to deliver targeted therapies in Asia-Pacific countries with a high implementation rate. Proportion of patients received targeted therapies depended on the approval and insurance reimbursement status in each country. For BRAF V600E and EGFR ex20ins mutations, it was shown that patients in Asia-Pacific countries tended to have less access to targeted therapies than those in Japan.

P3.12.50 A Prognostic Model Based on a Concurrent Gene Mutational Signature for EGFR Mutant NSCLC With TKI Treatments

Q. Wang, X. Liu, C. Su
Shanghai Pulmonary Hospital, Tongji University, Shanghai/CN

Introduction: EGFR-TKIs significantly improved the survival and the quality of life of NSCLC patients with EGFR mutations. Understanding specific concurrent genetic changes and how they influence the efficacy of EGFR-TKI therapy is necessary to optimize clinical outcomes.

Methods: Using next-generation sequencing (NGS), 82 individuals who harbored EGFR mutations and received TKI treatment were included. The K-M curve and log-rank test analyzed survival significance. SelectKBest was conducted 100 times to screen the concurrent genetic alterations (score > 20; select_num ≥ 80) that were crucial to predict PFS, and t-SNE was used to establish a co-mutational gene signature. Straightforward data augmentation was used to introduce 1000 new data samples as the training group, and the original 82 data served as the testing group. A multivariate model was developed using random forests and a bootstrap resampling method (n = 100) to predict the PFS of EGFRMT NSCLC treated with TKIs.

Results: Based on the univariate Cox regression, age (P = 0.023), M-stage (P = 0.037), the line of TKI treatment (P = 0.018), and the single nucleotide variation (SNV) of GSTM1 (P = 0.029) were independent predictors for PFS. Moreover, a remarkably shorter PFS was observed in GSTM1MT patients than in GSTM1WT patients. Six concurrent gene mutations were screened, and based on them, a concurrent gene mutational signature was established. The combination of age, M stage, the line of TKI treatment and the concurrent gene mutational signature demonstrated an accurate prediction for 6 month-PFS (Accuracy = 0.868 ± 0.021, F1-score = 0.924 ± 0.011) and 9 month-PFS (Accuracy = 0.807 ± 0.029, F1-score = 0.854 ± 0.023). There was also a dramatic improvement of the combinational model to the predictive ability of age, M-stage, the line of TKI treatment, and GSTM1 mutation status (all P < 0.001 for 6-month-PFS and 9-month-PFS).

Conclusions: This is the first study to report that SNV of GSTM1 reduces TKI responsiveness and worsens prognosis in patients with EGFRMT NSCLC. In addition, we developed a prognostic model based on a concurrent gene mutational signature for EGFR mutant NSCLC treated with TKIs.

P3.12.51 Patient-Derived Organoids as Preclinical Models for Drug Resistance in NSCLC

N. Radulovich, K. Jafarova, Q. Li, M. Wang, G. Liu, M.S. Tsao
University Health Network, Toronto/ON/CA

Introduction: Precision medicine has introduced targeted therapies for patients with non-small cell lung cancer (NSCLC) harboring molecular alterations in EGFR, ALK, ROS1, RET, NTRK, HER2, MET, and KRAS. However, at least 25% of NSCLC patients lack targetable drivers, and even those who initially respond to TKIs eventually develop drug resistance, making resistance a major cause of death. Available preclinical models like 2D cell lines fail to capture the heterogeneity and complexity of NSCLC, while patient-derived organoids (PDOs) offer a promising alternative by preserving key histologic and molecular traits and allowing rapid drug screening. Unlike patient-derived xenografts (PDXs), PDOs are scalable and can be established within weeks. Our group has developed a research pipeline at Princess Margaret Cancer Centre to generate and screen PDO models efficiently. Our project aims to assess whether molecular profiling and drug screening of PDO models, generated at the time of acquired TKI resistance, can guide the selection of optimal subsequent therapies for NSCLC patients.

Methods: PDO models were generated from patients with advanced, treatment-resistant lung adenocarcinoma at the time of resistance to initial TKIs. Long-term, renewable PDO models underwent quality control testing, including STR profiling, mycoplasma testing, and histological analysis. Additionally, whole-exome sequencing (WES) and RNA sequencing (RNA-seq) were used to profile genomic alterations in the PDOs. PDO models underwent drug screening to assess correlation with patient's response to TKI therapy. Organoids were plated in 384-well drug plates, treated with TKI drugs at different concentrations, and cell viability was measured after six days. Drug sensitivity curves were generated for individual compounds using a 21-point dose-response assay.

Results: We processed 52 biopsies and 61 pleural fluid samples from patients with advanced, TKI-resistant NSCLC to generate organoid models. Organoid initiation rates (any growth in P0) were 29% for biopsies and 36% for pleural fluid samples, while establishment rates (expansion for ≥10 passages) were 2% and 10%, respectively. We successfully developed seven long-term patient-derived organoid models with oncogenic mutations in ERBB2, KRAS, MET, and EGFR genes. These patients were resistant to TKI inhibitors, including Afatinib, Capmatinib, Gefitinib, Amivantamab, and Trastuzumab. Histopathological and genomic analyses confirmed that PDO models accurately reflected tumor biology, with sequencing verifying driver mutations from original patient tissues. PDO drug screening demonstrated high concordance with patient responses and proved amenable to high-throughput and synthetic lethality screening.

Conclusions: We demonstrate that patient-derived organoids (PDOs) can be successfully generated from treatment-resistant NSCLC patients and serve as a valuable preclinical model for studying TKI resistance. The high concordance between PDO drug screening and patient responses highlights the potential of these models to guide personalized treatment decisions. Additionally, the scalability and rapid establishment of PDOs make them well-suited for high-throughput and synthetic lethality screening, offering a promising platform for identifying novel therapeutic strategies in TKI-resistant NSCLC.

P3.12.52 Aumolertinib Plus Anlotinib in Advanced EGFR-Mutant NSCLC With TP53 Co-Mutation: A Single-Arm, Phase II Study

H. Sun[1], Z. Pan[1], Z. Jiang[1]
[1]Tianjin medical university cancer institute & hospital, Tianjin/CN

Introduction: Based on the AENEAS study, aumolertinib has superior efficacy as the first-line standard treatment. However, its efficacy against concurrent mutations remains unclear, especially for the high incidence (up to 55%-65%) of TP53 co-mutation. In recent RELAY and ACTIVE studies, subgroup analysis has shown particular benefits for patients receiving dual inhibition of EGFR and angiogenesis. Herein, we conduct a prospective study to explore aumolertinib combined with anlotinib as a first-line treatment option for advanced NSCLC harboring EGFR mutation and TP53 co-mutation. (NCT05778149)

Methods: Treatment-naïve EGFR-positive NSCLC pts with TP53 co-mutation were enrolled including pts with at least one assessable lesion (RECIST 1.1). All pts received aumolertinib (110mg, orally QD) plus anlotinib (12mg, orally QD, day 1 to 14 of a 21-day cycle) until disease progression or intolerable adverse reactions or death. The primary endpoint is progression free survival (PFS). Secondary endpoints include objective response rate (ORR), disease control rate (DCR), overall survival (OS) and safety.

Results: At data cut-off (February, 2025), we recruited 15pts in this trial, of which 14 pts were evaluable. All pts underwent NGS testing, and various types of exon mutations were identified. The baseline characteristics were presented in Table 1. The mPFS was 25 months (95%CI 11.0-NA), with a median follow-up time of 23 months (95%CI 8.0-31.0). The ORR and DCR were 57.1% (5/14) and 100% (14/14), respectively. Total pts were divided into two subgroups according to gene type, ORR was 66.7% (4/6) in the 19del group and 50% (4/8) in 21L858R group. Hypertension was the most common adverse reaction (64.2%), majority of the AEs were <Grade 3. No new safety signals were identified.

Table 1 Baseline Characteristics(n=15) p class="MsoNormal">

Conclusions: This represents the first prospective study evaluating aumolertinib plus anlotinib in NSCLC patients with TP53 co-mutations, demonstrating promising efficacy and favorable safety profile. Enrollment for this trial will continue, and further analyses are warranted.

P3.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY
TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.53 High-Dose Furmonertinib Plus Bevacizumab in EGFR-Mutant NSCLC With CNS Metastases After Resistance to Third-Generation EGFR-TKIs

Y. Pan, M. Li, M. Yu, J. Chen, H. Yu, K. Liu, l.k. chen
sun yat-sen university cancer center, guangzhou/CN

Introduction: Third-generation EGFR tyrosine kinase inhibitors (TKIs) have significantly improved outcomes in EGFR-mutant non-small cell lung cancer (NSCLC), but acquired resistance inevitably occurs, especially in patients with central nervous system (CNS) metastases. Antiangiogenic therapy (eg, bevacizumab) can transiently normalize the tumor vasculature and blood-brain barrier, potentially enhancing CNS drug delivery and efficacy of EGFR-TKIs. This research aimed to evaluate the efficacy of high-dose furmonertinib (a third-generation EGFR-TKI) combined with bevacizumab in EGFR-mutant NSCLC patients with CNS metastases who progressed after prior third-generation EGFR-TKI therapy.

Methods: A single-center retrospective study was performed focusing on EGFR-mutant NSCLC patients with CNS metastases (including leptomeningeal metastases and/or brain parenchymal) who had disease progression after at least one prior third-generation EGFR-TKI. All patients received furmonertinib 160 mg once daily plus bevacizumab 7.5 mg/kg every 3 weeks until progression or unacceptable toxicity. Intracranial progression-free survival (iPFS) and overall progression-free survival (PFS) were the primary endpoints; secondary endpoints included intracranial and systemic objective response rates (ORR) and safety. Kaplan-Meier methods were used to estimate survival outcomes, and Cox proportional hazards regression was employed for univariate and multivariate analysis of prognostic factors.

Results: As of February 2025, a total of 78 patients were included with a median follow-up of 8.75 months (Q1-Q3, 6.03-14.70), the median iPFS was 7.63 months (95% confidence interval [CI]: 0.95-not reached [NR]), and median overall PFS was 6.37 months (95% CI: 0.95-NR). The intracranial ORR was 29.5%, and the systemic ORR was 42.3%. Median overall survival data were not yet mature. In patients with both brain parenchymal and leptomeningeal metastases (n = 47), median iPFS was 7.63 months (95% CI: 0.95-NR) and PFS 5.80 months (95% CI: 0.95-NR), with an intracranial ORR of 31.9% and systemic ORR of 53.2%. In patients with brain-only metastases (n = 31), median iPFS was 7.20 months (95% CI: 0.95-NR) and PFS 6.70 months (95% CI: 0.95-NR), with iORR 25.8% and ORR 25.8%. Multivariate Cox analysis showed that EGFR exon 19 deletion (19del) mutation (hazard ratio [HR] = 0.24, 95% CI: 0.08-0.70, P = 0.009) and the use of intracranial radiotherapy during treatment (HR = 0.36, 95% CI: 0.15-0.87, P = 0.023) were independently associated with prolonged PFS.

Conclusions: High-dose furmonertinib combined with bevacizumab demonstrated notable intracranial and systemic activity in EGFR-mutant NSCLC patients with CNS metastases after third-generation TKI resistance. The combination yielded meaningful clinical benefit with manageable toxicity in this difficult-to-treat population, supporting its consideration as a therapeutic option pending further prospective validation.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.54 Predicting Osimertinib-Induced Pneumonitis in EGFR-Mutated NSCLC Using Multi-Modal Machine Learning Model

K. Nibuya, R. Tsugitomi, S. Fujishima, M. Ito, H. Iso, M. Sugai, T. Nemoto, Y. Amino, R. Ariyasu, K. Uchibori, N. Yanagitani, M. Nishio
Cancer Institute Hospital of Japanese Foundation For Cancer Research, Tokyo/JP

Introduction: Osimertinib improved overall survival in EGFR-mutated non-small cell lung cancer (NSCLC), but drug-induced interstitial lung disease (DILD) remains a significant concern, particularly among Asian patients. Existing clinical risk factors alone offer limited predictive accuracy, highlighting the need for integrated risk models.This study aims to develop and validate a machine learning model integrating clinical and computed tomography (CT) imaging features to predict DILD risk in NSCLC patients initiating osimertinib.

Methods: We retrospectively analyzed EGFR-mutated NSCLC patients treated with osimertinib. Patients were randomly split into training (70%) and test (30%) sets. Clinical features included demographics, laboratory values, prior therapies, and radiologic history. Pretreatment CT images were processed with a 3D ResNet for imaging feature extraction. All clinical and imaging features were initially considered, and relevant features were selected using the SelectKBest method. These selected features were used to train six machine learning models: Neural Networks, SVM, LightGBM, XGBoost, KNN, Random Forest, and logistic regression. Performance was evaluated on the test set using AUC-ROC. The Youden Index identified the optimal threshold for risk stratification. Kaplan-Meier curves compared DILD incidence between high- and low-risk groups.

Results: Among 203 patients, 32 (15.8%) developed pneumonitis: Grade 1 (n=14), Grade 2 (n=10), and Grade 3 (n=8). Significant clinical predictors included prior thoracic surgery, thoracic radiotherapy, and pre-existing interstitial lung disease. After feature selection, all models were trained and tested using the same optimized feature set. Random Forest yielded the highest AUC (0.865). Using the optimal threshold of 0.3, the test set was stratified into high- and low-risk groups. Kaplan-Meier analysis revealed a significantly higher pneumonitis incidence in the high-risk group (p=0.0075). Sensitivity and specificity at this threshold were 0.75 and 0.82.

Conclusions: A Random Forest model accurately predicts pneumonitis risk using clinical and imaging features. Further validation in multicenter cohorts is needed.

Introduction: Vebreltinib (PLB1001), a potent and highly selective c-MET inhibitor, demonstrated superior objective response rate (ORR) benefits in locally advanced or metastatic non-small-cell lung cancer (NSCLC) patients (pts) with MET exon 14 (METex14) skipping mutations in the previous analysis of the phase II KUPENG study. Here we present results from post-hoc analysis of KUNPENG study.

Methods: In this Phase II, open-label, multicenter, and multi-cohort study, tumor tissue was assessed for METex14 skipping mutation using next-generation sequencing (NGS) from CAP or CLIA certificated local or central laboratories. Pts in Cohort 1 received 200 mg of vebreltinib twice daily (28 days per cycle) until discontinuation criteria were met. The primary endpoint was ORR assessed by blinded independent review committee (BIRC).

Results: Between Jan 17, 2020 and Feb 09, 2021, 52 pts were enrolled in Cohort 1. In the Per-Protocol Set (PPS) of 46 patients, 21 were treatment-naïve, and 25 were previously treated. For this set, we conducted a post hoc analysis. As of the data cut-off (Nov 14, 2024), the median duration of follow-up was 21.4 months (range, 3.7-58.0) and the median duration of treatment was 12.5 months (range, 1.0-58.0). Per BIRC assessment, the ORR was 80.4% (95% CI: 69.0-91.9), the disease control rate (DCR) was 97.8% (95% CI 93.6-100.0), the median duration of response (DoR) was 19.1 months (95% CI 12.0-NE), the median progression-free survival (PFS) was 17.5 months (95% CI 6.4-31.3), and the median overall survival (OS) was 22.5 months (95% CI 17.9-44.3). The 3-year OS rate was 39.7%. Subgroup analyses showed the ORR of pts with any baseline brain metastases (N=5), treatment-naïve (N=21) and pre-treated (N=25) were 100.0%, 85.7% and 76.0%; mPFS were 6.4, 25.8 and 12.0 months and mOS was 17.9, 44.3 and 20.7 months, respectively.

Conclusions: Vebreltinib provided remarkable tumor response for locally advanced or metastatic NSCLC pts with exon 14 skipping, which can translate into long-term survival benefits, especially in treatment-naïve patients.

Summary of efficacy assessed by BIRC in Per-Protocol set

Variables	Treatment-naïve (n=21)	Pre-treated (n=25)	PPS (n=46)
ORR (%)	18(85.7)	19(76.0)	37(80.4%)
95% CI	70.7-100.0	59.3-92.7	69.0-91.9
DCR (%)	21(100.0)	24(96.0)	45(97.8)
95% CI	100.0-100.0	88.3-100.0	93.6-100.0
mDoR, months (95% CI)	30.4(12.0-NE)	16.7(5.5-NE)	19.1(12.0-NE)
mPFS, months (95% CI)	25.8(6.3-NE)	12.0(6.4-20.3)	17.5(6.4-31.3)
mOS, months (95% CI)	44.3(18.2-NE)	20.7(15.2-29.7)	22.5(17.9-44.3)

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.56 Medication Adherence to Osimertinib in Patients Diagnosed With Metastatic Non Small Cell Lung Cancer

T. Montague[1], S. Monestime[2], K. Dumais[3], H.W. Powery[3], C. Granville[4], L. Raez[3], D. Rosas[5]
[1]Florida A&M University & Bristol Myers Squibb, TALLAHASSEE/FL/USA ,[2]Go[2] For Lung Cancer, Washington DC/DC/USA ,[3]Memorial Cancer Institute, Pembroke Pines/FL/USA ,[4]Go[2] For Lung, Washington DC/DC/USA ,[5]Memorial Cancer Institute, Hollywood/FL/USA

Introduction: Lung cancer is the leading cause of cancer-related death in the United States. Guidelines currently recommend osimertinib as first-line therapy for metastatic non-small cell lung cancer (NSCLC) with EGFR exon 19 deletion or exon 21 L858R mutations. Oral oncolytics allow for more patient autonomy; however, medication adherence has been a concern due to the various barriers patients may encounter. A previous study determined that adherence to oral oncolytics among patients with lung cancer is 64.7%, while a study comparing pharmacy type found that 83% of internal pharmacy users and 69% of external pharmacy were adherent. Non-adherence to these therapies has been associated with increased rates of physician visits, hospitalization, and longer hospital stays. The purpose of this study is to assess medication adherence to osimertinib in a diverse patient population receiving treatment at a comprehensive cancer center.

Methods: A retrospective chart review was performed at a large multi-site community cancer center with an affiliated specialty pharmacy who received osimertinib between January 1, 2018 and December 31, 2023. Inclusion criteria included patients 18 years and older with EGFR-mutated advanced NSCLC. Exclusion criteria included patients who received osimertinib with concurrent chemotherapy, and patients who received medication through a patient assistance program. Data were collected from electronic medical records and prescription refill history. Medication adherence was defined as having a proportion of days covered (PDC) of 90% or higher over a span of the first six months of therapy. A two-sample t-test was conducted to compare medication adherence, measured by the PDC, between patients using internal and external pharmacies. All statistical analyses were conducted using Stata/BE 18, and results were considered statistically significant at $p < 0.05$.

Results: Of the 150 patient medical charts reviewed, 38 patients were included. The mean age was 63.2 years (SD = 10.5). The majority of patients were female (71.05%), married (57.89%), privately insured (68.42%), and non-smokers (71.05%). The study population included 42% Hispanic, 18% Black, 29% White, and 10% Asian. The majority of patients (65.79%) used an external pharmacy, while 34.21% used an internal pharmacy. Overall, 94.74% of patients were adherent to osimertinib with a PDC of 90% or higher. The combined mean PDC across all patients was 96.19%, with a mean PDC of 96.85% for internal pharmacies and 95.83% for external pharmacy users. (p= 0.53).

Conclusions: The findings from our study highlight that the majority of patients maintained high adherence rates regardless of where they filled their medications, reflecting the comprehensive approach to medication management within our healthcare system. This supports the efforts of the Memorial Healthcare System in ensuring appropriate coordination and execution of prescription refills when collaborating with both internal and external pharmacies, as demonstrated by the high adherence observed in both pharmacy types.

P3.12.57 Phase I/II Study of FHND9041 in T790M-Positive Advanced NSCLC Patients Progressed After Prior EGFR-TKI Therapy

X. Dong[1], Y. Zhang[2], D. Yuan[3], Y. Zhu[4]
[1]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN ,[2]Hunan Cancer Hospital, Changsha/CN ,[3]Jiangsu Chia Tai Fenghai Pharmaceutical Co. Ltd., Nanjing/CN ,[4]Jiangsu Chia Tai Fenghai Pharmaceutical Co. Ltd., Nanjing/GB

Introduction: FHND9041 is a novel third-generation EGFR-TKI developed for the treatment of patients with EGFR T790M-positive non-small cell lung cancer (NSCLC) who have progressed on prior EGFR-TKI therapy.

Methods: The study included dose-escalation and dose-expansion phase for patients with locally advanced or metastatic EGFR T790M-positive NSCLC. In the dose-escalation phase, 12 patients received oral FHND9041 at 40 mg (n=3), 80 mg (n=3), 120 mg (n=3), and 180 mg (n=3) once daily (QD). In the expansion phase, 112 patients were enrolled to receive FHND9041 at 80 mg (n=73) or 120 mg (n=39) QD. The primary endpoints were safety/tolerability and objective response rate (ORR) according to RECIST v1.1. Secondary endpoints included progression-free survival (PFS), duration of response (DOR), disease control rate (DCR), and overall survival (OS).

Results: A total of 112 patients were treated in Phase II. The confirmed ORR (N=109) was 49.5% (54/109; 95% CI: 39.8-59.3), and the disease control rate (DCR) was 96.3% (95% CI: 90.9-99.0). The median PFS in the overall population (N=112) was 15.1 months (95% CI: 11.1-16.6), with censored patients of 36 patients (32.1%). The P75 was 27.6 months (95% CI: 23.4-NE). The mean PFS was 18.5 months (SE: 1.4). Median DoR was 19.4 months (95% CI: 13.8-26.3). The median OS was 29.8 months (95% CI: 21.6-43.2), with 55 patients (49.1%) censored. These results suggest a promising duration of disease control with FHND9041.

In the dose-escalation phase, one dose-limiting toxicity (DLT) of elevated alanine aminotransferase (ALT) was observed at the 180 mg dose level. In the 80 mg (the Phase III dose) expansion cohort, grade ≥3 treatment-related adverse events (TRAEs) occurred in 8.2% (6/73) of patients, with no TRAEs leading to dose reduction. Across both 80 mg and 120 mg expansion cohorts, no treatment-related deaths were reported and grade ≥3 TRAEs were observed in 14.3% of patients (16/112).

Conclusions: FHND9041 showed durable efficacy and a favorable safety profile in patients with EGFR T790M-positive NSCLC who progressed after EGFR-TKI treatment, supporting its further development as a potential treatment option.

Introduction: Cancers with RET alterations have limited next-generation targeted therapeutic options. Vepafestinib (TAS0953/HM06), a RET-selective inhibitor, is being evaluated in patients with locally advanced or metastatic solid tumors harboring RET alterations in MARGARET (NCT04683250), an open-label, single-arm, phase 1/2, first-in-human study. Here, we present the preliminary phase 1 safety and antitumor-activity results (data cutoff date: November 15, 2024).

Methods: Phase 1 consists of dose escalation (DE; for patients with solid tumors harboring RET alterations) and dose expansion (EX; for patients with locally advanced or metastatic RET-fusion-positive non-small-cell lung cancer [NSCLC]). In EX, patients naïve to RET-selective inhibitors and systemic anticancer treatment were enrolled in cohort 1 (C1), and patients pretreated with RET-selective inhibitors were enrolled in cohort 2 (C2). The initial dose in DE was 20 mg BID, and accelerated titration was performed. The primary endpoints were the maximum tolerated dose (MTD) for DE and the recommended phase 2 dose in EX. The secondary endpoints included safety, tolerability, antitumor activity, pharmacokinetics, and predictive biomarkers.

Results: As of November 15, 2024, 32 patients were enrolled for DE (Asian: 41%, White: 50%, other: 9%), and 14 patients (C1: 4, C2: 10 patients) for EX (Asian: 100%). The DE tumor types were lung (n=23), thyroid (n=8), and pancreatic (n=1) cancer. The vepafestinib dose was escalated to 650 mg BID. Dose-limiting toxicities (DLTs) occurred in two of the three patients at 650 mg BID, and 500 mg BID was deemed the MTD. The DLTs were grade 3 headache (n=1) and grade 3 back pain (n=1). The most common treatment-emergent adverse events (TEAEs) in DE (any grade, grade ≥3) were headache (25%, 6%), nausea (25%, 0%), and malaise (19%, 3%). Confirmed/unconfirmed partial responses (PRs) in DE were reported in four of 32 patients: a patient with RET-fusion-positive NSCLC who was pretreated with an RET-selective inhibitor, a patient with RET-fusion-positive thyroid cancer who was pretreated with an RET-selective inhibitor, and two patients who were naïve to RET-selective inhibitors and had fusion-positive NSCLC. In EX, 500 mg vepafestinib was administered BID. The most common TEAEs (any grade, grade ≥3) in EX were headache (79%, 7%), nausea (29%, 0%), and malaise (21%, 0%). In C1, PRs were observed in two of four patients; the disease control rate (DCR) and median time to response (mTTR) were 50% and 1.3 months, respectively. On C2, PRs were observed in three of 10 patients, and the DCR and mTTR were 80% and 1.4 months, respectively.

Conclusions: Vepafestinib was well tolerated and displayed preliminary antitumor activity in patients with solid tumors harboring RET alterations, both in treatment-naïve and RET-selective inhibitor-pretreated cancers, indicating encouraging therapeutic potential. Enrollment in this trial continues.

P3.12.59 A Phase Ib/Ii Study of Vebreltinib Plus Tislelizumab in Patients With MET-Amplified and PD-L1-Positive Locally Advanced or Metastatic NSCLC

Z. Wang[1], Q. Chu[2], K-L. Fei[1], J-Z. Jiang[2], W-H. Li[1]
[1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN ,[2]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wu han/CN

Introduction: For patients with de novo MET amplification who lack driver mutations, treatments remain limited. The standard treatment for driver-negative patients offers only modest survival benefits. Moreover, MET-targeted monotherapy yields suboptimal outcomes in primary MET-amplified NSCLC. Given that MET aberrations are frequently associated with high PD-L1 expression, combining MET inhibitors with immune checkpoint inhibitors may confer enhanced clinical benefit. In this investigator-initiated trial, we evaluated the safety and efficacy of combining Vebreltinib-a highly selective MET-TKI with Tislelizumab in patients with MET-amplified and PD-L1-positive locally advanced or metastatic NSCLC.

Methods: Eligible patients with locally advanced or metastatic NSCLC demonstrating primary MET-amplified and positive PD-L1 expression received Vebreltinib and Tislelizumab every 21 days (Q21d). Tumor assessments were conducted every six weeks from the initiation of administration.

Results: To date, two patients have been enrolled. Patient 1: A 65-year-old male was diagnosed stage IVC NSCLC with primary MET amplification confirmed by fluorescence in situ hybridization (FISH; GCN of 10.8, MET-to-CEP7 ratio ≥2.40), and a PD-L1 tumor proportion score (TPS) of 60%. After six cycles of combined treatments, computed tomography (CT) scans demonstrated a marked reduction in the target lesions, achieving a partial response (PR). A subsequent assessment revealed further tumor shrinkage-70.9% reduction-confirming PR. At manuscript submission, the patient maintained a sustained response with a progression-free survival (PFS) exceeding six months. One serious adverse event-SAE (immune-related colitis), attributable to Tislelizumab, was reported; no SAE were related to Vebreltinib. Patient 2: A 68-year-old male with stage IIIC NSCLC exhibited primary MET amplification which was confirmed by FISH (GCN of 8.15, MET-to-CEP7 ratio ≥2.80), with a PD-L1 TPS of 60%. Following two cycles of treatments, CT scans indicated a significant reduction in the target lesions, reaching a PR. At manuscript submission, the patient continued to experience a sustained response with a PFS of more than five months, and treatments was well tolerated with no SAE.

Conclusions: In this study, first-line treatment with the combination of Vebreltinib and Tislelizumab resulted in rapid and durable antitumor activity in two patients with MET-amplified and PD-L1-positive locally advanced or metastatic NSCLC. However, clinicians should remain vigilant regarding immune-related adverse events. Notably, although both patients exhibited low-level MET amplification by NGS, FISH analysis revealed GCN exceeding 10, suggesting that the optimal cut-off for MET amplification merits further investigation. Larger studies are warranted to validate the efficacy and safety of this combined regimen.

P3.12.60 The Combination of USP24-i-101-Astemizole Sensitizes the Cytotoxicity of Taxol and Gefitinib in Drug-Resistant Lung Cancer

J-J. Hung
Department of Biotechnology and Bioindustry Sciences, National Cheng Kung University, Tainan/TW

Introduction: Cancer is one of the major causes of death worldwide. Genomic instability is the primary reason that triggers gene mutation and induces cancer progression. Genes such as Kras, EGFR and p53 are highly mutated, leading to hyperplasia and metastasis of tumors. Various treatments, including surgery, radiotherapy, chemotherapy, target therapy, and immune therapy, have been employed to treat cancer. However, genomic heterogeneity causes drug resistance and cancer recurrence after treatment. Overcoming drug resistance following therapies is important to prevent from cancer-led deaths in the future.

Methods: In this study, we created a gene signature for drug discovery utilizing the Connectivity Map (CMap). This strategy involves repurposing drugs by identifying those with genetic effects that counteract the USP24 signature, thereby potentially reversing or alleviating drug resistance. After rigorous screening and analysis, we identified several promising candidates, excluding those previously tested in lung cancer trials to maintain novelty in our research.

Results: In this study, we employed the yeast two-hybrid system to screen for proteins interacting with USP24. Among 250 such proteins, functional enrichment analysis using MetaCoreTM revealed that 33 of them were involved in lung cancer progression. Subsequently, we investigated gene expression and survival rates of these 33 proteins in lung cancer patients and cell lines utilizing TCGA databases, Kaplan-Meier Plotter databases, and RNA-seq profile from A549/A549-T24 cells. Our findings indicated high expression of genes like FEN1 and NEK2, coupled with low expression of MOAP1 and PIAS2, was associated with poor prognosis in lung cancer patients. Based on these gene signatures, we identified 10 potential drugs for inhibiting lung cancer progression or drug resistance through the Connectivity Map (CMap) database via drug repurposing strategy. Of these 10 drugs, six showed similar indicators in Clinical_Trials, while the other four candidates (15-delta prostaglandin J2, Astemizole, Trifluoperazine, and 1,4-chrysenequinone) were chosen to evaluate their effect on re-sensitizing cytotoxicity of Taxol and Gefitinib in drug-resistant cancer cells. Experiments demonstrated that treatment with USP24-i-101 and Astemizole alone significantly inhibited drug resistance and re-sensitized the cytotoxicity of Taxol and Gefitinib in drug-resistant lung cancer cells (Fig.1).

Conclusions: In this study, we combined global USP24-interacting proteins, gene expression profiles from TCGA and lung cancer drug sensitive and resistant cells, along with clinical survival rate to screen for drug repurposing. Several approved clinical drugs, including 15d-PGJ2, Trifluoperazine, 1,4-Chrysenequinone and Astemizole, were found to inhibit chemotherapy-induced and target therapy-induced cancer drug resistance.

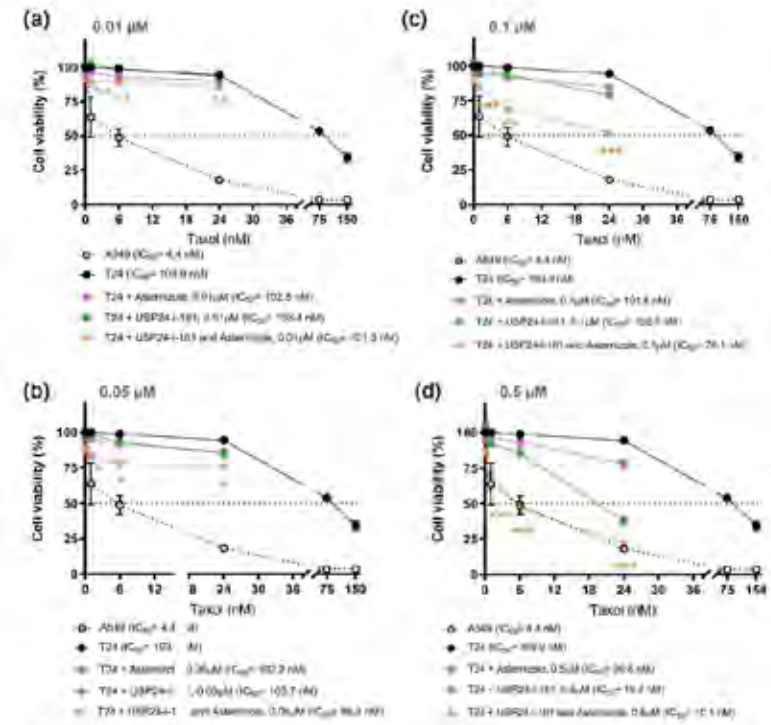

Fig. 6. USP24-i-101 and Astemizole cocktail treatment induced synergistic effect on resensitizing the cytotoxicity of Taxol. Taxol-induced drug-resistant lung cancer cells (T24 cells) were treated with various doses of Taxol combined with 0.01 μM (a), 0.05 μM (b), 0.1 μM (c), and 0.5 μM (d) USP24-i-101 and Astemizole for 48 h, and cell viability was measured by cell counting assay.

Introduction: EGFR mutations occur in between 15% and 50% 1,2 of non-small cell lung cancer cases (NSCLC), with third-generation tyrosine kinase inhibitors (TKI) providing clinical benefit until resistance emerges. Recent advancements in sequencing have identified RET-fusions as a potential resistance mechanism3-6. Emerging evidence suggests that combining EGFR- and RET-TKIs may overcome this resistance 7,8. Creating personalized assays, such as digital droplet - based ctDNA analysis allows for a dynamic assessment of tumor genetics over time, providing early insight into treatment efficacy. This study aimed to retrospectively evaluate the occurrence of RET fusions as a resistance mechanism in EGFR-mutated NSCLC patients within the national Network Genomic Medicine (nNGM) in Germany and analyse responses to different treatment approaches.

Methods: A multicenter retrospective analysis across all nNGM centers analysed EGFR-mutant NSCLC patients with concurrent RET fusions. Clinical data, treatments, and outcomes were evaluated, with PFS and OS as primary endpoints. In one patient, tumor and liquid biopsies were assessed and an individualized EGFR and RET-specific assay was developed using digital droplet PCR technology. Tissue and circulating tumor DNA were analyzed longitudinally and correlated with the clinical trajectory

Results: Nine nNGM centers contributed one patient each with an EGFR and concurrent RET fusion. Patients had a median age of 54; most were female (77%) and never-smokers (66%). Two patients (22%) harboured rare EGFR (Exon 20 insertion) mutations with KIF5B-RET fusions and received a selective RET-TKI as first-line monotherapy. The others (n=7) had common EGFR mutations (66% Del19, 11% L858R), with fusion partners including CCDC6 (57%) and NCOA4 (29%).In one case, the fusion partner could not be reported. Patients received an EGFR-TKI as first-line therapy and developed RET-mediated resistance in median 11.4 months after initial diagnosis (range: 6.3-19.7 months). For three patients, a combination of RET (Pralsetinib) and EGFR-TKIs (Osimertinib) was chosen, yielding a PFS of 3.9 months, 6.0 months (ongoing) and 10.5 months (ongoing). The results of the EGFR and RET-specific assay in the latter patient closely correlated with the clinical course: both alterations were identified during oligoprogression and again subsequently at systemic progression (Fig. 1). However, following treatment with Osimertinib and Selpercatinib, neither alteration was detectable.

Conclusions: RET fusions constitute a rare yet clinically significant resistance mechanism in EGFR-mutated NSCLC. Early detection via individualized EGFR and RET-specific cDNA-assay may enhance therapeutic decision-making. While combinatorial EGFR- and RET-TKI therapy holds promise, further research is essential to refine treatment strategies and evaluate long-term efficacy.

Introduction: In FLAURA2 (NCT04035486), first-line osimertinib (a third-generation, CNS-active EGFR-tyrosine kinase inhibitor) + chemotherapy showed a statistically significant progression-free survival (PFS) benefit versus osimertinib monotherapy in patients with EGFR-mutated advanced NSCLC. We report data from the non-Asian country cohort, defined as the full analysis set minus the Asian cohort.

Methods: In the global, Phase III, open-label FLAURA2 study, eligible patients were ≥18 years with EGFR-mutated (Ex19del/L858R) locally advanced/metastatic NSCLC, WHO PS 0/1 and no prior systemic treatment for advanced NSCLC; stable CNS metastases were permitted. Patients were randomised 1:1 to osimertinib 80 mg QD + chemotherapy (4 induction cycles: osimertinib + pemetrexed with cisplatin or carboplatin Q3W; then osimertinib + pemetrexed Q3W maintenance) or osimertinib monotherapy until progression/discontinuation. Stratification was by race (Chinese Asian/non-Chinese Asian/non-Asian), EGFR mutation test method (local/central) and WHO PS (0/1). Primary endpoint: PFS by investigator per RECIST 1.1. Secondary endpoints included overall survival (OS) and safety. PFS and OS hazard ratio (HR) analyses in the non-Asian country cohort were performed by stratified log-rank test. Data cut-off: 3 April 2023 (updated interim OS analysis [regulatory authority request]: 8 January 2024).

Results: In the non-Asian country cohort, 110 and 114 patients were randomised to osimertinib + chemotherapy and osimertinib monotherapy, respectively. Baseline characteristics were generally balanced between arms (osimertinib + chemotherapy/osimertinib monotherapy: median age, 61/62.5 years; male, 37%/33%; Ex19del, 72%/60%; L858R, 25%/39%; Ex19del + L858R, 3%/1%; CNS metastases, 34%/36%; median baseline target lesion tumour size, 64.5/71 mm). PFS and OS were improved with osimertinib + chemotherapy versus osimertinib monotherapy (Table). In the osimertinib + chemotherapy (safety analysis set; n=109) versus osimertinib monotherapy (n=111) arms, grade ≥3 adverse events (AEs) were reported in 64 (59%) versus 36 (32%) patients, and AEs led to osimertinib discontinuation in 14 (13%) versus 6 (5%) patients (further safety data will be presented).

Conclusions: First-line osimertinib + chemotherapy resulted in clinically meaningful benefits versus osimertinib monotherapy in patients from non-Asian countries with EGFR-mutated advanced NSCLC, consistent with the global FLAURA2 results (Planchard NEJM 2023); top-line safety results were also similar to the global data. These data support osimertinib + chemotherapy as a first-line treatment option for this patient population.

Introduction: Homozygous loss of MTAP (methylthioadenosine phosphorylase) defines a new therapeutic vulnerability based on emerging clinical data with MTA-cooperative PRMT5 (protein arginine methyltransferase 5) inhibitors. We report the frequency of MTAP loss in oncogene-driven NSCLC and evaluate the preclinical activity of PRMT5 inhibitors, alone or combined with tyrosine kinase inhibitors (TKIs), in patient-derived models of oncogene-driven NSCLC.

Methods: This retrospective study included NSCLC patients at Dana-Farber Cancer Institute whose MTAP status was assessed by next-generation sequencing (NGS) using Oncopanel v3-3.1. MTAP loss was defined as a homozygous deletion; samples with tumor purity <40% were excluded. MTAP status was assessed in patient-derived models by immunohistochemistry (IHC) and/or NGS (PDX), and by Western blot and Sanger sequencing (cell lines). MTAP was knocked out using CRISPR-Cas9 in MTAP-intact, EGFR+ or ALK+ cell lines to evaluate impact on TKI sensitivity via a 5-day viability assay. The efficacy of the MTA-cooperative PRMT5 inhibitor BMS-986504 (MRTX1719) was tested alone or with a TKI in patient-derived and commercial cell lines using a 10-day viability assay. Synergistic activity was assessed using Combenefit software.

Results: Among 2,027 NSCLC patients, MTAP loss was observed in 11.9% (242/2027), with highest prevalence in ALK$^+$ (28.3%, 17/60), followed by EGFR$^+$ (16.7%, 86/516), RET$^+$ (15.4%, 4/26), MET$^+$ (13.3%), ROS1$^+$ (12.5%, 2/16), KRAS$^+$ (9.9%, 58/584), HER2$^+$ (7.1%, 3/42), and BRAF$^+$ (7.1%, 7/99). Among patients without a targetable oncogene, MTAP loss was identified in 9.2% (59/639). Compared to MTAP-intact samples, MTAP-deleted tumors were significantly enriched for CDKN2A loss (100% vs. 5.7%, p<0.001), EGFR mutations (37% vs. 26%, p<0.001), and ALK fusions (7.5% vs. 2.7%, p<0.001). In patients with metastatic disease and unpaired biopsies collected before (N=229) or after TKI (N=238), the frequency of MTAP loss was similar between baseline and progression samples (14.8% vs. 21%, p=0.37 across all drivers; EGFR$^+$: 15.9% vs. 22.5%, p=0.37; ALK$^+$: 29.2% vs. 30%, p=1.00). MTAP deletion was detected in 19.4% (27/139) of patient-derived models of oncogene-driven NSCLC, including 20.6% (13/63) EGFR$^+$, 44.4% (4/9) ALK$^+$ and 15.8% (3/19) KRAS$^+$ models. CRISPR-engineered MTAP knockout in EGFR$^+$ (HCC827) and ALK$^+$ (DFCI76) cell lines did not alter sensitivity to respective TKIs, with IC_{50} values of 0.01 µM for osimertinib (HCC827sgMTAP) and 0.01 µM for alectinib and lorlatinib (DFCI76sgMTAP), all comparable to parental controls. MRTX1719 monotherapy showed IC_{50} <0.5 µM in 5/7 EGFR$^+$ MTAP-deleted models, and <0.16 µM in all 5 ALK$^+$ MTAP-deleted lines. Combination with osimertinib or lorlatinib demonstrated synergistic activity in 3/7 EGFR$^+$ and 3/5 ALK$^+$ MTAP-deleted models. In TKI-sensitive lines, 10-day treatment followed by drug washout and live-cell imaging showed delayed regrowth with combination compared to TKI alone (final confluence: 30-50% with TKI vs. <10% with combination).

Conclusions: MTAP loss occurs in nearly one-third of ALK+ NSCLC and one-sixth of EGFR+ NSCLC regardless of prior TKI treatment. Preclinical data suggest that oncogene-driven tumors with MTAP loss are sensitive to single agent PRMT5 inhibitors and that combination TKI and PRMT5 inhibitors may have additive or synergistic antitumor activity. These findings support clinical testing of combined TKI and PRMT5 inhibitors in oncogene-driven MTAP deleted NSCLC.

Introduction: MET amplification is an important mechanism of acquired resistance to third-generation (gen) EGFR-TKIs, which are widely used in treating advanced EGFR-mutated non-small cell lung cancer (NSCLC) patients. However, MET amplification testing is not routinely performed for all patients who fail first-line EGFR-TKI treatment. Consequently, data on characteristics of the acquired MET amplification patients is still being explored.

Methods: We evaluated all screened MET-amplified patients who had been previously treated with third-gen EGFR-TKIs from the SACHI study, which is a randomized, open-label, phase 3 study of savolitinib plus osimertinib versus chemotherapy, targeting MET-amplified advanced NSCLC patients who progressed on first-line EGFR-TKIs. MET amplification was assessed in a central laboratory using tumor samples collected after disease progression. Patients who had been previously treated with third-gen EGFR-TKI were required to have MET copy number ≥10 verified by Fluorescence In Situ Hybridizatio (FISH). In these population, the disease characteristics and prior treatments of this defined group were collected and analyzed.

Results: Among 307 patients who had been previously treated with third-gen EGFR-TKI, and provided valid tissue samples, 99 were verified to have MET copy number≥10. Among these patients, 96 (97.0%) were initially diagnosed with adenocarcinoma. EGFR mutation types were mainly 19Del (47.5%, 47 patients) and L858R (51.5%, 51 patients). Brain metastases were reported in 44 patients (44.4%), while the remaining patients had no brain metastases, except for 2 missing reports; 68 patients (68.7%) had metastases in three or more sites. The median duration of therapy (DoT) for previous therapy was 12.7 months among 93 patients with available start and end dates for front-line EGFR-TKI treatment. Of these patients, 68 (73.1%) received osimertinib, with a median treatment duration of 12.8 months, while the rest were mainly treated with almonertinib (19.4%) and furmonertinib (6.5%). Treatment durations were shorter than the median DoT reported in FLAURA study and other phase 3 studies of third gen EGFR-TKIs (15.2-18.3 months; Soria J et al, New Engl J Med; Lu S et al, J Clin Oncol; Shi Y et al, Lancet Respir Med).

Conclusions: NSCLC patients with MET amplification who failed first-line third-gen EGFR TKI treatment demonstrated a high disease burden, affecting their exposure to prior therapy. These data suggested that MET amplification might accelerate disease progression during prior therapy as an early resistance mechanism.

Table

Characteristic	*MET* Copy Number ≥ 10 (N=99)
Initial pathological diagnosis of adenocarcinoma, n (%)	96 (97.0)
EGFR mutation type at initial diagnosis, n (%)	
Exon 19 Deletion	47 (47.5)
L858R	51 (51.5)
Other	1 (1.0)
Clinical stage of IV at baseline, n (%)	99 (100.0)
Brain metastasis at baseline, n (%)	44 (44.4)
Number of metastasis sites, n (%)	
< 3	31 (31.3)

Introduction: Osimertinib is a third-generation, CNS-active, EGFR-TKI that potently and selectively inhibits EGFR-TKI sensitising and EGFR T790M resistance mutations and is a preferred first-line treatment for EGFR-mutated advanced NSCLC. In the Phase III FLAURA2 study (NCT04035486), osimertinib plus platinum-pemetrexed chemotherapy significantly improved PFS versus osimertinib monotherapy as first-line treatment of EGFR-mutated advanced NSCLC (investigator-assessed median PFS, 25.5 vs 16.7 months, respectively; HR 0.62, 95% CI 0.49, 0.79; p<0.001) and is now a recommended treatment option in this setting. The PFS benefit of osimertinib plus chemotherapy was consistent across pre-specified subgroups, including those associated with a poor prognosis, such as patients with L858R mutations. To better understand the impact of EGFR mutation subtype, we evaluated outcomes in the relevant patient subgroups from FLAURA2.

Methods: Eligible patients were randomised 1:1 to receive osimertinib plus platinum-based chemotherapy, or osimertinib monotherapy until progression or a discontinuation criterion was met. Primary endpoint was investigator-assessed PFS per RECIST 1.1. Secondary endpoints included OS and safety. Exploratory analyses by baseline EGFR mutation type (L858R and Ex19del) were performed, including baseline characteristics, clinical outcomes and safety. Data cut-off: PFS and safety, 03 April 2023; second interim analysis of OS, 08 January 2024.

Results: 557 patients were randomised to osimertinib plus chemotherapy (overall, n=279; L858R subgroup, n=106; Ex19del subgroup, n=172) or osimertinib monotherapy (overall n=278; L858R subgroup, n=107; Ex19del subgroup, n=169). Baseline characteristics by EGFR mutation subgroups were similar between treatment arms. In the L858R subgroup, osimertinib plus chemotherapy/osimertinib: median age, 63/65 years; male, 41%/41%; CNS metastases, 43%/47%. In the Ex19del subgroup, osimertinib plus chemotherapy/osimertinib: median age, 60/60 years; male, 36%/38%; CNS metastases, 40%/35%. PFS favoured osimertinib plus chemotherapy compared with osimertinib alone, in both the L858R subgroup and the Ex19del subgroup, with a trend towards improvement in OS (Table). The adverse event (AE) profiles in the two treatment arms were consistent between subgroups and with the global analysis. All causality grade ≥3 AEs: L858R, osimertinib plus chemotherapy 68%/osimertinib 27%; Ex19del, 61%/28%, respectively. AEs that led to treatment discontinuation: L858R, osimertinib plus chemotherapy 47%/osimertinib 6%; Ex19del, 48%/7%, respectively.

Conclusions: These data show a clinically meaningful PFS benefit with osimertinib plus chemotherapy compared with osimertinib monotherapy, and a trend towards an OS benefit at the second interim analysis for OS, irrespective of EGFR mutation subtype.

P3.12.66 Overcoming Osimertinib Resistance in EGFR<+ NSCLC: PI3K Inhibitor Combined With Osimertinib Restores Drug Sensitivity

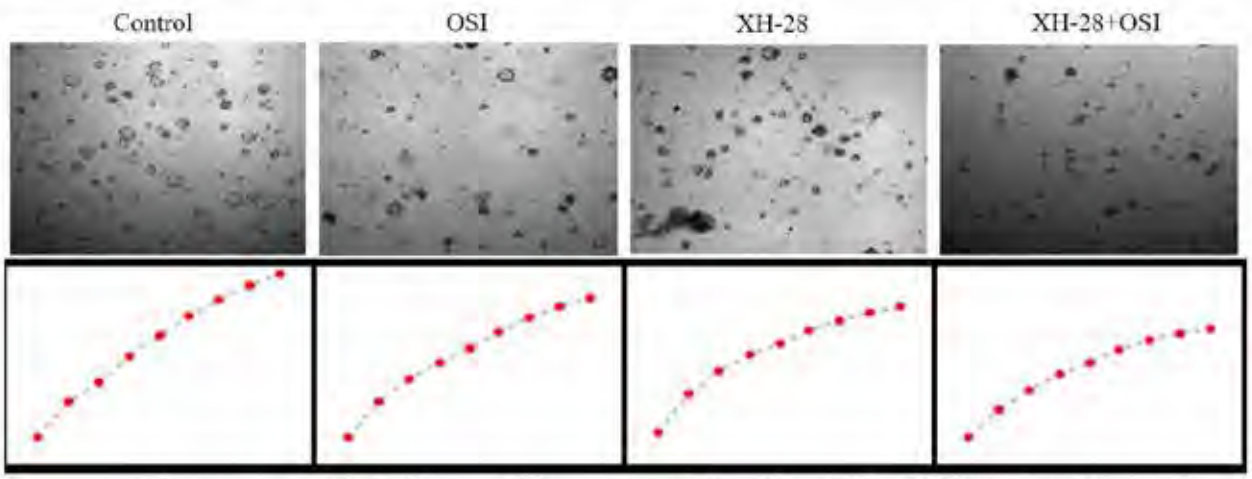
L. Jiang[1], Y. Xu[1], H. Xu[2], M. Wang[1]
[1]Peking Union Medical College Hospital, Beijing/CN ,[2]Institute of Materia Medica, Chinese Academy of Medical Sciences, Beijing/CN

Introduction: Lung cancer remains the leading cause of cancer-related mortality worldwide, with EGFR mutation-positive non-small cell lung cancer (EGFRm+ NSCLC) patients often developing resistance to EGFR tyrosine kinase inhibitors (TKIs) such as Osimertinib. Currently, effective strategies to overcome this resistance are limited. PI3K activation has emerged as a key mechanism contributing to Osimertinib resistance. In this study, we investigated the potential of a novel PI3K inhibitor, XH-28, combined with Osimertinib to suppress the EGFR-PI3K-AKT signaling pathway, induce apoptosis, and inhibit proliferation and metastasis in Osimertinib-resistant NSCLC cells.

Methods: A novel PI3K inhibitor, XH-28, was synthesized. Osimertinib-resistant NSCLC cell lines (PC9-OR and H1975-OR) were established from Osimertinib-sensitive EGFRm+ NSCLC cell lines (PC-9 and NCI-H1975). The combined effects of XH-28 and Osimertinib on cell proliferation, apoptosis, cell cycle progression, migration, and protein expression of EGFR, PI3K and AKT were evaluated. Three-dimensional (3D) tumor organoid models were generated from clinical NSCLC patient specimens using the hanging drop method to assess the synergistic effects of PI3K inhibition on Osimertinib cytotoxicity. Additionally, a xenograft mouse model of H1975-OR NSCLC was used to evaluate the antitumor activity of the combination therapy in vivo.

Results: The novel PI3K inhibitor XH-28 was successfully synthesized and validated. Osimertinib-resistant models (PC9-OR, H1975-OR, 3D organoids, and xenografts) exhibited significantly reduced sensitivity to Osimertinib. The combination of XH-28 and Osimertinib suppressed the EGFR-PI3K-AKT pathway, induced apoptosis, and arrested the cell cycle at the G1 phase. Migration capacity decreased by 60% ($p<0.001$). In 3D organoids, combination therapy reduced growth by 45% ($p<0.05$). In vivo, XH-28/Osimertinib dual therapy inhibited tumor growth by 70% ($p<0.001$) and suppressed EGFR phosphorylation in xenografts.

Conclusions: Our findings demonstrate that PI3K inhibition restores Osimertinib sensitivity in resistant NSCLC cells. The combination of XH-28 and Osimertinib offers a promising therapeutic strategy for overcoming Osimertinib resistance in EGFRm+ NSCLC, with significant clinical and economic implications.



The upper panel illustrates the morphological changes of 3D tumor organoids derived from EGFRm+ NSCLC patients following 48-hour treatment with XH-28 and/or Osimertinib. The lower panel displays the corresponding cell viability profiles, as determined by the Alamar Blue assay, at 0h, 6h, 12h, 18h, 24h, 30h, 36h, 42h, and 48h post-treatment.
Treatment groups:
- **Control**: Untreated organoids.
- **OSI**: Osimertinib monotherapy (200 nmol/L).
- **XH-28**: XH-28 monotherapy (20 nmol/L).
- **XH-28+OSI**: Combination therapy with Osimertinib (200 nmol/L) and XH-28 (20 nmol/L).

P3.12.67 Redefining Tolerability: A Head-To-Head IPD Toxicity Comparison of Amivantamab+Lazertinib vs Osimertinib+Chemotherapy in EGFR-Mutant NSCLC

B. Resuli, D. Kauffmann-Guerrero, P. Mertsch, P. Arnold, C. Schneider, J. Behr, A. Tufman
LMU University Clinic, Munich/DE

Introduction: Background: First-line treatment paradigms for EGFR-mutant non-small cell lung cancer (NSCLC) are rapidly evolving with the introduction of novel combination regimens. Amivantamab plus lazertinib (AMI+LAZ) and osimertinib combined with platinum-based chemotherapy (OSI+CT) have each demonstrated clinical efficacy as first-line treatments for EGFR-mutant NSCLC in phase III trials (MARIPOSA and FLAURA2, respectively); however, direct comparative data on their safety profiles remain unavailable.

Methods: Individual patient data (IPD) meta-analysis from the MARIPOSA (n=429; AM+LAZ) and FLAURA2 (n=276; OSI+CT) trials was conducted. Adverse events (AEs), grade ≥3 AEs, serious AEs (SAEs), and treatment discontinuation due to AEs were assessed. Odds Ratios (Ors) and p-values were calculated using Fisher's exact test. Subgroup analyses were performed based on age, sex and ECOG performance status.

Results: Baseline characteristics were balanced between groups (median age 64, 56% female, 60% ECOG PS1). In terms of high-grade toxicity, grade ≥3 AEs were reported in 75% of patients in the AMI+LAZ arm, compared to 64% in the OSI+CT arm. This translated to a significantly higher likehood of experiencing severe treatment-related toxicity with AMI+LAZ, with an OR of 1.68 (95% confidence interval [CI], 1.21-2.34 p=0.0022). Similarly, SAEs occurred in 49% of the patients treated with AMI+LAZ, compared to 38% of those who received OSI+CT. This differenced also reached statistical significance, with an OR of 1.56 (95% CI, 1.15-2.13, p=0.0052), suggesting a higher burden of serious toxicity with the dual EGFR-MET inhibition regimen. Treatment discontinuations due to AEs occurred in 10% of the AMI+LAZ combination and 11% of the OSI+CT. Despite the higher frequency of high-grade toxicity in the Amivantamab-based regimen, this did not translate into a significantly higher discontinuation rate. The OR for treatment discontinuation was 0.91 (95% CI, 0.56-1.50, p=0.7064), indicating no statistically significant difference between the two treatment strategies in terms of treatment cessation due to toxicity.

Conclusions: This IPD meta-analysis reveals a striking disconnect: AMI+LAZ carries a significantly higher burden of severe and serious AEs, yet discontinuation rates mirror those of OSI+CT. These findings challenge traditional definitions of "tolerability" and highlight the need to weigh toxicity trade-offs as critically as efficacy. In the absence of head-to-head trials, safety may emerge as the decisive factor in frontline treatment selection for EGFR-mutant NSCLC.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.12.68 Regulating Autophagy Will Be a Potential Key Point in Overcoming EGFR TKI Resistance in Non-Small Cell Lung Cancer

H. Jang[1], S. Kim[2], J. Oh[1], J-H. Kang[2]
[1]St Mary's Hospital, seoul/KR ,[2]St.Mary's hospital, seoul/KR

Introduction: Patients with non-small cell lung cancer (NSCLC) harboring EGFR mutations demonstrate high initial response rates to first- and second-generation EGFR tyrosine kinase inhibitors (TKIs). However, most patients develop drug resistance within one year of treatment, leading to cancer recurrence. Autophagy is an essential mechanism that regulates intracellular metabolism, and plays a dual role in promoting cell death by anticancer treatment while playing an important role in the survival of cancer cells. Therefore, it is possible that inhibiting autophagy can improve the efficacy of anticancer drugs. This study aims to investigate whether inhibiting autophagy can overcome EGFR TKI resistance in lung cancer.

Methods: We asssembled the TMA composed 579 surgically resected tumor tissues from lung adenocarcinoma patients and evaluated protein expreession of autophagy flux-related signal molecues. To identify autophagy-related processes affected in resistant cell lines, Gene Ontology (GO) analysis was conducted (http://www.geneontology.org), focusing on biological processes (BP) and molecular functions (MF).

Results: Immunohistochemical analysis was performed to assess the expression of autophagy-related markers (P-AMPK, p-Beclin1, ULK1, GABARAPL1) in FFPE tissues from patients with advanced or metastatic non-small cell lung cancer (NSCLC) harboring EGFR mutations. Among the 29 patients included in the study, 11 were male (53.9%), and the median age was 65.5 years (range, 41-83 years) When comparing tissue samples before EGFR TKI treatment and at the time of treatment failure, autophagy markers generally showed an increased expression after treatment. In particular, p-Beclin1 expression significantly increased after treatment failure (13.0 ± 10.9 vs. 59 ± 7.2, $P < 0.018$). These findings suggest that autophagy markers, especially p-Beclin1, may serve as potential predictive biomarkers for EGFR TKI resistance.

Conclusions: In this study, we demonstrated that ULK1 and GABARAPL1 partially contribute to resistance development in NSCLC cells through Osimertinib-induced autophagy. While these genes may not be ideal direct therapeutic targets, they show potential as biomarkers, warranting further investigation. Additionally, our findings suggest that combination therapy with the autophagy inhibitor HCQ may be an effective strategy for overcoming Osimertinib resistance.

Introduction: Taletrectinib, an oral, potent, central nervous system-active, selective next-generation ROS1 inhibitor, demonstrated high overall and intracranial response rates, prolonged progression-free survival (PFS), and activity against the G2032R acquired resistance mutation with a favorable safety profile in patients with ROS1+ non-small cell lung cancer (NSCLC) in the TRUST-I trial (NCT04395677; Li W, et al. J Clin Oncol. 2024;42(22):2660-2670). With an additional 11 months of follow-up, we report updated efficacy and safety in tyrosine kinase inhibitor (TKI)-naive and crizotinib-pretreated patients treated with taletrectinib in the regional pivotal TRUST-I trial.

Methods: The TRUST-I trial is a multicenter, single-arm, open-label, pivotal phase 2 study of taletrectinib conducted in China that enrolled TKI-naive and crizotinib-pretreated patients. All patients in the registrational cohorts received taletrectinib 600 mg once daily. The primary endpoint was objective response rate (ORR) by independent review committee per RECIST 1.1. Secondary endpoints included duration of response (DOR), PFS, overall survival (OS), and safety. The efficacy-evaluable population included patients who started treatment at the 600-mg dose of taletrectinib.

Results: As of October 28, 2024, 173 patients were enrolled in TRUST-I. Demographics and baseline patient characteristics were consistent with those previously reported in Li W, et al. J Clin Oncol. 2024;42(22):2660-2670 (median age: 55 years; 58% female; 74% never smoked). In 103 efficacy-evaluable TKI-naive patients, ORR was 90% (95% CI: 83, 95) and median DOR was not reached (NR). In 66 efficacy-evaluable TKI-pretreated patients, ORR was 52% (95% CI: 39, 64) and median DOR was 13.2 months (95% CI: 7.7, 24.9). Median PFS was 44.6 months in TKI-naive and 7.6 months in crizotinib-pretreated patients (Table). OS was NR for TKI-naive patients and 25.6 months for crizotinib-pretreated patients. With longer follow-up, there were no new or unexpected safety findings, and the reported frequency, types, and severity of adverse events were similar to previously reported safety profiles.

Conclusions: With longer follow-up in TRUST-I, taletrectinib continues to demonstrate high and durable ORRs and prolonged PFS with a favorable safety profile in both TKI-naive and TKI-pretreated patients. These results were also consistent with prior reports from the taletrectinib clinical program (Pérol M, et al. J Clin Oncol. 2025;epub April 3, 2025). The efficacy and safety of taletrectinib will be directly compared with crizotinib in an ongoing randomized head-to-head phase 3 trial in TKI-naive patients with locally advanced or metastatic ROS1+ NSCLC (NCT06564324).

Table: Responses in Evaluable Patients With *ROS1*+ NSCLC[a]

	TKI naive (n=103)	TKI pretreated (n=66)
ORR, % (95% CI)	90 (83, 95)	52 (39, 64)
Complete response, n (%)	5 (5)	0
Partial response, n (%)	88 (85)	34 (52)
Median DOR[b], months (95% CI)	NR (30.4, NR)	13.2 (7.7, 24.9)
Median PFS, months (95% CI)	44.6 (30.7, NR)	7.6 (5.5, 12.0)
Median OS, months (95% CI)	NR (41.6, NR)	25.6 (19.2, 31.9)

[a]Response-evaluable patients started treatment at taletrectinib 600 mg and had ≥1 measurable lesion at baseline.
[b]DOR was calculated for patients with confirmed responses.
DOR, duration of response; ORR, objective response rate; NR, not reached; NSCLC, non-small cell lung cancer; OS, overall survival; PFS, progression-free survival; TKI, tyrosine kinase inhibitor.

P3.12.70 Development of a Bispecific Antibody That Safely and Effectively Targets EGFR and B7H3 in NSCLC

X. Zhi, J. Wang, J. Guo
Shanghai pulmonary hospital, Shanghai/CN

Introduction: The advent of bispecific antibodies has introduced a transformative shift in the treatment of non-small cell lung cancer (NSCLC). The overexpression of epidermal growth factor receptor (EGFR) and B7 homolog 3 protein (B7-H3) is known to drive the growth of NSCLC, thereby positioning them as promising therapeutic targets. This study aimed to develop a bispecific antibody (bsAb) targeting B7H3 and EGFR and validate its efficacy in preclinical NSCLC models.

Methods: We analyzed the co-expression of B7-H3 and EGFR in 222 advanced NSCLC tissues by immunohistochemistry and examined their correlation with immune cells, including CD3, CD8, CD68, and Foxp3. Four bispecific antibodies were designed with varying affinities to B7H3 and EGFR, and their pharmacological activities including EGFR signaling blockade were evaluated. We selected FH-EB02 to assess the tumor growth inhibition in two cell line-derived xenograft (CDX) mouse models and four patient-derived xenograft (PDX) models bearing subcutaneous human NSCLC.

Results: B7H3 and EGFR were co-expressed in 62.6% of advanced NSCLC tissues, and this co-expression was correlated with the shorter PFS and OS. In vitro, the bsAbs demonstrated a stronger binding capacity to tumor cells compared to cetuximab in B7H3 and EGFR double-positive cells. However, the affinity of the bsAbs decreased in B7H3-knockout isogenic cells. FH-EB02, which has a weaker EGFR binding arm and a stronger B7H3 binding arm, showed limited EGFR binding in the absence of B7H3 and exhibited the largest therapeutic window. In vivo, treatment with FH-EB02 resulted in tumor growth inhibition in H1975 and SK-MES-1 xenograft tumor models. FH-EB02 significantly delayed tumor growth in B7H3/EGFR co-expression positive patient-derived xenograft (PDX) models, with tumor growth inhibition (TGI) values of 64.5% (PDX-011) and 54.7% (PDX-017). In contrast, no tumor growth inhibition was observed in two B7H3-negative PDX models.

Conclusions: FH-EB02 demonstrates promising preclinical efficacy in NSCLC models, warranting further investigation.

Introduction: RET fusions are targetable oncogenic drivers in 1-2% of non-small cell lung cancers (NSCLC). ARROW (NCT03037385) study results (final data lock May 20, 2024) supported the US FDA approval of pralsetinib, a highly potent, oral, selective RET inhibitor for metastatic RET-altered NSCLC. Here, we present final study results

Methods: ARROW was a phase 1/2 open-label study conducted at 84 sites in 13 countries. In phase 2, patients with RET fusion-positive NSCLC (confirmed by central analysis) received 400 mg pralsetinib once daily (QD). Initially, only treatment-naïve patients not candidates for platinum-based therapy were eligible and presented with unfavorable prognostic factors, a requirement removed by protocol amendment in 2019. Primary objectives were overall response rate (ORR, per RECIST v1.1) and safety. Progression-free survival (PFS) and overall survival (OS) are reported in the full efficacy population; the measurable disease population (MDP) was the primary analysis population for ORR and duration of response (DOR).

Results: 281 patients with RET fusion-positive NSCLC received pralsetinib 400 mg QD, with a median treatment duration of 14.95 months. Median age was 60 years; 46% of patients were male; 36% were current/former smokers; 70% had an Eastern Cooperative Oncology Group performance status score ≥1. In the MDP (n=259), ORR was 70.3% (95% confidence interval [CI]: 64.3, 75.8) and median DOR was 19.1 months (95% CI: 14.5, 27.9; Table). In the efficacy population (N=281), median OS was 44.3 months (95% CI: 30.9, 53.1) with median follow up of 47.6 months (95% CI: 44.8, 49.2), and median PFS was 13.1 months (95% CI: 11.4, 16.8). In the overall population, ORR, median DOR, and median PFS (Table) were higher in the US vs. Asia or Europe. Among patients <65 years (n=174; median age 54 years), ORR was 70% (95% CI: 62.7, 76.8) with a median DOR of 22.6 months (95% CI: 14.5, 38.3). In the safety population, 95% of patients experienced treatment-related adverse events (TRAEs); 66% experienced ≥grade 3. Common TRAEs included increased AST (n=128 [46%]), anemia (n=121 [43%]), increased ALT (n=98 [35%]), and hypertension (n=77 [27%]). 3 patients died due to TRAEs (pneumonia, n=2; interstitial lung disease and rhabdomyolysis, n=1 each). No new safety signals were identified with this update.

Conclusions: Pralsetinib produced clinically meaningful and durable responses in patients with RET fusion-positive NSCLC (regardless of prior therapies) with a manageable safety profile, confirming with this longer follow-up previously published results.

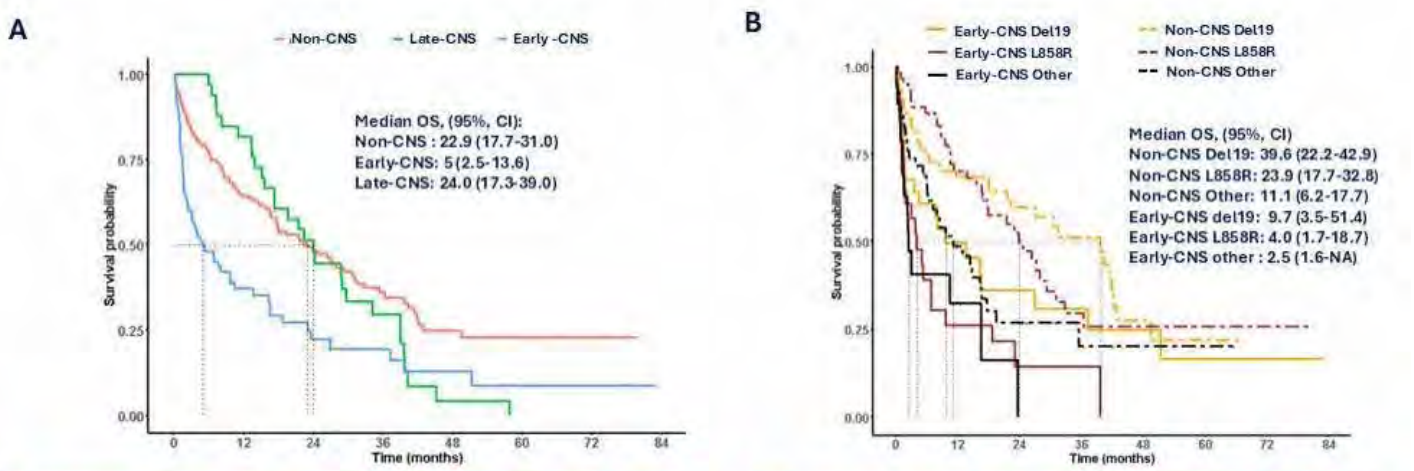
Introduction: The incidence of central nervous system (CNS) metastases is higher in Epidermal Growth Factor Receptor (EGFR)-mutation positive Non-Small Cell Lung Cancer (NSCLC) patients compared to those without EGFR-mutations. Approximately 30%-50% of the EGFR-mutation positive patients develop CNS metastases within 5 years of diagnosis. However, real-world studies on these patients, their characteristics, and treatment outcomes remain scarce.

Methods: This retrospective observational study analysed hospital data lakes and national registry data, for EGFR-positive NSCLC patients with CNS metastases from two Finnish university hospitals (2017-2023), representing ~55% of NSCLC diagnosed cases in Finland. The study assessed incidence, patient characteristics, treatment patterns and survival of EGFR-positive NSCLC patients with brain metastasis using Kaplan-Meier analysis.

Results: A total of 544 EGFR mutation positive NSCLC patients were included in the study. 286 (53%) were diagnosed with advanced stage disease (aNSCLC) of which 242 patients (85%) had stage IV disease at first diagnosis. During the study, 21% (n=115) of the whole study population and 40% of the patients with advanced disease developed CNS metastases. 24% (n=70) of the advanced stage patients had CNS metastases at first diagnosis +/- 3 months (Early-CNS group). 12% (n=33) developed CNS metastases later in the advanced stage treatment path (Late-CNS group) and ~5% of the early-stage patients were later diagnosed with CNS metastases (Recurrent-CNS group not included in analysis here). The Early-CNS group had a lower median age (69.2 years) compared to the aNSCLC without CNS-metastasis (Non-CNS group) (73.2 years). 56% of the Early-CNS patients were in first line treated with tyrosine kinase inhibitors, 25% received palliative radiotherapy only and 9% got no active lung cancer treatment. Median OS for the Non-CNS patients was 22.9 months (95% CI: 17.7-31.0 months), while it was 24 months (95% CI: 17.3-39.0 months) in the Late-CNS group and only 5 months (95% CI: 2.5-13.6 months) for the Early-CNS patients (Figure 1A). OS for the Early-CNS patients varied by mutation: Del19 (9.7 months), L858R (4.0 months), and all other EGFR-mutations combined (2.5 months). Corresponding OS-results for the Non-CNS-patients was 39.6, 23.9, and 11.1 months, respectively (Figure 1B).

Conclusions: EGFR mutation positive NSCLC patients with CNS metastases exhibit poor OS regardless of the EGFR mutation present. This highlights the need for early diagnosis and better treatments to prevent and manage CNS metastases in EGFR-mutant NSCLC.



Time (months)	0	12	24	36	48	60	72	84
Non-CNS	183	98	50	25	13	8	2	0

P3.12.73 Phase I/II Study on WSD0922-FU in EGFR C797S+ NSCLC

C. Zhou[1], A. Xionag[1], H. Zhong[2], D. Huang[3], Z. Huang[4], L. Xing[5], K. Tang[6], W. Zhong[7]
[1]Shanghai East Hospital, shanghai/CN ,[2]Shanghai Chest Hospital, Shanghai/CN ,[3]Tianjin Cancer Hospital, Tianjin/CN ,[4]Tianjin Cancer Hospital, Fuzhou/CN ,[5]Shangdong Cancer Hospital, Jinan/CN ,[6]The First Affiliated Hospital of Sun Yat sen University, Guangzhou/CN ,[7]WayShine Biopharm, LA/CA/USA

Introduction: Although 3rd-generation EGFR TKIs are highly effective in front-line treatment of metastatic EGFR-mutated (EGFRm) NSCLC, acquired resistance ultimately occurs, including the emergence of the on-target C797S mutation. WSD0922-FU is an oral, central nervous system (CNS)-penetration, wildtype-sparing, ATP non-competitive, reversible EGFR inhibitor targeting EGFR aberrations in NSCLC. It has shown promising preclinical and clinical activity. WSD0922-102 (NCT06631989) is an ongoing phase 1/2, open-label, multicenter trial evaluating the efficacy and safety of WSD0922-FU as a monotherapy in patients with EGFR C797Sm+ advanced NSCLC in China.

Methods: Adult patients with EGFR C797Sm+ NSCLC were given with WSD0922-FU orally, with five doses based on PK coverage and selected from phase I dose escalation (NCT04197934) as a bridging PK study in China. After DLT evaluation, expansion was initiated for each dose and then phase 2 study started using the dose of RP2D. Key inclusion criteria included patients ≥18 years of age with metastatic EGFR C797Sm+ NSCLC; ECOG PS 0-1; and previously treated with 3rd G EGFR TKI. EGFR C797S mutation was detected via tissue/liquid samples. Key exclusion criteria were tumors harboring EGFR T790M mutations, EGFR exon 20 insertions, or MET aberrations. Phase 1 dose escalation primary endpoints were maximum tolerated dose, RP2D and safety. The expansion and extension primary endpoint was overall response rate by RECIST 1.1. Secondary endpoints included duration of response, disease control rate, progression-free survival, overall survival, CNS activity (iORR) by RANO-BM, and safety. Patients were enrolled into 3 treatment cohorts: dose escalation (n≈12-15), dose expansion (n≈20), and dose extension (n≈70). The treatment continued until disease progression, unacceptable toxicity, or other discontinuation criteria were met. Clinical trial information: NCT06631989.

Results: All 42 patients received treatment at the time of data cutoff (Jul 31, 2025). For all evaluable patients in efficacy set (n = 33), ORR assessed by investigator is 60.6% (20/33), and the disease control rate was 100%. Median PFS is not reached. In the 120mg BID cohort, Overall ORR is 63.2% (12/19). Among the 4 subjects in 120mg BID cohort with baseline brain metastases eligible for RANO BM assessment, 3 subjects achieved objective response in the central nervous system, with an objective response rate of 75% (3/4), and another case had the central nervous system disease controlled, with DCR of 100% (4/4). In safety set (n=42), the most common possibly causally related adverse events were rash (59.5%), diarrhea (33.3%), anemia (33.3%), headache (33.3%), vomiting (26.2%), dry skin (26.2%), hypertriglyceridemia (23.8%), loss of appetite (21.4%), hair loss (21.4%), dizziness (21.4%), and weakness (21.4%). ≥grade 3 treatment-related adverse events (TRAE) associated with the study drug were rash (2.4%), decreased lymphocyte count (2.4%), diarrhea (2.4%), and vomiting (2.4%). Conclusion: In patients with EGFRm+ C797S advanced NSCLC who progress after 3rd generation EGFR-TKI treatment, WSD0922-FU provides a good efficacy and tolerability with an ORR of 63.2% at RP2D. This study supports further investigation of WSD0922 in extension cohort to potentially establish standard 2nd/3rd line for NSCLC patients progression after 1st line 3rd generation EGFR TKI treatment with C797S mutation.

P3.12.74 IMM2510, an Anti-PD-L1/VEGF Bispecific Antibody Fusion Protein for Advanced IO-treated SQ-NSCLC: A Phase I Study

P. WANG[1], Y. ZHANG[2], W. MA[3], S. GAO[4], R. JIA[4], S. LUO[5], S. AN[5], F. LIU[6], X. HU[7], J. ZHANG[7], Y. SUN[8], X. PENG[9], D. YANG[10], H. PANG[10], D. JING[10], Z. WANG[10], Z. WU[10], W. TIAN[10], X. CHENG[11]
[1]The Second Affiliated Hospital Zhejiang University School of Medicine, Hangzhou/CN ,[2]Hunan Cancer Hospital, Changsha/CN ,[3]The First Affiliated Hospital of Zhengzhou University, Zhengzhou/CN ,[4]The First Affiliated Hospital of Henan University of Science and Technology, Luoyang/CN ,[5]Henan Cancer Hospital, Zhengzhou/CN ,[6]The First Hospital of China Medical University, Shenyang/CN ,[7]Fudan University Shanghai Cancer Center, Shanghai/CN ,[8]Shandong Cancer Hospital and Institute, Jinan/CN ,[9]West China Hospital Sichuan University, Chengdu/CN ,[10]ImmuneOnco Biopharmaceuticals (Shanghai) Inc., Shanghai/CN ,[11]Zhejiang Cancer Hospital, Hangzhou/CN

Introduction: IMM2510 is a novel bispecific antibody fusion protein targeting PD-L1 and VEGF. The data of dose-escalation phase were previously reported in ASCO2024.Here we present preliminary data on efficacy and safety of IMM2510 in advanced immunotherapy-treated squamous non-small-cell-lung-cancer (NSCLC) patients from escalation and expansion stages.

Methods: The study IMM2510-01 was designed as a phase I, multicenter, open-label study to evaluate the safety, efficacy, recommended phase II dose (RP2D), and pharmacokinetics (PK) of IMM2510 monotherapy (NCT05972460).

Results: As of 13 June 2025, 23 squamous-NSCLC patients were treated with IMM2510, including 2 subjects at 3mg/kg, 1 subject at 6mg/kg, 4 subjects at 10mg/kg, 16 subjects at 20mg/kg. The median age of enrolled subjects was 61. Seventeen patients (73.9%) had an ECOG PS of 1. The median prior lines of systemic treatments were 2 (1-5 lines). The numbers of patients with TPS scores < 1%, 1-49% and ≥ 50% were 7 (30.4%), 8 (34.8%) and 3 (13.0%), respectively. Twenty-three patients (100%) previously received PD-(L)1 and chemotherapy, 6 patients (26.1%) previously received anti-VEGF treatments. All patients (100.0%) experienced treatment-related adverse events (TEAEs). 13 subjects experienced ≥G3 TEAE(56.5%), and 1 subject experienced TEAE(4.3%) leading to dose discontinuation. The most common TRAEs of any grade were infusion related reaction (IRR) (65.2%), anemia (52.2%), and platelet count decreased (43.5%). The most common TRAEs ≥ Grade 3 were platelet count decreased (8.7%), lymphocyte count decreased (8.7%) and IRR (8.7%). The occurrence rate of VEGF-related TRAEs is low, no≥G3 hypertension, ≥G3 proteinuria (n=1, 4.3%),≥G3 hemoptysis (n=1, 4.3%). No patient experienced TRAE that led to death. Of 17 efficacy-evaluable squamous-NSCLC patients, the ORR was 29.4% (5/17), and DCR was 76.5 % (5 PR and 8 SD). The median DoR was 7.59 months, and median PFS was 9.4 months. Notably, in 16 EGFR/ALK wild-type squamous-NSCLC patients, the ORR was 31.3% (5/16). The enrollment of squamous-NSCLC and further PD, PK analyses are ongoing.

Conclusion: IMM2510monotherapy demonstrated potent anti-tumor activity in advanced immunotherapy-treated squamous-NSCLC patients with tolerable and manageable safety profiles. Based on these findings, phase II studies of IMM2510 combined with chemotherapy in advanced NSCLC are in progress, to further explore its therapeutic potential.

P3.13.01 Effect of Patient Management System and Medical Resources on Outcomes of SCLC Treated With Chemo-ICI

Y. Yamanaka[1], K. Iwasaki[2], T. Uenishi[2], K. Kokubo[2,3], T. Kurata[1]
[1]Kansai Medical University, Osaka/JP ,[2]Healthcare Consulting, Inc., Chiyoda-ku, Tokyo/JP ,[3]Nishogakusha University, Tokyo/JP

Introduction: Although chemotherapy with immune checkpoint inhibitors (chemo-ICI) is the standard of care for the first-line treatment of extensive-stage small cell lung cancer (SCLC), some patients are compelled to discontinue treatment due to its toxicities. Effective patient management systems and sufficient medical resources may play a crucial role in managing the toxicities associated with chemo-ICI, potentially improving treatment continuity.In this study, we focused on evaluating treatment outcomes in terms of treatment continuity to assess the impact of hospital resources and patient management systems on patients with SCLC receiving chemo-ICI.

Methods: The study endpoints were the time to treatment failure (TTF) of ICI and the incidence of grade 3 or higher hematologic toxicities and other adverse events.Patients with SCLC who received first-line treatment with cisplatin/carboplatin + etoposide + ICI (atezolizumab/durvalumab) were extracted from the DATuM IDEA® database. This database integrates electronic medical records from multiple National Hospital Organization institutions in Japan based on the Next Generation Medical Infrastructure Act. The dataset provided for analysis was fully de-identified prior to access by researchers, ensuring patient confidentiality.Patients were categorized into two groups based on the number of hospital beds: hospitals with fewer than 500 beds (<500 group) and those with 500 or more beds (≥500 group). The number of beds was used as a surrogate marker for hospital resources and patient management systems, as larger hospitals generally have more comprehensive infrastructure and established management protocols. Baseline characteristics were adjusted between groups using propensity score matching (PSM), including regimen, gender, age, Charlson Comorbidity Index, interstitial pneumonia (IP), and the prescription of proton pump inhibitors, anti-infectives, and corticosteroids.

Results: After PSM, 80 patients were extracted from each of the <500 group and ≥500 group.The median TTF was 4.6 months in the <500 group and 4.8 months in the ≥500 group, with a difference of only 0.2 months. There was no statistically significant difference (P = 0.459, log-rank test), indicating that treatment outcomes in terms of efficacy were comparable between the groups.Among grade 3 or higher hematologic toxicities, the incidence of leukopenia was 66.3% versus 46.3%, and the incidence of neutropenia was 75.0% versus 57.5%, with both being significantly lower in the ≥500 group (P < 0.05, Fisher's exact test). This suggests that treatment outcomes in terms of safety were better in the ≥500 group.

Conclusions: Treatment efficacy was comparable between the <500 group and the ≥500 group.However, patients in the ≥500 group experienced fewer grade 3 or higher hematologic toxicities, indicating better treatment safety.These findings suggest that larger hospitals, with more established patient management systems and greater medical resources, may provide more appropriate patient care, leading to improved safety outcomes.

P3.13.02 The Effectiveness of Anatomical Versus Non-Anatomical Resection for Treatment of Small Cell Lung Carcinoma

M. Dziedzic[1], M. Pawlica[2], K. Chrzanowska[2], S. Antoniak[1], P. Ciepiałowska[1], M. Cackowski[3]
[1]Medical University of Gdańsk, Gdańsk/PL ,[2]Medical University of Warsaw, Warsaw/PL ,[3]National Research Institute of Chest Diseases, Warsaw/PL

Introduction: Small Cell Lung Carcinoma (SCLC) is a highly aggressive type of tumor with a significant potential for early metastases. Currently, chemotherapy serves as a gold standard for first-line treatment, with a significant number of studies conducted. However, the role of surgical management, especially the effectiveness of anatomical versus non-anatomical resections, remains a subject of debate and is often underestimated in clinical practice. The aim of the study was to assess the impact of resection extent on overall survival

Methods: The patient data was collected retrospectively from the Polish Lung Cancer Study Group database (PLCSG), which incorporates records of surgically treated patients from nearly 30 thoracic centers across Poland. The study included patients with confirmed SCLC in histopathology who underwent radical surgical resection between the years 2007-2023 and had complete data.

Results: A total of 564 patients were included in the analysis. Most of them were men (54.8% vs 45.2%), and the median age was 64 years. Smokers comprised a larger proportion of the cohort compared to non-smokers (72.0% vs. 28.0%). All of the patients were staged according to the 9th edition of tumor-nodes-metastases (TNM) classification, and the most common stages were IA3 (14.4%), IB (14.6%), and IIB (22.4%). Lymph node involvement was identified in 30.1% of cases, with pN1 (16.5%) and pN2B (11.3%) being the most frequently observed stages. Based on the size of the tumor, the most common stages were I and II, which were 50.5% and 30.5%, respectively. Surgical treatment included pneumonectomy (11.2%), lobectomy (67.4%), segmentectomy (7.6%), and wedge resection (13.8%). The overall survival rate (OSR) was assessed at the 5-year mark, and anatomical resections were favored over non-anatomical. Among the surgical procedures, lobectomy and pneumonectomy had the highest 5-year survival rates at 42.3 (95% CL; 47.90 - 37.32) and 36.3% (95% CL; 50.39 - 26.10), respectively. These were followed by segmentectomy at 29.6% (95% CL; 50.28 - 17.48) and wedge resection at 28.6% (95% CL; 41.37 - 19.82).

Conclusions: This multicenter retrospective analysis highlights the potential benefit of surgical intervention in selected patients with SCLC. The results demonstrate that anatomical compared to non-anatomical resections are associated with superior 5-year overall survival rates, with lobectomy correlated with the most favorable outcomes.

P3.13.03 Proteomic Profiling of Small Cell Lung Cancer Patients Reveals Blood-Based Prognostic Proteins

K. Boettiger[1], L. Horvath[2], B. Szeitz[2], C. Lang[1], I. Kovacs[2], V. Teglas[2,3], M.D. Pozonec[2,3], B. Ernhofer[1], R. Szegedi[2], K. Schelch[1], C. Aigner[1], K. Bogos[2], F. Renyi-Vamos[2,3], R. Hecz[4], G. Galffy[4], J. Gil Valdes[5], G. Marko-Varga[6], Z. Megyesfalvi[1,2,3], B. Döme[1,2,3,6]
[1]Medical University of Vienna, Vienna/AT ,[2]National Koranyi Institute of Pulmonology, Budapest/HU ,[3]Semmelweis University and National Institute of Oncology, Budapest/HU ,[4]Pulmonology Hospital Törökbálint, Törökbálint/HU ,[5]Department of Biomedical Engineering, Lund/SE ,[6]Lund University, Lund/SE

Introduction: Small cell lung cancer (SCLC) remains an aggressive thoracic malignancy with poor overall survival (OS) rates (5-year OS<7%). Additionally, since personalized therapeutic approaches are not yet available in routine clinical practice, there is a need to investigate the heterogeneous molecular profile for potential biomarkers. Our group is among the first to utilize mass spectrometry-based proteomics, which enables the detection of even low abundant proteins in a sample, to elucidate differences in the SCLC proteome for biomarker discovery. Here, we aimed to explore proteomic signatures in the blood plasma of SCLC patients, focusing specifically on prognostic proteins.

Methods: In this prospective study, we analyzed clinical data and pre-treatment blood plasma samples of 144 SCLC patients from two Central-European thoracic institutions. Proteomic profiling was performed via mass spectrometry-based proteomics at Lund University, Sweden, and 1,338±209.23 proteins were quantified per sample. Consecutive bioinformatic analysis for prognostic protein detection included multivariate Cox regression analyses, a custom-built machine-learning algorithm, weighted gene co-expression network analysis (WGCNA), or pathway enrichment analysis. Additionally, we analyzed patient progression-free survival data and examined predictive proteins in relation to SCLC standard-of-care therapy. Lastly, the appearance of treatment-related side effects was also investigated.

Results: The SCLC cohort was reflective of patients with extensive disease stage (69.44% stage 4). 47.92% of patients were female and the median age was 68.73 years. Multivariate Cox regression analysis including clinical data known at the time of sample collection yielded 60 proteins prognostic for OS (adjusted (adj.) p<0.05). Notably, CHGA (multivariate hazard ratio, HR=1.44, adj. p<0.001) was significantly associated with worse survival, whereas FETUB (multivariate HR=0.4, adj. p<0.001) demonstrated better prognosis, among others. Our machine-learning model strengthened the selected protein list. Subsequent data exploration through WGCNA yielded six distinct modules (=groups of co-expressed proteins). Of these, the MEpink module was associated with worse prognosis (multivariate HR=2.41, p=0.034), while the MEdarkred module was linked to better OS (multivariate HR=0.05, p=0.030 at sampling), respectively. We detected significant associations with clinical parameters for specific modules (e.g. liver metastasis presence at the time of sample collection for MEpink, female gender for MEdarkred, or associations with non-smokers for MEgreenyellow). Finally, proteins of the MEdarkred and MEpink modules showed enrichment of biologically relevant pathways such as ‘complement cascade’ or ‘coagulation’.

Conclusions: Coupling proteomic profiling with bioinformatic analyses of blood plasma samples yielded independent prognostic proteins concerning OS. SCLC is a disease reflective of short survival time. Therefore, it is necessary to investigate clinical samples to support patient surveillance and the selection of optimal treatment strategies for SCLC patients.

P3.13.04 Consolidation Thoracic Radiotherapy After Chemoimmunotherapy in ES-SCLC: A Multicentric Retrospective Analysis

F. Monaca[1], I. Randulfe[2], G. Walls[3], O. Cantale[4], V. Longo[5], D. Galetta[5], A. Parreira[2], A. Martino[1], E. Vita[1], L. Boldrini[1], M.A. Gambacorta[1], G. Tortora[1], S. Novello[4], Y. Summers[2], F. Blackhall[2], C. Chan[2], E. Bria[1], C. Faivre-Finn[2], R. Califano[2]
[1]Fondazione Policlinico Universitario A. Gemelli, Rome/IT ,[2]The Christie NHS Foundation Trust, Manchester/GB ,[3]Patrick G Johnston Centre for Cancer Research, Belfast/GB ,[4]University of Turin, San Luigi Gonzaga Hospital, Orbassano/IT ,[5]IRCCS Istituto Tumori "Giovanni Paolo II", Bari/IT

Introduction: The role of consolidative thoracic radiotherapy (TRT) following first-line (1L) chemotherapy in extensive-stage small cell lung cancer (ES-SCLC) was established by the CREST trial, which demonstrated an improvement in 2-year overall survival (OS). An exploratory analysis revealed that patients with residual intrathoracic disease treated with TRT had a significantly longer OS compared to those who did not receive TRT. However, registration 1L chemoimmunotherapy (ChIO) trials did not allow TRT, leaving its role in the immunotherapy era uncertain.

Methods: We retrospectively analysed consecutive patients (pts) with ES-SCLC who received 1L ChIO between January 2020 and January 2024 at The Christie (Manchester, UK) and Istituto Tumori Giovanni Paolo II (Bari, Italy). TRT was delivered at a total dose of 30 Gray over 10 fractions. Patients without radiological disease progression at the first post-treatment assessment were considered eligible. We compared local recurrence rates, progression-free survival (PFS), and OS between those who received TRT and those who did not.

Results: A total of 183 pts were identified, of whom 71 (38.8%) received TRT. Clinical characteristics are summarised in Table 1 and are well balanced. Patients who received TRT had a lower rate of intra-thoracic progressive disease (PD) compared to those who did not (42.3% vs 65.2%, $p < 0.001$). Among the 54 pts who developed PD despite TRT, only 15 (27.8%) experienced progression within the radiotherapy field. With a median follow-up of 29.0 months (95% CI, 23.5-34.4), there were no significant differences in median PFS (6.9 vs 5.9 months, $p = 0.128$) and OS (13.0 vs 12.9 months ,$p = 0.183$) between the TRT and non-TRT group.

Table 1. Clinical characteristics of patients who received TRT vs those who did not receive TRT.div>

Conclusions: TRT after 1L ChIO improved local control but did not result in a significant difference in survival outcomes. Prospective trials are needed to further evaluate the potential benefit of RT to the thorax and metastases on quality of life as well as survival in this patient population within the IO era.

P3.13.05 First-In-Human Study of 225Ac-ABD147 for SCLC and LCNEC Post-Chemotherapy: Pharmacokinetics, Biodistribution and Safety Insights

S. Carlin[1], G. Wang[1], D. Namjoshi[2], I. Kulic[2], J. Go[1], G. Ulaner[3,4], B. Saboury[5], M. Morris[6], C.M. Rudin[7], L. Bodei[7]
[1]Abdera Therapeutics Inc., South San Francisco/CA/USA ,[2]Abdera Therapeutics Inc., Vancouver/BC/CA ,[3]Hoag Family Cancer Institute, Irvine/CA/USA ,[4]University of Southern California, Los Angeles/CA/USA ,[5]United Theranostics, Glen Burnie/MD/USA ,[6]United Theranostics, Glen Burnie/NY/USA ,[7]Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: 225Ac-ABD147, a targeted radioligand therapy, uses actinium-225 (225Ac, an alpha emitting radionuclide) coordinated to the VHH-Fc -chelator conjugate ABD147. It specifically binds the delta-like ligand 3 (DLL3) receptor, over expressed in Small Cell Lung Cancer (SCLC) and Large Cell Neuroendocrine Carcinoma of the Lung (LCNEC) but not on normal tissue. 111In-ABD147 serves as a single-photon emission computerized tomography (SPECT) imaging surrogate to evaluate pharmacokinetics (PK), biodistribution and normal organ dosimetry. Preclinical data, previously presented at AACR [1], provide the foundation for this Phase 1a/b study, which evaluates the tolerability, biodistribution, PK, and preliminary tolerability of 225Ac-ABD147 in patients with locally advanced or metastatic SCLC and LCNEC post platinum-based chemotherapy.

Methods: Phase 1a involves escalating doses to determine the safety, tolerability, dosimetry, PK, and to establish the Phase 1b expansion dose. Phase 1b will assess safety and preliminary efficacy to recommend the Phase 2 dose (RP2D). Using centralized core lab services, organ-level SPECT-based dosimetry assessments will be made on up to 10 patients for 111In-ABD147 and 3 to 6 patients for 225Ac-ABD147. Radiation pharmacokinetic assessments will be performed using a two-compartment model. Eligible patients must have confirmed locally advanced or metastatic SCLC or LCNEC, completion of platinum-based chemotherapy. Subjects must have measurable disease by RECIST v1.1. Exclusion criteria include hypersensitivity to 225Ac or 111In, active infection, uncontrolled bleeding, or non-healing wound and prior EBRT to >25% of the bone marrow. Phase 1a dose escalation is ongoing in the US (NCT06736418).

Results: As of April 2025, PK, biodistribution, and dosimetry assessments with 111In-ABD147 are ongoing for Cohort 1. Patients who received 225Ac-ABD147 are being followed for safety. The presentation will summarize key PK findings, biodistribution patterns, dosimetry assessments, and early safety data from Cohort 1, with additional insights from Cohort 2 as data become available.

Conclusions: This marks the first clinical data presentation for ABD147. The findings will provide a foundational evaluation of the investigational agent's safety, PK profile, and potential clinical implications.

[1]Institut Universitaire de Cardiologie et de Pneumologie de Québec, Québec/QC/CA ,[2]McGill University, Montreal/QC/CA

Introduction: Small cell lung carcinoma (SCLC) accounts for approximately 15% of all lung cancer cases and remains one of the most aggressive subtypes, with a dismal five-year survival rate of less than 5%. Unlike non-small cell lung carcinoma (NSCLC), the development of targeted therapies for SCLC has been hindered by the lack of targetable alterations and treatment options remain limited. While immunotherapy has shown some benefit in selected patients, reliable predictive biomarkers are still lacking. The proposed classification system, based on transcriptomic data, categorizes SCLC into four subtypes, characterized by the expression of the transcription factors ASCL1, NeuroD1, POU2F3, and an "inflamed" phenotype (SCLC-A, N, P, and I, respectively). This classification has shown promise in predicting responses to immunotherapy. However, little is known about their relationship with the tumor microenvironment (TME) as well as how subclassifying diagnostic samples may provide insight into TME characteristics. In this study, we aim to investigate the TME in relation to SCLC molecular subtypes.

Methods: We retrospectively selected a cohort of 56 patients who underwent lung resection for primary SCLC between 2004 and 2021. Clinical and pathological data were retrieved from our institutional biobank. Tissue microarrays (TMAs) were constructed using three cores per tumor from different regions, distributed across three TMAs. Subtyping was performed by immunohistochemistry for ASCL1, NeuroD1, and POU2F3. Two readers assessed staining using an H-score, classifying each core based on the highest score. Triple-negative cores were categorized as the "inflamed" subtype. TME profiling was performed using mass cytometry (CyTOF), with single-cell analysis of over 500,000 cells and 36 markers to enable a detailed spatial characterization of 18 stromal and immune cell lineages. Differences in the percentage of cells and cellular neighborhoods across subtypes was assessed using Kruskal-Wallis with Bonferroni correction.

Results: The cohort included 31 females (56.4%) with a mean age of 65.2 years. Most patients had a smoking history (former 36.4%, active 61.8%). A total of 134 TMA cores were analyzed and classified as follows: SCLC-A (n=80, 59.7%), SCLC-N (n=16, 11.9%), SCLC-P (n=24, 17.9%), and SCLC-I (n=14, 10.4%). The TME of SCLC-P was significantly more vascularized than that of SCLC-A and SCLC-I, both at the cellular level ($p = 0.016$; $p = 0.023$, respectively) and within the cellular niche (CN) ($p = 0.012$; $p = 0.030$, respectively). Additionally, the TME of SCLC-N exhibited a significant enrichment in classical monocytes compared to SCLC-P, at both the cellular level ($p = 0.039$) and the CN level ($p = 0.043$). Clustering analysis based on TME composition identified cores enriched in cytotoxic and helper T cells and others enriched in M1 macrophages, though these patterns showed no significant association with molecular subtypes.

Conclusions: SCLC exhibits TME variability, with few consistent associations between molecular subtypes and immune composition. This variability may limit the utility of molecular subtyping in predicting TME characteristics from diagnostic samples.

P3.13.07 Real-World Implementation of Immunotherapy for Stage III-IV Small Cell Lung Cancer: Insights From the National Cancer Database (2016-2021)

S. Kalantri, T. Jones, P. Pachika, A. Shameem, B. Morguelan, M. Kong, G. Kloecker
Brown Cancer Center, University of Louisville, Louisville/KY/USA

Introduction: Immune checkpoint inhibitors (ICIs) have redefined the treatment landscape for extensive-stage small cell lung cancer (SCLC), with landmark approvals following the IMpower133 (2018) and CASPIAN (2019) trials. However, real-world adoption and equitable delivery remain uncertain. We examined temporal trends and access patterns in immunotherapy utilization using the National Cancer Database (NCDB)—a hospital-based oncology registry that captures over 70% of newly diagnosed cancer cases in the United States.

Methods: We conducted a retrospective analysis of over 55,000 patients diagnosed with Stage III-IV SCLC between 2016 and 2021 in the NCDB. The primary outcome was receipt of immunotherapy. Multivariable logistic regression was used to assess associations with demographic, socioeconomic, and treatment center variables. Odds ratios (OR), 95% confidence intervals (CI), and p-values were reported.

Results: Immunotherapy utilization rose from 1.7% in 2016 to 42% in 2021, with the sharpest increase following 2018, coinciding with IMpower133 and CASPIAN trial publications. However, fewer than half of patients received immunotherapy in 2021, despite national guideline recommendations, raising concerns about barriers to adoption that extend beyond clinical contraindications. Patients treated at academic centers were more likely to receive immunotherapy [OR: 1.23 (1.19-1.27), p<0.001]. Insurance type was strongly associated with treatment: private insurance was linked to increased odds of receipt [OR: 1.19 (1.12-1.26)], while Medicare [OR: 0.79 (0.75-0.83)], no insurance [OR: 0.75 (0.67-0.85)], and other government coverage [OR: 0.78 (0.69-0.88)] were associated with lower odds (all p<0.001). Patients from areas with high school non-completion ≥15.3% had reduced odds [OR: 0.80 (0.74-0.86), p<0.001]. Residence in rural areas was associated with increased use [OR: 1.21 (1.09-1.34), p<0.001], while urban vs. metro location showed no difference. Female patients had slightly lower odds than males [OR: 0.94 (0.91-0.97), p<0.001]. No statistically significant differences were observed across race/ethnicity groups.

Conclusions: This large national cohort demonstrates a substantial increase in immunotherapy use for Stage III-IV SCLC following pivotal trial publications. However, real-world delivery continues to lag behind clinical potential, with fewer than half of patients receiving immunotherapy even in 2021. Treatment variation persists across insurance type, education level, residential setting, and sex. These findings highlight the need for targeted strategies to close access gaps and better understand barriers beyond contraindications, ensuring that advances in SCLC therapy are implemented equitably.

P3.13.08 Autologous Vax-NK/HCC Consolidation Therapy in ES-SCLC

I-J. Oh[1,2], H.K. Park[1,2], H-J. Oh[1,2], C-K. Park[1,2], Y-C. Kim[1,2], S-Y. Park[2], S-W. Lee[1], J-H. Cho[1]
[1]Chonnam National University Medical School, Jeollanamdo/KR ,[2]Chonnam National University Hwasun Hospital, Jeollanamdo/KR

Introduction: While first-line treatment of extensive-stage small-cell lung cancer (ES-SCLC) with platinum-based chemotherapy combined with atezolizumab (ACE regimen) has demonstrated improved progression-free survival (PFS) and overall survival (OS) compared to chemotherapy alone, disease progression during atezolizumab maintenance remains a clinical challenge. This study aims to evaluate the feasibility and safety of autologous natural killer cell (Vax-NK/HCC) consolidation following the four cycles of ACE.

Methods: This is a single-center, open-label, prospective, single-arm clinical trial (Figure 1). Vax-NK/HCC, a natural killer cell product amplified from patient-derived peripheral blood mononuclear cells (PBMCs) via leukapheresis and co-cultured with 100 Gy gamma-irradiated K562 cells at a 1:6 ratio in the presence of proliferation-inducing cytokines, was administered. After completing the ACE, patients received two cycles of Vax-NK/HCC (1 x 109 cells/injection) over five consecutive days. Atezolizumab (1200 mg) was administered on the second day following each Vax-NK/HCC cycle and repeated every three weeks until disease progression or unacceptable toxicity. The primary endpoint was PFS. Secondary endpoints included OS and safety profile. Pre- and post-therapy PBMCs were collected from patients for immunophenotypic analysis of NK cells and various other immune cells.

Results: This ongoing trial has completed Vax-NK/HCC administration in eight patients with a median age of 62 (range, 50-70) years. The mean viability of the Vax-NK/HCC product was 95.0%, and the mean cytotoxicity was 78.0%. The median PFS was 4.79 months (95% CI, 4.59-4.98), and the median OS was 9.64 months (95% CI, 5.23-14.06). Grade 3 treatment-related adverse events (TRAEs) were observed in two patients, specifically ileus and immune-related myositis. Grade 2 TRAEs included nausea, constipation, myalgia, herpes zoster, and hypoglossal nerve palsy. Notably, patients with a relatively longer PFS showed high CXC chemokine receptor expression profiles in pre-therapy PBMCs.

Conclusions: This interim analysis indicates that autologous natural killer cell consolidation therapy following the ACE regimen is feasible and exhibits a manageable toxicity profile in patients with ES-SCLC. However, the antitumor activity and survival data are currently preliminary, and long-term outcomes may be improved with the aid of predictive blood biomarkers.

P3.13.09 Surface Targeting Strategies to Overcome Heterogeneity Associated With Treatment Resistance in Small Cell Lung Cancer (SCLC)

A. Stewart, K. Ramkumar, R. Wang, Y. Yang, B. Zhang, A. Halliday, Y. Xi, L. Diao, Q. Wang, A. Duarte, P. Li, A. Tanimoto, A. Serrano, J. Vykoukal, M. Bose, L. Karacosta, L.M.S. Soto, S. Hanash, J. Wang, J.V. Heymach, L.A. Byers, C.M. Gay
University of Texas M.D. Anderson Cancer Center, Houston/TX/USA

Introduction: Small cell lung cancer (SCLC) is an aggressive neuroendocrine malignancy characterized by rapid onset of chemoresistance and poor clinical outcomes. The recent FDA approval of tarlatamab, a DLL3 targeting bispecific T-cell engager (BiTE), alongside unprecedented response rates observed with multiple antibody-drug conjugates (ADCs), have ushered in a paradigm shift towards surface targeting strategies in relapsed SCLC patients. While providing much-needed optimism for SCLC patients, resistance, both intrinsic and acquired, is common and must be better characterized to maximize the potential of these new therapeutic classes. We hypothesize that combinatorial targeting of multiple surface proteins using distinct strategies (i.e., BiTEs, ADCs, etc.) represents a novel way to overcome intratumoral heterogeneity common to relapsed SCLC and enhance antitumor immunity engendered by ADC payloads (i.e., topoisomerase 1 [TOP1] inhibitor).

Methods: To better define the surfaceome of relapsed SCLC, we performed surfaceome mass spectrometry analysis of SCLC cell lines, naïve and relapsed patient derived xenografts (PDXs), and PDXs treated with frontline chemotherapy until relapse occurred, and identified a number of known (i.e., TROP2, HER2, B7H3) and novel surface proteins. These same surface targets were transcriptionally profiled at the single cell level in relapsed SCLC patient biopsies. To determine efficacy of combination surface targeting strategies, SCLC cell lines and PDX organoids, including those that are from neuroendocrine-low subtypes with poor response to platinum chemotherapy, were treated with DLL3-targeted therapies and TROP2- or HER-ADCs and proliferation was measured.

Results: Results: Single-agent surface targeting strategies are effective in preclinical models, including those resistant to other common SCLC therapies (i.e., platinum chemotherapy). Notably, single-cell transcriptional profiling of relapsed SCLC patient biopsies revealed mutually exclusive expression of surface genes in distinct cell populations (i.e., DLL3/SEZ6 vs. TROP2/HER2/B7-H3), including senescent, drug tolerant persister cells (DTPCs), representing a unique opportunity to target heterogeneous populations. Furthermore, combination targeting of different surface proteins (e.g., DLL3, TROP2, HER2) using both immune (i.e., chimeric antigen receptor T-cells, BiTEs) and payload-based modalities (i.e., ADCs) was more effective than single-agent targeting in resistant, neuroendocrine-low models.

Conclusions: Intratumoral heterogeneity associated with relapsed SCLC, which limits efficacy of single-agent surface targeting strategies, may be exploited with combinatorial therapies to target resistant cell populations, including DTPCs, using payload and immune-based methods.

P3.13.10 Real-World Outcomes of Prophylactic Cranial Irradiation (PCI) in Extensive-Stage Small Cell Lung Cancer (ES-SCLC) in the US

S. Reiss[1], C. Rinaldi[1], E. Castellanos[1,2], X. Li[1]
[1]Flatiron Health, New York/NY/USA ,[2]Fox Chase Cancer Center, Philadelphia/PA/USA

Introduction: The role of PCI in ES-SCLC remains controversial due to uncertain overall survival benefits and concerns about long-term neurocognitive toxicity. The integration of immunotherapy (IO) into ES-SCLC management further challenges the need for PCI, as IO can cross the blood-brain barrier and potentially reduce brain metastasis (BM) risk. This real-world study evaluated PCI utility in patients with ES-SCLC without BM who achieved a real-world response (rwR) to first-line (1L) platinum-based chemoimmunotherapy by evaluating real-world overall survival (rwOS), real-world progression-free survival (rwPFS), and cumulative incidence of BM and brain radiation treatment (RT) based on PCI exposure.

Methods: This retrospective observational cohort study used the US-based Flatiron Health Research Database, an electronic health record-derived deidentified database, to select 20,000 patients diagnosed with SCLC after January 1, 2018. Patients with ES-SCLC without BM who received 1L platinum-based chemotherapy with immunotherapy (atezolizumab or durvalumab), had an rwR during the baseline window, had no real-world progression (rwP) before index, survived through the baseline window, and who had five months of potential follow up from index date were included. Index date was the last order/administration of cisplatin/carboplatin in 1L, and patients were evaluated for PCI receipt during a baseline window from 1L start to 90 days post-index. Kaplan-Meier methods and log-rank tests evaluated rwOS and rwPFS. Cox proportional hazards regression was adjusted for covariates including Eastern Cooperative Oncology Group performance status, age, sex, race, ethnicity, number of metastases, receipt of upfront chest RT, and type of rwR (partial vs complete) to 1L. Cumulative Incidence Function estimated BM and therapeutic brain RT, accounting for death as a competing risk.

Results: Of 2,502 patients, 144 (6%) received PCI and were more likely to be younger (median age, 65 vs 68 years; P<.001) and diagnosed before 2022 (80% vs 56%; P<.001), achieve a real-world complete response (8.3% vs 4.1% P=.031), and receive upfront chest RT (44% vs 20%; P<.001). Median rwOS (95% CI) was 11.4 months (10.0-13.7) in the PCI group and 9.4 months (9.0-9.9) in the unexposed group (P=.053). The unadjusted rwOS hazard ratio (HR; unexposed vs PCI) was 0.83 (0.69-1.00; P=.05) and 0.85 after adjustment (0.70-1.03; P=.10). Median rwPFS (95% CI) was 4.8 months (4.3-5.8) in the PCI group and 3.7 months (3.7-3.9) in the unexposed group (P<.001). Unadjusted and adjusted rwPFS HR (unexposed vs PCI) were 0.70 (0.59-0.84; P<.001) and 0.72 (0.60-0.86; P<.001). The 1-year cumulative incidence of BM (95% CI) was 17% (11%-23%) in the PCI group and 44% (42%-46%) in the unexposed group (P<.001). The 1-year cumulative incidence of therapeutic brain RT was 5.2% (2.3%-9.8%) in the PCI group and 35% (33%-37%) in the unexposed group.

Conclusions: The use of PCI has declined in the chemoimmunotherapy era. Although PCI was associated with reduced incidence of BM and therapeutic brain RT at 1 year, it did not confer an rwOS benefit and provided a limited rwPFS advantage of 1 month. Risk-benefit assessment is needed when considering PCI in the modern treatment landscape.

P3.13.11 HER2- and TROP2-Directed Antibody Drug Conjugates Show Potent Antitumor Activities in Small Cell Lung Cancer

K. Ramkumar, C.A. Stewart, P. Li, R. Wang, A.H. Ibrahim, L. Diao, L. Shen, Y. Xi, S. Heeke, J. Wang, B. Zhang, L.A. Byers, C.M. Gay
The University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: Small cell lung cancer (SCLC) is a high-grade neuroendocrine carcinoma of the lung, characterized by poor prognoses, limited treatment options and rapid emergence of resistance. Recently, surface targeting strategies have shown considerable promise in SCLC. A DLL3-targeting T-cell engager (tarlatamab) has been FDA-approved for relapsed SCLC, with a 40% overall response rate. However, a majority of patients fail to derive benefit, likely due to heterogenous DLL3 expression. Antibody-drug conjugates (ADCs) targeting SEZ6, TROP2, and B7H3 have also demonstrated encouraging outcomes in clinical trials in relapsed SCLC. ADCs against HER2 and TROP2 are also approved for treatment of other solid cancers. We hypothesize that targeting cell surface HER2 or TROP2 using ADCs could provide an effective therapeutic strategy in biomarker-defined SCLC patient populations.

Methods: We analyzed ERBB2 (HER2) and TACSTD2 (TROP2) expression and regulation in treatment-naïve and relapsed SCLC patient tumors, LCNEC patient tumors, and other extrapulmonary hgNEC tumors using bulk and single-cell RNA sequencing, and methylation profiles. Efficacy of trastuzumab deruxtecan (HER2-ADC), trastuzumab, sacituzumab govitecan (TROP2-ADC), sacituzumab and the TOP1 inhibitor payloads (deruxtecan and SN-38) were evaluated in SCLC preclinical models.

Results: Both limited and extensive stage treatment-naïve SCLC tumors as well as relapsed tumors expressed a range of ERBB2 (HER2) and TACSTD2 (TROP2) expression, with enrichment in the non-neuroendocrine SCLC-P tumors. Expression of both targets (ERBB2 and TACSTD2) was negatively correlated with methylation levels in SCLC cell lines and patient tumors. Notably, SCLC tumors lacking DLL3 expression, the target of the newly approved drug tarlatamab, expressed abundant levels of both ERBB2 and TACSTD2. In preclinical models, both HER2- and TROP2-ADCs demonstrated potent in vitro activity with significant induction of apoptosis. While target expression was not predictive of ADC sensitivity, SLFN11 and TOP1 levels were identified as potential biomarkers of response. Compared to trastuzumab alone, HER2-ADC showed sustained tumor growth inhibition with prolonged tumor regression and survival in HER2-positive xenograft models. TROP2-ADC similarly demonstrated significant antitumor activity.

Conclusions: These findings demonstrate that targeting cell surface HER2 and TROP2 using ADCs is effective in SCLC, including the SCLC-P subtype, which typically is resistant to standard of care therapies and likely to tarlatamab, due to low DLL3 expression.

P3.13.12 Multi-Institution Analysis Evaluating Safety, Efficacy and ctDNA Dynamics Following Tarlatamab in ES-SCLC and LCNEC Patients

G. Fenton[1], S. Zhong[2], A.L. Zhang[2], C. Tatsuoka[1], M. Sittig[1], R. Mehra[1], A. Dowlati[2], T.K. Owonikoko[1], K. Scilla[1], M. Hsu[2], S. Rosner[1]
[1]Marlene and Stewart Greenebaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore/MD/USA ,[2]University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland/OH/USA

Introduction: Tarlatamab, a bispecific T-cell engager (BiTE) targeting delta-like ligand 3 (DLL3) and CD3 on T cells, recently received FDA approval for the treatment of relapsed extensive-stage small cell lung cancer (ES-SCLC), with additional evidence suggesting effectiveness in patients with large cell neuroendocrine carcinoma (LCNEC). This novel therapy has demonstrated promising antitumor activity and durable objective responses in phase I/II clinical trials, however, is also associated with a unique side effect profile which includes cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) requiring close monitoring. How these safety and efficacy outcomes translate into real-world practice is an ongoing question.

Methods: We performed a retrospective, multi-institutional analysis of patients who received tarlatamab for ES-SCLC or LCNEC from July 2024-March 2025 at two tertiary care centers. Side effects of special interest (SESI) including CRS, ICANS and dysgeusia were reported using Common Terminology Criteria for Adverse Events (CTCAE) v5.0. Treatment response was determined using clinical interpretation of radiological disease assessment from those patients with available post-treatment imaging. Median progression-free survival (PFS) and overall survival (OS) were estimated using Kaplan-Meier methods. A subcohort of patients had ctDNA collection using standard of care Guardant360 assay at pre- and post-treatment timepoints (drawn prior to C1D1 and on C3D1) and were included for molecular response assessment by measuring trends in tumor fraction.

Results: 32 patients received at least 1 dose of tarlatamab. The majority had SCLC histology (94%). Median age at C1D1 was 68 years, with 59% females and 88% being current/former smokers. Median number of prior therapies were two and ECOG PS ranged from 0-3 (9%/62%/26%/3%). SESI were observed in 26/32 patients (81%). CRS was observed in 56% of patients, all grade 1/2 in severity, with median onset within 24 hours following C1D1 and 44% requiring tocilizumab. ICANS was observed in 31% of patients, with one grade 3 event reported. Dysgeusia was noted in 57% of patients, with an average onset within 25 days from C1D1. 20 patients were included in our treatment response analysis. Best overall response rate was 60% and disease control rate (DCR) was 80% (1 CR, 11 PR, 4 SD, 4 PD). With median follow up of 4 months, median PFS was 4.5 months (95%CI: 3.1-NR) and median OS was 5.0 months (95%CI: 3.5-NR). 6 patients had ctDNA data available for molecular response analysis, with ctDNA trends corresponding with radiographic response. DCR was 100% for those patients with decreasing ctDNA fraction of ≥50% (n=4), while patients with increasing ctDNA had progressive disease at first interval imaging (n=2).

Conclusions: In our multicenter cohort of patients with SCLC/LCNEC, tarlatamab continued to show encouraging efficacy in terms of response and PFS, mirroring results from the DeLLphi-301 trial. However, in this non-trial setting, rates and timing of CRS/ICANS differed from previous reports, highlighting the need for careful observation and care coordination as this therapy is utilized in real-world practice. Novel biomarkers of response and resistance are needed in this setting, with longitudinal ctDNA dynamics showing potential promise, though larger, prospective studies are needed.

P3.13.13 A Phase II Study of Vobramitamab Duocarmazine in Patients With Relapsed or Refractory Extensive-Stage Small-Cell Lung Cancer

T. Roy[1], J. Zaemes[2], J. Reuss[1], V. Yeung[3], E. Dimeo[1], J. Thompson[1], N. Swanson[1], A. Duttargi[4], B. Gupta[1], M. Gonzalez Velez[5], D. de Miguel Perez[6], M. Gutierrez[5], J. Ahn[4], C. Rolfo[6], S. Liu[1], C. Kim[1]
[1]Georgetown University Hospital, WASHINGTON/DC/USA ,[2]Beth Israel Deaconess Medical Center, Boston/MA/USA ,[3]Rutgers Cancer Institute of New Jersey, Newark/NJ/USA ,[4]Georgetown University, WASHINGTON/DC/USA ,[5]Hackensack Unviversity Medical Center, Hackensack/NJ/USA ,[6]The Ohio State University, Columbus/OH/USA

Introduction: Relapsed/refractory extensive-stage small-cell lung cancer (ES-SCLC) carries a poor prognosis, with suboptimal treatments. B7 homolog 3 protein (B7-H3), a member of the B7 family of immune checkpoint molecules, is highly expressed in SCLC and has emerged as a promising therapeutic target. Several B7-H3-targeting antibody-drug conjugates (ADCs) in development utilize topoisomerase I inhibitors as their cytotoxic payloads. Vobramitamab duocarmazine (MGC018) is an ADC targeting B7-H3, utilizing DNA alkylating agent duocarmycin as its cytotoxic payload. We present a phase II study of vobramitamab duocarmazine for relapsed/refractory ES-SCLC.

Methods: We conducted an investigator-initiated, single arm, open-label, phase 2 trial to evaluate vobramitamab duocarmazine in patients with relapsed/refractory ES-SCLC. Patients with progression on platinum-based chemotherapy were enrolled (NCT06227546). The trial employed Simon's two-stage design. The initial dose was 2.7 mg/kg administered every 28 days, but mid-trial was reduced to 2.0 mg/kg with a maximum of 8 cycles, based on treatment-related adverse events (TRAEs) from other clinical trials using vobramitamab duocarmazine. Primary endpoint was overall response rate (ORR) assessed by RECIST v1.1. Secondary endpoints were AEs assessed using CTCAE v5.0, duration of response (DOR), progression free survival (PFS), and overall survival (OS). An exploratory objective was assessed to evaluate treatment efficacy based on tumor tissue and plasma extracellular vesicles (EVs) B7-H3 expression.

Results: A total of 9 patients were enrolled. The median age was 64 (range: 49-77) with 5 men and 4 women. Patients received a median of 1 prior line of therapy (range 1-2); all patients received frontline platinum-etoposide chemotherapy with anti-PD-L1 immunotherapy. The starting dose was 2.7 mg/kg for 6 patients (66.7%) and 2.0 mg/kg for 3 patients (33.3%). No objective responses were observed. Stable disease (SD) was observed in 4 patients (44.4%) with 1 patient having SD through 8 cycles of treatment. Median number of cycles of treatment was 2 (range: 2-8). The most common any-grade TRAEs were anorexia, fatigue, and anemia (each in 4 patients, 44.4%), followed by neutropenia, conjunctivitis, rash, and thrombocytopenia (each in 3 patients, 33.3%), and pleural effusions (in 2 patients, 22.2%). Grade 3 TRAEs were pneumonia, oral mucositis, lymphopenia (each in 1 patient, 11.1%). Grade 4 neutropenia occurred in one patient (11.1%). Dose reductions were required for two patients per sponsor guidance and for one patient due to AEs. Median PFS was 2.0 months (95% CI: 1.8, NA) and median OS was 4.3 months (95% CI: 3.4, NA). The trial did not proceed to the second stage due to no objective responses. B7-H3 expression in tumor tissue and EVs and its correlation with treatment efficacy will be presented at the conference.

Conclusions: In this phase II study of vobramitamab duocarmazine in patients with relapsed/refractory ES-SCLC, limited efficacy was observed, with no objective responses leading to early termination of trial. For optimization of B7-H3 ADCs for SCLC, further work is needed to understand the ideal cytotoxic payload, dosing strategy, and biomarkers of response and resistance.

Introduction: The combination therapy of programmed death-ligand 1 (PD-L1) inhibitors with chemotherapy has been established as the standard therapy for extensive-stage small cell lung cancer (ES-SCLC). It is widely recognized that neither PD-L1 expression nor tumor mutational burden can accurately predict the clinical efficacy of immunochemotherapy in patients with ES-SCLC. Although several studies have indicated a relationship between gene expression signatures from RNA-seq data and the clinical efficacy of immunochemotherapy, it is currently not practical to apply RNA-seq to clinical practice. Hence, we developed a statistical and machine learning model to predict the clinical efficacy of immunochemotherapy using lab data.

Methods: We defined patients with "prolonged progression-free survival (PFS)" as those with a PFS of 5 months or more. Of 213 patients with ES-SCLC who had progressed within 5 months after first-line immunochemotherapy or had a follow-up period of 5 months or more, 150 patients were randomly assigned to the training set and 63 patients to the test set to construct a prediction model for PFS. To calculate the probability of achieving a prolonged PFS, a non-linear logistic regression model was employed, using lab data collected just before the start of treatment as explanatory variables. In this model, an estimated probability of 0.58 or higher was interpreted as a marker for prolonged PFS. Furthermore, we defined "prolonged overall survival (OS)" patients as those with an OS of 12 months or more and constructed an OS prediction model in a similar manner. The predictive accuracy of the obtained models was verified on an independent validation set of 46 patients with ES-SCLC.

Results: We found a weak correlation between PFS/OS and lab data including NLR (Neutrophil-to-lymphocyte ratio), LDH, albumin and CRP levels. In the training set (n = 150), a non-linear logistic regression model was constructed to predict "prolonged PFS/OS" patients using the four lab data as explanatory variables. When the performance of the prediction model was evaluated on the test set (n = 63), a significant PFS/OS benefit was observed in patients predicted to have prolonged PFS/OS (PFS - 5.7 vs 4.3 months, HR 0.53 [95% CI, 0.31 to 0.92]; OS - 24.9 vs 10.3 months, HR 0.45 [95% CI, 0.22 to 0.95]). Further evaluation on the validation set (n = 46) also showed a clear PFS/OS benefit in patients predicted to have prolonged PFS/OS (PFS - 5.7 vs 4.3 months, HR 0.46 [95% CI, 0.21 to 1.00]; OS - 26.0 vs 10.6 months, HR 0.29 [95% CI, 0.10 to 0.86].

Conclusions: We developed a prediction model for PFS/OS in immunochemotherapy for ES-SCLC using lab data that can be measured in daily clinical practice.

Introduction: First-line immunochemotherapy regimens have been widely adopted for extensive-stage small cell lung cancer (ES-SCLC) based on multiple randomized controlled trials (RCTs). However, patients with poor performance status (PS) are often excluded from RCTs, leaving the efficacy of immunochemotherapy in patients with an Eastern Cooperative Oncology Group (ECOG) PS ≥2 uncertain. This subgroup analysis, based on the real-world ASTRUM-005R study, aimed to evaluate the effectiveness of first-line serplulimab-based immunochemotherapy in this underrepresented population.

Methods: ASTRUM-005R (NCT06748495) is a nationwide, real-world, observational study conducted in China to assess the safety and effectiveness of first-line serplulimab-based immunochemotherapy in patients with ES-SCLC. This subgroup analysis focused on patients with ECOG PS ≥2 to explore the feasibility and clinical outcomes in this population. Key endpoints included overall survival (OS), real-world progression-free survival (rwPFS), and overall response rate (ORR).

Results: A total of 75 patients with ECOG PS ≥2 were included in this analysis, accounting for 11.8% of the overall ASTRUM-005R cohort. Among them, 71 patients had PS 2 and 4 had PS 3. The median follow-up duration was 16.37 months (range, 1.90-23.60). Compared to patients with PS <2, poor performance status did not significantly affect rwPFS (HR = 1.15, P = 0.366). The median rwPFS for patients with PS ≥2 was 6.97 months (95% CI, 6.23-10.43), with a 1-year rwPFS rate of 26.62% (95% CI, 17.22-41.14). Similar to the overall cohort, baseline brain metastases had no significant impact on rwPFS (HR = 0.98, P = 0.953). However, patients with liver metastases had significantly shorter rwPFS than those without (4.93 vs. 10.30 months; HR = 1.95, P = 0.018). OS was poorer in patients with PS ≥2 compared to those with PS <2 (HR = 1.89, P < 0.001), with a median OS of 12.33 months (95% CI, 10.43-15.57). Again, brain metastases had no significant effect on OS (HR = 0.86, P = 0.640), while liver metastases were associated with inferior OS (9.67 vs. 14.03 months; HR = 3.01, P = 0.001). Among 74 patients with measurable disease and at least one post-treatment radiological evaluation, the ORR was 66.22% (95% CI, 54.28-76.81). Safety profiles in patients with ECOG PS ≥2 were generally consistent with those observed in the overall population. Adverse events (AEs) were reported in 20 patients (26.67%), and 15 patients experienced immune-related adverse events (irAEs), with 5 reporting grade ≥3 irAEs.

Conclusions: This subgroup analysis of the ASTRUM-005R study demonstrates that first-line serplulimab-based immunochemotherapy remains clinically effective and feasible in ES-SCLC patients with ECOG PS ≥2. Liver metastases, but not brain metastases, were associated with inferior outcomes. These findings support the potential benefit of immunochemotherapy even in patients traditionally excluded from clinical trials, warranting further investigation and validation in prospective studies.

P3.13.16 Survival Outcomes With Carboplatin Versus Cisplatin and the Impact of COVID-19 on Platinum Choice in SCLC in the Netherlands

I. Houda[1], D. Naves[1], E.B. Ulas[1], B.I. Lissenberg-Witte[2], N. Barlo[3], E.A. Kastelijn[4], H. Bouhaddou[1], R. Shaikh[1], C. Dickhoff[1], T. Radonic[1], F.L. Schneiders[1], S. Senan[1], R.A.M. Damhuis[5], I. Bahce[1]
[1]Amsterdam University Medical Center, location VU Medical Center, Amsterdam/NL ,[2]Amsterdam University Medical Center, Amsterdam/NL ,[3]Noordwest Ziekenhuisgroep, Alkmaar/NL ,[4]Sint Antonius Ziekenhuis, Nieuwegein/NL ,[5]Netherlands Comprehensive Cancer Organisation, Utrecht/NL

Introduction: Current guidelines recommend cisplatin as chemotherapy backbone in the first-line treatment for small cell lung cancer (SCLC), especially in limited-stage disease (LS-SCLC). However, during the COVID-19 pandemic, carboplatin use likely increased due to logistical advantages. We evaluated the pandemic's impact on platinum agent utilization in the Netherlands and compared overall survival (OS) and safety between cisplatin and carboplatin.

Methods: Netherlands Cancer Registry (NCR) data were analyzed for patients who received first-line platinum-based treatment for both LS-SCLC and extensive-stage SCLC (ES-SCLC) between January 2018 and March 2023. The COVID-19 epidemic period in the Netherlands extended from February 2020 to April 2022. Overall survival (OS) was evaluated using univariable and multivariable analyses. Additionally, patient records at three teaching hospitals were assessed to study grades 3-5 treatment-related adverse events.

Results: We identified a total of 1683 (32%) patients with LS-SCLC (median [IQR] age 68 [62-74] years; 985 [58.5%] females; carboplatin, N=1011 [60%]; cisplatin, N=672 [40%]) and 3668 (68%) ES-SCLC patients (median [IQR] age 68 [62-73] years; 1866 [50.9%] females; carboplatin, N=3002 [82%]; cisplatin, N=666 [18%]). During the pandemic, quarterly usage rates of carboplatin increased, reaching as high as 81% in LS-SCLC (Figure 1A) and 90% in ES-SCLC (Figure 1B). Post-pandemic use of carboplatin in ES-SCLC remained elevated (up to 94%). In LS-SCLC, univariable analysis showed the median OS to be significantly shorter with carboplatin compared to cisplatin (17.9 vs. 26.3 months; HR, 1.48; 95%CI, 1.31-1.68; P<0.001). Similar findings were observed in ES-SCLC (8.0 vs. 9.3 months; HR, 1.19; 95%CI, 1.09-1.30; P<0.001). However, multivariable analyses, after adjusting for confounders, showed no difference in OS between carboplatin and cisplatin in either LS-SCLC (HR, 1.06; 95%CI, 0.90-1.25; P=0.463) or ES-SCLC (HR, 1.01; 95%CI, 0.92-1.12; P=0.785). Confounders were performance status (PS), age, sex, and chemoradiotherapy type for LS-SCLC, and PS, age, sex, stage, and liver metastases for ES-SCLC. Individual patient data revealed more hematologic toxicity with carboplatin, while more nonhematologic toxicity was seen with cisplatin.

Conclusions: Population registry data revealed significant increases in carboplatin use during the COVID-19 pandemic. Comparable OS was seen in both LS-SCLC and ES-SCLC treated with carboplatin or cisplatin. These findings challenge the long-standing belief of the superiority of cisplatin-containing chemotherapy doublets in SCLC and support the adoption of carboplatin in SCLC.

P3.13.17 A Comparative Analysis of TNM 8 and TNM 9 Classification Systems in Small Cell Lung Cancer

A. Dan[1,2], S. Tendler[3], K. Viktorsson[1], O. Hjorthorn[1,2], C. Kamali[1,2], K. Kas-Elyas[1,2], K. Rounis[1,2], G. Wagenius[1,2], S. Ekman[1,2], L. De Petris[1,2]
[1]Karolinska Institutet, Stockholm/SE ,[2]Karolinska University Hospital, Stockholm/SE ,[3]Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: The Tumor-Node-Metastasis (TNM) classification system is the international accepted standard for staging lung cancer, facilitating prognosis and treatment decision. It has been primarily developed and validated for non-small cell lung cancer (NSCLC), with limited applicability to small-cell lung cancer (SCLC), due to the latter's distinct biology and fast progression. The previous TNM classification did not capture key prognostic factors, namely the extent of mediastinal nodal involvement and the number and distribution of distant metastases. The 9th edition of the TNM classification, released in 2024, addresses these limitations, subdividing N2 into N2a (single-zone) and N2b (multi-zone), and M1c into M1c1 (single-organ) and M1c2 (multi-organ). This study evaluates the impact of the 9th versus the 8th TNM classification in staging SCLC and survival prediction.

Methods: We analyzed a single-center cohort of SCLC patients diagnosed between 2016-2022. Available diagnostic imaging investigations (i.e. whole body CECT or FDG-PET) were retrospectively reviewed. Each case was thereafter reclassified according to both 8th and 9th edition. Overall survival (OS) was assessed based on the T, N, and M descriptors, with comparisons made between staging groups. Multivariate Cox regression models were used to evaluate the independent prognostic significance of TNM staging, adjusted for key clinical variables (Sex, age and WHO performance status).

Results: A total of 421 patients from the Karolinska University Hospital in Sweden were included. Stage migration between editions occurred in 5.5% of all cases (n = 23), primarily affecting Stage II and III patients. Specifically, one patient migrated from IIB to IIA; eight from IIIA to IIB; and 14 from IIIB to IIIA. Subclassification changes affected 328 cases (78%). The introduction of N2a and N2b reclassified 134 cases (45% N2a, 55% N2b), while M1c1 and M1c2 subdivided 212 cases (44% M1c1, 56% M1c2).Median OS improved for Stage IIA according to the 9th edition (57 vs. 37 months), while IIIA survival decreased (13 vs. 16 months), likely due to migration effects.Kaplan-Meier survival analysis demonstrated significantly worse survival for N2b (median OS 5 Months) vs N2a (Median OS 9 months; log-rank p = 0.008, regardless of M status) and M1c2 (median OS 4 months) versus M1c1 (Median OS 7 months, log-rank p = 0.02, regardless of N status).Univariate Cox regression identified N2b (HR = 1.6, 95% CI: 1.1-2.3) and M1c2 (HR = 1.4, 95% CI: 1.1-1.8) as negative prognostic factors. These findings were confirmed by multivariate analysis.

Conclusions: This study represents the first real-world evaluation of the 9th TNM edition in a SCLC cohort. While overall stage migration was limited (5.5%), making it difficult to determine whether the updated staging system improves survival stratification at the full stage level, the new N2a/N2b and M1c1/M1c2 subclassifications demonstrated prognostic relevance. Survival analysis confirmed a worse outcome for patients with N2b and M1c2 disease supporting the clinical utility of these reclassifications within the 9th TNM edition.

P3.13.18 Immunotherapy Pooled Analysis in 1L Extensive-Stage Small Cell Lung Cancer

J. Pérez-Granado, M. Gramling, B. Larvol
The Larvol Group LLC, San Francisco/CA/USA

Introduction: Extensive-stage small cell lung cancer (ES-SCLC) remains a challenging disease with limited treatment success. Survival benefits have been observed with the addition of immunotherapy (IO) to chemotherapy. To provide a unified and survival estimate with IO-based regimens in 1L ES-SCLC, we conducted a pooled analysis across landmark clinical trials.

Methods: We leveraged LARVOL CLIN, an oncology outcomes database with 130k+ Trials, 100k+ digitized Kaplan-Meier (KM) curves. We implemented the validated algorithm developed by Guyot et al. (2012) to obtain pseudo-individual patient data (pseudo-IPD) from published KM curves and at-risk data. We pooled the reconstructed datasets by treatment arm and performed a synthetic KM survival analysis to estimate the median OS.

Results: Three phase III clinical trials were selected based on the availability of published overall survival (OS) KM curves for 1L ES-SCLC. CASPIAN (durvalumab, HR=0.71*), KEYNOTE-604 (pembrolizumab, HR=0.76) and Impower133 (atezolizumab, HR=0.7*) evaluate the addition of their respective IO to chemotherapy (experimental arm N= 644 and control arm N= 643). The median OS in the IO + chemotherapy arm was 11.9 months, compared to 10.0 months in the chemotherapy-alone control arm. Estimated one-year survival probabilities were 49.9% in the IO + chemotherapy arm and 38.6% in the control arm. Two-year survival probabilities were 22.5% and 14%, respectively. Synthetic KM curves from the pooled pseudo-IPD analysis (Image 1) illustrated a separation in survival between arms beginning at approximately 5.8 months, which was maintained through follow-up. Cox proportional hazards modeling showed a hazard ratio (HR) of 0.76 (95% CI: 0.68-0.85, p-value <0.001), indicating statistically significant survival benefit with IO-based regimens compared to chemotherapy alone.

Conclusions: IO combined with chemotherapy has become the standard of care for 1L ES-SCLC. Pseudo-IPD-derived pooled KM curves affirm the statistically significant OS benefit of adding IO to chemotherapy. The analysis establishes a framework to benchmark IO-based regimens in this setting. Collectively, survival benefits diverge around 6 months and are maintained through follow-up, reflecting the delayed onset of immunotherapy's clinical effect. Pooled analysis findings of course should be interpreted with caution, as there might be heterogeneity in trial design, treatment exposure, or follow-up schedules. Nevertheless, this analysis provides a practical benchmark for evaluating emerging therapies in ES-SCLC, particularly in settings where delayed survival benefits are expected.

P3.13.19 High Throughput Drug Screening for Small Cell Lung Cancer Based on Machine Learning and Organoid Platforms

X. Feng, H. Zhang, D. Zhang, X. Liu, X. Guo, X. Gao, M. Chen, J. Zhao, Y. Xu, M. Wang
Peking Union Medical College Hospital, Beijing/CN

Introduction: Small cell lung cancer (SCLC) remains a therapeutic challenge with limited treatment options. We developed a high - throughput drug screening platform combining machine learning (ML) prediction models with patient-derived organoids (PDOs) to identify novel therapeutic agents and targets for SCLC.

Methods: The candidate drug library was screened from three sources. First, The R 'oncoPredict' package was applied to predict drug responses. Utilizing drug response data from CTRP v2, GDSC v1&v2, and PRISM databases, we trained ML models to predict drug sensitivity. SCLC datasets (GSE30219, GSE43346, GSE149507) from GEO were used as the prediction set, identifying 68 SCLC-specific drugs with selective efficacy. Second, by mining the phase I/II clinical trials for SCLC (excluding immunotherapy) on Clinical Trials. gov, 31 drugs were selected. Finally, for the other drug selection part, two points were considered: a. Select corresponding compounds according to the drug pathways or targets involved in SCLC clinical trials; b. the intersection of drugs from the cancer stem cell compound library and the anti-tumor metabolism compound library was selected. A total of 171 drugs were screened in this part. Ultimately, 270 compounds were subjected to high throughput primary screening on SCLC-LCOs. Drugs that could inhibit the viability of organoids below 30% were selected for the subsequent re-screening stage. Finally, the candidate drugs were screened out and further clarified the relevant mechanisms.

Results: Primary screening using 2 chemo-sensitive and 2 resistant SCLC-LCOs identified 25 compounds with potent activity. Subsequently, these 25 drugs were re-screened on sensitive/resistant cell lines and organoids, and several drugs with good inhibitory effects were finally screened out, including PI3K inhibitors, CDK7 inhibitors, etc. In particular, the natural product acriflavine showed good inhibitory effects on both sensitive and drug - resistant organoids (IC50 in sensitive PDOs was 0.1-0.2μM, and IC50 in drug-resistant PDOs was 0.4 μM). RNA-seq results showed that differential genes such as ATF3, CDKN1A, and GADD45B were significantly upregulated after acriflavine treatment. Over-expression analysis(ORA) indicated that acriflavine could upregulate the stress response of EIF2AK4 to amino acid deficiency. Verified by the GEO database, compared with normal lung tissues, the EIF2AK4 and ATF3 genes were significantly downregulated in SCLC. Western blot showed that acriflavine could induce the phosphorylation of EIF2AK4, resulting in the phosphorylation of EIF2A and the over-expression of ATF3. Quantitative PCR (qPCR) showed that after acriflavine treatment, the mRNA levels of EIF2AK4 and ATF3 were upregulated in a dose - dependent manner, confirming the transcriptional activation of the stress response pathway. In addition, apoptosis detection by flow cytometry presented an obvious acriflavine dose - dependent apoptosis. These findings further confirm the role of acriflavine in activating EIF2AK4 - mediated endoplasmic reticulum stress and mediating apoptosis in SCLC.

Conclusions: Acriflavine activates EIF2AK4-mediated endoplasmic reticulum stress and apoptosis in SCLC, highlighting its therapeutic potential. The ML-PDOs platform effectively identifies agents suppressing SCLC growth while revealing actionable targets and pathways, accelerating translational research in precision oncology.

P3.13.20 Integrative Spatial Analysis Reveals Ferroptosis Heterogeneity and Novel Therapeutic Vulnerabilities in Small Cell Lung Cancer

C. Deng[1], C. Zhu[2], T. Hu[2], J. Wang[2]
[1]Fudan University Shanghai Cancer Center, Shanghai/CN ,[2]Amoy Diagnostics Co., Ltd, Shanghai/CN

Introduction: Treatment of small cell lung cancer (SCLC) remains challenging. Deciphering the orchestration of molecular heterogeneity especially from the spatial dimension will provide new insights into SCLC therapeutic strategies.

Methods: We performed genomic, transcriptomic, metabolomic, lipidomics and spatial single-cell resolved transcriptomic (CosMx) and proteomic (CODEX) analyses on 100 patients from the Fudan University SCLC (FU-SCLC) cohort. A robust molecular classification was established with each subtype characterized by clinical, multi-omics and spatial signatures.

Results: Through comprehensive integrative analysis, we identified three subtypes of SCLC: proliferative, immunogenic, and metabolic reprogramming (MR) subtypes, which significantly stratified patient outcomes for recurrence-free survival, disease-free survival, and overall survival. The proliferative subtype was characterized by neuroendocrine lineage commitment (ASCL1+ tumor cell enriched), elevated proliferative activity, and an immune-deserted tumor microenvironment. The immunogenic subtype exhibited non-neuroendocrine differentiation, extensive immune cell infiltration, and extracellular matrix remodeling. The MR subtype represented a special transitional phase of SCLC neuroendocrine dedifferentiation, demonstrating enhanced glycolytic flux, tricarboxylic acid (TCA) cycle activity, and ferroptosis resistance, leading to poorest prognosis. Notably, non-canonical ferroptosis defense axis DHODH-COQH2 was aberrantly activated in the MR subtype, accompanied by elevated corresponding metabolites. Pharmacological inhibition of DHODH using Brequinar selectively suppressed proliferation and induced ferroptosis in MR SCLC cell lines. Spatial transcriptomic and proteomic profiling further revealed that ferroptosis-resistant tumor cells orchestrated a pro-tumorigenic ecotype marked by defective DNA damage repair and immune exclusion in their microenvironment, suggesting a potential immunotherapy target.

Conclusions: The ferroptosis heterogeneity across SCLC emphasizes the need to map individual patient landscapes to develop personalized treatment strategies. Our findings provide critical insights into SCLC biology and serve as a valuable resource for future molecular investigations and therapeutic exploration.

P3.13.21 Refining Patient Selection for Prophylactic Cranial Irradiation in Limited-Stage Small Cell Lung Cancer: A Multicenter Cohort Study

H.I. Lee[1], J.M. Noh[2], T.H. Lee[2], E.K. Choi[1], S.S. Kim[1], Y.S. Shin[1], Y.C. Ahn[2], H. Pyo[2], K. Yang[2], E. Yang[2], H-G. Wu[3], J.H. Lee[3], B.H. Kim[4], M. Koh[5], S.Y. Song[1], H.J. Kim[3]
[1]Asan Medical Center, Seoul/KR ,[2]Samsung Medical Center, Seoul/KR ,[3]Seoul National University Hospital, Seoul/KR ,[4]Seoul Metropolitan Government-Seoul National University Boramae Medical Center, Seoul/KR ,[5]Kangwon National University Hospital, Seoul/KR

Introduction: We aimed to evaluate the efficacy of prophylactic cranial irradiation (PCI) in the contemporary management of limited-stage small-cell lung cancer (LS-SCLC) and to identify optimal strategies for patient selection.

Methods: This multi-institutional cohort study included LS-SCLC patients who underwent definitive chemoradiation between 2006 and 2022, all staged using brain magnetic resonance imaging (MRI) and positron emission tomography. We compared the incidence of brain metastases (BM) and overall survival (OS) between patients who received PCI and those who did not. Additionally, we analyzed the differential effect of PCI across 22 subgroups. BM was classified as either isolated or non-isolated, with cumulative incidence calculated using a competing risk model. Outcomes of salvage treatments for isolated BM were also assessed.

Results: Among the 1302 study patients, 672 (51.6%) received PCI and 630 (48.4%) did not. During a median follow-up of 30.5 months (range, 4.2-227.2), PCI significantly reduced the cumulative incidence of BM (17.4% vs. 27.6% at 2 years; P<.001), primarily by decreasing isolated BM (6.5% vs. 16.1% at 2 years; P<.001), but had no significant effect on non-isolated BM. PCI consistently reduced the incidence of isolated BM across all subgroups, which led to improved OS except for patients who achieved complete response (CR) to primary treatment (hazard ratio [HR] 1.03; P=.865). CR patients who developed isolated BM, and received local salvage treatment achieved an 81.8% remission rate, resulting in OS comparable to those without BM development (HR 1.10; P=.631). Stereotactic radiosurgery for BM salvage treatment showed superior OS compared to whole-brain radiotherapy or systemic treatment alone.

Conclusions: PCI did not improve OS in patients achieving CR, who demonstrated excellent outcomes with BM salvage treatment. Our findings suggest that MRI surveillance, combined with effective salvage treatment, may serve as a viable alternative for selected LS-SCLC patients.

P3.13.22 Efficacy and Safety of Surufatinib, Durvalumab in Combined With Chemotherapy as First-Line Treatment of Extensive-Stage Small-Cell Lung Cancer

H. Zhang, S. Sheng, C. Wu, S. Wang, Z. Qian, Q. Zhang, J. Li, H. Zheng, X. Li, J. Lv, X. He, G. Lin, Y. Hu
Beijing Chest Hospital, Capital Medical University/Beijing Tuberculosis and Thoracic Tumor Research Institute,, Beijing/CN

Introduction: The combination of platinum-based chemotherapy plus etoposide with immunotherapy has become the new standard of care for the first-line treatment of extensive-stage(ES) small-cell lung cancer(SCLC). Surufatinib, a multi-kinase inhibitor on VEGFR, FGFR and CSF1R in combined with immunotherapy has shown synergistic effect in many solid tumors, including SCLC. To further improve the prognosis of ES-SCLC, we performed this study to explore the efficacy and safety of surufatinib in combination with standard durvalumab, etoposide and platinum chemotherapy regimen in ES-SCLC as first-line treatment. The trial is still ongoing, and we are now reporting the preliminary results.

Methods: This is an ongoing single-arm, multi-center, open-label study conducted in China. The study would enroll 20 patients with ES-SCLC. Patients would receive surufatinib at a dose of 250 mg once per day, with durvalumab 1500 mg intravenously on day 1, etoposide 100 mg/m2 intravenously on day 1-3, and cisplatin 75 mg/m^2, once daily, continuous IV infusion for over 3 hours, on day 1-3, or carboplatin, AUC 5-6, intravenous infusion, day 1 of each treatment cycle, in every 21-day cycle. If available, tumor assessments were performed every 2 cycles ± 7 days according to RECIST version 1.1.

Results: By March 10, 2025, 13 eligible patients had been enrolled, of whom 12 (92.3%) were female. The median age was 64 (range: 46-72). 12 (92.3%) patients presented with ECOG performance score of 1. 10 (76.9%) patients had smoking history. With a median follow-up time of 13.40 months, 11 patients received at least one post baseline tumor assessment, of whom all the patients achieved partial response(PR). The median overall survival(OS) was 15.80 (95% CI: 8.61-NA) months, and the median progress-free survival(PFS) was 7.95 (95% CI: 4.70-9.03) months. The median time-to-response was 1.58 (95% CI: 1.41-3.02) months and median duration of response was 5.22 (1.71-7.79) months. The most common adverse events(AEs) of all grades were white blood cells decreasing (61.54%), anemia (46.15%), and platelet decreasing (38.46%), and those of grade 3 or higher were white blood cells decreasing (46.15%), platelet decreasing (15.38%), fatigue (7.69%), and immune-related pneumonia (7.69%).

Conclusions: Surufatinib in combination with the current recommended durvalumab, etoposide, and EP/EC chemotherapy regimen exhibited promising efficacy and manageable toxicity as first-line treatment for patients with ES-SCLC. The trial is still ongoing.

P3.13.23 Copy Number Gain of MYC-Paralogs Represents Proliferative Phenotype and Poor Prognosis in Resected Small Cell Lung Cancer

Y. Ju, J. Zhang, X. Li
Peking University People's Hospital, Beijing/CN

Introduction: Emerging evidence highlighted the critical role of amplified MYC-paralogs (MYC, MYCL and MYCN) genes in driving chemoresistance and disease recurrence in small cell lung cancer (SCLC). However, the existing immunohistochemistry (IHC) and single-probe of fluorescence in situ hybridization (FISH) tend to miss copy number variations of MYC-paralogs at lower levels. This study developed a novel triple-probes of FISH (triple-FISH) to investigate the prevalence of MYC-paralogs copy number gain (CNG) and their clinical and biological implications in surgically resected SCLC specimens.

Methods: A novel triple-FISH (MYC, MYCL and MYCN) and IHC were employed to characterize the expression and copy number variation of MYC-paralogs in surgical resected SCLC samples (n = 56). The copy number gain was defined when any of the MYC-paralogs exhibited ≥ 3.0 signals per cell as detected by triple-FISH. Conversely, the neutral group was defined as the condition where all MYC-paralogs showed < 3.0 signals. Whole genome sequencing (WGS) was conducted to validate the copy number of MYC-paralogs. Multiplex immunohistochemical (mIHC) profiling with a 6-plex antibody panel (Pan-CK, Ki67, CD3, CD31, CD11b and CD68) characterized the cellular composition of the samples.

Results: A total of 30 MYC-paralogs CNG were identified using the triple-FISH, including 10 MYC, 18 MYCL and 2 MYCN. Kaplan-Meier survival curves revealed that SCLC patients with MYC-paralogs CNG had significantly poorer overall survival (OS) than those in the neutral group (p = 0.042). Furthermore, in multivariate analyses, apart from lymph node metastasis (HR = 7.05, 95%CI: 1.92-25.90, p = 0.003), the MYC-paralogs CNG also emerged as an independent prognostic risk factor for OS (HR = 5.72, 95%CI: 1.20-27.27, p = 0.028). Next, we identified 6 distinct cell populations with a resolution of more than 2 million cells, namely tumors cells, Ki67+ tumors, macrophages, T cells, endothelial cells and undefined cells. We found that the proportion of Ki67+ tumor was significantly higher in samples with MYC-paralogs CNG (p = 0.031) compared to the neutral group, suggesting that MYC-paralogs CNG promotes proliferative phenotype in SCLC, which may result in poor prognosis.

Conclusions: We established a novel triple-probes of FISH to identify copy number gain of MYC, MYCL and MYCN, which indicates the elevated Ki67+ tumor infiltration with poor prognosis in SCLC.

P3.13.24 Longitudinal Plasma Proteomics Identifies Predictive Biomarkers for Anti-PD-L1 Therapy in SCLC

G-L. Jie, J-X. Zhong, X-M. Niu, L-L. Xia, S. Lu
Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Immune checkpoint inhibitors have revolutionized the treatment of small cell lung cancer (SCLC). However, patient responses vary significantly, and reliable predictive biomarkers for treatment selection remain unavailable. This study characterizes dynamic plasma proteomic changes and identifies predictive biomarkers for SCLC patients undergoing immunotherapy.

Methods: Longitudinal plasma samples were collected from SCLC patients before and during chemo-immunotherapy. Protein quantification was performed using 4D-DIA mass spectrometry (MS). Patients with a median progression-free survival (PFS) of less than six months were classified as non-responders (NR), while others were categorized as responders (R). Bioinformatic analyses were conducted to delineate the dynamic plasma proteomic landscape. Machine learning models were applied to identify biomarkers predictive of immunotherapy response, and candidate biomarkers were validated using ELISA in an external cohort.

Results: A total of 82 SCLC patients treated with anti-PD-L1 plus chemotherapy were included, and plasma samples were analyzed using DIA-MS. Differential expression analysis identified 651 differentially expressed proteins (DEPs; 485 upregulated, 166 downregulated) in the R group compared to the NR group. Enrichment analysis revealed that upregulated proteins in responders were associated with TRC complex function and NF-kappaB-inducing kinase activity, while downregulated proteins were linked to negative regulation of interleukin-1 beta production and protease inhibitor complex activity. Longitudinal proteomic analysis at baseline, post-anti-PD-1 therapy, and at disease progression identified 648 proteins associated with immunotherapy benefits. A LASSO model was applied to identify predictive biomarkers, resulting in the selection of three key proteins: VASN, PTGES3, and PRAD3. In the training cohort (n = 42), these biomarkers achieved AUC values of 0.701, 0.703, and 0.637, respectively. The combined VPP-Model, integrating all three biomarkers, demonstrated superior predictive performance with an AUC of 0.846. External validation in a cohort of 40 patients confirmed its robustness, yielding an AUC of 0.832. The VPP-model was significantly superior to previously reported biomarkers, such as neuron-specific enolase (NSE, AUC=0.651, P = 0.03) and neutrophil-to-lymphocyte ratio (NLR, AUC=0.630, P = 0.02). Based on the VPP-model, response rates were significantly higher in the low-risk group (70%) compared to the high-risk group (20%; P = 0.004). Median PFS was 6.87 months in the low-risk group and 3.97 months in the high-risk group (HR = 0.39; 95% CI: 0.19-0.812; P = 0.005).

Conclusions: This study provides a comprehensive analysis of the dynamic plasma proteomic landscape in SCLC patients receiving chemo-immunotherapy. The identified plasma-derived biomarkers exhibit superior predictive performance compared to previously reported biomarkers.

P3.13.25 Comprehensive Immune Microenvironment Profile of EGFR-Mutant Non-Small Cell Lung Cancer Transformation Towards Small Cell Lung Cancer

Y. HUI, M. Li, J. Chen, Y. Pan, M. Yu, B. Zhang, J. Yun, L. Chen
Sun Yat-sen University Cancer Center, guangdong/CN

Introduction: Neuroendocrine transformation of epidermal growth factor receptor (EGFR)-mutant non-small cell lung cancer (NSCLC) represents a significant mechanism underlying acquired resistance to EGFR tyrosine kinase inhibitors (TKIs). This histological transformation lacks effective treatments. We investigated the immune microenvironment of primary EGFR-mutant NSCLC and paired transformed small cell lung cancer (T-SCLC) with the aim of understanding the immune landscape of this subtype of T-SCLC.

Methods: Nine patients harbouring EGFR mutations who developed T-SCLC and were treated with programmed cell death-1 (PD-1) axis blockade were enrolled. RNA transcriptome sequencing and multiplex immunohistochemistry were conducted to investigate the tumor immune microenvironment. We additionally used gene expression data of primary small cell lung cancer (P-SCLC) from GEO dataset to analyze the differences between T-SCLC and P-SCLC.

Results: Nine patients received EGFR-TKI before rebiopsy to confirm T-SCLC. The median progression-free survival (mPFS) and overall survival (mOS) of T-SCLC with ICIs were 5.1 and 11.7 months, respectively. T-SCLC harboring EGFR L858R tended to have inferior survival to EGFR 19del (mPFS:3.8 vs 5.7 months, P = 0.11; mOS:6.9 vs 11.7 months, P = 0.09). Our data revealed that paired T-SCLC exhibited an immune-suppressive microenvironment compared with EGFR-mutant NSCLC, which included the downregulation of multiple immune regulatory pathways, reduced immune cell infiltration, decreased scores of immune-related signatures. Additionally, we found a more immunosuppressive tumor microenvironment in P-SCLC compared with T-SCLC. In P-SCLC, the degree of almost all immune signatures was significantly lower than that in T-SCLC, such as MHC signature, T cell-inflamed GEP signature and IFN-gamma signature. Notably, clinically relevant immune checkpoints LAG3 and TIGIT were downregulated in T-SCLC compared with P-SCLC.

Conclusions: Our findings provide novel insights into the immune microenvironment profile of T-SCLC. Specifically, a significantly suppressed immune microenvironment is observed in T-SCLC that develops from EGFR-mutant NSCLC following TKI resistance; however, it remains more favorable compared to P-SCLC.

P3.13.26 Sequencing of Stereotactic Body Radiation Therapy and Chemotherapy in Stage I Small Cell Lung Cancer: Practice Patterns and Outcomes

T. Ziaks[1], H. Park[2], P. Oh[2], D. Hicks[2], C. Knowlton[2], J. Laird[2], T. Hayman[2]
[1]Yale School of Public Health, New Haven/CT/USA ,[2]Yale School of Medicine, New Haven/CT/USA

Introduction: The current standard-of-care for limited-stage small cell lung cancer (LS-SCLC) includes definitive thoracic radiotherapy (TRT) with concurrent chemotherapy. For patients with stage I disease who do not undergo surgical resection, stereotactic body radiation therapy (SBRT) has emerged in recent years as an alternative to conventionally fractionated radiation therapy. However, the optimal sequencing of SBRT with regards to chemotherapy remains unknown. We sought to identify practice patterns of SBRT timing relative to chemotherapy and assess survival outcomes for patients with stage I SCLC in the United States.

Methods: We identified patients in a large national database with clinical stage I SCLC who underwent SBRT and chemotherapy between 2004 and 2020. Patients were categorized into two cohorts: SBRT before chemotherapy initiation (Group 1) and SBRT concurrent with or after chemotherapy initiation (Group 2). Chi-squared tests were used to compare patient characteristics between the groups. Univariable and multivariable logistic regressions were used to determine patient characteristics associated with treatment cohorts, while Cox proportional hazard models evaluated their impact on survival outcomes. The Kaplan-Meier method and the log-rank test were used to compare survival outcomes between cohorts.

Results: Among 631 patients with clinical stage I SCLC who were treated with SBRT and chemotherapy, 416 patients were categorized in Group 1 and 215 patients in Group 2. Patients diagnosed between 2019-2020 were less likely to receive SBRT concurrent with or after chemotherapy (OR=0.46, 95% CI=0.31-0.65, p<0.001). Patients diagnosed with clinical T2 stage were more likely to receive RT concurrent with or after chemo (OR=1.76, 95% CI=1.05-2.95, p=0.03). No statistically significant difference in survival was observed between the two treatment sequencing cohorts (Group 1: median 40.5 months vs. Group 2: 35.6 months, log-rank p=0.30). On multivariable analysis, SBRT sequencing was not associated with overall survival (HR=1.11, p=0.35, 95% CI=0.89-1.37).

Conclusions: Our findings suggest there is no statistically significant difference in survival outcomes for patients who receive SBRT before chemotherapy compared to those who receive SBRT concurrent with or after chemotherapy.

P3.13.27 Toripalimab Consolidation After Chemoradiotherapy in Limited-Stage Small Cell Lung Cancer: A Phase II, Randomized Controlled Study

P. Zhang[1], D. Wang[1], W. He[1], Y. Dong[2], H. Zhang[3], Y. Situ[1], M. Wang[1], Y. Zhang[1], S. Wei[2], B. Qiu[1], Y. Huang[1], H. Liu[1]
[1]Sun Yat-sen University Cancer Center, Guangzhou/CN ,[2]Gansu Provincial Cancer Hospital, Lanzhou/CN ,[3]Air Force Hospital of Southern Theater Command of the People's Liberation Army, Guangzhou/CN

Introduction: Immune checkpoint inhibitors plus chemotherapy has demonstrated survival benefits in the management of extensive-stage small cell lung cancer (SCLC). The integration of immunotherapy with chemoradiotherapy may improve survival outcomes in limited-stage SCLC. This phase II, randomized controlled study was designed to evaluate the efficacy and safety of toripalimab consolidation versus observation in patients with limited-stage small cell lung cancer (LS-SCLC) after concurrent chemoradiotherapy (CCRT).

Methods: We enrolled patients with LS-SCLC who had an ECOG performance status of 0-1 and demonstrated no disease progression following CCRT. Eligible patients were randomized 1:1 to either toripalimab consolidation (240mg every 3 weeks for up to 6 months) or observation. Randomization was stratified according to disease stage (I or II vs. III) and receipt of prophylactic cranial irradiation (yes vs. no). The primary end point was progression-free survival (PFS). The secondary endpoints included overall survival (OS), duration of response (DOR) and toxicities. Toxicities were graded according to CTCAE v.5.0. Post hoc power analyses included conditional power (CP) and post hoc predictive power of success.

Results: Between June 30, 2020, and May 31, 2024, 96 patients were randomized to receive either toripalimab (n=48) or undergo observation (n=48) following CCRT. The median follow-up duration was 27.8 months. The baseline characteristics are well balanced between toripalimab and observation groups. The median PFS was not reached in the toripalimab group, compared with 11.8 months (95% CI, 3.2-20.5 months) in the observation group(HR= 0.55, 95% CI, 0.30-0.98). The median OS was not reached in the toripalimab group, compared with 33.7 months (95% CI, 20.1-47.3 months) in the observation group (HR= 0.44, 95% CI, 0.20-0.96). The incidence of grade 3 or 4 adverse events was 22.9% among patients receiving toripalimab and 27.1% among patients with observation. Adverse events led to toripalimab discontinuation in 8.3% (4/48) of the patients. Grade 3 or 4 pneumonitis or radiation pneumonitis occurred in 4.2% of the patients in toripalimab group and 2.1% of those in observation group. No grade 5 events occurred in both groups.

Conclusions: In patients with LS-SCLC, toripalimab consolidation significantly improved OS and PFS with an acceptable safety profile.

Baseline Characteristics of Patients

P3.13.28 Survival Outcomes in Advanced Large Cell Neuroendocrine Carcinoma of the Lung in Immunotherapy Era: An NCDB Analysis

U. Karki[1], P. Budhathoki[2], T. Roy[1], A. Shah[2], K. Chul[1]
[1]MedStar Georgetown University Hospital, Washington/DC/USA ,[2]H. Lee Moffit Cancer Center and Research Institute, Tampa/FL/USA

Introduction: Large cell neuroendocrine carcinoma of the lung (LCNEC) is a relatively rare and aggressive malignancy with a high recurrence rate. The impact of immunotherapy on survival in advanced LCNEC remains unclear, with existing data limited to case reports and small retrospective studies. Utilizing the National Cancer Database (NCDB), which captures over 70% of newly diagnosed lung cancers in the United States, we evaluated survival outcomes in advanced LCNEC based on treatment type and compared these outcomes with those of non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC).

Methods: Demographics, treatment, and survival data for histologically confirmed stage IV LCNEC cases diagnosed between 2015 and 2020 were extracted from NCDB. Stage IV NSCLC (adenocarcinoma and squamous cell carcinoma) and SCLC diagnosed during the same period were used as comparisons. Survival analyses were conducted using the log-rank test, and Cox multivariate regression adjusted for confounders, including age, sex, race, comorbidities, insurance, treatment facility type (academic vs. community), and brain metastases.

Results: A total of 238,920 patients were identified, including 2,945 LCNEC, 191,237 NSCLC, and 44,738 SCLC. Of the 2,014 LCNEC that received systemic therapy as the first course of treatment, 1,397 (69%) received chemotherapy alone, 46 (2%) received immunotherapy alone and 571 (29%) received chemoimmunotherapy. LCNEC patients treated with chemoimmunotherapy had improved survival compared to chemotherapy alone (median overall survival [OS] 10 vs. 8.5 months; HR 0.82, 95% CI 0.72-0.95, p = 0.007). LCNEC had significantly shorter survival compared to NSCLC when treated with chemotherapy alone (median OS 8.5 vs 11.4 months, HR 0.74, 95% CI 0.71 - 0.79, p<0.001) as well as when treated with chemoimmunotherapy (median OS 10 vs 12.9 months, HR 0.75, 95% CI 0.66-0.84, p<0.001). LCNEC had marginally longer median overall survival compared to SCLC when treated with chemotherapy alone (median OS 8.5 vs 8.4 months, HR 1.13, 95% CI 1.07 - 1.21, p<0.001). No difference in survival was observed between LCNEC and SCLC when treated with chemoimmunotherapy (median OS 10 months vs 9.6 months, HR 0.08, 95% CI 0.96 - 1.22, p = 0.2).

Conclusions: To our knowledge, this study represents the largest analysis of survival outcomes in advanced LCNEC in the immunotherapy era. Stage IV LCNEC patients demonstrated modestly improved survival with chemoimmunotherapy compared to chemotherapy alone; however, overall survival remained inferior to NSCLC regardless of treatment. LCNEC showed no clear survival advantage over SCLC, with only a marginal difference observed with chemotherapy alone and no significant difference with chemoimmunotherapy. These findings highlight the aggressive nature of LCNEC and the limited benefit of current systemic therapies. Future studies should integrate biomarkers such as PD-L1 expression and genomic alterations, as well as evaluate optimal chemotherapy partners in chemoimmunotherapy regimens to improve outcomes for this rare lung cancer subtype.

P3.13.29 Somatostatin Receptor Expression and First-Line Somatostatin Analog Therapy: A Comparative Analysis in Thoracic Neuroendocrine Neoplasms

M. Vorobeva, V. Delektorskaya, E. Evdokimova, Y. Zhulikov, A. Markovich, V. Gorbunova, P. Kononets, E. Artamonova
N.N. Blokhin National Medical Research Center of Oncology, Moscow/RU

Introduction: Thoracic neuroendocrine neoplasms (NENs) are rare group of neoplasms. Thoracic NENs are divided into well-differentiated typical carcinoid (TC, G1), atypical carcinoid (AC, G2), AC with higher mitotic index (MI) and Ki-67 (considered G3), and poorly differentiated neuroendocrine carcinomas (NECs), including large-cell (LCNEC) and small-cell (SCLC) types. AC G2 and G3 are not officially separated, however, for analysis, we identified a distinct subgroup - AC G3 - by analogy with gastrointestinal NETs, based on morphology, MI, Ki-67. Data on therapy efficacy in G3 subgroup are limited. The assessment of SSTR expression allows for the consideration of somatostatin analog (SSA) therapy.

Methods: We analyzed 155 patients with thoracic NENs (1997-2025), including lung (n=137/88%) and thymic neoplasms (n=18/12%). NENs were classified as G1 (n=34/22%), G2 (n=81/52%), G3 (n=20/13%), LCNEC (n=20/13%). SCLC was excluded from the analysis. SSA therapy was administered to 96 patients (62%); LCNEC patients received SSA plus platinum-based chemotherapy.

Results: SSTR expression was determined in 126 cases (81%): IHC in 61.9% (78/126), Ga68 DOTA-TATE PET/CT in 66,7% (84/126), and both in 30.2% (38/126). SSTR positivity was observed in 51.3% by IHC (40/78), 84.5% by PET/CT (71/84). Among 38 patients assessed by both methods, discordant results were seen in 52.6%. PET/CT identified 39.5% as IHC-negative but PET-positive, while 13.2% - PET-negative but IHC-positive. By IHC, SSTR positivity rates: G1 - 60% (n=9/15), G2 - 48.8% (n=20/41), G3 - 66.7% (n=6/9), LCNEC - 38.5% (n=5/13). SSTR2A expression: G1 - 46.7% (n = 7/15), G2 - 46.3% (n = 19/41), G3 - 55.6% (n = 5/9), LCNEC - 30.8% (n = 4/13). SSTR5 expression: G1 - 13.3% (n = 2/15), G2 - 9.8% (n = 4/41), G3 - 11.1% (n = 1/9), LCNEC - 7.7% (n = 1/13). 4 patients with G3 received monotherapy in first-line with SSA (4/16). These patients had favorable course (median of Ki-67 = 37%, low tumor burden). While the rest patients received SSA with chemotherapy (12/16). Median progression-free survival (mPFS) on first-line SSA: G1 - not reached, G2 - 22 mo ± 4,3 (13,6-30,4). The whole mPFS in G3 subgroup - 11 mo ± 4,5 (2,2-19,8) (SSA - 9 mo, combination - 11 mo, p=0,4), p=0.001. Disease Control Rate (DCR) in G1 - 94.1% (n = 16/17), objective response rate (ORR) - 5.9% (n = 1/17), no progressive disease (PD) cases. G2: DCR - 77.2% (n = 46/57), ORR - 3.5% (n = 2/57), PD - 14% (n = 8/57). G3 whole subgroup: DCR - 81.3% (n = 13/16), PD - 18.8% (n = 3/16). LCNEC: DCR - 83.3% (n = 5/6), PD - 16.7% (n = 1/6).

Conclusions: Ga-68 DOTA-TATE PET/CT showed higher sensitivity for SSTR detection, though IHC revealed 13% of additional SSTR-positive cases. SSA therapy was most effective in G1-G2 (DCR up to 94%) and showed meaningful activity in selected G3 and LCNEC patients. Dual-method SSTR assessment improves treatment selection in thoracic NENs.

Keywords: Thoracic NENs, SSTR, SSA

P3.13.30 Whole Exome Sequencing Analysis of Somatic Mutations in Diffuse Idiopathic Pulmonary Neuroendocrine Cell Hyperplasia

H. Yu[1], T. Danhorn[1], Y. Miller[2], D.T. Merrick[2]
[1]CU Anschutz Medical Campus, Aurora/CO/USA ,[2]University of Colorado Anschutz Medical Campus, Aurora/CO/USA

Introduction: Diffuse Idiopathic Pulmonary Neuroendocrine Cell Hyperplasia (DIPNECH) is a disease characterized by widespread foci of nodular proliferations of neuroendocrine cells in the small airways that can progress to aggressive carcinoid tumors or cause respiratory failure secondary to airway obstruction. The cause of DIPNECH is unknown. We hypothesize that a set of acquired somatic mutations in pulmonary neuroendocrine cells may lead to NECH development and their subsequent spread throughout the airways in affected individuals.

Methods: A cohort of 47 patients with clinical and pathologic features of DIPNECH was identified. All the patients showed more than three NECH lesions on histological review. Lesions classified histologically as NECH, carcinoid tumorlets and carcinoid tumors were collected using micro-dissection from the archived formalin-fixed, paraffin-embedded (FFPE) tissue blocks. Genomic DNA from the micro dissected lesions and the germline DNA from lymph nodes or matched normal lung tissue were extracted and whole exome sequencing (WES) was performed to identify common somatic mutations in DIPNECH patients.

Results: DNA was extracted from a total of 122 lesions from 47 patients collected by micro-dissection, including 87 NECH lesions, 12 tumorlets and 23 carcinoid tumors. After stringent filtering of polymorphisms and assessment of potential oncogenic impact, an average gene variant impact score (AGVIS) for each gene affected was calculated providing a score ranging from 0 to 4. A high number represents potential high impact of the gene in disease development and progression. We then identified 69 genes with a high frequency of somatic mutations (variants ≥ 10) and a high AGVIS >2 in the DIPNECH cohort (Table 1). With further confirmation of the potential tumorigenicity of these gene mutations using the cBioPortal database, we identified the PABPC family, NOTCH1 and MTOR as harboring potential critical gene mutations in the pathogenesis and the progression of DIPNECH. PABPC proteins have global effects on gene expression and mutations in NOTCH1 and MTOR effect cellular proliferation and other cellular activities that are associated with tumorigenesis. Thirty-one patients of the DIPNECH cohort carry potentially oncogenic somatic variants in at least one of these three genes (or gene family).

Conclusions: Somatic mutations with high tumorigenic impact are common in DIPNECH patients. A set of potential driver mutations were identified in WES results. These gene variants are present within and across patients with high frequency. Further investigations are planned to validate the function of these gene variants in the pathogenesis and progression of DIPNECH.

Table 1. Top 25 high AGVIS genes mutation frequency. AGVIS, average gene variant impact score.

Introduction: Lurbinectedin is approved for adults with metastatic (US and Switzerland) or stage III/metastatic (Canada) SCLC who progressed on/after platinum-based chemotherapy based on results from a phase 2 basket trial (NCT02454972).

Methods: EMERGE 402 is a prospective, observational, phase 4 trial (NCT04894591), evaluating lurbinectedin in extensive stage (ES)-SCLC in real-world practice in North America initiated in 2021. The primary endpoint is overall response rate (ORR). Secondary endpoints include progression-free survival (PFS) and overall survival (OS). Tumor responses are assessed in patients with baseline measurable disease per RECIST v1.1.

Results: As of February 4, 2025, 265 patients had received ≥1 cycle of lurbinectedin; 14 (5%) had ongoing treatment. Among 250 (94%) discontinuations, disease progression was the most common reason (n=169 [68%]). At baseline, median patient age was 67 years, 51 (19%) had an ECOG score ≥2, and 66 (25%) had CNS metastases. 137 (52%) patients had platinum-sensitive disease (chemotherapy-free interval [CTFI] ≥90 days). All except one patient received lurbinectedin as monotherapy: 168 (63%) as second-line (2L) and 77 (29%) as third-line. Overall median (interquartile range [IQR]) number of lurbinectedin treatment cycles was 4 (2-7), with a median (IQR) duration of 91 (60-168) days. Among all patients with measurable disease at baseline, ORR (95% CI) was 26.6% (20.5-33.4) overall (n=192), 28.9% (20.1-39.0) with CTFI ≥90 days (n=97), and 29.3% (22.2-37.3) without CNS metastases (n=150). Overall median (95% CI) PFS and OS were 3.3 (2.6-4.1) and 7.6 (6.6-9.2) months, respectively; 3.1 (2.5-4.2) and 9.4 (7.6-11.9) months with CTFI ≥90 days; and 3.8 (2.7-4.9) and 8.5 (6.5-10.0) months without CNS metastases. Overall 6- and 12-month OS rates were 61% and 34%, respectively. Table shows effectiveness by line of therapy. With lurbinectedin in 2L, ORR was 29.3% overall, 36.7% with CTFI ≥90 days, and 32.3% without CNS metastases. Also with 2L, median PFS and OS were 3.3 and 7.6 months, respectively, overall; 3.8 and 11.9 months with CTFI ≥90 days; and 4.0 and 8.6 months without CNS metastases. Among all patients (N=265), 86 (32.5%) patients experienced treatment-related adverse events (AEs), including 28 (10.6%) with serious AEs. The most common AEs of special interest included increased hepatic enzyme (10.6%), anemia (9.4%), neutropenia (7.9%), and thrombocytopenia (7.5%).

Conclusions: The study enrolled an SCLC population with worse prognostic factors than those in the phase 2 basket trial. Lurbinectedin demonstrated clinically meaningful effectiveness and an acceptable safety profile in this real-world patient population, including poor prognosis subgroups.

Table 1. Effectiveness outcomes by line of therapy

	Overall (n=192[a])		CTFI ≥90 days (n=97[b])		CTFI <90 days (n=64[b])		CNS metastases (n=42[b])		No CNS metastases (n=150[b])

P3.13.32 Real-World Outcomes of Patients With Bronchopulmonary Neuroendocrine Tumors Treated With Lutetium Lu 177 DOTATATE (Lutathera)

G. Maiocco[1], A. Hazim[1], T.R. Halfdanarson[1], M. Shanshal[1], K. Leventakos[1], A.S. Mansfield[1], A. Dimou[1], J. Molina[1], K.E. Smith[1], V. Ernani[2], Y. Lou[3], R. Manochakian[3], A.J. Schwecke[1], A. Luce[1], G. Johnson[1], K. Parikh[1]
[1]Mayo Clinic, Rochester/MN/USA ,[2]Mayo Clinic, Scottsdale/AZ/USA ,[3]Mayo Clinic, Jacksonville/FL/USA

Introduction: Bronchopulmonary neuroendocrine tumors (BPNETs) comprise an estimated 20-30% of all neuroendocrine tumors (NETs). Management of metastatic BPNETs remains largely individualized, with lutetium-177 (177Lu) DOTATATE (Lutathera), a peptide receptor radionuclide therapy (PRRT), emerging as a promising treatment in NETs with selective targeting of somatostatin receptor expressing cells. Here, we present real-world utilization and outcome data of PRRT in BPNETs.

Methods: We conducted a retrospective analysis of patients with metastatic BPNETs treated at Mayo Clinic sites (AZ/FL/MN) with PRRT between 2014 and 2025. Patients were identified via institutional records and confirmed using the Mayo Data Explorer platform. Tumor grade and histology were defined by Ki-67 and per WHO 2017 criteria, respectively. Treatment response was assessed by 3-month post-treatment interval restaging imaging and clinician document assessment. Progression free survival (PFS) defined as time from PRRT initiation to any disease progression, death or last follow up at conclusion of data review (3/15/25). Overall survival (OS) was defined as time from PRRT initiation to death or last known follow up. Statistical analyses were performed with Stata 18.0.

Results: Twenty-three patients [median age 66] were included [14 (61%) males]. Eleven patients had active or former tobacco use with 33 average pack-years. Grade 1, 2, and 3 tumors were seen in 26% (n=6), 39% (n=9) and 26% (n=6) patients, respectively. Histologically, 10 patients had typical carcinoid while 13 had atypical carcinoid. Seven patients (30%) reported functional carcinoid syndrome. Most frequent sites of metastasis were liver (78%, n=18), bone (61%, n=14), pancreas (9%, n=2) and contralateral lung (4%, n=1). Majority of patients had Krenning score-4 (57%), followed by score-3 (30%), and score-2 (13%). PRRT was most commonly administered as third-line systemic therapy (52%), followed by fourth-line (22%), second-line (17%), and later-lines (9%). Preceding cancer-directed therapies included somatostatin analogs (100%), systemic chemotherapy (65%; 10/15 single-line, 5/15 multiple-lines; 8/15 platinum/etoposide, 4/15 capecitabine-temozolomide), everolimus (43%), and tyrosine kinase inhibitor (9%). 17/23 (74%) patients received 4 doses PRRT (median 4, range 2-6). No patient had complete response; partial response was observed in 17% (4/23), stable disease in 30% (8/23), progressive disease in 43% (9/23). Most common adverse events included fatigue (35%), nausea (26%), abdominal pain (22%), and decreased appetite (13%); no events ≥ grade 3 were reported. Median PFS was 10.8 months (IQR: 7.3-18.6; 95% CI: 6.5-15.2). In subgroup analysis, median PFS by Krenning score 4 vs. ≤3 was 14.7 vs. 7.5 months (p=0.036). By histology, median PFS for typical vs. atypical tumors was 13.5 vs. 8.4 months (p=0.172). Median OS was 21.2 months (IQR:12.2-34.0; 95% CI:13.9-28.5) with 9/23 (39%) patients alive at time of data collection. Following PRRT, 10/23 (43%) patients received no further treatment, with 4/23 (17%) receiving 1 additional line and 7/23 (30%) receiving ≥2 lines.

Conclusions: In this retrospective analysis of patients with metastatic BPNETS, lutetium (177Lu) DOTATATE demonstrated a response rate of 17%, disease control rate of 48%, and a median PFS of 10.8 months. In clinical practice, decision of when to utilize PRRT varies widely, found here most commonly as a 3rd line systemic agent.

P3.13.33 Clinical Outcomes and Single-Cell Map of Neoadjuvant Immunochemotherapy for Stage II-IIIb LS-SCLC : A Real-World Study

C. Huang, Z-y. Chen, Z-y. Xu, J-t. Zhang, R. Fu, X-n. Yang, Y-l. Wu, W-z. Zhong
Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University,, Guangzhou/CN

Introduction: Approximately one-third of small cell lung cancer (SCLC) cases are diagnosed at the limited stage. For those with N1-N2 nodal metastasis, the standard concurrent chemoradiotherapy (CCRT) based regimen yields suboptimal outcomes. While immunotherapy has revolutionized SCLC treatment, the neoadjuvant immunochemotherapy has shown curative potential in NSCLC. This study investigates the efficacy of neoadjuvant immunochemotherapy in stage II-IIIB SCLC, with parallel exploration of underlying mechanisms through translational research.

Methods: Based on the objective performance criterion of single-arm rate, we estimated that 16 patients would be required. In this study, we retrospectively enrolled 9 patients and prospectively included 16 patients in potentially resectable stage II-IIIB(N2) LS-SCLC. Patients underwent Multidisciplinary team (MDT) evaluation for local treatment after at least 3 cycles of neoadjuvant immunochemotherapy, non-surgical candidates converted to radiotherapy. All candidates received neoadjuvant immunochemoterapy as Full Analysis Set (FAS), while surgical patients completing protocol as Treatment-Completed Cohort (TCC). Additionally, we retrospectively collected 87 patients treated with concurrent CCRT and 10 patients who received neoadjuvant chemotherapy as control groups. Propensity score matching (PSM) was applied to the CCRT group based on stage, age, sex, and smoking-status. The primary endpoints were 18-month Event-free survival (EFS) rate and pathological complete response (pCR) rate. Secondary endpoints included 18-month overall survival (OS) rate and objective response rate (ORR) to neoadjuvant therapy.We also collected single-cell RNA sequencing (scRNA-seq) on fresh surgery tumor tissue and tumor-draining lymph nodes(tdLN) at post-IO treatment.

Results: Among 25 enrolled patients, 16 underwent surgery, other 9 received consolidative radiotherapy after neoadjuvant therapy. In the FAS, the 18-month EFS and OS rates were 58.8% and 89.2%, respectively, with an ORR of 84%. TCC analysis revealed a pCR rate of 50% and an MPR rate of 56.3%, with 18-month EFS and OS rates of 76.6% and 80.8%, respectively. Notably, no tumor progression was observed in pCR patients.The TCC demonstrated significantly superior 18-month EFS rates compared to the IC+Radiotherapy group (33.3%) (HR=4.066, P=0.032), though 18-month OS (100%) did not reach statistical significance. PSM yielded 15 paired controls, confirming the TCC survival advantage 18-month EFS rates: 83.9% vs. 33.3%, P=0.011; OS rates: 90% vs. 66.7%, P=0.031). The chemotherapy-only neoadjuvant group showed comparable outcomes (18-month EFS/OS rates: 70%/90%) to the TCC.TCC with 87.5% R0 resection and minimally invasive surgery rates. No SAEs occurred in the FAS. 22 specimens of scRNA-seq (8 patients) were divided into pCR(5/8) and non-pCR(3/8). We found that the pCR group has expanded marcophage and naïve CD4+ T cells with upregulated migration-related genes expressed in both tumor and tdLNs. While the non-pCR group has expanded CD14+ monocytes and exhausted T cells with enhanced immune activation pathway, but suppressed migratory signatures in tdLNs.

Conclusions: Our study demonstrates the efficacy of neoadjuvant chemoimmunotherapy followed by surgery in potentially resectable stage II-IIIB LS-SCLC, showing significant EFS benefits compared to current regimens, though OS advantages require longer follow-up. Mechanistically, scRNA-seq analysis revealed that expanded naïve CD4+ and proliferating T cells, coupled with enhanced immune migration-related gene expression in tdLN, underlie the superior treatment response.

Introduction: Small cell lung cancer (SCLC) is an aggressive disease with poor survival rates. Despite response to initial therapy for extensive-stage disease, relapses are common and treatment options remain limited. Tarlatamab, a bispecific T-cell engager (BiTE®) immunotherapy that harnesses cytotoxic T cells to kill SCLC cells by targeting delta-like ligand 3 (DLL3), has demonstrated durable responses and significant survival benefit with long-term tolerability in patients with previously treated SCLC (Ahn, NEJM 2023; Sands, WCLC 2024; Mountzios, NEJM 2025). We report results from the DeLLphi-307 phase 2a trial, evaluating tarlatamab in the third-line and beyond (3L+) SCLC setting in China.

Methods: Eligible patients were Chinese adults with extensive-stage SCLC who progressed following a platinum-based first-line regimen (including anti-PD-[L]1) and at least one other prior line of therapy. The primary endpoint was objective response rate (ORR) based on blinded independent central review per RECIST 1.1. Secondary endpoints included duration of response (DOR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety.

Results A total of 31 patients (84% male, median age 57 years) received tarlatamab. The median follow-up for this analysis was 3.8 months for efficacy outcomes (Table). ORR was 39% and median DOR was not reached, with responses ongoing in 11 of 12 (92%) responders at data cutoff. Median PFS was 2.9 months, and median OS was not reached. The most common treatment-emergent adverse event (TEAE) was cytokine release syndrome (CRS, 87%), which primarily occurred after the first and/or second tarlatamab dose. CRS events were low grade (Table) per ASTCT 2019 Consensus grading, with grade 1 reported for 19 patients (61%), of which about half (10 of 19 patients; 53%) had fever as the only recorded CRS symptom, and grade 2 reported in 8 patients (26%). There were no Grade 3 or above CRS events and no report of any immune effector cell-associated neurotoxicity syndrome (ICANS) event. The most common grade 3 or higher TEAEs were lymphopenia (16%), neutropenia (13%), and hyponatremia (13%). No treatment discontinuations occurred due to an adverse event.

Conclusions Tarlatamab demonstrated anticancer efficacy with promising durable responses and survival outcomes in Chinese patients. There were no new or unexpected safety concerns. This encouraging region-specific clinical evidence supports tarlatamab's potential as a new treatment option for Chinese patients with previously treated extensive-stage SCLC.

P3.14.01 Global Trends in Asbestos Related Mesothelioma Mortality From 1990 to 2021

K. Edwards[1], C. Jani[2], C. Olazagasti[2], G. Lopes[2], E. Rodriguez[2]
[1]University of Miami Miller School of Medicine, Miami/FL/USA ,[2]University of Miami Sylvester Comprehensive Cancer Center, Miami/FL/USA

Introduction: Mesothelioma, a rare but aggressive cancer primarily caused by asbestos exposure, remains a significant global health concern. Despite regulatory efforts to limit asbestos use, the burden of mesothelioma continues to rise, with notable variations across age groups, sexes, and socio-demographic regions. This study examines trends in asbestos-related mesothelioma deaths from 1990 to 2021, highlighting shifts in incidence, mortality, and exposure patterns worldwide.

Methods: We utilized data from the Global Burden of Disease database to analyze global mesothelioma deaths attributable to occupational asbestos exposure from 1990 to 2021. Results were reported per 100,000 population and stratified by gender, age groups (20-54, 55+), and global sociodemographic index (SDI; high, high-middle, middle, low-middle, low).

Results: Between 1990 and 2021, the global incidence of mesothelioma nearly doubled, rising from 16,493 cases in 1990 to 31,908 in 2021. In 2021, mesothelioma caused 29,619 deaths worldwide, with 27,136 (92%) linked to occupational asbestos exposure—almost twice the 13,763 asbestos-related deaths reported in 1990. Most deaths occurred in men aged 55 and older (n=18,257), representing a 101% increase from 1990 (n=9,070). Deaths among older women also rose substantially, reaching 6,293 in 2021, a 99% increase from 31 years prior. Younger individuals experienced smaller but notable increases: mesothelioma deaths among younger men rose 62.5% (1,137 to 1,848), while younger women saw an 86.3% increase (396 to 738).Despite the overall rise in deaths, age-adjusted mortality rates per 100,000 people declined slightly among older adults, decreasing by 10% for both men (2.91 to 2.61) and women (0.88 to 0.80). However, rates increased among younger adults, rising by 11% for men (0.09 to 0.10) and 33% for women (0.03 to 0.04). Occupational asbestos exposure was the leading cause of mesothelioma deaths in 2021, accounting for 97% of cases in older men and 94% in older women. Among younger adults, asbestos-related cases were lower, at 66% in men and 53% in women. Mesothelioma deaths increased across nearly all SDI levels, ages, and sexes. In 2021, most deaths occurred in older men (n=11,062) and women (n=2,790) in high-SDI countries, consistent with 1990 patterns. The largest increases occurred in middle- and low-middle-SDI countries, where asbestos-related deaths rose by 145%-312% in older adults and 149%-237% in younger adults.

Conclusions: These findings highlight the shifting burden of asbestos-related mesothelioma. The persistence of occupational asbestos exposure as a primary cause underscores the need for stronger global policies on asbestos regulation, early detection, and workplace safety.

P3.14.02 Clinical Implications of BAP1 Status in Pleural Mesothelioma (PM)

S. Cedres, I. Priano, P. Rocha, A. Valdivia, P. Iranzo, N. Pardo, A. Martinez-Marti, J. Yaringaño, S. Bueno, E. Garcia-Galea, R. Dienstmann, E. Felip
Vall d´Hebron Universitari Hospital and Vall d´Hebron Institute of Oncology (VHIO), Barcelona/ES

Introduction: PM is a rare and locally advanced cancer with poor prognosis. BAP1 mutations are the most common molecular alteration in PM. The prognostic value of somatic BAP1 has been analyzed in several studies with controversial results. BAP1 is a predictive biomarker for survival after chemotherapy with platinum, but the predictive role of somatic BAP1 mutations with immunotherapy (IO) has not been evaluated in clinical trials. Preclinical data suggest that BAP1 loss may sensitize to IO. The objective of this study is to describe the prognosis and predictive value of BAP1 in a series of patients (pts) with PM.

Methods: Retrospective real-world cohort of pts visited at our institution. Associations between clinical variables and outcome were assessed with multivariate time-dependent Cox regression models. Survival data were calculated by the Kaplan-Meier method.

Results: 257 pts with PM attended at our institution from 2005 to 2024. Clinical characteristics: median age 68 years (range 29-88 years), mostly males (72%), PS1 (66%), asbestos exposure (80%), epithelioid (81%), first line therapy in 87%. Median overall survival (OS) of the entire cohort was 21.3 months [m](18.3- 23.9). Significant prognostic factors for survival in the series were performance status, clinical stage, histology, and treatment with cisplatin. Median OS of pts with PS0,1 and 2 was 28.4 m, 18.5 m and 1.7 m (p<0.001). Median OS of pts with epithelioid histology was 23.8 vs 10.3 m no-epithelioid (p<0.001). Median OS for pts with stage I-II was 27.8 m and for III-IV 18.2 m (p=0.002). Patients treated with cisplatin in first line had OS of 23.3 m vs 18.3 m p treated with carboplatin (p=0.009). In total, 50 patients were evaluated for BAP1 through immunohistochemistry and 28 pts (56%) had BAP1 loss. In our series BAP1was not prognosis nor predictive factor for therapy. Median OS of patients with BAP1 loss was 21.8 m vs 21.0 m BAP1 retained (p= 0.7). Considering platinum treatment in first line (cisplatin or carboplatin) we did not detect any differences in OS according to BAP1 status: median OS for BAP1 positive pts treated with platinum was 20.9 m versus 22.5 m in those with BAP1 loss (p=0.9). In our series, 14 pts with BAP1 status received IO in first line, and median OS for BAP1 loss was 19.5 m vs 37.6 m for those with BAP1 positive (P=0.3). In second line, 11 pts with BAP1 status received IO and OS was 11.3 m for BAP1 vs 8.5 m for BAP retained (p=0.6). In a time dependent Cox analysis, there was no association of BAP1 status with OS according to IO exposure (p=0.13).

Conclusions: In our series BAP1 status is not a reliable marker for selecting treatment with platinum or immunotherapy. Confirmatory studies with larger numbers of patients are needed to establish the predictive value of BAP1 in PM.

P3.14.03 Loss of MHC Class I and II Defines an Immune Excluded Subtype in Pleural Mesothelioma

J. van Genugten
Netherlands Cancer Institute, Amsterdam/NL

Introduction: First-line immune checkpoint blockade (ICB) has shown clinical benefits in a subset of pleural mesothelioma (PM) patients, but not all patients respond, and reliable predictive biomarkers remain lacking. The antigen presentation machinery (APM), including MHC class I and II complexes, is essential for T-cell activation and has been implicated in immune evasion in several cancers. Its role in PM and its influence on ICB response remain underexplored.

Methods: We analyzed MHC class I and II gene expression in two independent ICB-naïve PM cohorts (n = 211 and n = 150) using unsupervised hierarchical clustering. Associations between MHC expression and T-cell infiltration were assessed, and patients were stratified into subgroups based on APM status and immune infiltration. These subgroups were evaluated for differential copy-number alterations, predicted neoantigen expression, and overall survival using Kaplan-Meier analysis.

Results: We identified four reproducible PM subtypes based on differential MHC class I and II expression and T-cell infiltration. Approximately 25% of tumors showed loss of either MHC class I or II, while ~45% lacked both. Dual expression of both MHC class I and II was associated with higher T-cell infiltration, while absence of MHC class II, and to a lesser extent MHC class I, was linked to reduced T-cell infiltration. Loss of chromosome 22q12.2, which contains the NF2 tumor suppressor gene, was more frequent in APM-deficient tumors. No associations were observed between APM status and predicted neoantigen load, protein coding mutation burden, or overall survival in ICB-naïve patients.

Conclusions: This study provides the first comprehensive transcriptomic characterization of APM in PM. We show that ~70% of tumors exhibit loss of MHC class I, II, or both, which may underlie immune evasion and resistance to immunotherapy. Ongoing work will evaluate how APM loss affects ICB response and the interplay between APM expression and cytokine signaling in the tumor microenvironment.

P3.14.04 High-Volume Surgical Centers for Pleural Mesothelioma Are Associated With Lower Perioperative Mortality

S. Mack, R. Nordgren, L. Landeras, F. Ufuk, S.G. Armato III, C.M. Straus, M. Drazer, M. Malec, O. Mitchell, H.L. Kindler, D.S. Bryan
The University of Chicago, Chicago/IL/USA

Introduction: Volume-outcome relationships have been defined for various operations, often demonstrating improved outcomes in high-volume centers for complex procedures requiring nuanced management. Prior work in the era of extrapleural pneumonectomy suggested improved outcomes following surgery for pleural mesothelioma at centers performing > 5 cases per year. We evaluate factors associated with 90-day survival across a broad range of centers performing mesothelioma surgery in the contemporary era.

Methods: A retrospective cohort analysis was completed using the National Cancer Database, the largest clinical cancer registry in the world. The NCDB includes Commission on Cancer accredited programs, which account for nearly 80% of new cancer diagnoses in the United States. Patients undergoing definitive resection from 2012-2019 were included in the analysis. High-volume surgical centers were defined as facilities performing more than 5 operations per year. Pearson's Chi-square and Student's t-tests were utilized to compare groups. Multivariable logistic regression was completed to analyze factors associated with 90-day survival from definitive resection.

Results: A total of 3,101 patients underwent operations at 664 centers. Epithelioid histology was most common (61.2%), as was pathologic stage III disease (30.2%). Ten facilities (1.5%) met the definition of "high-volume;" they performed 31% of the operations with a median of 13 cases per year. Low-volume centers performed, on average, at least one operation in only 4 of the 8 eligible years. High-volume centers were more likely to be academic (100% vs. 42%, p<0.001) and have patients treated at multiple centers for multidisciplinary care (51.3% vs. 34.2%, p<0.01). High-volume centers were less likely to operate on patients with sarcomatoid disease (4.4% vs. 8.7%) and more likely to on epithelioid or biphasic histology (89.1% vs. 73.6%, p<0.01). There were no statistically significant differences in patient age, sex, or race between groups. Patients in high-volume centers were more likely to receive nodal resection (84.9% vs. 49.5%, p<0.01), and less likely to undergo resections classified as "partial/debulking" (38.6% vs. 54.3%, p<0.01). Thirty-day readmission rates were greater at high-volume centers (11.1% vs 5.6%, p<0.01). 30- and 90-day mortality was lower in high-volume centers (2.4% and 7.5% vs. 5.4% and 12.6%, p<0.001). On multivariable analysis controlling for several patient, surgical and tumor characteristics, high-volume centers were associated with improved 90-day survival (odds ratio for death: 0.47, 95% confidence interval [0.32-0.69]).

Conclusions: A small number of centers perform most resections for pleural mesothelioma. High-volume surgical centers are associated with improved survival in the perioperative period following resection.

P3.14.05 Survival Outcomes of Sequential Therapies in Malignant Pleural Mesothelioma: A Real-World Analysis of Second-Line Treatments

M. Maffezzoli[1,2], J. Lau[1], H.M. Yusof[3], J. Cave[3], S.M. Acharige[3], M.R. Kim[3], M. Elgendy[4], M. Zarroug[4], Y. Mangan[5], K. Zaki[5], P. Tamarozzi[2], S. Muthuramalingam[1], M. Tiseo[2], G.L. Banna[1,6]
[1]Portsmouth Hospitals University NHS Trust, Portsmouth/GB ,[2]University Hospital of Parma, Parma/IT ,[3]Southampton University Hospitals NHS Trust, Southampton/GB ,[4]The Newcastle upon Tyne NHS Foundation Trust, Newcastle upon Tyne/GB ,[5]University Hospitals Sussex NHS Foundation Trust, West Sussex/GB ,[6]University of Portsmouth, Portsmouth/GB

Introduction: Dual immunotherapy with ipilimumab and nivolumab (IPI-NIVO) has recently become the standard first-line option for malignant pleural mesothelioma (MPM), though platinum-based chemotherapy remains a viable alternative. However, the real-world effectiveness of second-line treatments following immunotherapy or chemotherapy remains unclear. This study aimed to assess survival outcomes in patients with MPM receiving second-line carboplatin-pemetrexed (CARBO-PEM) or nivolumab (NIVO) after progression on first-line treatment.

Methods: We performed a multicentre retrospective study involving patients with MPM who received second-line treatment with CARBO-PEM or NIVO. Primary endpoints were progression-free survival (PFS) and overall survival (OS) from second-line therapy initiation (PFS2 and OS2). Survival curves were estimated using Kaplan-Meier analysis, and differences between groups evaluated using the log-rank test, with statistical significance set at $p<0.05$.

Results: A total of 98 patients were included, of whom 81 (82.7%) had epithelioid histology. 41 patients (41.8%) received second-line CARBO-PEM, while 57 patients (58.2%) had second-line NIVO. Baseline characteristics, including age, sex, ECOG performance status, and histology, were well-balanced between the two groups. The median follow-up was 45.2 months. The median PFS2 and OS2 for second-line CARBO-PEM were 6.15 and 11.6 months, respectively, compared to 2.73 and 11.6 months for second-line NIVO (Table 1). Log-rank tests revealed no significant differences in PFS2 ($p=0.437$) or OS2 ($p=0.554$) between the two cohorts. From first-line treatment initiation, the median PFS1 was 8.26 months with IPI-NIVO and 8.13 months with CARBO-PEM. Sequential treatment strategies showed no significant differences in OS: IPI-NIVO followed by CARBO-PEM achieved a median OS of 24.9 months, compared to 22.3 months for CARBO-PEM followed by NIVO ($p=0.946$), Figure 1.

Conclusions: Second-line CARBO-PEM following first-line IPI-NIVO showed numerically superior PFS2 versus NIVO post-chemotherapy, though without statistical significance. Sequential treatment sequences demonstrated comparable OS outcomes. Further investigations are warranted to identify predictive biomarkers and optimize therapeutic sequencing in real-world practice.

Table 1. Summary of survival outcomes for each treatment cohort and comparison with available data. *NR: not reached; N/A: not applicable; CI: confidence interval.*

OUTCOME	IPI-NIVO ↓ CARBO-PEM median (95%CI)	CARBO-PEM ↓ NIVO median (95%CI)	CHECKMATE 743 median (95%CI)	CONFIRM median (95%CI)	FLORA median (95%CI)
PFS1	8.26 months (5.49–10.23)	8.13 months (6.74–9.44)	IPI-NIVO: 6.8 months (5.6–7.4) CARBO-PEM: 7.2 months (6.9–8.0)	N/A	IPI-NIVO: 5.5 months (4.8–6.3)
PFS2	6.15 months (3.32–8.06)	2.73 months (2.34–4.80)	N/A	NIVO: 3.0 months (2.8–4.1)	CARBO-PEM: 5.6 months (4.9–6.3)
OS2	11.6 months (7.76–NR)	11.6 months (8.72–15.6)	N/A	NIVO: 10.2 months (8.5–12.1)	CARBO-PEM: 8.2 months (7.4–9.1)

Introduction: Up to 10% of patients (PTS) with pleural mesothelioma (PM) harbor a pathogenic germline mutation in cancer predisposing genes, a condition generally associated with better overall survival at diagnosis. Conversely, less than 1% of PTS with PM present potentially actionable somatic mutations. The 2025 ASCO guidelines on PM recommend germline genetic testing for all PM PTS, while discouraging routine somatic testing. This survey aims to assess the attitude and current clinical practice of Italian physicians treating PM regarding genetic testing.

Methods: From March 1st, 2025 to March 31th, 2025, a nationwide survey was distributed to an expert network of Italian physicians treating PM (MEsothelioma Team Italy- MET-I). The questionnaire investigated clinical practice in genetic testing, barriers to its implementation and educational needs.

Results: Thirty-seven responders (RS) completed the survey. Most RS were female (23, 62%), aged 30-45 years (24, 65%), medical oncologists (26, 70%), working in academic hospitals (32, 87%) based in the North of Italy (31, 83%), and managing at least 20 PM cases per year (16, 43%).Most RS don't recommend germline testing (22, 60%) or do it occasionally (12, 34%), and only three (8%) routinely recommend it in PM PTS. The main criteria for requesting germline testing include: a family history (FH) of PM (87%), FH of genetic mutations predisposing to PM (78%) and FH of tumors associated with PM (70%). In most cases, germline testing is available through genetic counselling (23, 62%), witheither monogenic BAP1 testing (11, 30%) or multigenic panelsincluding BAP1 (18, 49%).The main barriers to routine germline testing in PM include: cost (65%), limited access to dedicated genetic counselling (54%), and lack of physician awareness (51%). Proposed solutions involved increasing education on the topic (24, 65%), improving access to genetic counselling (21, 57%), and implementing dedicated institutional policies (54%).Somatic testing is routinely performed by four RS (11%), occasionally performed by 13 RS (35%), and never performed by 20 RS (54%). The main criteria for somatic testing in mesothelioma are the availability of a clinical trials with targeted agents (62%) and a young age (<50 years) at diagnosis (51%). Somatic test results influenced treatment decisions often or never in six RS (16%) and sometimes in nine RS (24%).Finally, 68% of RS were aware of the 2025 ASCO guidelines on PM, and 54% stated they would modify their clinical practice accordingly.

Conclusions: The survey highlights the underuse of germline testing among Italian physicians managing PM. High costs, limited access to genetic counselling, and lack of physician awareness are the primary barriers to germline testing. Implementing medical education programs on PM genetics, establishing dedicated genetic counselling services, and introducing institutional policies for germline testing could enhance the management of PM PTS in Italy.

P3.14.07 Recent Studies on Mesothelioma as a Model to Understand the Interaction of Gene and Environment (G X E)

H. Yang[1], J. Grzymski[2], M. Carbone[1]
[1]University of Hawaii Cancer Center, Honolulu/HI/USA ,[2]University of Nevada Reno, Reno/NV/USA

Introduction: Mesothelioma arises from transformed mesothelial cells (HM) and is associated with asbestos exposure. HM exposed to crocidolite, chrysotile, and erionite experience programmed cell necrosis, releasing HMGB1, which initiates and sustains chronic inflammation, and it plays critical role in mesothelioma development and progression. Mesothelioma development involves complex gene-environment interactions. Germline mutations of BAP1, a multifunctional deubiquitylase, are linked to mesothelioma incidence, by affecting transcription, metabolism, and DNA repair. BAP1's role in mesothelial transformation also involves HMGB1, as BAP1 forms a trimeric complex with HMGB1 and HDAC1. BAP1 mutations lead to hyper-acetylated HMGB1 release, promoting inflammation and cell transformation. The Gene-Environment (GxE) interactions approach, integrating genetic features and environmental factors, significantly advanced the knowledge of asbestos-related carcinogenesis. Northern Nevada's terrain is rich in minerals, including asbestos, erionite, arsenic (As), and other carcinogens. Inhalation of long, thin, mineral fibers may cause mesothelioma and other respiratory diseases, while ingestion of arsenic from groundwater is associated with various skin, pulmonary, and cardiovascular diseases, including cancer. Recent data show higher mortality rates among young individuals residing in Northern Nevada. However, despite the higher presence of carcinogens in the environment and the higher mortality rates for associated diseases, the amount and extent of human exposure remain unknown. This multidisciplinary study aimed to evaluate the carcinogenic potential of mineral fibers and arsenic naturally found in the Northern Nevada environment causing mesothelioma.

Methods: We identified and collected mineral fibers present in the natural environment of three different areas in Northern Nevada nearby the Reese River, the Eastgate communities, and the Segerstrom-Heizer Min. In the first two locations, we identified mainly erionite, while tremolite asbestos was found at Segerstrom-Heizer Mine. These mineral fibers were tested comprehensively by using both in vitro and in vivo assays to evaluate the toxicity and carcinogenesis.

Results: In tissue culture, all the mineral fibers significantly reduced the cell viability of primary human mesothelial (HM) cells in a dose-dependent manner, shorter fibers displayed less cytotoxic effects. The amount of arsenite present in wells was not cytotoxic and did not increase fiber cytotoxicity in vivo, although cells co-esposed to both fibers and arsenite showed a reduction in mitochondrial respiration. In mice, the erionite fibers longer than 10 µm present in the natural environment of the Eastgate communities caused mesothelioma in wild type mice. Moreover, these fibers caused a higher frequency of mesothelioma in mice carrying germline BAP1 mutations (gene x environment interaction) suggesting individuals carrying these mutations may be at higher risk of mesothelioma if living in this environment.

Conclusions: Our studies suggest that preventive strategies should be implemented among Nevadans to reduce exposure to the erionite present in the natural environment, and that that the ongoing Healthy Nevada Project to genotype the Northern NV population will be very helpful to identify families at higher risk.

P3.14.08 Genetically Defined Mouse Models of Malignant Pleural Mesothelioma Recapitulate Human MPM Phenotypes and Response to Therapy

P. Farahmand[1], D. McKinven[1], J. Doig[1], S. Lilla[2], D. Sumpton[2], X. Raffo-Iraolagoitia[2], S. Ali[2], H. Hall[2], R. Shaw[2], E. Shokri[2], K. Gyuraszova[1], L. Carlin[2], K. Blyth[1], M. Macfarlane[3], R. Duffin[4], S. Zanivan[2], C. Miller[2], J. Le Quesne[1], D. Murphy[1]
[1]University of Glasgow, Glasgow/GB ,[2]CRUK Scotland Institute, Glasgow/GB ,[3]MRC Toxicology, Cambridge/GB ,[4]University of Edinburg, Edinburg/GB

Introduction: Introduction: Malignant Pleural Mesothelioma (MPM) is a devastating cancer that lacks a clear pre-malignant precursor, is difficult to distinguish from chronically inflamed hyperplastic mesothelium, and is largely refractory to treatment. To use genetically defined mouse models of mesothelioma to advance the understanding of autochthonous disease biology and, in particular, to garner insight into the biological differences between benign and malignant disease and the transition between the two.

Methods: Adult mice carrying multiple conditional alleles for CRE-mediated deletion of Bap1, Cdkn2a, Nf2 and/or Tp53 in various combinations were induced by intrapleural injection with Lentiviral vectors carrying Mesothelin promoter-driven CRE recombinase, followed by Amosite Asbestos. Mice were harvested at different time points, with tissue and pleural lavage (or effusion, when present) subject to analysis by transcriptomics, proteomics, metabolomics, histology, flow cytometry and immunohistochemistry.

Results:

• Combined deletion of Cdkn2a, Nf2 and Tp53 yields predominantly epithelioid MPM whereas loss of Bap1, Cdkn2a and Nf2 yields sarcomatoid MPM, spanning the histological subtypes of human disease. • Disease progression is dramatically accelerated by asbestos injection, indicating a critical role for chronic inflammation beyond acquisition of causative mutations. • Transcriptional profiling showed differential expression of signalling and metabolomic pathways. • Comparative analysis of pleural fluid proteomics data indicates differences across various genotypes and disease stages. • Flow cytometry data suggest a dynamic relationship of nascent mesothelioma tumours with the immune cells of the pleural cavity. • PD1 blockade resulted in a profound survival benefit in the sarcomatoid model but had no impact on epithelioid MPM, similar to the results of the Checkmate 743 trial of canonical immune checkpoint inhibition in human MPM.

Conclusions: Our models provide an unparalleled opportunity for mechanistic investigation of MPM aetiology and differential responses to therapy.

P3.14.09 Sex-Based Differences in Mesothelioma: Insights From the ICO Cancer Registry

J. Brenes[1], M. Mosteiro Lamas[1], M. Doménech[2], J. Bosch-Barrera[3], E. Sais[3], L. Moliner[1], E. Teixidor[3], S. Padrones[4], J.M. Escribà[51], L. Pareja[1], J. Ribes[1], E. Nadal[1]
[1]Catalan Institute of Oncology (ICO), Bellvitge Campus, L'Hospitalet de Llobregat/ES ,[2]Catalan Institute of Oncology (ICO), Can Ruti Campus, Badalona/ES ,[3]Catalan Institute of Oncology (ICO), Trueta Campus, Girona/ES ,[4]Bellvitge Universitary Hospital, L'Hospitalet de Llobregat/ES

Introduction: Several European countries, including France and Italy, established national mesothelioma registries to monitor and determine the incidence and causes of this asbestos-related cancer. These registries provide data on both occupational and non-occupational exposure sources.

Methods: We conducted a retrospective analysis of incident mesothelioma cases recorded in the ICO registry. Patient data, including demographics, clinical characteristics, histological subtypes, and treatment modalities, were extracted. Survival outcomes were assessed using relative survival analysis, comparing observed survival with expected survival in a matched general population. The primary endpoint was to determine the 3-year relative survival (RS).

Results: From 2013 to 2023, a total of 420 incident mesothelioma cases were recorded, distributed across different anatomical locations: pleural (91%), peritoneal (8%), and pericardial and testicular (0.5% each). The median age at diagnosis was 73 years (IQR, 67-78), with a predominance of male patients (70%). Occupational exposure to asbestos was more frequently reported in males (52%) than in females (10%), while ambiental exposure was more commonly reported in females (24%) than in males (5%) p<0.001). Exposure to asbestos could not be captured in 18% of patients. The 3-year RS was higher in women (33%, CI95%: 24.7-43.6) than in men (20%, CI 95%: 15.4-26.5). Additionally, a progressive improvement in 3-year RS was observed, increasing from 20% (CI 95%: 13.7-28.6) in the 2013-2016 period to 28% (CI 95%: 18.2-43.7) in 2021-2022.

Conclusions: Women with mesothelioma have better survival outcomes and distinct pattern of asbestos exposure compared to men. Collection of asbestos exposure is challenging in retrospective studies. Mesothelioma surveillance and prospective data collection on asbestos exposure is warranted to assess the health impact of asbestos and promote policies aimed at preventing exposure risks.

Keywords: mesothelioma, asbestos

P3.14.10 Ultrasound Detection of Effusion and Neoplasia in Genetically Defined Mouse Models of Mesothelioma

X. Hong[1,2], P. Farahmand[1], D. Lubawska[1], D. McKinven[1], J. Doig[1], R. Duffin[3], K. Blyth[1,4], D.J. Murphy[1,4]
[1]University of Glasgow, Glasgow/GB ,[2]Zhongshan Hospital Affiliated to Xiamen University, Xiamen/CN ,[3]University of Edinburgh, Edinburgh/GB ,[4]CRUK Scotland Institute, Glasgow/GB

Introduction: Malignant pleural mesothelioma (MPM), driven by asbestos exposure and genetic susceptibility, lacks reliable early detection methods and effective therapies. To model MPM pathogenesis, we developed genetically engineered mouse models with combined CRE-mediated Bap1, Cdkn2a, Nf2, and Tp53 deletions alongside asbestos exposure (BCN and CNP models). Using longitudinal ultrasound imaging, we characterised pleural effusion dynamics and tumour onset patterns to establish biomarkers of disease progression.

Methods: Tumours were initiated in adult BCN and CNP mice by intrapleural injection of Lenti-Msln-CRE, followed by 25ug asbestos. Mice underwent serial ultrasound scans, commencing at 30 days post induction until the study endpoint. Effusion volume and tumour localisation were monitored and correlated with survival outcomes. Negative and blank controls were included for baseline comparison. Histopathological analysis validated ultrasound findings, with targeted examination of tumour sites: pericardial fat pad, diaphragm, ribcage, and mediastinal lymph nodes.

Results: 1) Survival. The BCN model demonstrated a longer median survival (121 days) compared to the CNP model (112 days). Sex-based differences were observed in both models: BCN: Males = 121 days, Females = 130.5 days; CNP: Males = 97 days, Females = 116 days.2) Effusion. Pre-tumour effusion was minimal (<200 µL). An effusion surge (>400 µL) predicted endpoint within 30 days (observed in 60% of BCN mice vs. 100% of CNP mice). All CNP and BCN males developed significant effusion; only 1/3 of BCN females did. Controls maintained low effusion, consistent with injected volumes (<200 µL).3) Tumour Onset: Ultrasound imaging revealed the pericardial fat pad as the earliest and most frequent site of tumour development, with detection rates of 40% at 30 days, 80% at 60 days, and 100% by 90 days post-injection. This site consistently showed tumour formation ≥30 days earlier than diaphragm or ribcage involvement. The second most common site was the diaphragm, followed by the ribcage. Histopathological analysis confirmed these findings and further demonstrated frequent oesophageal involvement (>90% of cases), while cardiac involvement was the least observed.

Conclusions: Pleural effusion volume is a critical prognostic marker for late-stage MPM in GDMMs, with rapid escalation preceding death. Ultrasound enabled early detection of pericardial fat pad tumours—the primary site of onset—suggesting utility for preclinical intervention studies. These findings underscore the potential of imaging-driven biomarkers to refine MPM modelling and therapeutic testing.

P3.14.11 Real-World Outcomes and Toxicity of First-Line Dual Immunotherapy in Unresectable Pleural Mesothelioma

B.E. Jimenez Munarriz[1], M. Herrera[1], D. Patel[1], B. Urtecho[1], F. Shepherd[1], N. Leighl[1], A. Sacher[1], L. Eng[1], B.C.J. Cho[1], M. De Perrot[1], S. Schmid[2], M. Garcia-Pardo[3], G. Liu[1], P. Bradbury[1]
[1]Princess Margaret Cancer Centre, Toronto/ON/CA ,[2]Inselspital, Universitätsspital Bern, Bern, Switzerland/CH ,[3]Hospital Universitario Ramon y Cajal, Madrid/ES

Introduction: Nivolumab/Ipilimumab (N/I) is a standard of care first line treatment for patients with inoperable pleural mesothelioma (PM). Checkmate 743 reported 30% of patients (pts) experienced grade ≥3 treatment-related adverse events (AEs). We undertook a real-world analysis to determine the incidence and management of AEs in patients with PM treated with N/I.

Methods: This retrospective single institution study included patients treated with first line N/I at the Princess Margaret Cancer Centre, Toronto, CA between 2020-2023. Primary endpoints were incidence and management of AEs related to N/I. Clinical data were abstracted from electronic medical records following REB approval. Toxicity was assessed retrospectively using Common Terminology Criteria for Adverse Events (CTCAE) v5.0. Immune-related adverse-events (irAE) were categorised based on whether they were simply asymptomatic laboratory abnormalities or associated with symptoms. Steroid usage for managing irAE was reported descriptively. Kaplan-Meier survival analysis was performed, with subgroup comparisons using the log-rank test.

Results: Of 41 pts, the median age at start of treatment was 69 years (65.7-73.3), 28 male (68%); 15 (36%) had previous occupational asbestos exposure, 59% (24/41) never-smokers, 88% (36/41) had an ECOG ≤1 at baseline, 10% (4/41) had a pre-existing autoimmune disease, and 70% had an epithelioid histology.Twenty seven pts experienced ≥1 irAE (66%); 29% grade ≥3 (12/41); 22% (9/41) required hospitalization of which 2 required ICU and 1 dialysis; 26% (7/27) of irAE were laboratory abnormalities only. Systemic steroids were administered in 59% (16/27); 75% (12/16) oral. 37.5% (6/16) required >1 course of steroid; 6 pts required an increase in the steroid dose during initial treatment. Excluding infusion related reactions, the median duration on steroids was 65 days (7-380). Eighteen percent (5/27) required additional immunosuppressive agents. Steroid-related complications occurred in 38% (6/16), mainly hyperglycemia. Treatment-related AE that led to permanent discontinuation to either component of the regimen was observed in 10 pts (24%). The median OS for the entire cohort was 20.1 months (m) (95% CI 11.7-NR). Patients with irAEs had significantly longer survival (27.2 months) compared to those without irAEs (11.7 months, HR=0.29, p=0.005).

Conclusions: In this real-world cohort, real world N/I had a similar toxicity profile compared to the clinical trial population. Steroid use and hospitalization were commonly required However, patients who experienced irAEs had longer survival outcomes compared to those who did not.

P3.14.12 Pseudo-Senescence Induced by Palbociclib Does Not Sensitize Pleural Mesothelioma Cells to Combinations With Classical Senolytics

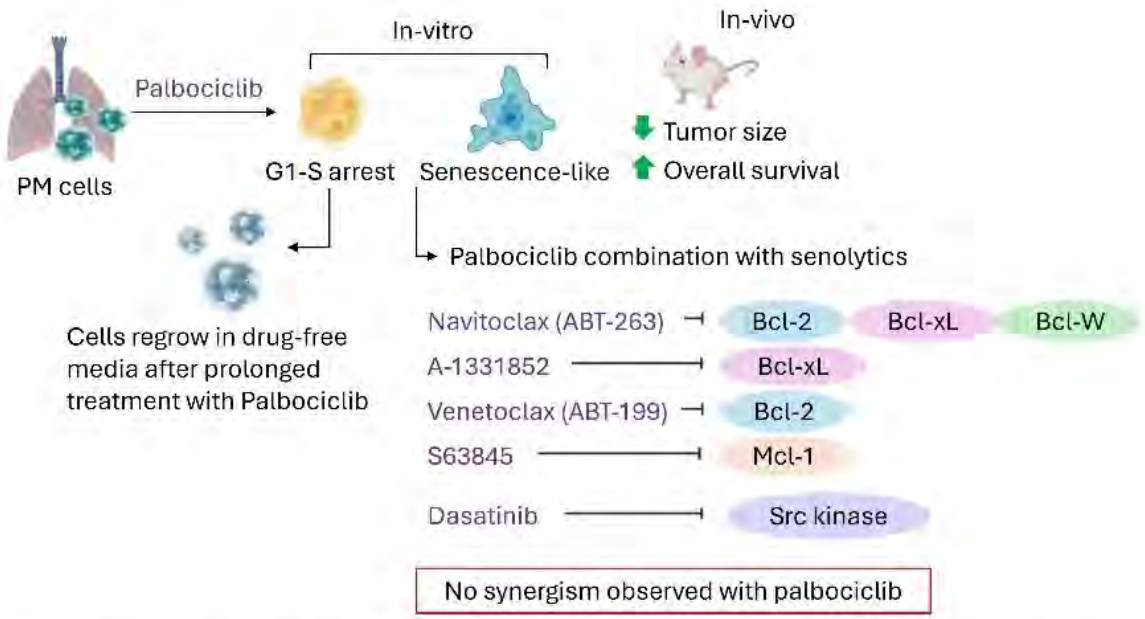
I. Sreeram[1], E. Aliagas[1], S. Plans-Marin[1], C. Muñoz-Pinedo[1], E. Nadal[1,2]
[1]Institut d'Investigació Biomèdica de Bellvitge, L'Hospitalet de Llobregat (Barcelona)/ES ,[2]Catalan Institute of Oncology (ICO), L'Hospitalet de Llobregat (Barcelona)/ES

Introduction: Pleural Mesothelioma (PM) is an aggressive neoplasm of the lung pleura with a dismal prognosis, necessitating the exploration of novel therapeutic options. CDK4/6 inhibitors have shown therapeutic efficiency in various tumour models, especially in treating metastatic breast cancer. In mice models of MPM, abemaciclib and palbociclib reduced tumour growth and prolonged overall survival.

Methods: We have studied the nature of senescence induced by the CDK4/6 inhibitor palbociclib and the chemotherapeutic drug cisplatin in commercial and patient-derived PM cell line models. We observed markers for senescence (Cell size, β-galactosidase activity, ability to re-enter the cell cycle) both during palbociclib treatment and after drug removal. We attempted to eradicate palbociclib pre-treated PM cells with conventional senolytics like Navitoclax and Dasatinib.

Results: Palbociclib-induced cell cycle arrest leads to senescence-like cell size increase and increased β-galactosidase activity but no apoptosis. However, the effects of palbociclib were reversed upon drug removal as cells regrew and lost their senescent-like features. Combining BH3 mimetics like venetoclax (Bcl-2 inhibitor), navitoclax, the specific Bcl-xL inhibitor A-1331852, or the Mcl-1 inhibitor S63845 with palbociclib did not enhance cell death. Other drugs previously described as senolytics, like dasatinib, do not synergize with palbociclib and failed to kill the cells. In contrast, we found that the chemotherapeutic drug cisplatin induces permanent cell cycle arrest and complete senescence in PM.

Conclusions: Our observations challenge the notion that Palbociclib induces classical senescence in PM, as it did not sensitize the cells to combinations with senolytics. If palbociclib induces "pseudo-senescence" in mesothelioma, the clinical use of CDK4/6 inhibitors is challenged by the risk of tumour regrowth. Our findings underscore the complexity of therapy-induced senescence and the importance of understanding its nature when assessing the effectiveness of senolytics in specific tumour models.



Palbociclib-induced cell cycle arrest leads to senescence-like cell size increase and increased β-galactosidase activity but no apoptosis in PM. However, the effects of palbociclib were reversed upon drug removal as cells regrew and lost their senescent-like features. Combining BH3 mimetics like venetoclax (Bcl-2 inhibitor), navitoclax, the specific Bcl-xL inhibitor A-1331852, or the Mcl-1 inhibitor S63845 with palbociclib did not enhance cell death. Other drugs previously described as senolytics, like dasatinib, do not synergize with palbociclib and failed to kill the cells.

P3.14.13 Sex and Histology Related Profile of Gut Microbiota (GM) in Pleural Mesothelioma (PM): Preliminary Results of a Prospective Observational Study

L. CERBONE[1], C. Bazzano[2], S. Delfanti[1], A. Caramaschi[3], P. Barbieri[1], C. Bertolina[4], S. Biasion[4], F. Boccuzzi[1], A. Cimorelli[1], A.M. De Angelis[1], I. Dianzani[5], F. Marengo[1], F. Prodam[6], M. Bertolotti[4], E. Bona[3], F. Grosso[1]
[1]Azienda Ospedaliera Universitaria SS Antonio e Biagio e Cesare Arrigo, Alessandria/IT ,[2]Università del Piemonte Orientale, Vercelli/IT ,[3]Università degli Studi del Piemonte Orientale, Vercelli/IT ,[4]Azienda Ospedaliera S Spirito Casale Monferrato, Casale Monferrato/IT ,[5]Università degli Studi del Piemonte Orientale, Novara/IT ,[6]Università degli Studi del Piemonte Orientale, Alessandria/IT

Introduction: There is scarce evidence regarding the prognostic and predictive role of GM in PM patients. A single prospective experience highlights the positive prognostic value of Prevotella and Eubacterium ventriosum and the negative prognostic value of Erysipelatoclostridium in a small cohort of patients treated with atezolizumab and bevacizumab as salvage therapy. Nevertheless, the differences in GM composition according to demography and pathology are undisclosed yet. In this preliminary report we highlight the differences in GM composition in naïve PM patients according to sex and histology.

Methods: Since February 2022, a prospective translational study (Micromeso) of GM assessed at baseline and at subsequent relevant time points has been performed at AOUAL. All enrolled patients signed an informed consent and were treated according to national guidelines. For each patient enrolled, rectal swabs were collected and sequenced with 16s RNA sequencing. Baseline demographic, body composition, pathology and treatment related data have been collected, as well as treatment related adverse events and survival data. In this preliminary report we focus on differences in the baseline gut microbiota related to sex and histology features.

Results: Fifty pts have been enrolled in the study. Pts were mostly male (41/50), median age was 72 years (IQR 65-76), were treated with pemetrexed and platinum derivatives chemotherapy (34/50), had an epithelioid histology (34/50). Alpha diversity did not significantly differ according to sex and histology when assessed with the Shannon (p 0.33) and Simpson index (p=0.24), respectively. Conversely, beta diversity was significatively different between the epithelioid and non-epithelioid patients and between male and female patients (p 0.019). Non-epithelioid histology was enriched with Anaerococcus sp. (p 0.04) and Dialister propionifaciens (p 0.04). Epithelioid histology was enriched with Phocaeicola vulgatus (p=0.03) and unclassified Lachnospiracee (p=0.02). Finally, Fusicatenibacter sp., unclassified Prevotellaceae were more abundant in epithelioid histology male and non-epithelioid female patients (p 0.02 and 0.04), respectively.

Conclusions: These preliminary results highlight a significant difference in beta diversity as well as species specific GM composition in PM patients, related to histology and sex. Further correlative analyses on the impact of GM composition, its modification during treatment and its association with response and survival are planned.

P3.14.14 Ten-Year Longitudinal Analysis of Mesothelioma Incidence: A Nationwide Cohort Study Based on the 2012 Korean Health Screening Registry

K. Hyun, D.G. Cho
St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Seoul/KR

Introduction: Mesothelioma is a rare but aggressive malignancy primarily associated with asbestos exposure. Its long latency period poses challenges for early detection and population-level surveillance. Despite its clinical importance, large-scale, long-term epidemiological data on mesothelioma incidence remain limited, particularly in East Asian populations.

Methods: We conducted a nationwide, population-based cohort study using data from the Korean National Health Insurance Service (NHIS). A total of 4.51 million adults who underwent health screening between January 1 and December 31, 2012, were enrolled and prospectively followed for up to 10 years (median follow-up: 9.33 years). Incident mesothelioma cases were identified through linked claims data. Cox proportional hazards models were used to estimate hazard ratios (HRs) for potential risk factors.

Results: A total of 246 mesothelioma cases were identified during the 10-year follow-up period, corresponding to an average annual incidence of 5.45 cases per 1,000,000 population. Older age, male sex, urban residence, and lack of regular exercise were significantly associated with increased mesothelioma incidence. The risk was nearly threefold higher in men compared to women (HR 2.78, 95% CI: 2.03-3.80), and urban residents had a higher risk than those in rural areas (HR 1.30, 95% CI: 1.01-1.67). Regular physical activity was associated with reduced risk, particularly among younger adults (HR 0.42, 95% CI: 0.18-0.96 in the 20-49 age group). In contrast, metabolic and biochemical factors—including smoking, alcohol consumption, diabetes, obesity, metabolic syndrome, elevated γ-GTP, chronic kidney disease, and proteinuria—were not significantly associated with mesothelioma incidence.Among the 246 mesothelioma cases, pleural mesothelioma was the most common subtype (76.8%), followed by peritoneal (17.1%), pericardial (2.0%), and other forms (4.1%). A total of 155 patients (63.0%) died during the follow-up period. The mean survival time was 1.34 ± 1.8 years, with a median survival of 0.68 years (interquartile range: 0.26-1.57 years).

Conclusions: In this large-scale nationwide cohort, mesothelioma incidence was primarily associated with demographic and environmental factors rather than metabolic or systemic health conditions. These findings underscore the importance of targeted surveillance strategies in high-risk populations, particularly older men and urban residents.

P3.14.15 Thymic Cancer in France: A Comprehensive Analysis of Incidence Based on French National Healthcare Data

Á. López Gutiérrez[1], A. Loliver[1], J.C. Benitez Montañez[2], J. Remon Masip[1], A. Rousseau[1], D. Planchard[1], F. Barlesi[1], P. Lavaud[1], M. Frelaut[1], A. Gazzah[1], C. Parisi[1], P. Abdayem[1], D. Miliziano[1], L. Zullo[1], V. Favorito[1], M. Gasparro[1], D. Diaz-Jimenez[1], N. Girard[3], V. Thomas de Montpreville[4], O. Mercier[4], P. Missy[5], S. Foulon[1], B. Besse[1]
[1]Institut Gustave Roussy, Villejuif/FR ,[2]University Hospital Virgen de la Victoria, Málaga, Spain, Málaga/ES ,[3]Institut Curie, Paris/FR ,[4]Marie Lannelongue Hospital, Le Plessis Robinson/FR ,[5]Intergroupe Francophone de Cancérologie Thoracique (IFCT), Paris/FR

Introduction: Thymic epithelial tumors (TETs) are rare malignancies with an estimated incidence in the European Union of 0.18 cases per 100,000 person-years. Comprehensive national data are limited. This study aimed to evaluate the epidemiology, clinical characteristics and associated conditions of TETs in France.

Methods: A retrospective cohort was extracted from the French National Health Data System (SNDS), which covers >99% of the French population and integrates data from health insurance reimbursements and hospital records. We identified patients hospitalized with a primary diagnosis of malignant thymic neoplasm (ICD-10 code C37). Demographic and clinical data were collected. Incidence rates were calculated based on the first hospitalization for a malignant thymic neoplasm and were expressed as the mean number of new cases per year divided by the mean total French population during the study period.

Results: Between 2015 and 2019, 2,205 patients (pts) were identified, of whom 42.06% (927) were female. The median age was 64 years. The mean annual incidence of TETs was 0.71 cases per 100,000 persons. Among the patients, 349 pts (15.83%) had autoimmune conditions, including myasthenia gravis (12.97%), aplasia (1%), and systemic lupus erythematosus (1.18%). Autoimmune conditions preceded TET diagnosis in 22 pts (1%), with a mean lead time of -17.66 months (median: -25 months). Autoimmune conditions coincided with or followed the TET diagnosis within two years in 221 pts (10%), with a mean delay of 15.44 months (median: 2.03 months). A total of 326 pts (14.8%) received immunoglobulin therapy. We evaluated the occurrence of second primary malignancies. To reduce misclassification and diagnostic overlap, thoracic tumors (C33, C34, C38, and C39) and unspecified secondary malignancies (C76-C80) were excluded. Overall, 719 pts (32.6%) had other malignancies, with the most common second primary tumors being male genital malignancies (C60-C63, 118 cases), and hematologic malignancies (C81-C96, 110 cases). An estimated 430 hospitalization episodes for another cancer were recorded in the two years preceding thymic cancer diagnosis, with a gradual increase from 8 cases/month at -24 months to 42 estimated cases in the month immediately prior. In the two years following diagnosis, an estimated 850 hospitalization episodes occurred, with 210 cases (24.7%) within the first three months and 75 (8.8%) in the second month alone.

Conclusions: This study indicates a much higher incidence of TETs compared to previous reports. The rate of autoimmune diseases was consistent with existing literature, while the incidence of secondary malignancies was remarkably high despite a relatively short follow-up period. These findings raise critical questions about the underlying causes of increased cancer risk in this population.

P3.14.16 Prospects of Applyingconvolutional Neural Network Models for of Surgical Videos in Clinical Practice

S. Kong
shanghaijiaotong university, shanghai/CN

Introduction: With the widespread adoption of AI and artificial intelligence technologies, high-tech innovations have permeated various fields, including da Vinci Surgical System,robotic bronchoscopy for precise positioning, and 3D reconstruction for visualization. However, applications in medical image processing remain limited. Currently, semantic segmentation models have been used in radiology to identify tumors and inflammatory regions. By leveraging annotations from clinical experts, convolutional neural network (CNN) models can be trained to autonomously recognize tumor locations.Our goal is to apply semantic segmentation to surgical videos, identifying anatomical structures, tumors, and surgical instruments. By training a model to recognize these elements in real-time, we aim to enable automated identification of instruments, organs, and tumor regions during surgeries. This advancement could greatly assist surgeons in anatomical localization and deep tumor detection, enhancing surgical precision and efficiency.

Methods: We collected surgical videos from 90 cases of simple thymic epithelial tumors and 36 cases of complex thymic epithelial tumors. Using the LabelMe software, we manually annotated the videos. These annotations were then used to train a convolutional neural network model. The model achieved an accuracy of 80%-95% in recognizing surgical instruments and 85% in identifying anatomical structures. Further refinement of the model will be conducted using EI VIDEO software for video fitting.

Results: The model demonstrated an 80%-95% accuracy in recognizing surgical instruments and 85% accuracy in identifying anatomical structures. These results validate the feasibility of semantic segmentation in surgical imaging, offering significant benefits in preserving critical anatomical structures during surgery and improving tumor localization.

Conclusions: By employing a convolutional neural network model based on machine learning, we processed and annotated key frames from 126 surgical videos for semantic segmentation of anatomical structures and tumor regions. This approach enables accurate prediction of these critical areas, paving the way for improved surgical outcomes and decision-making.It's much more easy to apply in Lung cancer surgery because the shape of lung is more well-defined than thymus.

Pascale"-IRCCS, Naples/IT

Introduction: Limited thymectomy, resecting the tumour alone or en-bloc with a part of thymic gland, has been proposed as a tissue-sparing alternative to complete thymectomy in early-stage thymic epithelial tumours (TETs). However, previous analyses are heterogeneous in both used survival measures and in the extent of thymus removed during limited thymectomy hindering generalizability and comparability of findings across studies.

To clarify the role of limited versus complete thymectomy in stage I TETs we performed a systematic-review and an individual patient data (IPD) meta-analysis using standardised survival measures and predefined oncological outcomes.

Methods: An IPD meta-analysis of studies investigating complete versus limited thymectomy for stage I TETs was conducted. IPD was extracted from published Kaplan Meier curves using the IPDfromKM method. When possible, we extracted IPD from propensity-score matched curves. Survival measures were defined as: freedom from recurrence (FFR) from surgery to recurrence in studies without R+ patients; time to progression (TTP) from surgery to recurrence in studies with R+ patients. Primary endpoint of the study was FFR in complete versus limited thymectomy. Secondary endpoints were: TTP; overall survival; recurrence rate in the overall population and stratified per Masaoka-Koga stage; survival measures according to resection extension (thymomectomy-alone vs hemi-thymectomy vs subtotal thymectomy). Hazard-ratios (HR) and relative 95% confidence intervals (95%CI) were estimated with Cox regression analyses. Odds-ratio (OR) with 95%CI were used to derive categorical variables.

Results: Of the 7 eligible retrospective studies, four were based on nationwide databases. Three studies used propensity-score matching. Overall, IPD from 2314 patients (1434 complete thymectomy and 880 limited thymectomy) were retrieved. For FFR, IPD were extracted from three studies including 307 patients receiving complete thymectomy (n=178) and limited thymectomy (n=129). Median follow up was 51.2 months 95%CI 37.5-64.8 in complete thymectomy and 63.4 months 95%CI 53.2-73.6 in limited thymectomy. The 10-year FFR for complete versus limited thymectomy were 90.2% vs 92.1%, respectively (Fig1A). No differences were found in TTP, overall survival and recurrence rate in the two groups. In those patients presenting a Masaoka-Koga stage II disease, OR for recurrence favoured complete over limited thymectomy (p=0.02). Finally, according to limited thymectomy extension, FFR favoured subtotal thymectomy compared to thymomectomy-alone (fig1C).

Conclusions: In conclusion, no evidence favoured limited over complete thymectomy in early-stage TETs treatment according to standardise survival measures. However, in Masaoka Koga stage II disease, complete thymectomy showed lower recurrence rate. Finally, among patients receiving limited thymectomy, thymomectomy-alone may lead to worse prognosis.

IRCCS ISTITUTO NAZIONALE TUMORI FOUNDATION, Milan/IT

Introduction: Despite the availability of multimodal treatment strategies, there is currently no universally accepted guidelines for management of advanced Thymic Epithelial Tumors (TETs). To address this issue, we conducted a systematic review and meta-analysis to evaluate surgico-pathological and oncological outcomes in patients with Masaoka-Koga stage III-IVA TETs who underwent induction therapy (IT) followed by surgical resection.

Methods: According to the MOOSE guidelines, 24 studies on TETs undergoing IT were included in the meta-analysis. We performed a random-effects meta-analysis and assessed heterogeneity and publication bias. Meta-regression was used to examine moderators of the effect, including year of publication, histology and stage.

Results: Included studies were published from 2003 to 2023, 6 were prospective and 18 retrospective, with a total of 749 patients. Nine studies included thymomas only, while 15 included both thymoma and thymic carcinoma. Four, 11 and 3 studies included, respectively, only stage III tumors, stage III and stage IV TETs and stage IV only; 2 papers analyzed stage I and stage II tumors as well. The response was evaluated by RECIST and WHO criteria in 11 and 4 studies, respectively. The pooled rate of radiological response to IT, completeness of resection, 5-year OS, 10-year OS and 5-year PFS were, respectively, 62.8%, 71.6%, 77.6%, 54.3% and 55.6% (Fig. 1). Meta-regression analyses revealed no significant effects, except for histology on 10-year OS from surgery (p-value 0.0418) as well as on PFS (p-value 0.0042) and treatment period on PFS (p-value 0.0007) (Fig. 2).

Conclusions: Our meta-analysis demonstrates that IT followed by surgical resection is associated with acceptable long-term outcomes in patients with advanced TETs. However, while histology remained a significant prognosticator for the outcome, 10-yr OS has not changed yet in the last 20-year, underling the need for novel therapeutic approaches to enhance long-term survival, according to different histologies as well.

Introduction: Tumor size is recently proposed as prognosticator in thymic tumors and introduced as descriptor in the 9th TNM edition. The aim of this study is to investigate the prognostic role of different tumor size cut-offs in the different thymic tumor histology

Methods: Clinical and pathological data of patients from ESTS thymic database underwent surgery for TETs from 1/2000to12/2022 were reviewed and analysed.Patients clinical data, tumour characteristics, size at 5cm and 3 cm cut-off, WHO histology and organs infiltration were collected and correlated to overall survival(OS), Disease free Survival (DFS) And Cancer Specific Survival(CSS) using Kaplan-Meier curves. The log-rank test was used to assess differences between subgroups.

Results: The final analysis was conducted on 2556patients. Histology resulted thymoma in 2231 (87.3%), thymic carcinoma in 271 (10.6%) and neuroendocrine tumors (NET) in 54(2.1%) cases. In 1518(59.4%) size resulted >5cm.During a FUP, a recurrence occurred in 390(15.2%) patients, 255(9.9%)died,95 due to tumor progression.A significant difference was present considering the 5 cm size cut-off: 5-10YDFS of 82.4% and 76% vs 73.8% and 60.0%(p<0.001) in TETs ≤5cm vs >5cm, 5-10YOS of 91.2% and 82.8% vs 86.1% and 73%(p<0.001) in TETs ≤5cm vs >5cm, 5-10Y CSS 96.9% and 92.3% vs 94.1 and 88.8%(p=0.012) in TETs ≤5cm vs >5cm..The survival difference was significant also considering thymoma and thymic carcinoma/NET, with a 5-10Y DFS of 85.4% and 78.1% vs 77.6% and 62.4% in ≤5cm vs >5cm thymomas (p<0.001) and a 5-10YOS of 92.4%and79.4% vs 88% and 74.5% in ≤5cm vs >5cm thymomas (p=0.002). In thymic carcinoma/NET, 5-10Y DFS resulted of 61.3% vs 53.3% and 46.9% in ≤5cm vs >5cm carcinomas/NET (p=0.042), while 5-10YOS resulted 84.9%and 79.4% vs 74.9% and 64.9% in ≤5cm vs >5cm (p=0.002)(table). The survival difference resulted statistically significant for CSS also thymic carcinoma/NET(p=0.014) but not in thymomas(p=0.225). No significant differences were present considering a 3cm cut-off.Patients with B3 histology presented a significant worse survival outcome compared to other histology in all size subgroups but not in case of tumors ≤3cm. Considering size ≤5cm or >5cm, B3 tumors presented a significant worse CSS (p= 0.042 and p=0.003) and DFS (p=0.027 and p<0.001) compared to A-B2. Same results were presents in CSS and DFS terms considering tumors >3cm while the difference in OS was not statistically significant(figure table).

Conclusions: Tumor size resulted a significant prognosticator in TET, in thymoma and thymic carcinoma/NET, confirming its validity in prognosis prediction in these tumors independently by the histotype.

Survival outcome according to tumor size and histology.
DFS: disease free survival; OS: overall survival, CSS cancer specific survival. TET: Thymic Epithelial Tumor

P3.14.20 MTAP Deficiency in Thymic Epithelial Tumors

J.A. Marks, K. Curreri, K. Miller, J. Sands, N. Florez, D. Barbie
Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: Thymic epithelial tumors (TETs), including thymoma and thymic carcinoma, represent rare malignancies with challenging outcomes and limited therapeutic options, especially in the advanced setting. Standard treatment typically involves platinum-based chemotherapy; however, the proportion of responders is minimal, with an urgent need for alternative treatments. MTAP (methylthioadenosine phosphorylase) deficiency, often co-occurring with deletions in CDKN2A and CDKN2B, has emerged as a promising target in other malignancies due to sensitivity to PRMT5 inhibitors. We aimed to characterize the prevalence of MTAP deficiency and related genomic alterations in patients with TETs.

Methods: We conducted a retrospective genomic analysis of 85 thymic tumor samples from the Dana-Farber Cancer Institute (DFCI) cBioPortal database that underwent molecular testing with next-generation sequencing (NGS). Tumors were categorized by histology into thymic carcinoma, thymoma, thymic neuroendocrine tumors, and thymic epithelial tumors not otherwise specified (TET, NOS). Copy number alterations (CNAs) in MTAP, CDKN2A, and CDKN2B were analyzed. An additional validation cohort was obtained using genomic data from DFCI's OncDRS, a comprehensive data retrieval tool that provides clinical, genomic, and specimen oncology data for research. Data analysis included the identification of homozygous (dual copy) deletions and co-deletion patterns.

Results: A total of 85 TET samples were identified in DFCI cBioPortal (cohort 1), with 47.1% (n = 40) classified as thymic carcinoma, 42.4% (n = 36) as thymoma, 5.9% (n = 5) as TET, NOS, and 4.7% (n = 4) as thymic neuroendocrine tumors. The cohort was evenly distributed by sex (41 males, 42 females, and 2 others). CNA analysis revealed deletions in CDKN2A and CDKN2B in 11.8% of cases (n = 10/85 each), and MTAP deletions in 9.1% (n = 4/44) of cases. A similar analysis of 548 TETs from DFCI OncDRS (cohort 2) identified 350 thymic carcinomas, 163 thymomas, 24 TET-NOS, and 11 thymic neuroendocrine tumors. Somatic mutation data were available for only 11/548 tumors, among which 10 (91%) harbored CDKN2A and 1 (9%) had a CDKN2B mutation, corresponding to 1.8% (10/548) of the overall TET cohort. Copy number variation (CNV) data were available for 48 TETs, representing 1.25% (48/3833) of all TET tumors profiled, demonstrating the low proportion of these patients that get next-generation sequencing. Of these, 9 tumors (18.75%) harbored MTAP CNVs, including 8 thymic carcinomas and 1 thymoma. CNVs in CDKN2A and CDKN2B were found in 41.7% (n = 20/48) and 39.6% (n = 19/48), respectively, with homozygous loss observed in 11 cases for each gene. These alterations were primarily observed in thymic carcinoma.

Conclusions: MTAP deficiency is prevalent in thymic epithelial tumors, particularly thymic carcinoma, and frequently co-occurs with CDKN2A/B deletions. However, the majority of the patients in our cohort did not have full NGS testing, emphasizing the importance of genomic testing in this population that harbors poor prognosis with new potential targeted therapeutic options.

P3.14.21 Single-Nucleus RNA Sequencing Reveals Key Pathways and Prognostic Markers in Thymic Carcinoma

X. Gao[1], X. Zhou[1], Z. Qian[1], C. Guo[1], S. Li[1], Y. Chen[1]
[1]Peking Union Medical College Hospital, Beijing/CN

Introduction: Thymic carcinoma (TC), a rare and aggressive malignancy of the anterior mediastinum, is associated with limited therapeutic options and poor prognosis. The identification of novel biomarkers and therapeutic targets remains critical.

Methods: Comprehensive analysis of single-nucleus RNA sequencing (snRNA-seq) and bulk RNA-seq was performed to characterize transcriptional dynamics in the tumor immune microenvironment of TC and establish a prognostic model.

Results: A total of 1,244 differentially expressed genes (DEGs) were identified across TC, thymoma, and normal thymic tissue. Weighted gene co-expression network analysis (WGCNA) revealed two key gene modules, enriched in immune and membrane-related processes. Functional enrichment analysis highlighted pathways linked to cell adhesion molecules (CAMs) and immune response. A LASSO machine learning model prioritized five hub genes (JAM-A, VCAN, NECTIN1, CD8B, and NEGR1), with JAM-A demonstrating the highest diagnostic accuracy (AUC = 1.0 in PUMCH_TC and 0.94 in GEO cohort). Combining the snRNA-seq data of 2 normal and 3 TC samples, a total of 45,673 cells were divided into eight clusters, including epithelial cells (KRT5, KRT19), fibroblasts (CFD, ACACB, COL1A1), macrophages (CD163), B cells (CD79A, MS4A1, IGHM), plasma cells (MZB1, IGKC), T_NK cells (CD3D, IL7R, TRAC), endothelial cells (PECAM1), and smooth muscle cells (ACTA2, MYL9). SnRNA-seq analysis highlighted cellular heterogeneity in TC, revealing ectopic JAM-A expression in epithelial subtypes. The elevated expression of JAM-A in TC was validated by qPCR and Western. Immunohistochemistry-based survival analysis confirmed that high JAM-A expression was associated with poor overall survival (OS, $P < 0.001$, 95%CI 1.68 - 100.53) and progression-free survival (PFS, $P < 0.001$, 95%CI 1.96 - 109.86) in TC patients.

Conclusions: This study identifies JAM-A as a novel prognostic biomarker in TC, implicating its role in tumorigenesis through CAMs-related pathways. Elevated JAM-A expression independently predicts adverse clinical outcomes, underscoring its potential as a therapeutic target.

P3.14.22 Outcomes to Systemic Standard-Of-Care Therapies in Patients With MTAP-Deleted Advanced Non-Small Cell Lung Cancer

J. Huang[1], M. Aldea[2], K. Miller[3], J. Rotow[3], M. Nishino[3], L. Sholl[1], P. Janne[3], D. Barbie[3], A. Shaw[3], K. Kehl[4], J. Luo[3]
[1]Brigham & Women's Hospital, Boston/MA/USA ,[2]Gustave Roussy, Paris Saclay University, Villejuif/FR ,[3]Dana-Farber Cancer Institute, Boston/MA/USA ,[4]Dana-Farber Cancer Institute and Harvard Medical School, Boston/MA/USA

Introduction: Methylthioadenosine phosphorylase two-copy deleted (MTAPdel) cancer cells are vulnerable to protein arginine methyltransferase 5 (PRMT5) or methionine adenosyltransferase 2 (MAT2A) inhibition, making them promising therapeutic targets. There are limited outcomes data, however, for MTAPdel metastatic advanced non-small cell lung cancer (mNSCLC) within current treatment paradigms.

Methods: Patients with mNSCLC who had large panel, tissue-based, DNA NGS at a single center from 7/2013-3/2024 and known MTAP status (MTAP two-copy deletion [MTAPdel] vs MTAP-intact [MTAPwt]) were included. All patients received platinum doublet + anti-PD-(L)1, anti-PD-(L)1 monotherapy, and/or docetaxel-based chemotherapy and were followed through 11/2024. Patients included in the MTAPwt cohort were randomly selected without matching. Measured outcomes included PFS and OS. Response rate (ORRp) was determined using a validated natural language processing model trained on imaging radiology reports annotated with the Pathology, Radiology/Imaging, Signs/Symptoms, Medical oncologist assessment, and bioMarkers (PRISSMM) framework. Kaplan Meier curves were used to estimate survival and corresponding logrank tests were used to compare endpoints.

Results: Overall, 105 MTAPdel and 120 MTAPwt patients were included; 64.0% were women, 83.1% had adenocarcinomas, and 68.4% had stage IV disease at diagnosis. MTAPdel patients had less of a smoking history (median 15.0 vs. 30.0 pack-years, p=0.039) and lower PD-L1 TPS (median 3.5% vs. 10.0%, p=0.040), but were more likely to have stage IV disease at diagnosis (78.1% vs. 60.0%, p=0.004). CDKN2Adel (88.6% vs 7.5%), CDKN2Bdel (87.6% vs. 5.6%), and 9p21.3del (77.1% vs 6.7%) were enriched in MTAPdel vs MTAPwt patients (p<0.001). On univariate analysis, among targetable co-mutations, MTAPdel patients were more likely to have EGFR mutations (24.8% vs. 13.3%, p=0.039), and among the top 30 frequently co-mutated genes not limited to targetable mutations, MTAPdel was associated with EGFR and FANCM mutations (44.8% vs. 25.8%, p=0.003; 9.5% vs. 2.5%, p=0.041). ORRp, PFS, and OS after platinum doublet + anti-PD-(L)1 or anti-PD-(L)1 monotherapy did not differ between the two cohorts. MTAPdel patients had lower ORRp after docetaxel-based chemotherapy (0.0% vs. 35.5%, p=0.019), and numerically worse PFS/OS (mPFS 4.8 vs. 7.7 months, HR 0.6, 95% CI 0.3-1.2, p=0.156; 6-month PFS 41.7% vs. 61.3%, p=0.314; mOS 11.5 vs. 17.0 months, HR 0.7, 95% CI 0.3-1.4, p=0.336; 6-month OS 75.0% vs. 83.9%, p=0.665) (Figure).

Conclusions: Compared to patients with MTAPwt mNSCLC, those with MTAPdel mNSCLC have no significant difference in PFS or OS after standard therapy, but may have worse response rates to docetaxel. Effective agents targeting MTAPdel mNSCLC are needed, particularly in those with previously-treated disease.

P3.14.23 The Mechanism of Immunotherapeutic Resistance in Pulmonary Sarcomatoid Carcinoma

H. Guo[1], T. He[1], F. Zhou[2], C. Zhou[2]
[1]Shanghai Pulmonary Hospital, Shanghai/CN ,[2]Shanghai East Hospital, Shanghai/CN

Introduction: Pulmonary sarcomatoid carcinoma (PSC) represents a rare subset (0.4%) of highly aggressive and poorly differentiated NSCLC, characterized by sarcoma-like or sarcoma (spindle- or giant-cell) elements. Currently, there is no research specifically investigating the mechanisms of immunotherapy resistance in PSC. To address this gap, we conducted scRNA-seq on baseline treatment samples and immunotherapy-resistant specimens of PSC. We also performed relevant experimental validations and implemented targeted interventions in animal models. This comprehensive approach aims to develop novel therapeutic strategies for enhancing sensitivity to immunotherapy or reversing resistance in PSC.

Methods: The scRNA-seq protocol used here was following the manual instructions of Singleron Biotechnologies. PDX models were established by subcutaneously implanting small tissue fragments from PSC patients into HuHSC-NOG-EXL mice (Charles River Laboratories). Experimental mice were divided into four groups, with the exposure of following drugs: IPG1576 (MIF inhibitor; 10 mg/kg, i.p., q2d), BX471 (CCR1 antagonist; 50 mg/kg, s.c., q2d), Camrelizumab, Ociperlimab and Maraviroc [CCR5 antagonist] (all 10 mg/kg, i.p., q3d).

Results: We analyzed 4 baseline and 3 immunotherapy-resistant PSC specimens using scRNA-seq (Fig.1A). Resistant samples exhibited increased stromal cells (Fig.1B), SLC8A1+/CXCL10+/CXCL5+ macrophages (Fig.1C), and GZMK+ CD8 Teff, LDHB+ T naïve (Fig.1E) with enhanced macrophage immunosuppressive/angiogenic functions (Fig.1D) and T cell terminal exhaustion (Fig.1F). Cell communication analysis revealed CCL3/CCL5-mediated crosstalk driving macrophage polarization and T cell exhaustion (Figs.1G-H, J), alongside upregulated MIF and TIGIT-Nectin2 signaling (Fig.1I). Flow cytometry of PSC patient PBMCs confirmed elevated precursor-exhausted CD8+ T cells in responders (n=5) versus terminal-exhausted subsets in non-responders (n=9) and progressive disease (n=5) (Fig.1L). In humanized PDX models (Fig.1M), the CCR1/CCR5 inhibitor combination (G4) outperformed MIF inhibitor/ anti-TIGIT (G3) (Figs.1O-P), reversing resistance by increasing precursor-exhausted and reducing terminal-exhausted CD8+ T cells (Fig.1Q). These findings identify CCR1/CCR5 blockade as a novel strategy to reverse immunotherapeutic resistance in PSC

Conclusions: The additional combination of CCR1/CCR5 blockade with anti-PD-1 demonstrated a synergistic efficacy to immunotherapy-resistant tumors via reshaping the microenvironment, potentially offering a novel approach to combat immunotherapy resistance in PSC.

P3.14.24 Tracheal Resection Surgery: Comparison of Continuous Vs. Interrupted Suture of the Membranous Wall in a Series of 162 Cases

P.L. Paglialunga, A. Vidal, N. Iglecia
Hospital San Juan de Dios de La Plata, La Plata/AR

Introduction: Tracheal tumors are a rare entity, and their surgical treatment generally requires segmental resection with reconstruction through tracheoplasty. This technique is also used in the management of benign tracheal stenosis, where tracheal anastomosis is traditionally performed using interrupted sutures. At our center, we have implemented continuous suturing of the posterior wall of the anastomosis and seek to compare its outcomes with the conventional interrupted suture technique in terms of safety and postoperative complications.

Methods: A retrospective study was conducted using prospectively collected data from a referral thoracic surgery center. A total of 162 patients who underwent tracheoplasty for benign tracheal stenosis associated with mechanical ventilation (MV) between 2010 and 2023 were included. Patients were divided into two groups based on the suturing technique: Group A (interrupted sutures, n=85) and Group B (continuous sutures, n=77). Demographic variables such as age at surgery, sex, comorbidities, associated injuries, underlying condition leading to MV, duration of MV, time to symptom onset after extubation, lesion extent, and prior treatments were analyzed. Postoperative outcomes, including short- and long-term complications, were compared. Follow-up was at least 12 months. Statistical analysis was performed using R software version 4.3.1, applying Chi-square, Fisher's exact, and Mann-Whitney tests, with a significance level of $p<0.05$.

Results: No significant differences were found between groups in terms of age, sex, or associated risk factors. However, two differences were noted: Group B had a higher rate of previous endoscopic dilations (84.4% vs. 63.5%; p=0.004), whereas Group A had a higher rate of stent placement (14.1% vs. 2.6%; p=0.011). Additionally, protective muscle flap reinforcement of the anastomosis was more frequently used in Group B (50.6% vs. 14.1%; $p<0.001$). Immediate postoperative complications showed no significant differences between groups (29.4% in A vs. 32.5% in B; p=0.735). However, complications at one month were more frequent in Group A (11.8% vs. 1.3%; p=0.010), as was dysphonia at one month (8.2% in A vs. 0% in B; p=0.014). No significant differences were observed in the restenosis rate at 3 months or 1 year.

Conclusions: Continuous suturing of the membranous portion of the tracheal anastomosis is a safe technique, with an incidence of immediate complications comparable to that of interrupted suturing. However, it is associated with a lower rate of complications at one month and a reduced incidence of early dysphonia. Although this study focused on cases of benign pathology, these findings may be extrapolated to tracheal resection and reconstruction for tracheal tumors. Prospective studies are needed to evaluate its impact on the oncologic treatment of this rare condition.

P3.16.01 Lung Cancer Patients' Understanding of and Involvement in Their Treatment and Care: Insights From a Global Patient Experience Survey

J. Fox[1], K. Clayton[2], M. Daniels[3], B. Gaspar[4], M. Hennink[5], J. Mayans[4], K. O'Hagan[6], L. Pretorius[3], M. Rigney[7], K. Tong[8], M. Dohr[9]
[1]Roy Castle Lung Cancer Foundation, Liverpool/GB ,[2]Lung Cancer Nursing UK, London/GB ,[3]Campaigning for Cancer, Randburg/ZA ,[4]Asociación Española de Afectados de Cáncer de Pulmón, Valencia/ES ,[5]Longkanker Nederland, Utrecht/NL ,[6]Irish Cancer Society, Dublin/GB ,[7]GO[2] Foundation for Lung Cancer, Washington D.C./DC/USA ,[8]Cancer Information Network, Hong Kong/HK ,[9]Incisive Health, London/GB

Introduction: The Global Lung Cancer Coalition (GLCC), a partnership of 43 patient organisations across 31 nations, reaffirms in its charter the right of all lung cancer patients to be treated with dignity and respect and to have access to quality health care, including informed self-determination and physical and mental integrity.

Essential to these rights is how patients engage with their treatment and support teams. To better understand patient experiences, GLCC sought to explore patients' involvement in decision-making, whether they receive and understand information about their condition, and their preferences on how this information is delivered.

Methods: For its sixth annual survey, GLCC commissioned Censuswide to conduct a global survey of lung cancer patients. The survey is currently in the field across 18 countries (Australia, Argentina, Brazil, Canada, Greece, Hong Kong, Hungary, Ireland, Israel, Italy, Japan, Mexico, Portugal, South Africa, Spain, Taiwan, UK, USA). As part of this survey, GLCC included questions to understand respondents' involvement in decision-making, what information they received and if they understand it, and their preferred format for receiving information.

Results: Results will be available for presentation. The survey assesses the levels of involvement patients have in decision-making and patients' satisfaction with the quality, timing, comprehensibility, and relevance of the information provided by their treatment and support teams. The results will also include findings on patients' preferred formats for receiving information.

Conclusions: It is anticipated that these findings can help healthcare providers better understand and meet the needs of lung cancer patients, ensuring they appropriately involve patients in decisions about their care, and tailor their current approaches to providing patients with information about their condition.

Questions	Answer options										
When talking to your treatment and support team, did you feel involved in the decisions about your treatment and care? Please choose the option that best describes you.	Yes, I've been fully involved	Yes, I've been involved mostly, but wanted to be more involved	Yes, I've been involved mostly, and didn't want to be more involved	Yes, I've been involved sometimes, but wanted to be more involved	Yes, I've been involved sometimes and didn't want to be more involved	Yes, other please specify	No, but I would like to be involved	No, but I didn't want to be involved	No, but my caregiver was involved	No, other please specify	
The GLCC believes that lung cancer patients should receive high quality information, which tells you what you want to know, at the right time for you. What best describes how you feel about the information you received from your treatment and support team about your lung cancer? Please choose the option that best describes you. Matrix: Answers are provided across a row of the following options: •At diagnosis •When starting treatment •When changing treatment •When ending treatment / follow-up •When accessing palliative care	I got the information I needed at the right time	The information wasn't helpful	The information came too late	The information wasn't helpful and it was also given too late	I had to look for other information on my own	I didn't understand the information provided	I didn't get any information	I didn't want to know any information	Other way	No way in particular	Not applicable
To accompany the discussions with your treatment and support team, what is your preferred format for receiving information about your condition: Select one	Audio materials	Apps	Cancer support hotline	Infographic	Print material	Videos	Website	Education programme (for example chemo education)	Other (please use the text box below)	No preference/ no preferred way

P3.16.02 Cancer Patients' Advocacy and Policy Impact in Japan, How 3,623 Voices Halted a National Cost-Sharing Reform

K. Hasegawa[1,2]
[1]NPO Lung Cancer Patient Association ONE STEP, YOKOHAMA/JP ,[2]Japan Federation of Cancer Patient Associations, Yokohama/JP

Introduction: Japan's High-Cost Medical Expense Benefit system is a national policy designed to limit monthly out-of-pocket payments for medical care, thereby ensuring that all citizens—including those with serious illnesses—can access necessary treatment without incurring catastrophic health expenditures. As part of Japan's universal health coverage framework, this system has long served as a critical safety net, especially for patients requiring ongoing and high-cost treatments, such as cancer care.

In 2025, a government proposal to raise this cap sparked concern among patients and healthcare professionals. Fears centered on treatment discontinuation and increased financial hardship.

This abstract describes a unique patient advocacy movement that arose in response: a coalition of cancer patient organizations, including our group One Step, rapidly gathered 3,623 voices through a national survey. The initiative drew public and political attention, ultimately leading the government to suspend the proposed reform. This report aims to present how a collective patient response can influence national health policy, with relevance to global discussions on equitable access and financial protection in cancer care.

Methods: We reviewed open-ended responses from the January 2025 survey and documented the advocacy process. This included coordinated communication, media engagement, and petition delivery to the Prime Minister. One Step supported outreach to include lung cancer patient perspectives.

Results: Many feared the policy would force them to stop treatment or compromise daily life. Younger patients noted current costs were already burdensome. The petition's public handover to the Prime Minister amplified patient voices and contributed to halting the reform.

Conclusions: This case highlights rare direct policy impact by patient voices in Japan. The campaign encouraged civic participation and cross-cancer solidarity. Statements from academic societies, including the Japan Lung Cancer Society, further influenced the decision. This may offer a model for advocacy in other nations facing similar healthcare challenges.

P3.16.04 Lung Cancer Treatment in Brazil: The Gap Between Incorporation and Real-World Access

P. Sachs Kindl[1], P. Franzoni da Silva[2], H. Esteves[1], A.C. Arena Siqueira[1], F. Moura[2], L. Holtz de Camargo Barros[1]
[1]Instituto Oncoguia, São Paulo/BR ,[2]Hospital Israelita Albert Einstein, São Paulo/BR

Introduction: Lung cancer is the most commonly diagnosed cancer worldwide (excluding nonmelanoma skin cancer) and remains the leading cause of cancer-related deaths globally. In Brazil, it is the fourth most common cancer, with an estimated 32,560 new cases annually. Brazil has a universal healthcare system (SUS), which serves approximately 160 million people, or 75% of the population. Ensuring equitable access to lung cancer treatment within such a complex system is a significant challenge. The incorporation of new technologies in SUS is determined by the National Commission for Technology Incorporation in the Public Health System (Conitec), which conducts Health Technology Assessments (HTA) to decide on their adoption. Theoretically, once incorporated by Conitec, the technologies should be available to all patients cared for by SUS.However, Patient Advocacy Organizations frequently support patients who face barriers to accessing approved treatments. To strengthen advocacy efforts and generate evidence regarding the real-world availability of incorporated treatments, a Brazilian Cancer Advocacy Group conducted a study to assess the accessibility of lung cancer drugs incorporated by Conitec.

Methods: The study focused on all medications incorporated by Conitec for lung cancer until September 2023, namely: Erlotinib and Gefitinib, for treatment of patients with advanced or metastatic non-small cell lung cancer with EGFR mutation (incorporated in 2013), and Crizotinib for advanced ALK-positive non-small cell lung cancer (incorporated in 2022).To investigate the availability of these treatments, the Brazilian Freedom of Information Law was used, which allows citizens to request data from public institutions. Between September 2023 and January 2024, requests were submitted to 268 accredited public cancer centers, asking for their treatment protocols for five types of cancer (breast, prostate, colorectal, lung, and melanoma). This publication focuses on the responses related to lung cancer.

Results: A total of 43 cancer centers submitted their lung cancer treatment protocols specifying the medications available. Each protocol was analyzed to determine the inclusion of the most recently incorporated Conitec-approved lung cancer treatments. Of the protocols received, 12 (27.9%) included Erlotinib in their treatment protocols, 18 (41.9%) included Gefitinib and only 2 (4.7%) included Crizotinib. Notably, only 2 hospitals (4.65%) had full adherence to Conitec incorporations, offering targeted treatments for both ALK and EGFR mutations. Most glaringly, 22 (51,2%) of respondent hospitals offer none of the incorporated drugs.

Conclusions: This study highlights significant disparities in the availability of lung cancer treatments within Brazil's public healthcare system. Despite their official incorporation, access to these medications remains inconsistent across hospitals. Furthermore, the inclusion of a drug in a hospital's protocol does not guarantee its consistent availability or usage, as factors such as stock shortages and implementation barriers may impact actual patient access.The findings underscore the need for improved mechanisms to ensure that the incorporation of new treatments translates into real-world access for patients. Strengthening monitoring and enforcement strategies is essential to bridging the gap between policy decisions and patient care.

P3.16.05 Exploring Quality of Life in Oncogene Addicted NSCLC Patients and Their Caregivers

M. Cani[1], P. Cotogni[2], M. Gasparro[1], A. Cipi[1], C. Lanzetta[1], P. Fanuli[1], S. Butticè[1], E. Garbo[1], E. Capelletto[1], S. Carnio[1], V. Bertaglia[1], S. Poletto[1], G. Farinea[1], L. Consito[1], P. Bironzo[1], F. Passiglia[1], A. Mogavero[1], M.L. Reale[3], C. Sini[4], M.R. Migliorino[5], S. Pilotto[6], D. Galetta[7], D. Bafunno[7], C. Destro[8], S. Vallone[8], F. Arizio[8], G. Macchi[2], M.V. Pacchiana[1], S. Novello[1]
[1]Department of Oncology, University of Turin, San Luigi Hospital, Orbassano/IT ,[2]Pain Management and Palliative Care, Department of Anesthesia, Intensive Care and Emergency, Molinette Hospital, University of Turin, Turin/IT ,[3]Medical Oncology Unit, Vito Fazzi Hospital, Lecce/IT ,[4]Medical Oncology Unit, Giovanni Paolo II Hospital, Olbia/IT ,[5]Department of Oncology, San Camillo-Forlanini Hospital, Rome/IT ,[6]Section of Medical Oncology, Department of Medicine, University of Verona, Verona/IT ,[7]Medical Thoracic Oncology Unit, IRCCS Istituto Tumori Giovanni Paolo II, Bari/IT ,[8]Women Against Lung Cancer in Europe, Turin/IT

Introduction: The introduction of targeted therapies has radically changed the therapeutic landscape of oncogene-addicted non-small cell lung cancer (NSCLC). Despite this progress, data on quality of life (QoL) remain heterogeneous, and those concerning self-efficacy for caregiving are particularly limited. Here we present the results of a QoL-focused survey conducted in collaboration with the patient advocacy group Women Against Lung Cancer in Europe (WALCE), during two events entirely dedicated to patients and their caregivers (BeMutual Days, Rome, November 2023 and November 2024).

Methods: Patients with oncogene-addicted advanced NSCLC receiving targeted therapies were included. Self-efficacy for caregiving was assessed through the Caregiver Inventory (CGI). Patients completed the Functional Assessment of Cancer Therapy-Lung (FACT-L) and the Brief Pain Inventory (BPI) to evaluate QoL and pain impact, respectively. Data were collected anonymously and analysed in aggregate form.

Results: A total of 87 patients and 72 caregivers from 12 Italian oncology centres participated. FACT-L results showed higher scores in the physical well-being domain compared to emotional and functional well-being ($p<0.001$). Notably, satisfaction with sexual activity was significantly lower than other aspects within the social/family well-being domain ($p<0.001$). Pain, as assessed by the BPI, was generally mild and well-controlled. Interestingly, 17.2% (n=15) patients reported using their TKI as the main treatment for pain control, likely reflecting the effective symptom management achieved over time. When present, pain was most disruptive in terms of work ability, sleep, and enjoyment of life. Caregivers (CGI) reported greater confidence and competence in maintaining a close relationship with the patient over time. Conversely, they expressed lower self-efficacy when addressing the patient's potential death, the inability to control events (e.g., disease progression), or when managing negative emotions related to illness ($p<0.001$). Additionally, caregivers tended to neglect self-care while prioritizing coping strategies for both themselves and the patient ($p<0.001$).

Conclusions: These findings highlight the presence of unmet needs among both patients (emotional/functional well-being and sexuality) and caregivers, particularly in the area of self-care. Joint initiatives with patient organizations (e.g., WALCE) may help address these gaps and enhance the overall oncological care.

P3.16.06 The Saving Lungs Behind the Chair Model Is Increasing Lung Cancer Awareness in US Black Communities

K. Norris[1], K. Bodell[2], S. Barned[3]
[1]Lung Cancer Foundation of America, KAMAS/UT/USA ,[2]Lung Cancer Foundation of America, Los Angeles/CA/USA ,[3]Anne Arundel Medical Center, Annapolis/CA/USA

Introduction: Despite advances in lung cancer treatment, awareness and early detection remain significant challenges in underserved communities. Lung cancer is the #1 cause of cancer-related death in Black men in the US, and Black Americans have the highest lung cancer mortality rate of all racial and ethnic groups in the US. In 2021, only 5.8% of eligible Americans were screened. Lung Cancer Foundation of America (LCFA) developed the Saving Lungs Behind The Chair campaign to address these health inequities by leveraging trusted relationships in the Black community via licensed beauty hair professionals in Metro Atlanta.

Methods: This pilot program recruited and trained 59 hair professionals (33 stylists, 26 barbers) to serve as community health ambassadors, providing lung cancer education to clients. Critical messaging conveyed included screening and biomarker testing. The campaign operated across seven counties with high Black populations (26.1% to 68.1%). Implementation included hair professional training, community event participation, and direct client education, with data collected through participant surveys and tracked client interactions. LCFA collaborated with a local community organization, Community Spark Solutions, which was recommended to enhance the reach and impact of health initiatives.

Results: In less than 90 days, the campaign reached 2,404 community members: 700 through direct client conversations of which 22% registered for more information, 153 hair professionals approached in which 59 were recruited as ambassadors, and 1,551 individuals via social media. Following education, among clients eligible for screening, 90% expressed intent to schedule screening within 3-6 months, which was higher than the 77% expressed in a similar study regarding Barbers and prostate cancer education. The pilot demonstrated remarkable sustainability potential, with 98% of hair professionals willing to participate in future events.
