The campaign fostered a space for survivors to share their experiences, and fight stigma by highlighting that lung cancer affects anyone with lungs. This peer-led approach effectively reached communities with healthcare mistrust and may improve survival outcomes.Community Impact and Innovation: Through the trusted hair professional-client relationship, the campaign established natural health conversations in non-clinical settings that might otherwise never occur. The remarkable 90% intent-to-screen rate signals a potential breakthrough in community-based lung cancer advocacy. With 22% of conversations converting to registrations, this model effectively overcomes engagement barriers in underserved communities. By transforming hair professionals and clients into lung cancer awareness advocates, the program created a ripple effect of information through established community networks.

Conclusions: The Saving Lungs Behind The Chair campaign demonstrates the effectiveness of community-based approaches to lung cancer education. This model effectively addresses specific barriers to lung cancer screening in Black communities—medical mistrust, lack of awareness, and limited access - in ways that many healthcare-centered initiatives cannot. The model shows promise for expansion to other metropolitan areas with large Black populations, which LCFA is currently exploring. By meeting people within their trusted community spaces, this innovative approach has potential to significantly impact lung cancer outcomes and reduce health disparities in underserved communities.

P3.16.07 Canadian Action Plan for Lung Cancer - Patient Perspective

A. Pratt
Independent, Surrey/BC/CA

Introduction: Lung cancer remains the leading cause of cancer-related deaths in Canada, underscoring the urgent need for a unified approach to improve outcomes. The Canadian Action Plan for Lung Cancer represents a groundbreaking effort to incorporate patient perspectives into national cancer strategy development. This initiative, co-designed by patient advocates, researchers, clinicians, and policymakers, emphasizes the value of lived experience in shaping evidence-based solutions.

Methods: The development process began with a nationwide survey using open-ended questions. Patients, caregivers, clinicians, and policymakers shared their priorities, challenges, and unmet needs. Key themes emerged: reducing stigma, enhancing early detection, improving access to treatment, and investing in research for innovative therapies. These insights informed a second survey, in which a select group of constituents were asked to prioritize these themes.

The plan culminated in a one-day summit, during which Patient advocates worked alongside scientific and medical experts to co-create actionable goals. The day included a mix of panels and workshops presenting specific issues and viewpoints.

Results: To ensure inclusivity, special focus was given to engaging underrepresented groups, such as Indigenous communities and rural populations, whose experiences with lung cancer often differ. The resulting Action Plan integrates patient-centered recommendations with measurable objectives, such as increasing lung cancer screening participation rates, funding research on targeted therapies, and implementing supportive care programs.

Conclusions: This initiative exemplifies the transformative potential of patient-researcher partnerships in addressing complex health challenges. The Canadian Action Plan for Lung Cancer sets a precedent for future cancer strategies globally by amplifying patient voices and prioritizing equitable access.

P3.16.08 Feasibility of Engaging Latino Individuals in a Lung Cancer Screening Study Through Mychart

A. Chavez Iniguez[1], V. Chavez-Uceda[2], C. De Los Reyes[1], J.W. Ramos-Santiago[1], R.H. Orfin[1], C. Gardner[1], M.J. Evans[1], S. McIntosh[1], D. Adler[1], A.P. Cupertino[1], M.P. Rivera[1], F. Cartujano-Barrera[1]
[1]University of Rochester, Rochester/NY/USA ,[2]St Georges University, Grenada/GD

Introduction: To assess the feasibility of engaging Latino individuals in a lung cancer screening study using MyChart.

Methods: The electronic health record (EHR) at the University of Rochester Medical Center was used to identify individuals who: (1) self-identified as Hispanic/Latino, (2) were between 50 and 80 years old, and (3) currently smoked. Identified individuals with a MyChart account received an invitation to participate in a lung cancer screening study tailored for Latino individuals. Those who expressed interest were contacted by the study team for eligibility assessment and potential enrollment. Eligibility criteria, aligned with U.S. Preventive Services Task Force recommendations, included: (1) a history of 20 pack-years of smoking, (2) current smoking or having quit within the past 15 years, and (3) no recent lung cancer screening. The interest rate was calculated as the proportion of individuals who expressed interest relative to those invited. The enrollment rate was calculated as the proportion of eligible individuals who enrolled.

Results: A total of 1,745 individuals were identified in the EHR. Among them, 668 had a MyChart account and were invited to participate. Forty-six individuals expressed interest (6.8% interest rate, 46/668), and 33 were contacted by the study team. Fifteen individuals were ineligible, with the most common reason for ineligibility being a smoking history of less than 20 pack-years (40%, 6/15). Among those eligible, nine individuals qualified for the study, and seven enrolled (77.7% enrollment rate, 7/9).

Conclusions: Findings suggest that engaging Latino individuals in a lung cancer screening study through MyChart is feasible. This approach may enhance outreach efforts and promote early detection within this population.

P3.16.09 A Study of Testing Knowledge Regarding Lung Cancer Screening Among General Population and Caregivers

N. Mandal
Chittanranjan National Cancer Institute, Kolkata/IN

Introduction: Over 70000 yearly cases of Lung-Cancer are reported in India. Smoking is a leading cause of Lung-Cancer beside sources like second-hand smoke, hazardous substances at work, etc. Awareness about sources and screening methods play major in battling Lung-Cancer. Early detection is key. Objectives of the study were to identify difference in awareness about sources and screening of Lung-Cancer between general-population and caregivers of Lung-Cancer patients and assess attitude towards Lung-Cancer screening procedures and prevention.

Methods: Caregivers of Lung-Cancer patients were approached for one-on-one interview both in-person and online.

A section of general-population was interviewed both online and in-person. Candidates were selected based on prerequisites and eligibility criteria such as age (over 50y), smoking history, exposure to hazardous factors at work, etc.

Questionnaire was provided to individuals enquiring about respective demographics, knowledge, experience, and opinions about Lung-Cancer.

Results: The survey reports most of the general-population to be employed males whereas most caregivers to be female homemakers. Most respondents from either group have received formal education. In general-population candidates, over 65% had a history of regular smoking, nearly 20% smoked occasionally and around 15% had never smoked. Nearly 30% had tried to quit. No respondents from either group had undergone Lung-Cancer screening. More than 70% of the caregiver-population and only 35% from the general-population reported engaging in activities and behaviours for reducing Lung-Cancer risk that included diet, exercise, quitting smoking etc. Most caregivers reported that their respective patients were receiving palliative care. The average time of experience in caregiving was 1 year. Most caregivers reported undertaking medical and lifestyle management of the patient, however only few reported spiritual, emotional and psychological support. Around 95% of caregivers agreed that Lung-Cancer is preventable. Most of them agreed that death by Lung-Cancer was preventable with early detection. Whereas only 30% of general-population thought that Lung-Cancer is preventable. All caregivers responded to have known or learnt about Lung-Cancer screening processes such as CT-Scans, PET-Scans, X-Ray, MRI, and USG. Whereas over half of the general-population had no knowledge of such screening methods. Almost everyone from either group agreed that smoking causes Lung-Cancer. However, most of them, primarily respondents from the general-population, did not report any awareness about second-hand smoke and exposure to harmful substances such as asbestos as reasons, many of whom were exposed to hazardous substances at work or second-hand smoke in their daily lives. Most respondents denied wearing a mask outside or at work-place. Majority from both groups agreed to be part of Lung-Cancer Awareness programs and webinars and workshops if offered a chance.

Conclusions: The study shows that Caregivers of Lung-Cancer patients are significantly more aware about the sources of the disease and its screening methods compared to general-population. Many are unaware that second-hand smoke or other sources like asbestos can cause cancer. Most agree that smoking causes cancer. Early detection and prevention of Lung-Cancer is possible with more awareness among general-population. Caregivers could play an active role in spreading awareness among general population.

P3.16.10 Co-Designing a Resource to Reduce Stigma in Lung Cancer Screening

K. McFadden[1], N. Harrison[2], S. Rose[1], G. Hollinshead[3], N. Rankin[4], M. Weber[1], B. Nickel[1], N. Houssami[1], R. Dodd[1]
[1]The University of Sydney, Sydney/AU ,[2]Flinders University, Adelaide/AU ,[3]Consumer Advocate/Advisor, Sydney/AU ,[4]The University of Melbourne, Melbourne/AU

Introduction: Stigma in lung cancer is widespread and worse than for other cancer types. It not only has psychosocial consequences for patients (e.g., shame, distress), but also negatively impacts healthcare engagement. Currently, little is known about stigma prior to diagnosis, particularly during lung cancer screening (LCS). With many jurisdictions now designing or implementing LCS programs, understanding and managing stigma for people during LCS is paramount. For the Australian National LCS Program commencing July 2025, the strength and success of tobacco control policies suggest stigma will be a critical issue.

Methods: This project involved two studies in the context of the Australian National LCS Program. First, qualitative investigation using semi-structured interviews to explore potential experiences and impacts of stigma in LCS with consumers, i.e., people eligible for LCS. Second, co-design of a communication-based strategy to reduce stigma in LCS with consumers and experts, i.e., health professionals including general practitioners, medical and nursing specialists (respiratory medicine and other), radiographers, behavioural scientists and health managers. Participants were purposively sampled to achieve representation across key variables (for consumers, smoking characteristics, cultural and linguistic diversity, and education levels; for experts, job role). Interviews and workshops were analysed using abductive thematic analysis. We collaborated with a consumer advisor for the project's duration, including co-facilitation of consumer workshops in Study 2.

Results: In Study 1, 24 consumers were interviewed. One quarter identified as from culturally and linguistically diverse backgrounds; most reported education after high school (71%), high levels of health literacy (96%), and resided in major cities (75%). Four themes were identified: (1) Harmful narratives of personal responsibility and self-infliction; (2) Smoking stigma is a "necessary evil"; (3) Self-perception as part of the LCS group; (4) Previous interpersonal interactions with health professionals shape expectations of stigma in LCS. The co-design process in Study 2 consisted of design and iterative revision of a solution through consultation with consumers (2 workshops, n=5) and experts (interviews and focus groups, n=44). Similar characteristics to Study 1 were reported for consumers. Half of experts were from primary care (as the national program is primary care-led). The final designed solution was a 4-page A4 document targeted at health professionals to support communication during LCS for use in the Australian National LCS Program. Key thematic content included: (1) Taking the onus off the individual; (2) Fostering understanding and empathy; (3) Positive framing. A lexicon guide for person-first and empowerment language was also included based on existing literature.

Conclusions: People eligible for LCS have likely perceived previous stigma in healthcare, and this is a key barrier to LCS. This project developed a practical, scalable resource to reduce stigma for LCS participants, for implementation in a national screening program. This is expected to support health professionals in delivering LCS, and (1) reduce psychological harm to participants, and (2) improve screening engagement. Measurement of these outcomes, and feasibility and acceptability of the resource in practice, are future research priorities. Intersectional stigma for LCS-eligible populations additionally needs further investigation, along with targeted stigma-reduction strategies for marginalised communities.

P3.16.11 A Pulmón - Lunging It: Climbing Mountains and Breaking Barriers in Lung Cancer Advocacy

S. Viteri[1,2], A. Urtasun[3], B. Gaspar[4]
[1]UOMI Cancer Center. Clínicas Mi, Barcelona/ES ,[2]Pratia Siirius, Barcelona/ES ,[3]Nive Mendiak, Roncal/ES ,[4]Asociación Española de Afectados de Cáncer de Pulmón. AEACAP, Valencia/ES

Introduction: Lung cancer remains one of the most stigmatized cancers, often associated with guilt, blame, and fatalism. This stigma negatively impacts diagnosis, patient well-being, and public perception. A pulmón-Lunging It is a Spanish patient advocacy initiative that seeks to transform this narrative through a bold symbolic act: multidisciplinary teams of lung cancer patients, healthcare professionals, and professional mountaineers ascend the highest peaks across Spain, demonstrating resilience, solidarity, and life beyond the disease.

Methods: Since 2023, A pulmón has organized mountain expeditions combining physical challenge with education, reflection, and community-building. Over 50 individuals affected by lung cancer—with clinical stages ranging from I to IV—have participated in climbs alongside oncologists, thoracic surgeons, nurses, psychologists, and researchers. All patients undergo a thorough medical evaluation prior to participation to ensure their physical condition is suitable for the effort. Each climb is dedicated to a specific theme related to lung cancer—such as early diagnosis, immunotherapy, small cell lung cancer, clinical trials, communication, biomarkers, sexuality, or rural health—addressing both the medical and psychosocial dimensions of the disease. Beyond the climb itself, the project includes the creation and dissemination of audiovisual content, outreach campaigns, media appearances, and open dialogues with communities. These activities aim to normalize the presence of people living with lung cancer, increase public awareness, and promote more empathetic and informed narratives around the disease.

Results: In its first two years, A pulmón has completed 12 mountain ascents across Spain, including Mulhacén (3,482 m), Pic de Sotllo (3,073 m), Peña Vieja (2,614 m), and Mesa Tres Reyes (2,434 m). Participants consistently report improved communication between patients and healthcare teams, a stronger sense of agency, and the emotional benefit of achieving shared goals. The presence of researchers on expeditions has fostered deeper insight into the lived experience of lung cancer, strengthening patient-researcher bonds. In 2025, the project plans three additional climbs—including Mount Teide, Spain's highest peak—and will culminate with an international expedition to Mount Ararat, a mountain of profound historical and symbolic significance. This ambitious next phase seeks to further amplify the voice of lung cancer patients and expand the project's impact across borders.

Conclusions: A pulmón represents an innovative model of patient advocacy through symbolic physical action, storytelling, and shared experience. By climbing mountains—literally and metaphorically—lung cancer patients and healthcare teams are reshaping public perception, challenging stigma, and building new narratives rooted in strength, dignity, and connection. The ongoing growth of the project reflects a deep need for initiatives that humanize the disease and create space for visibility, solidarity, and hope.

P3.16.12 Analysis of the Nationwide Database on the Penetration Rate of Lung Cancer Biomarker Tests in Japan

T. Takahama[1], K. Hasegawa[2], M. Yoshida[3], S. Ikeda[4], K. Kachi[5], S. Kawakami[6], M. Sakai[3], S. Watanabe[3], A. Yanagisawa[6], K. Nakagawa[7]
[1]Kindai University, Osakasayama/JP ,[2]Onestep, Yokohama/JP ,[3]Global Health Consulting Japan, Tokyo/JP ,[4]Kanagawa Cardiovascular and Respiratory Center, Kanagawa/JP ,[53]H Medi solution, Tokyo/JP ,[6]Medical Mobile Communications co.,Ltd, Tokyo/JP ,[7]Kindai University Hospital, Osakasayama/JP

Introduction: Since 2000, many molecularly targeted therapies have been developed for non-small cell lung cancer (NSCLC) with driver gene mutations. In Japan, 21 agents targeting 11 distinct driver genes have been approved; however, companion diagnostics (CDx) are essential for their use. Japan's universal health insurance system covers all citizens, with out-of-pocket medical expenses ranging from 10% to 30%. Monthly medical expense caps are also approximately $300 to USD 1,000. However, the complex coverage status of CDx tests for individual drugs under the national health insurance system raises concerns about the widespread adoption of CDx testing.Patient advocacy activities have revealed that many patients are unaware of CDx information for drugs launched since 2020. Therefore, we investigated this situation using Diagnosis Procedure Combination (DPC) data.

Methods: We analyzed DPC data provided by Global Health Consulting Japan, Inc., from April 2019 to May 2024. Data were extracted for each month, focusing on cases that met the following criteria: "underwent lung biopsy," "diagnosed with non-small cell lung cancer," and "diagnosed with stage IV disease according to the TNM classification." The implementation status of CDx testing was then evaluated.

Results: Data from 302 hospitals, encompassing 25,015 patients (male/female ratio: 68.7%/31.3%; age distribution: <50 years, 3.3%; 50-60 years, 33.9%; 70s, 47.4%; ≥80 years, 15.1%) were extracted. The average number of lung biopsies performed per month was recorded as 388, and the average monthly CDx testing rate was found to be 70.1%. A comparison of CDx rates for specific gene mutations between April 2019 and April 2024 revealed the following changes: EGFR (66.3% to 69.7%), ALK (43.2% to 67.8%), ROS1 (42.6% to 66.7%), BRAF (6.8% to 65.5%), METex14sk (2.1% to 46.8%), RET (0.2% to 52.1%), KRAS G12C (2.1% to 37.5%), HER2 (0% to 14.2%), and NTRK (0% to 0.7%). The CDx rates for specific gene mutations were found to be associated with the insurance coverage status of multiplex testing platforms, including the Oncomine Dx Target Test multi-CDx system and the AmoyDx lung cancer multi-gene PCR panel test. For example, although Tepotinib and Capmatinib were launched in June 2020 and August 2020, respectively, the CDx rate for METex14sk remained around 10% until January 2022, when AmoyDx received insurance coverage for CDx testing of Tepotinib. Following this approval, the CDx rate increased to approximately 30%.

Conclusions: Our study shows that driver gene searches using multiple diagnostics are becoming more widespread in Japan in 2019 compared to 2024.

P3.16.13 Using Group Concept Mapping to Identify Research Priorities by Patient and Caregiver Stakeholders Affected by Lung Cancer

J. Ostroff[1], J. Fathi[2], J. Studts[3], J. Pantelas[4], S. Lloyd[5], S. Ulloa[5]
[1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]Go[2] for Lung Cancer, Washington DC/DC/USA ,[3]University of Colorado Cancer Center, Denver/CO/USA ,[4]University of Michigan, Ann Arbor/MI/USA ,[5]Go[2] for Lung Cancer, Washington, DC/DC/USA

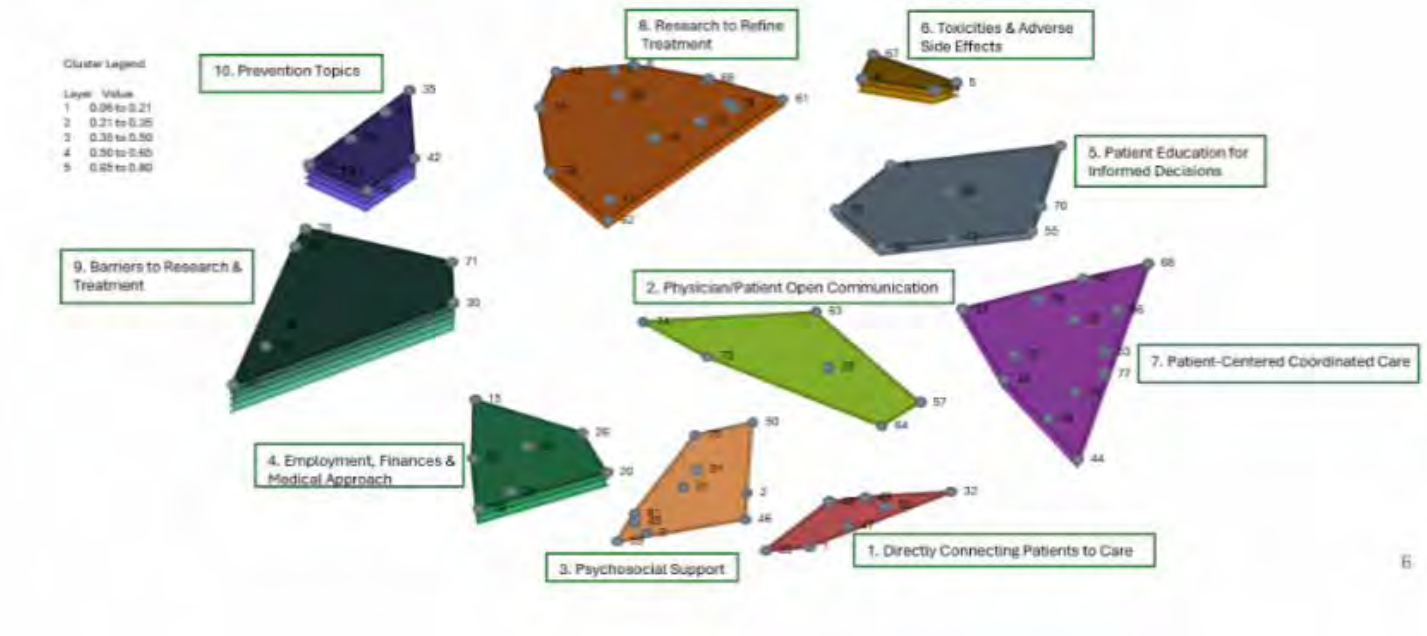
Introduction: To improve the lives of individuals affected by lung cancer, greater investment is needed in patient-centered quality of care and quality of life research. Given constrained funding resources, it is essential to identify research priorities of greatest importance to patients and family caregivers affected by lung cancer.

Methods: This PCORI-funded project convened a broad network of patients and caregivers affected by lung cancer (LCEN) and engaged them in a rigorous multi-phase research prioritization project. Between May and October 2024, LCEN recruitment was conducted using several outreach strategies including personalized email communications, direct mail campaigns, and targeted social media marketing. This work was guided by a scientific advisory board and followed a mixed methods approach to Group Concept Mapping (Kane & Rosas, 2018). In addition to providing information on patient background characteristics (demographics, illness and treatment), participants completed surveys and participated in semi-structured focus group discussions addressing research priorities. During the brainstorming phase, participants were asked to identify one or more specific areas of research that could improve how care is provided and/or the quality of life for people with lung cancer. In the sorting and rating phase, a subset of the brainstorming phase participants sorted the specific research topics into broader research categories and rated on 5-point likert scales the perceived importance and likely impact of these research topics for improving the quality of care delivery and/or quality of life for people affected by lung cancer.

Results: In total, 140 participants (125 patients and 15 caregivers) identified 143 research priority statements that were subsequently consolidated into 81 unique research priority themes. Of the 24 participants who completed the sorting and rating phase, 22 were patients/survivors and 17 had a known mutation with a targeted treatment. As shown in the Figure below, multidimensional scaling/cluster analysis was performed using groupwisdom™, web-based software revealing a final cluster solution of 10 unique research priorities having the highest importance and impact endorsement. Bridging values for clusters were generally low-medium (0.06-0.37) indicating adequate agreement. Focus group discussions cross-validated the cluster solution.

Conclusions: This patient-engaged study identified 10 important and impactful research priorities representing the opinions of patient and caregiver stakeholders affected by lung cancer. The findings represent a patient-centered blueprint for future patient-centered lung cancer research.

Figure: 10-Cluster Solution for Research Priorities



Keywords: quality of life, quality of care, patient-centered research

P3.16.14 The Influence of Deprivation on Lung Cancer Care Experiences in Urban, Rural, and Coastal Areas: A Qualitative IPA Study

M. Achira[1], D. Nelson[1], Z. Pogson[2], S. Civello[2], D. Skinner[2], R. Kane[1], L. Mitchinson[3], S.L. Quaife[3], S. Cooke[1]
[1]University of Lincoln, Lincoln/GB ,[2]United Lincolnshire Hospitals NHS Trust, Lincoln/GB ,[3]Queen Mary University of London, London/GB

Introduction: Globally, lung cancer remains the leading cause of cancer-related mortality, disproportionately affecting individuals residing in socio-economically deprived areas. Geographic distance and deprivation are well known barriers to timely and effective care, yet few studies qualitatively explore how these factors impact patient experiences. This research aimed to explore how deprivation can influence lung cancer patients' and carers' experiences across urban, rural, and coastal areas in the East of England.

Methods: This study undertook a secondary analysis of semi-structured qualitative interviews with lung cancer patients and informal carers (conducted as part of a wider study) between January-October 2024. Transcripts of participants from urban (n=6), rural (n=4), and coastal (n=6) areas who resided in the most deprived quintiles (i.e. quintile 1 and 2) according to the UK Index of Multiple Deprivation were purposefully selected for analysis. An Interpretative Phenomenological Analysis (IPA) methodology was chosen due its focus on idiographic depth; prioritising individual meaning and its capacity to explore how socio structural contexts (such as deprivation) influence health-related experiences.

Results: Analysis revealed five main themes which highlight unique and shared patient and carer experiences of deprivation: (1) Healthcare access barriers; (2) Lack of structured support and guidance; (3) Delayed diagnosis and fragmented healthcare communication; (4) Psychological, physical, and financial impacts; (5) Role of formal and informal support. Patients from all settings described healthcare access difficulties, including inadequate parking, insufficient proactive guidance, and unclear information about treatment pathways. Distinct geographical disparities were also evident. Coastal and rural participants encountered more pronounced travel barriers compared to those from urban areas, due to the significant distance from specialist cancer services. Coastal participants frequently reported logistical complexities such as overnight hotel stays, unreliable public transport, and exhausting long-distance journeys for treatments (daily for radiotherapy) which caused substantial impact. Rural participants similarly faced extensive travel-related burdens, for example collecting medications required repeated journeys lasting several hours, which significantly exacerbated their physical strain and stress levels. Financial hardship was particularly severe amongst coastal residents, and was compounded by higher travel expenses, fuel costs, and limited local healthcare infrastructure. Psychological distress was universally reported among all settings. Formal support from clinical nurse specialists, cancer charities, and other healthcare professionals, along with informal networks of families and friends, offered critical alleviation of these burdens but was insufficient in fully addressing the extensive inequities faced by lung cancer patients and carers from deprived areas.

Conclusions: This qualitative IPA study provides novel insights into the experiences of lung cancer patients and carers who reside in deprived urban, rural, and coastal areas. Inadequate structured information, fragmented communication, and psychological distress were experienced across all settings. Lung cancer patients and carers who resided in deprived rural and coastal areas were further disadvantaged by long travel distances, poor transport capabilities, financial strain and restrictive employment. Informal networks and formal healthcare support can partially mitigate or reduce the strain of these issues. Addressing these challenges through tailored interventions, as well as policy recommendations, is essential for achieving equitable and patient-centred lung cancer care across diverse geographical contexts.

Keywords: Lung Cancer, Deprivation, Qualitative

P3.16.15 Giving Back - Co-Creation of Data Dashboard to Share Survey Results With Patients and Caregivers

B. King-Kallimanis[1], T. Chihuri[2], C. Yu[3], G. Arroyo de Leon[4], S. Petterson[5], J. Feldman[6], K. Glynn[2], J. Lin[7], U. Basu Roy[2]
[1]LUNGevity Foundation, Tarpon Springs/FL/USA ,[2]LUNGevity Foundation, Bethesda/MD/USA ,[3]Consultant, Seattle/WA/USA ,[4]Patient Advocate, Puerto Rico/PR/USA ,[5]Olympic College, Bremerton/WA/USA ,[6]EGFR Resisters, Chicago/IL/USA ,[7]Mass General Brigham, Boston/MA/USA

Introduction: Dissemination of research results relies heavily on conference presentations and peer-reviewed manuscripts. These often are not the optimal method to disseminate research findings to research participants or people living with the conditions being studied. Here we report on a community dissemination model that can be used for observational data that uses an online interface.

Methods: A collaborative team including patients and caregivers, dashboard developers, and researchers used descriptive data analytics from an online survey of people living with EGFR-positive cell lung cancer. The descriptive analytics were storyboarded by the team to guide the development of an interactive and user-friendly dashboard to effectively share the survey results with the EGFR-positive lung cancer community. Post-creation of version 1.0 of the dashboard, a short usability survey was created. The goal of the useability survey was to gather feedback on the dashboard from additional patients/caregivers and use the feedback to create the final version.

Results: The team inspected publicly available health dashboards, reviewed software and created a storyboard of the flow for the dashboard. Tableau software was selected to build the dashboard. All descriptive data visualizations selected are familiar to the public (i.e., bar and pie charts). There were 39 patients and caregivers who evaluated the dashboard, approximately half (54%) were using other digital health programs/devices. Most reported the quality of the dashboard was "Good"/"Very Good", and advice was offered to improve the user experience. For example, one participant reported "The main issue is that the text was not properly contained on the webpage. So the user has to scroll over to see the full text." The interactive filters (i.e., select a subset of the data, see Figure 1, sidebar) were also tested by asking participants to use the filters to report the percentage of a subgroup from a figure. Most (83%) participants who attempted (n=23) were able to correctly answer.

Conclusions: There would be no major advancements in high quality lung cancer treatment and care without the dedicated contribution of patients and caregivers. Yet, patients and caregivers rarely see the results of the studies they participate in. This harms research by discouraging diverse participation. Co-creating a data dashboard honors participants' contributions as well as offers other community members important results from people like them to aid in their healthcare decision-making. It can also encourage continued participation in research by offering tangible outcomes from their involvement.

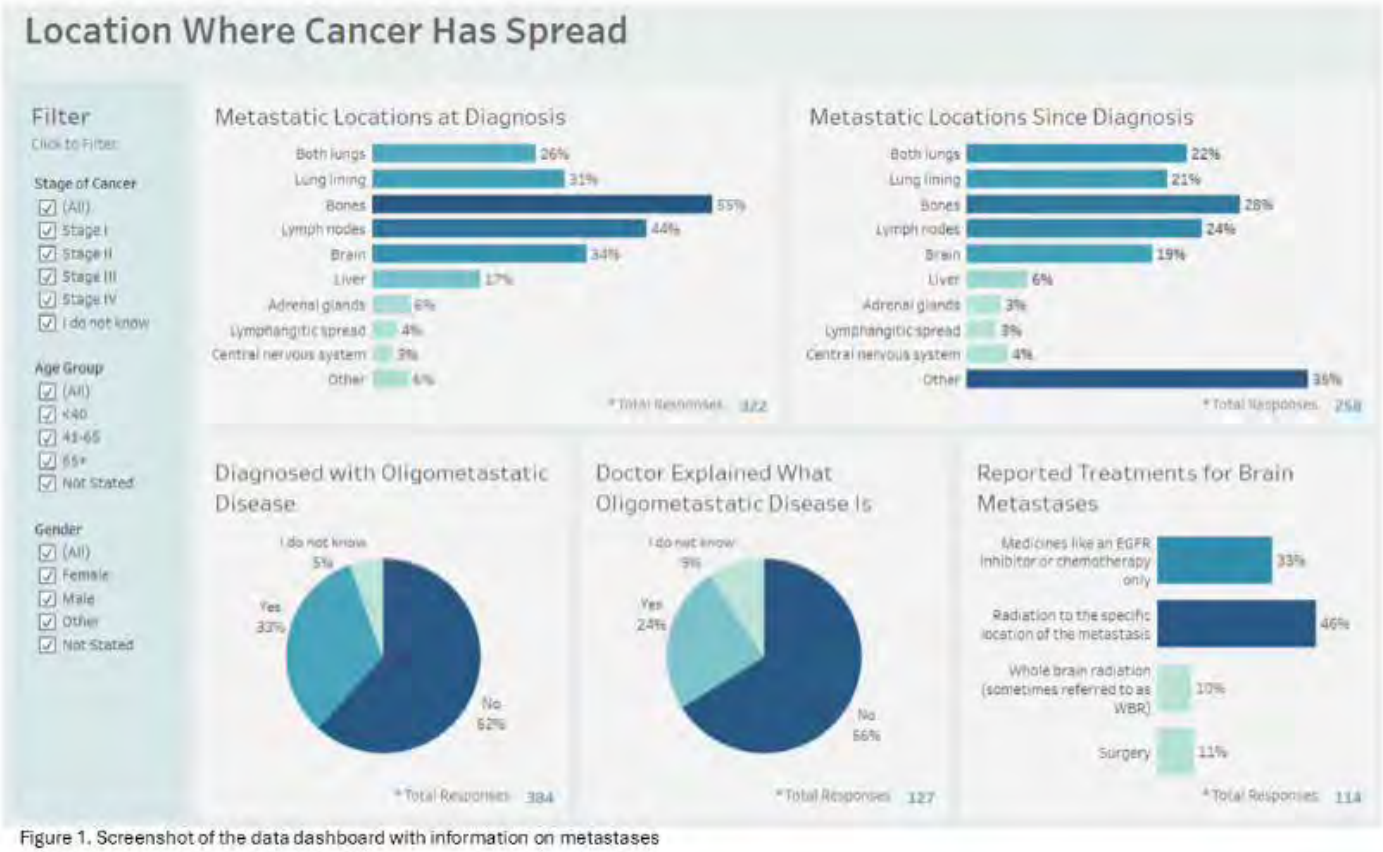

Figure 1. Screenshot of the data dashboard with information on metastases

P3.16.16 The Development of a Patient Education Lung Cancer Nodal Staging Video Toolkit: American Cancer Society National Lung Cancer Roundtable

J.B. Velotta[1], B. Lovely[2], L.S. Rosenthal[3], K. Burn[3], H. Burson[3], K. Hofmann[3], G.A. Silvestri[4], J. Feldman[5], F. Farjah[6], R.A. Smith[3], E.A. Kazerooni[7]
[1]Kaiser Permanente Northern California, Oakland/CA/USA ,[2]Department of Patient Support, American Cancer Society, Atlanta/GA/USA ,[3]National Lung Cancer Roundtable, American Cancer Society, Atlanta/GA/USA ,[4]Medical University of South Carolina, Charleston/SC/USA ,[5]EGFR Resisters, Chicago/IL/USA ,[6]University of Washington, Seattle/WA/USA ,[7]University of Michigan, Ann Arbor/MI/USA

Introduction:

Lung cancer staging is an important step in selecting appropriate treatment options for patients. The American Cancer Society National Lung Cancer Roundtable (ACS NLCRT) convened a Staging Summit in March 2023 to develop and prioritize ideas to improve guideline-concordant lung cancer staging. At the summit, clinicians, researchers, patient advocates, and industry partners noted significant variation in lung cancer staging knowledge, particularly nodal staging. A search of publicly accessible online resources revealed a deficiency in patient-centered materials that are approachable and explain the complexities of lung cancer staging in plain language and at a reading level suitable for the general public. The ACS NLCRT developed the Lung Cancer Staging Video Series for Patients to improve their knowledge of staging and prepare for the treatment journey ahead.

Methods: A survey was conducted of all patients previously treated for lung cancer and all multidisciplinary attendees of the ACS NLCRT March 2023 Lung Cancer Staging Summit. The data were analyzed to identify important themes for optimal patient education. The data were analyzed in a numerical ordering system and reported to the group who then individually ranked each item after final presentations and discussions of each concept was discussed in a breakout group. Concepts with the highest number of votes were included as points for focus in the lung cancer nodal staging education platform. Artificial intelligence software was used to develop the narrative component by Kindea Labs. In a collaborative effort of the ACS NLCRT Lung Cancer Staging and Patient Education Taskforce and Triage for Appropriate Treatment Taskforce, we designed and executed 6 succinct patient education videos focused entirely on lung cancer nodal staging to improve patient understanding about this important topic as informed decision makers. Through an iterative process, additional cycles of content development, review, and revision have been completed prior to product launch.

Results: Of the 60 participants surveyed in the ACS NLCRT Patient Education Taskforce, the two most important ranked concepts were: 1) Lack of understanding of lymph node locations and 2) inefficient patient and clinician discussions around lung cancer nodal staging. All participants voted in favor of short segment patient centered lung cancer nodal staging online videos. Six short-segment <3 minute patient education videos were compiled at the 6th grade reading level utilizing Kindea Labs. Each video underwent multiple rounds of editing and revising for both content and patient applicability utilizing feedback from clinician leaders and patient advocates from different age, sex, racial/ethnic, and sociodemographic backgrounds. The final videos were produced and published online and are available in 5 languages including English, Spanish, Mandarin, Hindi and Vietnamese.

Conclusions: To our knowledge, this is the first comprehensive online patient education video series specifically focused on lung cancer nodal staging. This collaborative effort of the ACS NLCRT with lung cancer patient advocates resulted in real-world patient-centered educational content available for individuals and their families facing this disease. Future studies will focus on performance satisfaction surveys of these videos, and the development of a clinician-facing lung cancer nodal staging video series.

P3.16.17 Understanding the Awareness of Treatment, Clinical Trails, Biomarkers and Unmet Needs of Chinese NSCLC Patients: A Mixed-Methods Study in China

X. Cai[1], D. Zheng[1], F. Lan[1], H. Gu[3]
[1]Sun Yat-sen University Cancer Center, Guangzhou/CN ,[3]Patient Centricity, Hongmian Cancers and Rare Disorders Charity Foundation of Guangzhou, Guangzhou/CN

Introduction: Recent advances in non-small cell lung cancer (NSCLC) therapies involve novel biomarkers and numerous clinical trials. While diverse treatments improve efficacy yet cause adverse effects, understanding patient perspectives on treatment trade-offs, satisfaction, clinical trial barriers, treatment experiences, and biomarker awareness remains crucial for patient-centered care. In China, unmet needs persist in NSCLC management with no existing studies addressing these aspects from patients' viewpoints. To address this gap and provide guidance for future treatment strategies, we conducted this study.

Methods: This mixed-methods study combined an online survey (Dec 2023-Jan 2024) and qualitative interviews (Jan 2024) to explore experiences of Chinese NSCLC patients. The survey, distributed via IQVIA's platform, included 40 items across six domains (demographics, treatment experiences, future expectations, clinical trial/biomarker perceptions, QoL impacts) and required ≥10 minutes for validity. Interviews involved 10 patients who experienced post-immunotherapy progression and participated in clinical trials, using semi-structured guides aligned with survey themes. Both methods adhered to COREQ and AAPOR guidelines. Participants were recruited nationally through IQVIA and Sun Yat-Sen University Cancer Center, with ethics approval from Fudan University. Data included treatment satisfaction (4-point scale), clinical trial willingness, biopsy preferences, and QoL impacts. Quantitative analysis employed descriptive statistics, Pearson's chi-squared/Fisher's exact tests (SPSS v29), while qualitative data were coded using NVivo 12. Confidentiality was maintained throughout.

Results: This mixed-methods study analyzed 100 NSCLC patient surveys and 15 interviews (patients/caregivers) in China. Participants (mean age 51, 55% female, 95% adenocarcinoma, 67% stage IV) predominantly received targeted therapy (86%), reporting higher satisfaction (3.4/5) versus chemotherapy (2.7) and immunotherapy (3.1). Over 60% changed treatments due to symptom progression or tumor growth. Treatment decisions were predominantly physician/family-driven (55%), with only 22% patient-led. Oral administration was favored (72%) for convenience, while survival extension and tumor shrinkage were key treatment priorities. Cost-effectiveness concerns emerged, with most accepting ≤¥5,000/month. Clinical trial willingness was high (79%), driven by efficacy expectations, though 21% hesitated due to trust in standard care. Trial barriers included safety uncertainties and logistical challenges (e.g., frequent tests). Biomarker awareness was substantial (71%), with EGFR/KRAS being most recognized; 88% supported initial biopsy for biomarker testing, yet 18% resisted re-biopsy fearing tumor spread or costs. Quality-of-life impacts were profound: 58% reported disrupted social/family life, 50% experienced anxiety/depression, and 72% maintained daily activities despite fatigue (37%) and sleep issues (29%) as predominant symptoms. Patients emphasized needs for psychological support and streamlined biomarker communication. Findings highlight NSCLC patients' prioritization of efficacy, cost, and convenience, alongside unmet needs in shared decision-making, biomarker education, and psychosocial care to optimize patient-centered management.

Conclusions: Numerous unmet needs persist in the NSCLC treatment journey, such as poor treatment efficacy and accessibility, significant economic and psychological burdens. Thus, urgent actions are called for highly effective and low-toxicity drugs, optimal clinical trial protocols, enhanced patient awareness of clinical trials and biomarker testing, and robust support system.

P3.16.18 Beyond Clinical Outcomes: A Qualitative Exploration of Wellbeing Among People Living With Onco-Driven Lung Cancer

V. Harrison, K. Jones, C. Hyde
Open University, Milton Keynes/GB

Introduction: Lung cancer patients face a unique set of challenges that extend beyond physical health, with significant implications for psychological, emotional, and social wellbeing. Despite advances in treatment, wellbeing remains under-addressed in routine care. This study examines how individuals living with lung cancer in the UK understand and experience wellbeing, identifies sources of support they find beneficial, and explores existing gaps and barriers in wellbeing provision.

Methods: A qualitative thematic analysis was conducted using transcripts from eight semi-structured focus groups with lung cancer patients in the UK. Participants included individuals with varying stages and genetic mutations of lung cancer (including EGFR, ALK and ROS1), the majority of whom were undergoing or had undergone targeted therapies. Discussions were facilitated by trained moderators and focused on the patient's experiences of wellbeing and any helpful supportive resources they had used, as well as identifying unmet needs and any facilitators/barriers to accessing support. Transcripts were systematically reviewed and coded to identify recurring themes.

Results: Five core themes were found. First, 'experiential challenges to wellbeing' where participants described intense emotional distress, particularly at diagnosis, and ongoing "scanxiety" around surveillance imaging. Isolation and a loss of identity, particularly after stopping work or experiencing reduced independence, were also commonly expressed.

Second, 'protective factors' were defined as the ability to maintain emotional resilience, autonomy and normalcy, and connection with others. Peer relationships and a sense of purpose beyond illness were crucial.

Third, 'sources of wellbeing support' included medication, peer support networks (both in-person and online), responsive oncology teams (particularly clinical nurse specialists), active mental health support, and maintaining routine and structure.

Fourth, participants identified 'critical gaps in wellbeing provision', such as a lack of psychological support, poor continuity of care, unmet informational needs, and a scarcity of resources tailored to younger patients or those adjusting post-treatment.

The fifth theme identified multiple 'barriers to accessing wellbeing support', including geographic inequalities, fragmented communication between services, depersonalisation during clinical trials, overwhelmed healthcare services, stigma, and individually internalised pressures to appear "strong". These barriers often left patients feeling isolated or unsupported during periods of vulnerability.

Across the different themes, several participants referenced the benefits of eHealth resources—such as online peer support groups, symptom-tracking apps, and social media communities—as valuable extensions of care.

Conclusions: This study highlights the complex and multifaceted nature of wellbeing in lung cancer patients, which remains under-prioritised despite its critical role in quality of life. Addressing emotional and psychological wellbeing requires more integrated, personalised support, alongside efforts to close systemic gaps and reduce geographical inequalities in care access.

eHealth solutions—such as digital peer networks, self-management tools, and remote psychological support—offer promising avenues to enhance equity, autonomy, and responsiveness in lung cancer care, particularly for those with limited access to in-person services. These findings underscore the need for a holistic, digitally enabled model of care that prioritises lived experiences and wellbeing needs of lung cancer patients.

P3.16.19 Multilevel Assessment of ChatGPT-4O in Radiation Oncology for Lung Cancer Patient Education

C. Richlitzki[1], S. Mansoorian[1], L. Käsmann[1], M.G. Stoleriu[2], J. Kovacs[2], W. Sienel[2], D. Kauffmann-Guerrero[3], T.D. Duell[4], N.S. Schmidt-Hegemann[1], C. Belka[1,5,6,7], S.C. Corradini[1], C. Eze[1]
[1]Department of Radiation Oncology, University Hospital LMU, Munich, Germany, Munich/DE ,[2]Division for Thoracic Surgery Munich, Ludwig-Maximilians-University of Munich (LMU) and Asklepios Medical Center, Munich, Germany., Munich/DE ,[3]Department of Medicine V, University Hospital, Ludwig-Maximilians-University Munich, Munich, Germany, Munich/DE ,[4]Asklepios Lungenfachkliniken GmbH, Asklepios Fachkliniken Munich - Gauting, Germany, Munich/DE ,[5]German Cancer Consortium (DKTK), partner site Munich; and German Cancer Research Center (DKFZ), Heidelberg, Germany, Munich/DE ,[6]Comprehensive Pneumology Center Munich (CPC-M), Member of the German Center for Lung Research (DZL), Munich, Germany , Munich/DE ,[7]Bavarian Cancer Research Center (BZKF), Munich, Germany, Munich/DE

Introduction: Large language models (LLMs) such as ChatGPT are increasingly discussed as potential tools for patient education in healthcare. In radiation oncology, where patients are often confronted with complex medical terminology and complex treatment plans, LLMs may support patient understanding and promote more active participation in care. However, the readability, accuracy, completeness and overall acceptance of LLM-generated medical content remain underexplored. This study aimed to evaluate the potential of ChatGPT-4o as a supplementary tool for patient education in the context of lung cancer radiotherapy by assessing the readability, content quality, and perceived usefulness of AI-generated responses from both clinician and patient perspectives.

Methods: Eight frequently asked questions about radiotherapy for lung cancer were developed based on clinical experience from a team of clinicians specialized in lung cancer treatment at a university hospital. The questions were submitted individually to ChatGPT-4o (version as of July 2024) using the prompt: “I am a lung cancer patient looking for answers to the following questions.” Responses were evaluated using three approaches: (1) a readability analysis applying the Modified Flesch Reading Ease (FRE) formula for German and the 4th Vienna Formula (WSTF); (2) a multicenter expert evaluation by six multidisciplinary clinicians (radiation oncologists, medical oncologists, and thoracic surgeons) specialized in lung cancer treatment using a 5-point Likert scale to assess relevance, correctness and completeness; and (3) a patient evaluation during the first follow-up appointment after radiotherapy, assessing comprehensibility, accuracy, relevance, trustworthiness and willingness to use ChatGPT for future medical questions.

Results: Readability analysis classified most responses as “very difficult to read” (university level) or “difficult to read” (upper secondary school), likely due to the use of medical language and long sentence structures. Clinician assessments yielded high scores for relevance (mean: 4.5 ± 0.52) and correctness (mean: 4.3 ± 0.65), but completeness received slightly lower ratings (mean: 3.9 ± 0.59). Patients rated the responses positively for clarity (mean: 4.4 ± 0.61) and relevance (mean: 4.3 ± 0.64), but lower for trustworthiness (mean: 3.8 ± 0.68) and usability (mean: 3.7 ± 0.73). No harmful misinformation was identified in the responses.

Conclusions: ChatGPT-4o shows promise as a supplementary tool for patient education in radiation oncology. While patients and clinicians appreciated the clarity and relevance of the information, limitations in completeness, trust and readability highlighted the need for clinician oversight and further optimization of LLM-generated content. Future developments should focus on improving accessibility, integrating real-time readability adaptation and establishing standardized evaluation frameworks to ensure safe and effective clinical use.

P3.16.20 Improving Lung Cancer Screening Uptake in 20 Disadvantaged New York Counties: Early Findings From a Demonstration Project

A. Gonnella[1], M. Reid[2], W. Mendel[2], S. Ulloa[1], S. Weston[1], M. Podsiad[1], H. Sanders[1], J.T. Fathi[1]
[1]GO[2] for Lung Cancer, Washington/DC/USA ,[2]Roswell Park Comprehensive Cancer Center, Buffalo/NY/USA

Introduction: Lung cancer screening (LCS) has proven effective in early lung cancer detection, yet uptake in disadvantaged communities remains low due to various systemic barriers, including lack of patient and provider awareness and knowledge, and disparities in healthcare access. Led by GO2 for Lung Cancer (a patient advocacy organization) and Roswell Park Cancer Center, this BMSF-funded, 3-year demonstration project aims to reduce the burden of lung cancer by improving LCS rates in 20 disadvantaged New York counties.

Methods: Beginning January 2024, four large-scale interventions were deployed (Table 1.): 1. engagement of community and healthcare partnerships committed to LCS, 2. expansion of high-quality LCS through growth of GO2's designation program, 3. development and activation of a navigator network with shared commitment to impacting lung cancer outcomes. 4. development and uptake of HCP and community informed education. Two approaches to measuring the impact of these interventions in uptake of LCS have been taken: 1. calculation of total number of LDCTs performed over # of individuals currently smoking cigarettes in targeted areas and 2. Using the All Claims Payor Database in targeted areas, analysts calculated a baseline total number of LDCTs performed in 2020. Using 2020 and 2023 data as comparators, 2024 LDCT claims will be calculated to determine the rate of change between 2020, 2023, and 2024 to determine the measurable impact of our interventions.

Results: Measurable progress made (Table 1.) represents successful engagement and activation of a regional community and growing network of equipped leaders and HCPs to provide and promote evidence-based, high-quality LCS. Early efforts have expeditiously reached over 122 PCP offices, 94 CBOs and stakeholders, and 39+ health systems, culminating in newly designated screening programs, HCP educational resources, and a Navigator Network. Finally, the highly anticipated first look at LCS uptake rates in the targeted project counties, measuring the primary aim and success of this project, will be available by June 2025.

Conclusions: Early in its lifecycle, this innovative demonstration project has set itself apart from other state-based initiatives. This initiative has leveraged four novel interventions and galvanized a community to address barriers to LCS, foster community and provider engagement and education, and establish quality initiatives. Ongoing data and lessons learned from this work will inform current efforts, help build a scalable infrastructure for sustainable and local progress. All leading to improved access and uptake of LCS in disadvantaged communities and serving as a template for future regional work.

Table 1. Demonstration Project Interventions, Approaches, and Progress to Date

	Intervention 1 Stakeholder Engagement	**Intervention 2** Quality Screening Initiative	**Intervention 3** Lung Cancer Navigator Network	**Intervention 4** Healthcare Provider Education
Method	Establish a network of engaged stakeholders committed to identifying eligible individuals, enhancing referral pathways, and improving access to LCS.	Improve access and uptake of high-quality lung cancer screening for eligible individuals.	Initiate, grow, and equip a professional cancer navigator network with shared commitment to impacting lung cancer outcomes.	Improve preparedness, competency, and awareness about lung cancer screening and needs of eligible individuals.
Tactical Approach	**Implement Community Outreach:** • Organize and activate the LCS community • Cultivate bidirectional partnerships with healthcare systems, Community Based Organizations (CBOs), public health officials, and local leaders • Identify and partner with organizations that support underserved populations to expand community-driven improvement in equitable access to LCS	**Organizing and Establishing a Mission-Driven Network of Dedicated Collaborators:** • Expand a network of facilities meeting evidence-based, high-quality standards in screening, across NYS under GO2's Centers of Excellence (COEs) lung cancer screening and care designation program.	**Establish NY Lung Cancer Navigator Network:** • Create broad navigator community reach & and collaboration • Prepare navigators through education and development • Build on the collective strengths of the newly established lung cancer navigator community • Improve advocacy and spreading awareness	**Advance Comprehensive Education for Healthcare Professionals:** • Expand education for the delivery of high-quality LCS and care • Provide a communication hub and resource center • Advance LCS screening, program development, and professional growth
Results to Date	**Cultivated a Continuously Expanding Network of Dedicated Leaders Representing:** • 39 Community and Public Health Leaders • 26 County Officials • 29 Community Based Organizations (CBOs) • Regional Commissioner of Health, • Primary Care Providers, • Medical Directors, • Population health, quality improvement initiatives, and practice transformation experts • Cancer navigators, and community health workers (CHWs)	**Newly Established Healthsystem Networks:** • 26 Health Systems • 4 Upstate NY Veteran Health Administration (VHA) Facilities • 4 Newly designated GO2 for Lung Cancer lung cancer screening designated Centers of Excellence • VHA Strategic Screening Summit convened by GO2 for Lung Cancer o 26 Attendees from VHA VISN 2	**Navigator Network Launched March 2025:** • 9 Regional/ Statewide HCP Member Organizations referred cancer navigators to network • 11 Healthcare Systems Represented • 35 navigators joined network • Navigator network comprised of 6 Community Navigators	**Newly Established Contacts and Key Relationships:** • 32 PCP Practices contacted and LCS and project related resource dissemination o Covering Over 98 Offices • VHA-wide Primary Care Practices • 5 FQHCs Practices o 24 Offices represented • 23 Key informant interviews with PCP and other specialties and disciplines • 16 Key topics identified where barriers, current challenges, knowledge gaps and specific needs exist • 13 subject matter experts identified for 16-course content development, launch October 2024 • A micro-education 16-course bundle developed focusing on key topical areas with a target audience of PCPs and community teams. Course bundle available February 2025 • Creation of a regional peer-to-peer forum designed to facilitate the exchange of emerging news and resources.

P3.16.21 The Role of Neighborhood Deprivation in Lung Cancer Diagnosis and Treatment

B.N. Nichols, J. Wells, S. Monestime, M. Reiss, H. Law, C. Granville
GO² for Lung Cancer, Washington/DC/USA

Introduction: Lung cancer is the leading cause of cancer-related deaths in the United States, with significant disparities in early detection, treatment access, and clinical trial participation. Social determinants of health (SDOH), including socioeconomic status, healthcare availability, and geographic location, play a critical role in shaping these disparities. Previous research also highlights the disparities that exist between well-resourced populations and those facing systemic barriers to care. While these disparities are well documented, there is a need for a deeper exploration for how SDoH specifically impacts access to care. This study seeks to examine these connections and identify opportunities for more equitable cancer care delivery that have been shown to boost a person's overall length and quality of life.

Methods: Our analysis included participants who had voluntarily enrolled in the GO2 for Lung Cancer's LungMATCH or Lung Cancer Registry programs in 2023. To approximate socioeconomic status, we used the Area Deprivation Index (ADI), which assigns a score from 1 to 10 based on variables such as income, employment, and education. A score of 1 represents the least deprived, highly resourced areas, while a score of 10 indicates the highest level of deprivation and scarcity. We examined several key factors in our analysis, including receipt and stage at diagnosis, timing of biomarker testing, and discussions about or participation in clinical trials. Participants were categorized into either Low ADI (1-5) or High ADI (6-10).

Results: A total of 174 participants were included in the analysis. Individuals residing in Low ADI zip codes were 13% more likely to report having undergone biomarker testing (73% vs. 60%). For this, we calculated a p-value of 0.4274 by using Fisher's Exact Test. While both groups had a majority of metastatic diagnoses (58% Low ADI, 53% High ADI), individuals in High ADI zip codes actually reported higher rates of stage I diagnoses (21% vs. 13%, with a p-value of p=0.3016 by Fishers Exact Test). Additionally, those in Low ADI zip codes were 3% more likely to report participation in a clinical trial (9% vs. 6%). Notably, residing in a Low ADI zip code was correlated with greater odds of discussing clinical trials with a healthcare provider (54% vs 36%, p=0.6658 by Fisher's Exact Test).

Conclusions: This research highlights disparities in the receipt of high-quality lung cancer care based on socioeconomic factors, emphasizing the influence of resource availability on cancer diagnosis, treatment, and clinical trial participation. Understanding these factors will enable providers to better address community needs, improve care delivery, and work to eliminate disparities in cancer outcomes.

P3.16.22 Frontline Insights in US Payer Barriers Impacting Patient Access and Participation in Comprehensive Lung Cancer Screening Programs

A.M. Barry, M.F. Mortman, R. Mohon, K. Levy, M. Podsiad, C. Lemery, J. Fathi
GO² for Lung Cancer, Washington/DC/USA

Introduction: GO2 for Lung Cancer-designated Centers of Excellence (COE) in Screening implement a structured low-dose CT (LDCT) program utilizing evidence-based, best practice guidelines. Current quality metrics recommended in the US (Mazzone, 2021) and proposed globally (Tammemagi, 2025) anticipate a multi-disciplinary screening process and comprehensive program approach. In contrast, US payers may impose site-of-service restrictions that exclude coverage for lung cancer screening (LCS) in hospital outpatient settings as non-medically necessary, requiring it occur in less expensive free-standing imaging centers independent of a hospital system. This creates patient access barriers to a comprehensive, multi-disciplinary process and undermines screening implementation consistent with recommended quality measures.

Methods: GO2 for Lung Cancer launched an annual Impact Survey among Screening COEs on November 12, 2024. The survey platform Mahalo was used for data collection, and invitations to participate were sent via Mailchimp to the primary point of contact for each COE, followed by individualized phone and email outreach to identify and correct out-of-date contact records. Data was extracted March 10, 2025. 118 programs responded, or 28% of invitees, and represented 37 states plus DC. Community non-teaching hospitals, community teaching/AMC affiliated hospitals, and academic medical centers were evenly reflected in responses (27%, 24% and 22% respectively), with the remainder being VA Medical Centers, independent clinics, and "other" facility types.

Results: One quarter (25%) of COE programs participating in the survey indicated they experienced site-of-service access restrictions for LDCT LCS and/or follow-up LDCT from commercial payers. Optional open-ended responses describe the impact this has on both patients and programs (Table 1).Notably, less than a third (29%) of survey participants indicated that they have awareness, actively track, or attempt to identify when patients receive a bill for their LCS that was expected to be covered as a preventive service by insurance. As such, patients experiencing coverage denial by their commercial payer due to site of service restrictions may occur undetected and at a greater frequency than reported by the comprehensive screening programs completing this survey.

Conclusions: Site-of-service restrictions hinder patient access to screening programs implementing a comprehensive, multidisciplinary screening process. Furthermore, the rate of programs identifying and tracking patients experiencing unexpected screening cost imposition is low even among comprehensive programs. With cost perception being a well-recognized barrier to patient screening adherence, inattention to patient cost experience is an anticipated contributor to low adherence rates and an under-recognized detriment to a patient-centered, high-quality screening process.

Table 1. Impact of Site-of-Service Restrictions for Screening Patients and Programs

Types of Impact	Site-of-Service Denial Frontline Experiences
Screening Participation/Adherence	• "Patient[s] refuse to continue annual screenings…the stress of seeing a huge bill scares people away from ever wanting to screen again." • "We lose track of the patients if they [the payer] wants them to go to an alternate site." • "Unable to ensure patients are getting their follow-up CTs." • "We get a few patients who do not complete screening. It isn't severe, yet." • "Many patients would like to participate in lung screening but are unable to due to cost."
Results Management	• "When patients have had screens done for years at our hospital and all of a sudden…[are required] to go to a free standing facility that has none of their records, is poor patient care. The new facility has nothing to compare their scan to…[and] often calls for a follow up scan because they don't know WE have been watching the nodules they found for years." • "Hav[ing] to go to a stand alone facility…causes a delay in follow up since we…have difficulty obtaining images from various outside facilities."
Program Workflow/Workload	• "We do our best to facilitate getting patients to a program that is covered by insurance or working with their PCP to order the exam for [an] approved facility that does not have a screening program." • "This creates work for navigators who have to send a disk to [an] outside facility to compare to our screening. Also work to get disk from follow up scan for our providers to review if seen in our lung nodule clinic." • "This disrupts the screening process….We are not always the first point of contact when patients are denied, thus delaying the step to coordinate a site of service." • "It takes time to call the patient back to explain that they are able to have the exam performed but may be charged out of pocket."

P3.16.23 Facilitators to Patient Advocacy Group-Led Engagement of Diverse, Community, Clinical Sites in Multiple Research Types

A. Ciupek, B. Nichols, J. Fathi, A. Barry, R. Mohon, C. Granville
GO² for Lung Cancer, Washington/DC/USA

Introduction: Only about 8% of US patients with cancer participate in clinical trials. One contributor is that 80% of US patients with cancer are treated in community-based practices, while most clinical trials are conducted in academic practices. We previously demonstrated that a novel trial site recruitment partnership, leveraging an informal, disease-specific, patient-advocacy group (PAG)-led clinical network, successfully engaged diverse, community-based practices in the context of a lung cancer screening implementation-effectiveness study (Ciupek, et.al., 2024). Here, to determine if similar effectiveness could be observed across a diverse array of lung cancer clinical study types, we determined the outcomes of applying this model in several research partnerships.

Methods: Staff at the PAG, GO2 for Lung Cancer (GO2), were actively managing study site recruitment for 5 clinical studies between January 1st, 2022, and March 24th, 2025. Sites were recruited using a "targeted proactive outreach campaign", as previously detailed in Ciupek, et. al., 2024. In brief, sites were identified for outreach using GO2 institutional data from past collaborations alongside self-reported and publicly available data from centers belonging to an informal voluntary network of lung cancer screening and care centers, called the GO2 Centers of Excellence Network. Following study discussion with GO2 staff, sites indicating positive intent to join were connected to the study investigator's team for onboarding. Reasons sites were found ineligible or declined to join were documented. Descriptive statistics were used to report recruitment outcomes and site demographics.

Results: 15 sites were recruited across 5 studies during the tracking period. Study types varied, including 3 non-interventional biospecimen collection studies, 1 clinical implementation feasibility study, and 1 provider skills training evaluation. 80% of recruited sites self-identified or were confirmed by the study team as community hospitals or community teaching hospitals. 6 were in the US Census defined South Region, 4 in the West Region, 3 in the Midwest Region, and 2 in the Northeast Region. 33% of sites were in areas with a "high" area-of-deprivation index score (defined as a score ≥6 out of 10), indicating higher levels of socioeconomic disadvantage locally. 318 active and passive declines to join a study were received. Among 98 active declines to join a study, the top reasons were insufficient staffing numbers or bandwidth (37% of declines) and a lack of interest in or reported poor fit of the research study topic (16%).

Conclusions: Results suggest this model may be broadly applicable for engaging geographically and demographically diverse community-based field sites across a variety of non-therapeutic clinical research types. The model should be explored further as a method for increasing research participant diversity. Additionally, PAGs, who have established relationships with the clinical community through their programmatic work, can be effective partners in diverse study site recruitment. Utility for understanding community sites' study participation barriers was also observed. Reported barriers suggest providing staffing support, decentralizing study activities, and tailoring study design to minimize staff burden, alongside outreach tailored to sites' programmatic priorities and interests may facilitate diverse study site recruitment.

P3.18 CLINICAL TRIALS IN PROGRESS
TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.01 Sex-Based Differences in STAS Positivity and Survival in Stage I Lung Adenocarcinoma: Is Female Prognosis Still Better Despite STAS?

Y. Kahya[1], S.G. Güneş[1], S. Dursun[1], S. Yılmaz[1], G. Kocaman[1], D. Karasoy[2], S. Enön[1], S. Dizbay Sak[1], A. Kayı Cangır[1]
[1]Ankara University, Ankara/TR ,[2]Hacettepe University, Ankara/TR

Introduction: Tumor spread through air spaces (STAS) is an emerging negative prognostic factor, especially in lung adenocarcinomas. While men are more likely to present with aggressive histologic subtypes (micropapillary/solid), women often have lepidic or non-mucinous patterns. Although female sex is generally associated with better survival in non-small cell lung cancer (NSCLC), the impact of STAS on this survival advantage remains unclear. This study aimed to assess STAS prevalence and prognostic implications across sexes, with a specific focus on Stage I lung adenocarcinoma.

Methods: This retrospective cohort study included 296 surgically resected adenocarsinoma patients (2016-2024). STAS positivity status was histo-pathologically identified in 111 cases. Female and male patients were analyzed for differences in STAS positivity, histologic subtypes, and clinical outcomes using Chi-square and Fisher's exact tests. Survivals were analyzed using the Kaplan-Meier method and Cox regression test. Special emphasis was placed on Stage I adenocarcinoma patients.

Results: Among the patients included in the study, 53.7% (n=159) were male, while 46.2% (n=137) were female. There was no difference in the distribution of resection type, T stage, tumor size and visceral pleura invasion between the two genders (p values were 0.33, 0.11, 0.47 and 0.59, respectively). There were statistical differences in the distribution of smoking status, STAS positivity, adenocarcinoma subtype, lympho-vascular invasion and overall survival between genders (p values were 0.00, 0.00, 0.04 and 0.001, respectively). STAS positivity was identified in 44.7% (n= 71/159) of male patients and in 29.2% (n= 40/137) of female patients, demonstrating a statistically significant difference between gender (p = 0.001). When tumor size was analyzed using 2 cm as a cutoff value, tumors smaller than 2 cm and STAS negativity were more frequently observed in both sexes (p = 0.04), particularly in the group without STAS positivity. In subgroup analyses, female patients exhibited more favorable survival outcomes across multiple comparisons: in the overall cohort, in the combined evaluation of STAS and sex, within different histologic subtypes, and among patients without lympho-vascular invasion (p = 0.001, p = 0.000, p = 0.001, p = 0.000, respectively) (Table 1). Although STAS - positive women had better survival compared to STAS-positive men, the survival difference between STAS-positive and STAS-negative women was not statistically significant. However, the difference between STAS-positive women and men was significant (p = 0.001). Amogn histologic subtypes, the best overall survival was observed in women with a lepidic pattern, whereas the worst survival was seen in men with the acinar + papillary subtype.

Conclusions: Women live better than men, even if they are STAS positive. These findings suggest that female sex may serve as a protective modifier of STAS-related risk. This sex-based disparity may be linked to underlying immune-genetic and hormonal factors and highlights the importance of sex-specific approaches in lung cancer screening, prognostication, and personalized treatment planning.$$graphic_{93BFBF7C-B553-4CD6-BB56-B27CA400E327}$$

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.02 Sex-Based Differences in Immunotherapy Response via Blood Biomarkers in NSCLC: Interim Results From the ALICE Study

M. Aykac-Bicer[1], B. Resuli[1,2], S. Hermann[1,2], M. Nieves Arredondo Lasso[1], R. Kiefl[1], A. Dick[3], T. Kauke[4], D. Kauffmann-Guerrero[1,2], A. Tufman[1,2]
[1]LMU University Hospital, Department of Internal Medicine V, Munich/DE ,[2]Comprehensive Pneumology Center Munich (CPC-M), German Center for Lung Research (DZL), Munich/DE ,[3]LMU University Hospital, Division of Transfusion Medicine, Munich/DE ,[4]LMU University Hospital, Division of Thoracic Surgery/DE

Introduction: Immune checkpoint inhibitors (ICIs) have significantly enhanced the treatment landscape of non-small cell lung cancer (NSCLC). However, accumulating evidence suggests sex-related disparities in treatment response, with female patients often experiencing inferior outcomes. One potential mechanism may involve alloimmunization—immune activation induced by exposure to non-self human leukocyte antigens (HLA) through pregnancy or blood transfusion—leading to the formation of alloantibodies. The ALICE (Alloimmunization and alloantibodies in male and female NSCLC patients treated with checkpoint inhibitors ICI) study aims to investigate the prevalence of HLA alloantibodies in NSCLC patients and explore their correlation with clinical outcomes on ICI therapy, with a focus on sex-specific patterns.

Methods: The ALICE study is an ongoing, prospective, single-center translational study aiming to recruit 90-100 patients with NSCLC, stages I-IV, all with current or prior treatment with ICIs. At the time of this interim analysis, 59 patients have been enrolled. As part of the study protocol, structured clinical histories are being collected, including prior blood transfusions, pregnancies, menopause status, and previous hormone therapies, to assess potential alloimmunization and hormonal influences. Peripheral blood and tumor samples have been collected for these 59 patients and will continue to be collected in subsequent participants. Analyses include HLA typing, HLA antibodies, immune cell subpopulations, hormone levels. The primary endpoint is to establish a correlation between positive alloimmunization status and objective response rate (ORR) to ICI therapy. Secondary endpoints include the evaluation of clinical parameters, such as progression-free survival (PFS), overall survival (OS) and immune-related adverse events (irAEs), with all outcomes stratified by sex and alloimmunization status.

Results: This first interim analysis of the ongoing prospective ALICE study includes 59 patients with histologically confirmed NSCLC, comprising 27 females and 32 males. The majority of patients had adenocarcinoma (n=47), while 8 had squamous cell carcinoma and 4 had other histologies, including adenosquamous carcinoma. In this interim cohort, antibodies were detected in two cases, one of which may have been due to pregnancy. Participant enrollment and data collection are currently in progress. Final analyses will be initiated once the target sample size has been reached for both the male and female cohorts, ensuring adequate statistical power for sex-specific comparisons and overall study endpoints.

Conclusions: Alloimmunization may represent an underrecognized, sex-linked immunologic factor influencing ICI efficacy in NSCLC. Understanding the role of HLA alloantibodies could pave the way for sex-specific biomarkers and personalized immunotherapy strategies in thoracic oncology.

Keywords: NSCLC, immunotherapy, alloimmunization

P3.18.03 Implementation Study of Lung Cancer Screening Combined With a Smoking Cessation RCT in the Flemish Region: The ZORALCS- and TAMIRO-Stop-Study

C. Theuns
University of Antwerp, Antwerp/BE

Introduction: Lung cancer (LC) is the leading cause of cancer-related mortality worldwide and in Belgium. Early detection through an annual Low Dose Computed Tomography (LDCT) has been shown to significantly reduce LC mortality in high-risk populations. Despite strong scientific evidence supporting LDCT-based lung cancer screening (LCS), implementation at the population level remains a challenge in Belgium. The ZORALCS-study aims to assess the feasibility of implementing an LCS program in the Flemish region, targeting high-risk adults with a history of heavy smoking.

Methods: The ZORALCS-study is a four-year prospective, non-randomized population based feasibility implementation study designed to evaluate the participation rate and effectiveness of a LCS program combined with a structured smoking cessation program. Every adult aged 55-74 living in the primary care zone South-East Region of Antwerp (ZORA) gets a letter at home (N=26.000). If they smoked more than 100 cigarettes in their life, they are asked to fill in an online questionnaire which contains the two following risk prediction models: PLCOm2012 and HUNT. These models measure the risk of developing a LC in the following six years, respectively >1,51% and >0,64%. When eligible, the respondents have to read and confirm the informed decision making and informed consent. Participants undergo annual LDCT screening for two years. For the recruitment, there is a close collaboration between the study team and all local authorities, digital help services, the primary care zone and all caregivers. They support the participants with (practical) questions and follow-up. Reporting is done by a radiologist, with AI as second reader. Pulmonary nodules are assessed by volumetry and management is according to the new Nodule Management Recommendations from the European Society of Thoracic Imaging (ESTI - accepted for publication European Radiology). If a participant of the ZORALCS-study still smokes or stopped less than one year ago, they are offered smoking cessation support in the TAMIRO-STOP study. This is a randomised controlled trial where participants are randomly assigned to two groups (1:1 - block randomization). After the minimal intervention at the hospital, the intervention group receives eight free sessions of evidence-based smoking cessation counselling by a tobaccologist, including reimbursed pharmacotherapy. The control group gets a referral to a primary health care provider of their own choice.

Objectives: The primary objective is to determine the participation rate of eligible individuals who attend at least one LDCT-scan. Secondary objectives include evaluating all steps of the screening process (e.g. recruitment strategies, assessing the effectiveness of smoking cessation interventions, reporting, compliance rates···).

Expected outcomes: The study will identify barriers and facilitators to participation, assess screening effectiveness, and contribute to the development of regional policies for LC prevention. Additionally, data on incidental findings, radiation exposure, and informed decision-making will inform future screening strategies.

Conclusion: The ZORALCS-study is a Flemish pioneering initiative that bridges the gap between evidence-based LCS recommendations and real-world implementation. The outcomes of this study will be instrumental in guiding national and regional governments in Belgium, providing the necessary insights to support informed decisions on the launch of a nationwide, population-based LCS program.

Introduction: There is currently no adequate method to determine which patients will derive survival benefits from immune checkpoint inhibitors or molecularly targeted therapies utilized as perioperative treatment or as consolidation therapy following chemoradiotherapy. It is expected that detecting molecular residual disease (MRD) through the assessment of circulating tumor (ct) DNA may help identify a subgroup of patients with a significantly better prognosis. A concept of de-escalation (or escalation) for MRD-negative (or -positive) subpopulation can be worth evaluating via confirmatory trials. However, there is a significant lack of Japanese data on MRD for predicting prognosis after curative treatment in patients with curative-intent non-small cell lung cancer (NSCLC), and MRD testing is not yet part of routine clinical practice in Japan.

Methods: MRDSEEKER (JCOG2111A) is a prospective cohort study using a personalized, tumor-informed MRD assay (SignateraTM) to evaluate the association between MRD detection and prognosis in patients with NSCLC after curative-intent treatment. Patients aged 18 years or older with histologically confirmed NSCLC are eligible if they meet any of the following criteria: are considered resectable at preoperative clinical stage IB-III with no plan for neoadjuvant therapy; are considered resectable at preoperative clinical stage II-III with a plan for neoadjuvant therapy; or are determined to be suitable for definitive chemoradiotherapy at clinical stage III. The primary aims of this study are to demonstrate that (i) the 2-year progression-free survival (PFS) is sufficiently high in MRD-negative cases, and (ii) the 2-year PFS of MRD-negative cases shows a superior trend compared to that of MRD-positive cases. In this study, we will define multiple patient cohorts and perform survival analyses within each cohort, enabling a more detailed evaluation of therapeutic outcomes. This cohort study will enroll a total of 350 patients: 50 with epidermal growth factor receptor (EGFR) mutation-positive NSCLC, 250 with EGFR mutation-negative NSCLC (including 100 at clinical stage IB, 50 at stage II, 40 at resectable stage III, and 60 at unresectable stage III), and an additional 50 resectable patients at preoperative clinical stage II-III scheduled to receive neoadjuvant therapy including immune checkpoint inhibitors. This study was activated in April 2025. The study is registered with clinicaltrials.gov (NCT06854939).

P3.18.05 Enrollment Update for the CSP #2005 Phase III Veterans Affaris Lung Cancer Surgery or Stereotactic Radiotherapy Study [VALOR]

D. Harpole[1], T. Karas[2], R. Timmerman[3], R. Cameron[4], T. Ritter[5], M. Leiner[6], H. Feng[6], V. Skinner[4], S. Hyoung[4], C. Odle[6], T. Sindowski[6], A. Snodgrass[7], G. Huang[8], K. Carlson[6], D. Moghanaki[4]
[1]Durham VA Medical Center, Durham/NC/USA ,[2]AdventHealth Orlando, Orlando/FL/USA ,[3]UT Southwestern, Dallas/TX/USA ,[4]VA Greater Los Angeles Healthcare System, Los Angeles/CA/USA ,[5]Hunter Holmes McGuire VA Medical Center, Richmond/VA/USA ,[6]CSP Coordinating Center Hines, Chicago/IL/USA ,[7]CSP Clinical Research Pharmacy Coordinating Center, Albuquerque/NM/USA ,[8]VA Office of Research and Development, Washington/DC/USA

Introduction: Current evidence-based guidelines recommend upfront lung resection for patients with early-stage non-small cell lung cancer (NSCLC) who have no clinical evidence of lymph node metastasis. Stereotactic body radiation therapy (SBRT) is recommended only for medically inoperable patients, poor surgical candidates, or those who decline surgery after evaluation by a thoracic surgeon. This is despite a growing number of comparative studies suggesting that SBRT offers similar lung cancer-specific and overall survival (OS) outcomes, as well as the absence of randomized clinical trial data demonstrating the superiority of surgical management.

Methods: A multi-site phase III randomized clinical trial was designed to compare OS rates between surgery and SBRT for operable participants with AJCC 7th edition stage I NSCLC. Eligibility requirements include biopsy-confirmed tumors measuring ≤5 cm in maximum diameter, located more than 1 cm from critical structures (e.g. trachea, proximal bronchial tree, esophagus, and spinal cord), and deemed suitable for either an anatomic resection or SBRT. Mandatory staging procedures include fluorodeoxyglucose positron emission tomography (FDG-PET) scans with biopsies of all radiographically suspicious areas for regional or distant metastasis. The study is an event-driven trial designed to randomize 670 patients in a 1:1 ratio to detect a 10% absolute difference in 5-year OS between the treatment groups. The trial will conclude once 339 participants experience a primary event. Two interim analyses will be conducted to assess efficacy or futility. The first interim analysis will occur when one-third (113) of the primary events have occurred, and the second when two-thirds (226) of the primary events have been reached. A sensitivity analysis with OS as the primary outcome is planned to compare only patients who received their randomized treatment. Secondary outcome measures are structured hierarchically to compare: (1) patient-reported quality of life (EORTC QLQ-C30 and LC-13), (2) respiratory function assessed by patient-reported surveys (St George's Respiratory Questionnaire), (3) respiratory function assessed by pulmonary function testing (FEV1, DLCO), (4) health state utilities (EuroQol EQ-5D-5L), (5) lung cancer-specific mortality, and (6) patterns of relapse during post-treatment surveillance.

Results: The trial commenced in April 2017, and as of March 24, 2025, 440 of the planned 670 participants have been randomized. Following randomization, 96% of participants accepted and received their allocated treatment, with only 1% withdrawing consent after refusing both treatment arms. Baseline patient, tumor, and treatment characteristics are summarized in the table. With a median follow-up time of 2.3 years for all surviving participants, no safety concerns have arisen to interrupt the study, nor have there been enough events to trigger the first efficacy or futility analysis. Completion of accrual is estimated for September 2027.

Conclusions: The VALOR study has successfully enrolled 66% of its target accrual within a time frame similar to that required for the CALGB 140503 study, which enrolled a comparable number of participants with early-stage NSCLC (n=697). The final results are expected to clarify the role of SBRT as a potential alternative to surgery for operable clinical stage I NSCLC and facilitate more informed discussions regarding SBRT as a viable option for certain operable patient populations.

P3.18.06 Phase 1b Study of a Novel Fluorescent Imaging Agent, LS301, for Lung Cancer Surgery to Localize Tumors and Assess Margins

S. Singhal[1], L. Chen[1], A. Din[1], N. Staten[2], B. Honigberg[2]
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia/PA/USA ,[2]Integro Theranostics, St. Louis/MO/USA

Introduction: Surgery for lung cancer has multiple challenges including localizing nodules, ensuring negative margins, and identifying synchronous cancers. One proposed solution is intraoperative molecular imaging (IMI), that is, administering a tumor-targeting fluorescent agent to highlight cancer cells. LS301 is a cyclic peptide that binds phosphorylated Annexin A2 (pANXA2) on malignant cells, conjugated to a near infrared fluorescent molecule, in development for the visualization of cancer. LS301 was evaluated in an open-label Phase 1b clinical trial (NCT06713564), and we present preliminary results of LS301 dose-escalation study from the first 3 of 4 dose cohorts.

Methods: Patients are dosed at least 1 day before surgery across four dose cohorts: 0.025, 0.05, 0.075 mg/kg, and 0.1 mg/kg. LS301 is then imaged during minimally invasive and robotic surgery using multiple NIR devices including the Medtronic VisionSense, Karl Storz IMAGE1 S Rubina, and Intuitive Surgical's Firefly Fluorescence Imaging System for in vivo and ex vivo imaging. The mean fluorescence intensity is calculated to characterize the tumor-to-background ratio. Clinically significant events (CSEs) that altered the surgical procedure were defined as localization of the primary tumor, identification of synchronous tumors and margin assessment, are identified through LS301 imaging alone and confirmed by final histology, which is the gold standard for all outcomes.

Results: A total of 11 patients completed the infusion, surgery and IMI. In vivo and ex vivo fluorescence imaging demonstrated dose-dependent signal enhancement, with stronger fluorescence signals observed at higher dose cohorts. LS301 fluorescence signal was detected and demonstrated reliable signal differentiation from background with all devices including robotic and video assisted thoracoscopic surgery. Preliminary analysis of the imaging data has been completed, and tumor-to-background ratios were calculated for both in vivo and ex vivo imaging that demonstrated high contrast between tumor and background. To date, sensitivity for the primary lung cancer was 100% for ex vivo imaging and there were no false positives by histology. From a surgical outcome perspective, LS301 imaging contributed to four clinically significant events in three patients: (Patient A) aiding primary tumor localization and margin assessment; (Patient B) identifying a synchronous lesion; (Patient C) aiding in primary tumor localization, none of which were found by white light. One patient with a history of hypertension experienced a transient, Grade 2 blood pressure elevation on the day of infusion, which resolved without intervention. The event was considered possibly related to LS301. No other treatment-related adverse events or dose-limiting toxicities were observed.

Conclusions: Findings to date support that LS301 is safe and well-tolerated and provides distinctive intraoperative tumor contrast influenced by dose level, tumor characteristics, and imaging device. These findings also suggest that LS301 aids in localizing the primary tumor, performing margin assessments, and identifying synchronous lesions.

P3.18.07 Immunotherapy Combined With Radiotherapy as Neoadjuvant Therapy in Resectable NSCLC: A Single Arm, Phase II Clinical Study

B. Wang, L. Pan, X. Wang, Y. Liang, L. Liu, Y. Shu
Northern Jiangsu People's Hospital Affiliated to Yangzhou University, Yanzhou/CN

Introduction: Phase III clinical trials have demonstrated that neoadjuvant immunochemotherapy can elevate the pathological complete response (pCR) rate to approximately 20%-25%. Our center's prior clinical experience has revealed that concurrent radio-immunotherapy can also achieve favorable pathological remission, yet the optimal dosing and timing for combination therapy remain undetermined. This study is designed to evaluate the efficacy and safety of a chemo-free treatment regimen in the neoadjuvant setting.

Methods: This study is a non-randomized, single-arm phase II trial assessing the safety and efficacy of combining the PD-1 inhibitor tislelizumab with chest radiotherapy as neoadjuvant treatment for resectable stage IB-IIIA non-small cell lung cancer (NSCLC) patients aged 18 years or older. Eligible patients will receive intensity-modulated radiotherapy (IMRT) at 40 Gy in 20 fractions (days 1-20) targeting the primary tumor and positive lymph nodes, combined with three to four cycles of tislelizumab (200 mg on day 1, every 3 weeks), followed by curative-intent resection within 3-6 weeks after the last neoadjuvant dose. Adjuvant tislelizumab treatment (200 mg on day 1, every 3 weeks) will commence within 8 weeks post-surgery for up to 1 year. Postoperative minimal residual disease (MRD) detection will be performed at 3-4 weeks, 4 months, and every 6 months thereafter. Patients with detectable MRD will receive additional four cycles of chemotherapy based on their pathological type. The primary endpoints are safety and pCR rate, while secondary endpoints include major pathological response (MPR) and 1-year event-free survival (EFS) rate. Efficacy analyses will follow an intention-to-treat principle, encompassing all patients scheduled for neoadjuvant treatment. Safety assessments will include all patients who have received at least one dose of the study treatment.

Introduction: In China, alectinib was approved for adjuvant treatment of patients with resected anaplastic lymphoma kinase (ALK)-positive early-stage non-small cell lung cancer (NSCLC) in July 2024. The approval was based on the global phase III ALINA study, which demonstrated significantly longer disease-free survival (DFS) in patients treated with alectinib compared with platinum-based chemotherapy. Although alectinib has been the standard of care in this population and was recommended by main guidelines including the National Comprehensive Cancer Network (NCCN) and Chinese Society of Clinical Oncology (CSCO), the effectiveness data and the patient journey for Chinese patients in the clinical practice in the real world settings remains scarce.

Methods: This is a multicenter, prospective, cohort study (NCT06862869) enrolled histologically-confirmed, stage II-IIIB (UICC/AJCC v8), ALK-positive, NSCLC adult patients. A decentralized model is employed, representing a contemporary approach where data collection and participant engagement occur remotely. This model capitalizes on digital technologies, including mobile applications and online platforms, to procure data directly from participants within their natural environments and facilitates real-time data collection and analysis. Patients are eligible if they are treated with alectinib monotherapy as adjuvant therapy after complete resection. The planned accrual is 800 patients in about 50 sites from various provinces and cities in China to achieve geographical representation. All evaluations and treatments that the patients receive will be determined by the physicians according to the clinical practice at each study site. Data will be obtained from inpatient and outpatient medical records and patient self-reported information including patient-reported outcomes (PRO) questionnaires. The follow-up visit follows routine visits in real-world practice. Data cut-off for final analysis will occur approximately 2.5 years after the last patient enters the study cohort. The primary effectiveness objective is to evaluate real-world disease-free survival (rwDFS), defined as the time from the first dose of alectinib as adjuvant therapy to cancer recurrence or death from any cause. The secondary effectiveness objectives include the duration of alectinib therapy, patient demographics and disease characteristics, and PROs (emotional and physical function) by SF-36 v2 questionnaires. The safety profile of alectinib as an adjuvant treatment in resected ALK-positive NSCLC in routine clinical practice will be evaluated. The study also explores prognostic factors of recurrence, the healthcare utilization before or after the recurrence, the alterations of ALK or other biomarkers identified between the recurrence and initiation of the next anticancer therapy, and treatment options after recurrence.

Introduction: KRAS mutations are well-characterized oncogenic drivers in multiple solid tumors. KRAS mutations are the most common oncogenic driver in non-small cell lung cancer (NSCLC) and KRAS G12C accounts for 40% of KRAS-mutant lung cancer. Olomorasib is a potent and highly selective second-generation inhibitor of KRAS G12C, which delivers >90% sustained target occupancy at low absolute exposures in preclinical models. The phase 1/2 LOXO-RAS-20001 study (NCT04956640) showed that olomorasib alone and in combination with pembrolizumab demonstrated promising preliminary efficacy and a favorable safety profile in patients with metastatic KRAS G12C-mutant NSCLC. The safety and efficacy of olomorasib in combination with immunotherapy, allows movement into the curative setting, where immunotherapy is the standard perioperative or consolidation therapy with surgery or radiation, respectively.

Methods: SUNRAY-02 (NCT06890598) is a global, multicenter, randomized, double-blind, placebo-controlled phase 3 study that aims to determine the efficacy of olomorasib in combination with standard of care immunotherapy following definitive treatment of stage II-III NSCLC. Eligible participants are at least 18 years old, ECOG PS 0-1, with pathological confirmation of NSCLC (resected stage II-IIIB or unresectable stage III based on AJCC 9th edition) with known KRAS G12C mutation (tissue or blood) and PD-L1 expression (0-100%). Key exclusion criteria include a known EGFR mutation or ALK rearrangement, prior history of NSCLC, pneumonitis/interstitial lung disease requiring steroids, or active autoimmune disease. This study includes two parts: Part A enrolls participants with resected stage II-IIIB NSCLC, who received either neoadjuvant chemoimmunotherapy without achieving a pathological complete response or received adjuvant chemotherapy; Part B enrolls participants with unresectable stage III NSCLC with no evidence of disease progression following concurrent chemoradiation therapy. In Part A, approximately 400 participants will be randomized in a 1:1 ratio to receive either olomorasib or placebo in combination with pembrolizumab. In Part B, approximately 300 participants will be randomized in a 1:1 ratio to receive either olomorasib or placebo in combination with durvalumab. All participants will receive combination treatment for up to approximately 1 year, followed by olomorasib or placebo monotherapy to complete up to 3 years of total treatment. The primary endpoint for Part A is disease-free survival (DFS). Secondary endpoints include overall survival (OS), changes in health-related quality of life (HRQoL), safety, and patient-reported tolerability. The primary endpoint for Part B is progression-free survival (PFS) by blinded independent central review. Secondary endpoints include OS, objective response rate (ORR), duration of response (DoR), disease control rate (DCR), time to response (TTR), progression-free survival 2 (PFS2), safety, changes in HRQoL, and patient-reported outcomes.

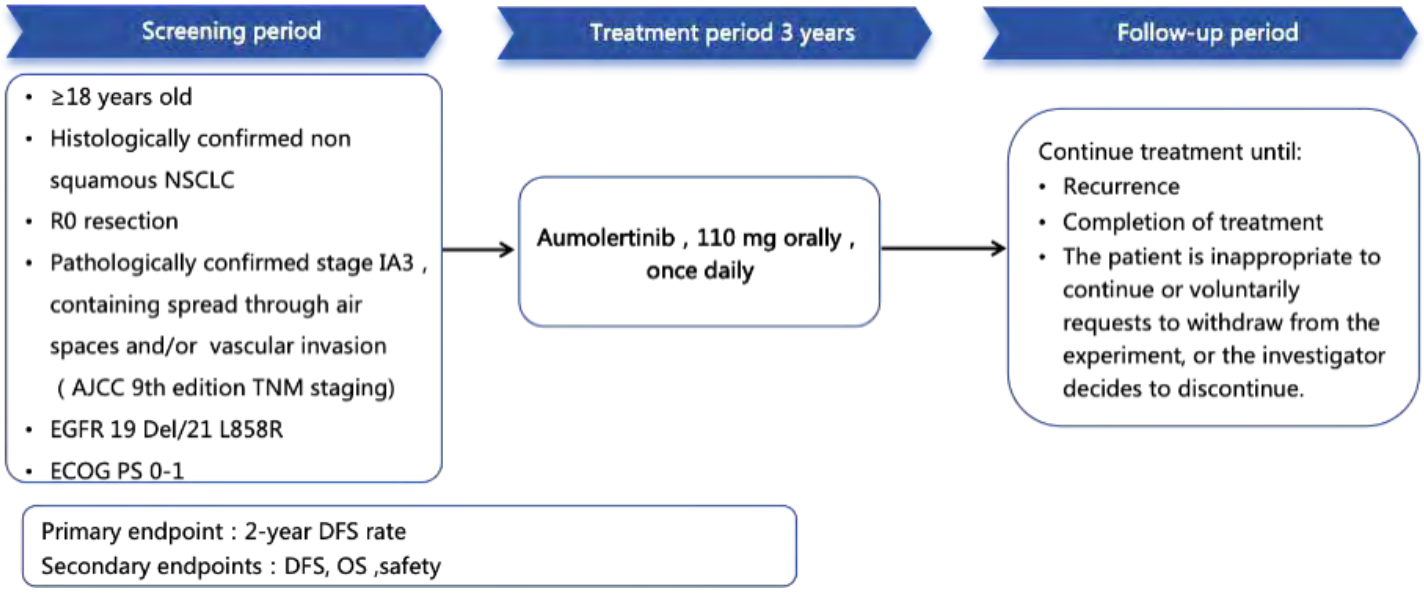
Keywords: KRAS-G12C, Olomorasib, NSCLC

P3.18.10 Efficacy and Safety of Aumolertinib as Adjuvant Therapy in Resectable Stage IA3 EGFRm NSCLC With High Risk Factors

B. Zhao, H. Yu, L. Zhao, Z. Zhang, T. Liu
The Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/CN

Introduction: With the widespread adoption of low-dose CT screening and the impact of COVID-19, the incidence of stage I NSCLC(especially IA)has risen. While radical surgery remains a key curative approach for stage I NSCLC, historical data indicate that a subset of patients still fail to achieve long-term survival beyond five years.According to the 9th edition of the TNM classification by the International Association for the Study of Lung Cancer (IASLC), stage IA3 is defined as a tumor measuring 2-3 cm without lymph node involvement (N0) or distant metastasis (M0), accounting for approximately 30% of all IA-stage NSCLC. Despite being categorized as "early-stage," IA3 patients with high-risk recurrence factors,such as spread through air spaces (STAS) and vascular invasion(VI),exhibit significantly worse prognoses, with 5-year recurrence-free survival (RFS) rates dropping to 65%-75%. Their postoperative recurrence risk is markedly higher than that of IA1 and IA2 patients, highlighting the urgent need for more precise adjuvant treatment strategies to improve long-term outcomes.Aumolertinib is a novel, promising oral third generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), which has demonstrated efficacy in tumors harboring sensitive EGFR mutations . Besides, the results of phase III registration trial with adjuvant aumolertinb versus placebo is about to be released soon and aumolertinb will be the third EGFR-TKI comprising indication concerning adjuvant therapy worldwide. However, no prospective data exist on the adjuvant targeted therapy benefit in IA3 EGFR-mutant NSCLC with high-risk factors. Therefore, this study aims to evaluate the efficacy and safety of aumolertinib as adjuvant therapy in resectable stage IA3 NSCLC patients with high-risk factors.

Methods: This prospective, single-center, single-arm phase II trial enrolls patients with pathologically confirmed stage IA3 (T1cN0M0) NSCLC exhibiting high-risk factors (STAS and/or VI) who underwent complete resection (R0). Key eligibility criteria include EGFR sensitizing mutations (exon 19 deletion or L858R), Eastern Cooperative Oncology Group performance status (ECOG PS) 0-1. This trial is prepared to enroll 30 patients which receiving aumolertinib (110 mg orally once daily) adjuvant treatment for up to 3 years or until disease recurrence/ unacceptable toxicity. Primary endpoint is the 2-year disease-free survival (DFS) rate by investigator assessment, while secondary endpoints include median DFS, overall survival (OS), and safety. Stratification factors include EGFR mutation subtype (exon 19del or L858R) and high-risk factors type (STAS and/or VI). The trial initiated on March, 2025. Now is ongoing.



Keywords: Aumolertinib, Adjuvant Therapy, High risk factors

P3.18.11 Adding Certolizumab to Neoadjuvant Chemoimmunotherapy - Control of Immune-Related Adverse Events and Prevention of Surgical Delays

P.K. Paik, P. Agrawal, M. Bott, I. Preeshagul, B. Park, D. Jones, P. Adusumilli, G. Rocco, J. Isbell, J. Huang, J. Eng, A. Iqbal, F. Santini, R. Rosenblum, W. Travis, R. Daly, J.E. Chaft, M.G. Kris
Memorial Sloan Kettering, New York/NY/USA

Introduction: We have identified a paracrine inflammatory loop (TNF-α, CXCL1/2, S100A8/9) involving both tumor and stromal compartments that engenders chemoresistance and metastatic propagation in lung adenocarcinoma models. Interruption of this loop by TNF blockers leads to chemotherapy re-sensitization and abrogation of metastases. We showed that the addition of certolizumab, a TNF blocker, to platinum doublet chemotherapy in patients with advanced lung cancers increased efficacy with attendant decreases in TNF-α and S100A8 expression compared to controls (Paik et al. Nat Comm 2022). TNF blockers do not increase perioperative morbidity and may lessen immune-related adverse events (irAEs). Based on these data, we designed NEOCERTO (NCT04991025), a phase 2 trial of neoadjuvant certolizumab added to platinum doublet chemotherapy + nivolumab in patients with resectable stage IIA to IIIB squamous and adenocarcinomas, hypothesizing that TNF-α inhibition will increase the efficacy of chemoimmunotherapy, abrogate metastatic propagation, and mitigate irAEs. We report here initial drug delivery, side effect data, and time to resection post neoadjuvant therapy.

Methods: This is a phase 2 study of certolizumab, a TNF blocker, added to histology-specific platinum doublet chemotherapy (paclitaxel, albumin-bound paclitaxel, gemcitabine, or pemetrexed) + nivolumab as neoadjuvant therapy in pts with clinical stage II and III resectable lung cancers. Treatment is given every 3 weeks for 4 cycles. The primary endpoint is pCR rate. Secondary endpoints include safety, ORR, DFS, and metastasis-free survival. Serial blood is being collected for exploratory cytokine analysis and ctDNA dynamics. Transcriptomic analysis of the resection specimens is planned.

Results: Twenty-six patients have completed neoadjuvant treatment and proceeded to surgery; 5 additional patients are currently undergoing neoadjuvant treatment. Among the 26 patients, median age=66 years (range 38-76); 46% female; 92% former/current smoker. Histology: 18 (69%) adenocarcinoma and 8 (31%) squamous cell carcinoma. cStage II 7 (27%), cStage III 19 (73%). Of the total 104 planned cycles of therapy, 102 were completed (98%). No grade 2/3/4 irAEs have been recorded (0%, 95% CI 0 -11%). The only grade 1 possible irAE was rash (N=3). The most common treatment-related AEs were anemia (23%), thrombocytopenia (23%), neutropenia (19%), and nausea (19%). Most were grade 1. Grade ≥ 3 related AEs were hematologic: neutropenia (15%), anemia (8%), and thrombocytopenia (12%). There were 3 treatment-related SAEs (1 febrile neutropenia; 2 creatinine increases) which resolved. All 26 patients underwent surgical exploration. The median time from the end of the last cycle of therapy to surgery was 13 days (range 0-51 days). Surgery was not postponed in any patient due to treatment-related AEs. Among 26 patients who underwent surgical exploration, 25 had an R0 resection (96%). The pCR rate was 31% and MPR rate 62%.

Conclusions: When the TNF blocker certolizumab was added to standard of care neoadjuvant chemotherapy plus nivolumab, 98% of planned neoadjuvant therapy cycles were delivered, no dose-limiting immune related adverse events were observed, surgery was completed within 2 weeks after completion of therapy in most patients, and 96% had complete resections. Accrual is ongoing, with a target goal of 50 patients. Supported by NCI P01CA129243 and UCB Inc.

Introduction: Surgery continues to be the gold standard treatment with curative intent for patients with resectable early-stage and locally advanced non-small cell lung cancer (NSCLC). Achieving pathological complete response (pCR) following neoadjuvant treatment is considered a potential early predictor of survival in resectable NSCLC whereas the absence of pCR may be associated with poorer outcomes in this patient population. The emerging understanding of the therapeutic synergy between immune checkpoint inhibitors (ICIs) and antibody-drug conjugates (ADCs) - such as Sacituzumab Govitecan, a TROP-2-directed ADC - has opened a new chapter in adjuvant NSCLC therapy, offering promising survival benefits in clinical practice.

Methods: ARIAN is an multicenter, open-label, randomized, phase III clinical trial (EUCT Number: 2024-512960-75-00). Patients with stage IB to IIIA-IIIB (T3N2) treated with neoadjuvant chemo-immunotherapy and who do not achieve a pathological complete response (pCR) after complete surgical resection (R0), will be stratified (PDL1- vs PDL1+) and randomized 1:1:1 to: observation for 10 months (Arm 1), Zimberelimab for 13 cycles (Arm 2) or Sacituzumab Govitecan and Zimberelimab for 8 cycles followed by Zimberelimab monotherapy for 5 cycles (Arm 3). 129 patients will be enrolled (43 per arm) in 30 sites and patients must have adequate organic function and do not harbor EGFR, ALK, STK11 or KEAP1 genomic alterations. The primary endpoint is disease-free survival (DFS), defined as time from randomization to first disease recurrence, any new lung cancer or death from any cause. Patients will undergo tumor assessments by body CT scan at baseline (before randomization), during adjuvant treatment or observation every 12 weeks and thereafter, every 3 months for 2 years and every 6 months the 3rd year. Secondary endpoints include overall survival (OS) at 12, 24 and 36 months after the start of adjuvant treatment and safety based on CTCAE v5. Exploratory endpoints include assessing the prognostic value of ctDNA and the antitumor immune response. The study was approved by health authorities on 19 August 2024.

Introduction: Some patients with unresectable stage III non-small cell lung cancer (NSCLC) may be cured by chemoradiotherapy (CRT) and adjuvant checkpoint inhibition through PD-L1 blockade. Durvalumab improved survival compared to placebo in the PACIFIC trial (median progression-free survival (mPFS) 16.9 vs 5.6 months (mo), median overall survival (mOS) 47.5 vs 29.1 mo compared to CRT alone) (Spigel D, et al J Clin Oncol 2022). Five-year survival remained below 50% and only patients completing CRT without progression and with good performance status (PS) were eligible to receive adjuvant immunotherapy.

Neoadjuvant checkpoint inhibition allows more patients the potential benefit of immunotherapy and may attenuate tumor-related immunosuppression via depletion of regulatory T cells and clonal expansion of effector T cells, thereby improving tumor immunogenicity. Neoadjuvant atezolizumab appeared promising compared to historic PACIFIC data in the phase II single-arm AFT-16 trial (mPFS 30 mo and mOS not reached; Ross HJ et al JAMA Oncology 2024).

Tiragolumab blocks the immunosuppressive protein TIGIT, and may decrease aspects of the immunosuppressive tumor microenvironment through effects on both lymphoid and myeloid cells. Whether combination immunotherapy with atezolizumab and tiragolumab before and after CRT will further improve outcomes in this setting is the question posed in the AFT-57 trial.

Methods: This phase II randomized Alliance Foundation Trials study (AFT-57) evaluates safety and efficacy of atezolizumab with or without the anti-TIGIT monoclonal antibody tiragolumab before and after definitive CRT. The primary endpoint is PFS in the two experimental arms to select the most promising regimen for further study. AFT-57 will randomly assign 158 patients with unresectable stage III NSCLC (AJCC v8), Eastern Cooperative Oncology Group PS 0-1, no active autoimmune disease and no significant underlying organ dysfunction to 2 cycles of neoadjuvant atezolizumab (intravenous [IV] 1200 mg every 21 days or subcutaneous 1875 mg every 21 days) with or without tiragolumab (600 mg IV). Non-progressing patients undergo CRT with carboplatin and paclitaxel weekly concurrent with 60 Gray involved-field thoracic radiation in 30 daily fractions delivered Monday to Friday over 6 weeks followed by atezolizumab with or without tiragolumab every 21 days on the same schedule as the neoadjuvant doses, with a plan for one year of therapy absent progression or intolerance.

Correlative science includes tissue and blood-based immune-related biomarkers at baseline and during therapy. This trial utilizes the Alliance Participant Engagement Portal, a patient-facing site designed to provide information and resources to Alliance clinical trial participants. The trial was activated on 12/7/23 and the first patient was screened 1/19/24.

P3.18.14 Quick Start Durvalumab: A Phase II Pilot Study of Early Durvalumab Initiation Following Chemoradiation in Unresectable Stage II-III NSCLC

S. Brinton, J. Ruiz, L. Hart, E. Stoen, M. Farris, S. Price, J. Hunting, B. Levine, S. Brirken, W.J. Petty, T.W. Lycan Jr.
Wake Forest University School of Medicine, Winston Salem/NC/USA

Introduction: Durvalumab is the standard consolidation therapy for unresectable stage II-III non-small cell lung cancer (NSCLC) following chemoradiation, based on improved survival reported in the PACIFIC trial. However, optimal timing for initiation remains undefined. Preclinical data and post-hoc analyses suggest that earlier initiation of durvalumab may enhance efficacy, potentially by capitalizing on treatment-induced upregulation of PD-L1 expression. Prior analyses also found no significant difference in incidence of immune-related adverse events with early administration. Despite these findings, in current clinical practice, most patients begin durvalumab more than 14 days after radiotherapy due to a number of barriers (e.g., post-radiation toxicity, logistical barriers, and lack of prospective data). An investigation of patients at our institution with Stage III NSCLC revealed that the majority of patients were started on durvalumab 14 to 42 days post-radiotherapy, and no patients received durvalumab within 14 days of radiotherapy completion. Our study objective is to evaluate the feasibility, safety, and early efficacy of quickly starting durvalumab within 14 days of chemoradiation.

Methods: This open-label, single-arm, pilot phase II trial will enroll approximately 28 patients aged ≥18 years with unresectable or medically inoperable stage II-III NSCLC who have received platinum-based chemotherapy and definitive thoracic radiotherapy (54-66 Gy). Eligible patients must have ECOG performance status 0-2 and no evidence of early disease progression. The study intervention includes the typical one-year course of durvalumab 1500 mg IV every 28 days starting 1 to 14 days post-radiation. The study has IRB approval and is registered as NCT05696782.

The primary endpoint is treatment fidelity to the early initiation of durvalumab within 14 days of the last day of radiotherapy. Secondary endpoints include fidelity to very early initiation (i.e., within 7 days), qualitative assessment of barriers to early initiation, incidence of adverse events, and measures of efficacy (i.e., overall survival, progression-free survival, and objective response rate). Exploratory endpoints include patient-reported outcomes (i.e., quality of life, symptom burden, dyspnea, sleep disruption), immune profiling of peripheral blood mononuclear cells, and feasibility of monitoring circulating tumor DNA (ctDNA).

Blood samples will be collected prior to durvalumab initiation, after cycle 3, and at disease progression if applicable, to assess peripheral immunophenotype and measure ctDNA levels. Imaging and quality-of-life assessments will occur at baseline, throughout treatment, and into surveillance. Participants will be followed for toxicity, progression, and 12-month survival outcomes. Recruitment is currently ongoing.

P3.18.15 Neoadjuvant and Adjuvant Chemoimmunotherapy in Resectable Stage II-IIIA NSCLC: Interim Results of a Prospective Cohort Study

Y. Xu, H. Liu
peking union medical college hospital, Beijing/CN

Introduction: Neoadjuvant and adjuvant immunotherapy combined with chemotherapy have demonstrated promising efficacy in resectable stage II-IIIA non-small cell lung cancer (NSCLC). However, the optimal timing for initiating immunotherapy remains under investigation.

Methods: This is an interim analysis of an ongoing prospective, registered clinical study (ChiCTR2200067160) conducted at a single tertiary center. Eligible patients with resectable stage II-IIIA NSCLC were enrolled between January 2023 and December 2024 and randomized via the envelope method into two groups:Neoadjuvant arm (Group 1): Four cycles of pembrolizumab (200 mg) plus paclitaxel (200 mg/m^2 or genomically guided alternative) and carboplatin (AUC 6) every 3 weeks, followed by surgery and up to one-year pembrolizumab maintenance. Adjuvant arm (Group 2): Upfront surgery followed by four cycles of adjuvant pembrolizumab plus chemotherapy (carboplatin AUC 5 + paclitaxel), and pembrolizumab maintenance for up to 1 year.Progression-free survival (PFS) was analyzed using the Kaplan-Meier method and compared using the log-rank test. Hazard ratios (HR) were estimated via Cox proportional hazards regression. The study protocol was approved by the institutional ethics board (No. I-22PJ956).

Results: As of the data cutoff (March 1, 2025), 83 patients were enrolled, and 59 were included in the intention-to-treat population (27 in Group 1; 32 in Group 2). Twenty-four patients were excluded due to protocol deviations or early withdrawal.At the time of analysis, median PFS was not reached in either group. The estimated mean PFS was 21.6 months (95% CI, 19.7-23.4) in the neoadjuvant arm and 24.6 months (95% CI, 19.5-29.6) in the adjuvant arm. The between-group difference in PFS was not statistically significant (log-rank P = 0.150). Cox proportional hazards analysis yielded a hazard ratio (HR) of 0.384 (95% CI, 0.099-1.488; P = 0.166), suggesting a non-significant trend favoring the neoadjuvant arm. Despite the longer mean PFS observed in the adjuvant group, Kaplan-Meier curves consistently showed higher PFS probabilities in the neoadjuvant group across most time points. This apparent discrepancy may be attributable to differential censoring patterns, with a higher censoring rate in the adjuvant group at later follow-up, which may have skewed mean-based estimates. Further follow-up is required to clarify long-term outcomes.

Conclusions: In this interim analysis, neoadjuvant chemoimmunotherapy demonstrated a numerical trend toward improved PFS compared to the adjuvant approach in resectable stage II-IIIA NSCLC, although the difference did not reach statistical significance. These findings are preliminary and should be interpreted with caution. Ongoing follow-up and final analysis are needed to determine the long-term efficacy of each strategy.$$graphic_{8C3EBB44-FF45-4EE1-881A-F289696AF49C}$$

P3.18.16 CROWD: Chemoradiotherapy With Surgery Followed by Consolidation Durvalumab for Initially Unresectable Stage III NSCLC

I. Houda[1], S. Senan[1], D.J. Heineman[1], M. van Dorp[1], B.I. Lissenberg-Witte[2], N. Barlo[3], A. Bressers[4], P. Plomp[5], S.M. Samii[6], O.M. Mets[2], G. Zwezerijnen[2], M.F. Fransen[1], T.D. de Gruijl[1], F. van Maldegem[1], T. Radonic[2], F.L. Schneiders[1], I. Bahce[1], C. Dickhoff[1]
[1]Amsterdam University Medical Center, location VU Medical Center, Amsterdam/NL ,[2]Amsterdam University Medical Center, Amsterdam/NL ,[3]Noordwest Ziekenhuisgroep Alkmaar, Alkmaar/NL ,[4]Rijnstate, Arnhem/NL ,[5]Isala, Zwolle/NL ,[6]Deventer Ziekenhuis, Deventer/NL

Introduction: The introduction of durvalumab consolidation therapy after chemoradiotherapy (CRT) for patients with unresectable stage III non-small cell lung cancer (NSCLC) resulted in improved overall survival, primarily attributed to enhanced distant control. Additional improvements in locoregional control could lead to better survival outcomes. The phase IV CROWD trial aims to evaluate the feasibility of post-CRT surgery for locoregional control in patients who were initially considered to have unresectable stage III NSCLC.

Methods: This single-center, phase IV feasibility trial conducted at Amsterdam University Medical Center (AUMC, The Netherlands) will enroll adult patients presenting with initially unresectable stage III NSCLC who are planned for definitive CRT followed by consolidation durvalumab. After CRT completion, eligible patients will be re-evaluated for resectability by the multidisciplinary AUMC thoracic oncology tumor board (MDT). If considered resectable, patients will undergo surgery at AUMC followed by consolidation durvalumab (Figure). Key inclusion criteria include a pathologically confirmed stage III (non-N3) NSCLC according to the 8th TNM classification (9th TNM classification: stages IIB-IIIB (excluding T2-3N0-1 or N3)) and an initial nonsurgical treatment recommendation by the referring MDT for concurrent CRT (platinum-doublet, 60 Gy in 30 fractions of 2 Gy once daily) followed by durvalumab. Key exclusion criteria include N3 or M1 disease, tumors with known actionable genomic alterations, and the use of any CRT schemes other than a platinum-doublet and 60 Gy in 30 fractions. After completion of CRT, an 18F-FDG PET/CT-scan and brain-MRI will be performed for restaging. Resectability is considered during MDT discussion in AUMC attended by dedicated thoracic radiologists, nuclear physicians, at least 2 thoracic surgeons, and other specialists. The co-primary study endpoints are safety and the proportion of patients able to proceed to durvalumab. Safety will be assessed by the proportion of patients with severe surgical morbidity and mortality (Clavien-Dindo grades 3-5) and grades 3-5 treatment-related adverse events within 90-days of surgery. With 38 evaluable patients, this study will have 80% power at a one-sided significance level of 0.05 to prove starting durvalumab consolidation after CRT plus surgery is non-inferior (non-inferiority margin of 20%) against a reference of 57% of patients that start with durvalumab after CRT alone (Ronden M et al. JTO-CRR 2021). Secondary endpoints are complete surgical resection (R0) rates and disease-free survival at two years.

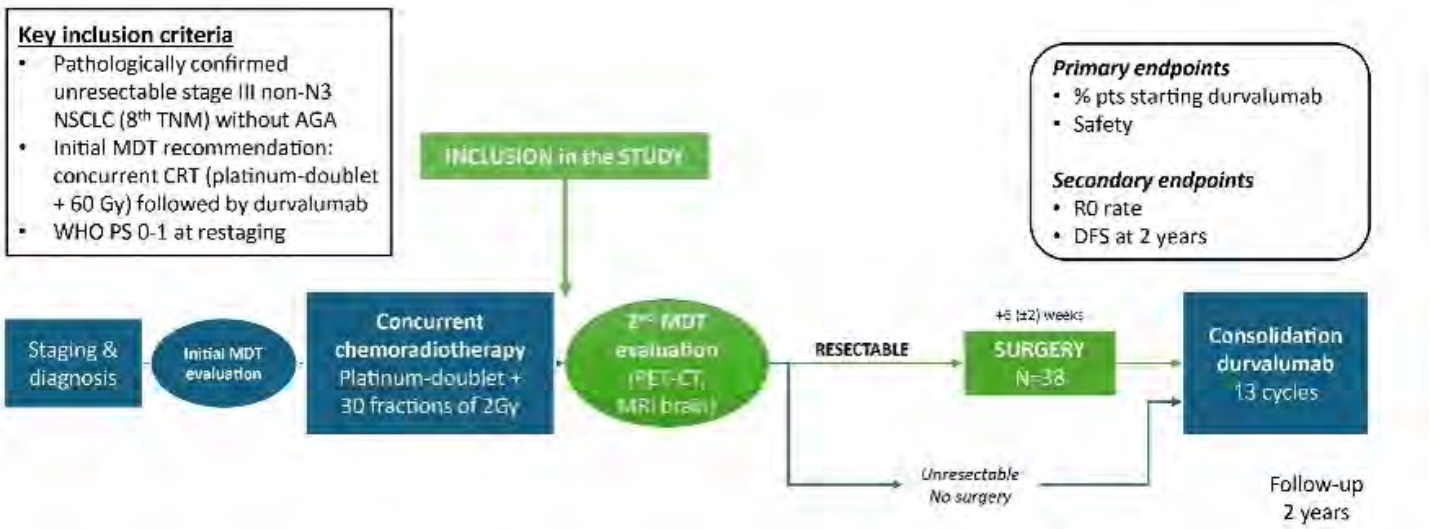

Figure. CROWD study design: Chemoradiotherapy with surgery followed by consolidation durvalumab for initially unresectable stage III NSCLC, a single-arm phase IV feasibility trial

Results:

Conclusions: The first subject was enrolled in December 2024. Primary completion is anticipated in March 2027.

P3.18.17 Neoadjuvant Chemoimmunotherapy With Immunosensitizing Radiation for Borderline Resectable Non-Small Cell Lung Cancer (NeoRADjuvant)

S. Rosner[1], S.J. Stewart[2], K. Sun[1], D. Shu[1], C. Eggleston[2], K. Scilla[1], Z. Rana[2], S. Wimbush[2], E. Krause[2], M. Egyud[2], A. Krupnick[2], R. Mehra[1], T.K. Owonikoko[1], M. Ferris[2]
[1]University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore/MD/USA ,[2]University of Maryland School of Medicine, Baltimore/MD/USA

Introduction: Neoadjuvant and perioperative chemoimmunotherapy have become the new standard of care for resectable NSCLC without targetable activating mutations in the EGFR/ALK genes, demonstrating significant improvements in pathologic response, event-free survival and overall survival compared to chemotherapy alone. Despite these advancements, ~50% of patients still suffer tumor recurrence within 48 months of surgery, highlighting the need for novel therapeutic approaches. Ongoing efforts seek to augment immune responses and expand benefit to a greater proportion of patients, including strategies for patients with "borderline" resectable disease. Prior studies have evaluated the synergistic role of sub-ablative (8 Gy x 3 fractions) radiation with immune checkpoint blockade, exhibiting encouraging rates of pathologic regression in patients with resectable NSCLC. The NeoRADjuvant study is a phase I trial designed to evaluate the safety, tolerability and preliminary efficacy signal of sub-ablative radiation combined with neoadjuvant chemoimmunotherapy for patients with borderline resectable disease.

Methods: Single-arm, phase I study, planning to enroll up to 18 eligible participants with borderline resectable EGFR/ALK wild-type NSCLC. Patients will receive sub-ablative radiation to the primary tumor (8 Gy x 3 fractions) followed by three cycles of histology specific platinum-doublet chemotherapy and nivolumab. Borderline resectable will be defined as the presence of one or more of the following features: mediastinal invasion, multi-station or bulky N2 disease, contralateral hilar/mediastinal N3 involvement, and/or initial extent of surgery deemed outside the range of a patient's baseline pulmonary function without undergoing tumor downstaging following neoadjuvant therapy. Patients will proceed to definitive treatment within 6 weeks of the last dose of systemic therapy, consisting of either surgical resection if deemed resectable post neoadjuvant chemo-radioimmunotherapy or concurrent chemoradiotherapy and then maintenance immune checkpoint blockade. The primary endpoint of this study is to assess the tolerability of this strategy, with key secondary endpoints being safety and efficacy measured by pathologic response and rate of resection. Surgical outcomes for those patients who undergo definitive resection after neoadjuvant therapy will be reported. Proposed correlate analyses will evaluate circulating tumor DNA (ctDNA) dynamics and minimal residual disease testing as predictors of recurrence after definitive therapy. Spatial transcriptomic profiling on pre- and available post-treatment specimens in resected tumors will be performed to identify patterns of response and resistance to neoadjuvant therapy.

Introduction: Stage III unresectable non-small cell lung cancer (NSCLC) represents a heterogeneous group, for which consolidation immunotherapy with durvalumab, after chemo-radiotherapy, is currently considered the standard of treatment by all national and international guidelines, based on data from the PACIFIC trial. Regarding adverse reactions, pulmonary toxicities represent the most difficult to diagnose and manage.

Methods: It is planned to include 123 patients at 28 sites in Southern Italy experiencing lung cancer in this observational study. The recruitment phase is scheduled to last 24 months (from October 1, 2024, to October 1, 2026) and the follow-up phase is scheduled to last 24-36 months after durvalumab discontinuation. Retrospective data collection can be considered from 09/01/2023. The duration of the study will be 60 months. We propose to estimate the incidence and grading of pulmonary toxicity from radiation therapy and immunotherapy, according to Common Terminology Criteria for Adverse Events (CTCAE) v5.0 and to investigate the correlation of pulmonary toxicity with pulmonary function tests (PFTs), with a particular focus on forced expiratory volume in one second (%FEV1) and forced vital capacity (%FVC) based on spirometry, diffusing capacity of the lung for carbon monoxide (%DLCO), partial pressure of arterial oxygen (PaO2) based on arterial blood gas (ABG) sampling and maximal distance that patients can walk at their own pace in 6 minutes and minimal oxygen saturation (SpO2) during the 6-minute walking test (6MWT). Pulmonary function tests (basal spirometry, DLCO, 6MWT, ABG) are evaluated at Time 0 (baseline), at Time 1 (post- RT), at Time 2 (after 6 cycles of immunotherapy) and at Time 3 (end of treatment). At data cut-off (31 mar 2025), 45 patients were enrolled and 10 patients were screened failure. Patients were predominantly male (71%) and were a median age of 67 years (range, 49-78 years) and a median PS ECOG of 0 (0-2). 26 of lung cancer cases were adenocarcinoma, 17 cases were squamous-cell carcinoma; 2 subtypes were reported as NSCLC, NOS (not otherwise specified) and as NSCLC with sarcomatoid features. Regarding smoking habits and pre-existing lung diseases, 24 patients (53,3%) were active smokers and 20 patients (44.4%) were previous smokers (p/y 25 - 110); 40% of patients had diagnosis of COPD at baseline. Of 45 patients evaluated at baseline, 19 patients were evaluated also after thoraco-mediastinal RT, 7 patients after 6 administrations of durvalumab. Among the 45 patients enrolled, there were 7 cases of pulmonary toxicity (15.5%). All of the cases showed post-actinic pneumonia (4 cases of grade 2, 2 cases of grade 3 and one case of grade 4 pneumonia).

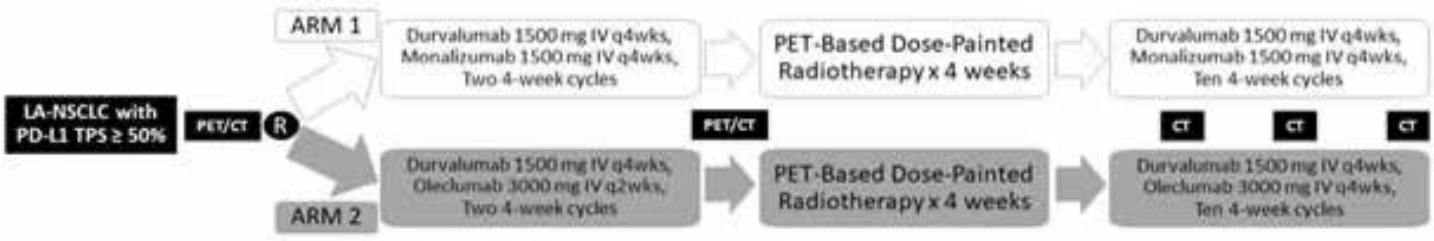
P3.18.19 The Selective Personalized Radio-Immunotherapy for Locally Advanced NSCLC Trial 2 (SPRINT2)

N. Ohri[1], E. Cali Daylan[2], H. Cheng[1], A. D'Aiello[1], B-H. Rhieu[1], B. Stiles[1], B. Halmos[1]
[1]Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA ,[2]Washington University in St Louis, Saint Louis/MO/USA

Introduction: In the Selective Personalized Radio-Immunotherapy for locally advanced NSCLC Trial (SPRINT), patients with locally advanced NSCLC (LA-NSCLC) with PD-L1 tumor proportion score (TPS) of ≥50% were treated with induction pembrolizumab, followed by a 20-fraction course of risk-adapted thoracic radiotherapy, followed by consolidation pembrolizumab to complete a 1-year treatment course. This treatment regimen was found to be safe and effective, warranting further study of chemotherapy-free treatment approaches for LA-NSCLC. Additionally, response to induction immunotherapy on FDG-PET, which was observed in 48% of participants, was identified as a promising surrogate endpoint for long-term clinical outcomes. Durvalumab (D) is a PD-L1 antagonist with established activity in NSCLC. Monalizumab and oleclumab are emerging immunotherapeutic agents being developed for the treatment of NSCLC and other malignancies. We hypothesize that dual-agent immunotherapy with durvalumab and either monalizumab or oleclumab will enhance the efficacy of the SPRINT approach.

Methods: Fifty-two patients with a new diagnosis of unresectable stage II or stage III NSCLC and PD-L1 TPS ≥50% will be enrolled on this randomized phase II trial. Participants will be stratified by PD-L1 TPS and disease stage and randomized 1:1 to receive dual-agent immunotherapy with durvalumab + monalizumab or durvalumab + oleclumab. Participants will receive two 4-week cycles of induction immunotherapy, followed by response assessment with FDG-PET. Participants will then receive a 20-fraction course of risk-adapted radiotherapy, where lesions with metabolic tumor volume exceeding 20 cc on FDG-PET receive a dose of 55 Gy, while smaller lesions receive a dose of 48 Gy. Participants will then receive 10 additional cycles of dual-agent immunotherapy. The primary study endpoint is response on FDG-PET after induction immunotherapy, evaluated using PERCIST criteria. Other endpoints include progression-free survival, overall survival, clinician- and patient-reported adverse events, and physical activity metrics captured using wearable devices.



Keywords: locally advanced non-small cell lung cancer, radiotherapy, immunotherapy

P3.18.20 PELAGOS: Integrating Surgery and Radiotherapy in EGFR-Mutant N3-Stage III NSCLC After Conversion Therapy

A. Li, J. Yu, S. Mu, H. Liu
Cancer Hospital of China Medical University, Liaoning Cancer Hospital & Institute, Shenyang/CN

Introduction: The LAURA trial demonstrated a significant improvement in progression-free survival (PFS) for patients with EGFR-mutant, unresectable stage III non-small cell lung cancer (NSCLC), reporting a median PFS of 39.1 months and 2-year PFS rate of 65%. Additionally, the ADAURA trial demonstrated that adjuvant osimertinib effectively reduces the incidence of distant metastasis in stage IB-IIIA NSCLC from 31% to 13% following surgical resection. Similarly, findings from the POLESTAR study on almonertinib, a third-generation EGFR-TKI, showed promising efficacy in reducing CNS progression and distant metastasis of unresectable stage III NSCLC. Emerging evidence suggests that intrathoracic recurrence represents a major cause of disease progression in stage III NSCLC. This concern is particularly pronounced in more advanced cases, such as stage III disease with N3 involvement (part of IIIB and IIIC), where the optimal treatment strategy remains undefined. To address these challenges, this study evaluates a multimodal approach combining surgery and radiotherapy after induction therapy with almonertinib and chemotherapy, followed by consolidative almonertinib. This approach aims to enhance local disease control and improve survival outcomes in patients with N3 involvement stage III EGFR-mutant NSCLC.

Methods: This is a prospective, multicenter, single-arm phase II clinical trial enrolling 30 treatment-naïve patients with N3 lymph node-positive stage III-NSCLC harboring EGFR mutations (T1-4N3M0, AJCC 9th edition). Eligible patients must be aged ≥18 years, have an Eastern Cooperative Oncolgy Group (ECOG) performance status of 0 or 1, and possess at least one measurable lesion per RECIST 1.1 criteria at baseline. Key exclusion criteria include invasion of critical structures such as the aorta, trachea, esophagus, or heart by the primary tumor or metastatic lymph nodes, as well as the presence of Pancoast tumors. Following induction therapy with three cycles of almonertinib combined with chemotherapy, patients without disease progression will be evaluated by a multidisciplinary team (MDT) and assigned to treatment strategies based on eligibility and patient preference. Patients deemed suitable for surgery will undergo standard lung cancer resection (excluding total pneumonectomy), including removal of the primary tumor and ipsilateral hilar and mediastinal lymph nodes, followed by hypofractionated radiotherapy targeting N3 metastatic lymph nodes concurrent with almonertinib. Patients who are ineligible for or undergo surgery will receive concurrent chemoradiotherapy. After completing local treatment, all patients will continue maintenance therapy with almonertinib until radiographic disease progression, unacceptable toxicity, or completion of one year of treatment. The primary endpoint is the 1-year event-free survival rate (1y-EFS). Secondary endpoints include event-free survival (EFS), overall survival (OS), surgical conversion rate, time to distant metastasis (TTDM), time to local recurrence (TTLR), adverse events (AEs), and the impact of the integrated treatment approach on patient-reported outcomes (PROs). Exploratory analyses will investigate predictive and prognostic biomarkers using tumor tissue and blood samples collected at multiple time points throughout the study. The study protocol was approved by the Ethics Committee of Liaoning Cancer Hospital & Institute (Approval No. 2025302), and written informed consent was obtained from all participants. This trial is prospectively registered with the Chinese Clinical Trial Registry (ChiCTR2400093459).

P3.18.21 Durvalumab (D) and Chemotherapy Followed by Either Surgery + D or Chemoradiotherapy + D in Borderline Resectable Stage III NSCLC

Y. Wang[1], G. Zhang[1], R. Li[1], N. Bi[1], F. Tan[1]
[1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Immunotherapy as a component of perioperative treatment has demonstrated survival benefit in resectable non-small-cell lung cancer (NSCLC). Immunotherapy with chemoradiotherapy also showed improvement of outcome for unresectable stage III NSCLC. While the exploration of treatment paradigm for borderline resectable stage III NSCLC is limited.

Methods: This is a multicenter, phase II study assessing the efficacy and safety of neoadjuvant durvalumab and platinum-based chemotherapy, given intravenously, followed by either surgery and adjuvant durvalumab or definitive CRT and consolidation durvalumab in borderline resectable stage III EGFR/ALK wild type NSCLC. Approximately 80 eligible patients will be assessed by multidisciplinary team (MDT), receive two cycles of neoadjuvant durvalumab and platinum-based chemotherapy, then re-assessed by MDT. Patients assessed as having resectable tumors will receive a maximum of 2 cycles neoadjuvant durvalumab and platinum-based chemotherapy (CT) followed by surgery and adjuvant durvalumab for one year (Cohort 1). Patients with tumors deemed unresectable will receive definitive CRT and consolidation durvalumab for one year (Cohort 2). Cross over is allowed if patients were still unresectable after receiving one or two more cycles neoadjuvant durvalumab and platinum-based Chemotherapy. The primary objective is to assess the efficacy of neoadjuvant durvalumab + CT in terms of resection rate in all patients. The secondary objectives include: to assess the efficacy of neoadjuvant durvalumab + CT in terms of pathological complete response (pCR) in cohort 1; to assess the efficacy of neoadjuvant durvalumab + CT followed by definitive CRT and consolidation durvalumab in terms of progression-free survival (PFS) in cohort 2; to assess the efficacy of neoadjuvant durvalumab + CT in terms of objective response rate (ORR) and the efficacy of neoadjuvant durvalumab + CT followed by surgery and then adjuvant durvalumab or definitive CRT and then consolidation durvalumab in terms of event-free survival (EFS).

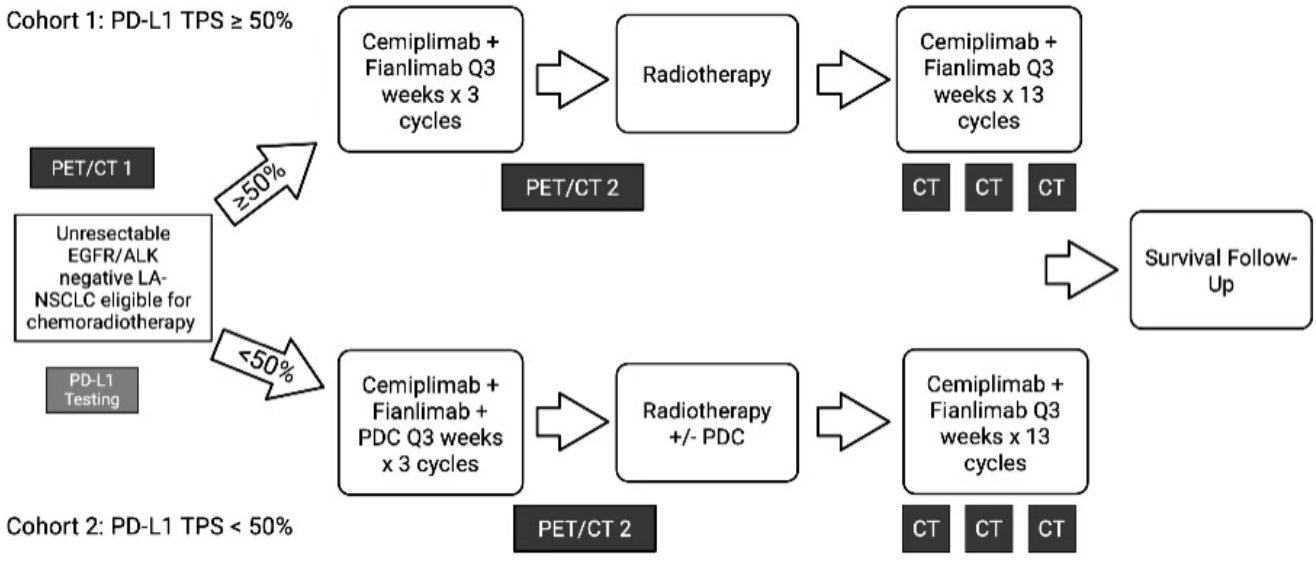
P3.18.22 TRIPL: Thoracic Radiotherapy and Inhibition of PD-1 and LAG-3 for Locally Advanced Non-Small Cell Lung Cancer

A. D'Aiello, H. Cheng, B. Stiles, Y. Saenger, B. Halmos, N. Ohri
Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA

Introduction: SPRINT (NCT03523702) was a multi-center Phase II trial where biomarker-selected (PD-L1 TPS ≥ 50%) locally advanced non-small cell lung cancer (LA-NSCLC) patients were treated with 3 cycles of induction therapy with the PD-1 inhibitor pembrolizumab followed by risk-adapted radiotherapy (RT), then consolidation pembrolizumab to complete a 1-year course while chemotherapy was omitted (PMID: 37988638). The study met its efficacy objectives demonstrating a 1-year progression-free survival (PFS) rate of 76%, 1-year overall survival (OS) rate of 92%, and exploratory analyses suggest that PET response to induction pembrolizumab predicts treatment outcomes best, with a median PFS of 42 months for PET responders. SPRINT demonstrated high treatment efficacy with limited toxicity and introduces PET response to induction immunotherapy (IO) as a novel endpoint allowing for early assessment of treatment activity. An additional advantage of this approach is the ability to clearly evaluate the contribution of treatment components.

Given the promising findings of SPRINT, we now pursue this treatment approach (induction IO followed by RT and consolidation IO) to investigate other novel IO combinations for biomarker-selected LA-NSCLC. One such target is lymphocyte activation gene 3 (LAG-3), which is expressed by immune cells and regulates effector T-cell activation and responses. Thus, we hypothesize that dual IO with the PD-1 inhibitor cemiplimab plus the LAG-3 inhibitor fianlimab administered before and after thoracic RT, as per the SPRINT approach, has valuable potential as a biomarker-driven treatment regimen for LA-NSCLC patients.

Methods: This Phase II study will enroll a total of 76 participants, with at least 32 participants in each of the two cohorts including LA-NSCLC patients with PD-L1 TPS ≥ 50% (Cohort 1) and those with PD-L1 TPS < 50% (Cohort 2). Treatment will be administered in three phases: (1) 3 cycles of induction IO, with histology-specific platinum doublet chemotherapy (PDC) added for subjects with PD-L1 TPS < 50%; (2) risk-adapted thoracic RT (with concurrent PDC recommended for those PD-L1 TPS < 50%); (3) 13 cycles of consolidation IO. The primary endpoint will be objective response rate (ORR) on PET scan via PERCIST criteria following induction IO with 3 cycles of cemiplimab plus fianlimab. Safety will be assessed via a safety-run in phase and extended adverse events collection. Additional endpoints will include ORR on CT, PFS, OS, quality of life assessments, and exploratory analyses focused on tissue and blood-based immune effector signatures.



LA-NSCLC: locally advanced non-small cell lung cancer

PDC: histology-specific platinum-doublet chemotherapy

P3.18.23 Management of Synchronous Oligometastatic NSCLC With Surgical Resection of the Primary Tumor: Preliminary Results From the Prospective Trial

P. Karatkevich, S. Pivavarchyk, V. Malkevich, S. Krasny
N.N. Alexandrov National Cancer Center of Belarus, Minsk Region/BY

Introduction: Lung cancer ranks among the leading causes of mortality in oncology patients. In the Republic of Belarus, 4,401 new cases of lung cancer were diagnosed in 2023. The standardized incidence and mortality rates were 48.0 and 31.4 per 100,000 population, respectively. Results from several studies have demonstrated the benefits of local consolidation therapy in patients with oligometastatic cancer compared to traditional chemotherapy approaches. Since there is currently no established optimal multimodal treatment strategy, we initiated a prospective non-randomized single-arm phase 2 study at our center.

Methods: The patients with pathologically confirmed oligometastatic NSCLC (T1-3N0-2M1a-c) without activating mutations in EGFR, ALK, ROS1, or BRAF, were included in the study. Patients were selected based on EORTC criteria: number of distant metastases: 1-5; number of metastatic site: 1-3; feasibility of local treatment for all tumor sites. Disease spread was assessed using FDG PET-CT and contrast-enhanced brain MRI. The therapeutic regimen initiates with two cycles of platinum-based induction chemotherapy, followed by surgical resection of the primary tumor and local consolidation therapy for distant metastases. The protocol concludes with two cycles of adjuvant chemotherapy. The protocol prohibits sublobar resections and mandates systematic lymph node dissection in all cases. For patients with brain metastases, treatment initiates with local management of cranial lesions using one of the following approaches: surgical resection, Gamma Knife radiosurgery, or a combination of both modalities.

Results: Since 01.01.2021, 32 patients were enrolled: 18 with brain metastases and 14 with extracranial metastases (adrenal gland [n=2], liver [n=3], bones [n=7], skin and soft tissue [n=2]). Adenocarcinoma was confirmed in 22 (68.7%) patients, while 10 (31.3%) had squamous cell carcinoma. 17 (53,1%) patients showed no regional lymph node involvement (N0). Bronchopulmonary lymph node involvement (N1) was confirmed in 4 (12.5%) cases, and mediastinal lymph node involvement (N2) in 11 (34.4%) patients. Metastatic burden distribution: 20 (62.5%) patients had 1 metastasis, 9 (28.1%) patients had 2 metastases, 3 (9.3%) patients had 3 or more distant metastases. The majority of patients (93.8%, n=30) presented with single metastatic site. Following induction chemotherapy, assessment by RECIST 1.1 criteria revealed partial response in 6 patients (21.4%), stable disease in 20 patients (71.4%), and disease progression in 2 patients (7.1%). Twenty-seven patients underwent surgical resection of the primary tumor: 21 lobectomies (77.8%) and 6 pneumonectomies (22.3%), including 10 VATS procedures (37%). Pathological assessment according to IASLC criteria identified PCR in 2 patients and MPR in 7 patients. The treatment regimen demonstrated satisfactory tolerability with no mortality events observed. Median event-free survival (EFS) was 12.0 months (95% CI 8.3-19.7), with median overall survival (OS) reaching 34.0 months (95% CI 20.6-53.0).

Conclusions: The multimodal treatment approach incorporating induction chemotherapy, primary tumor resection, local therapy for distant metastases, and adjuvant chemotherapy demonstrated satisfactory tolerability. Interim analysis of long-term outcomes reveals superior survival rates compared to historical controls.

P3.18.24 A Multicenter, Open Label, Dual Cohort Study: The Efficacy and Safety of Vinorelbine Combined With a First-Line Treatment for Metastatic NSCLC

Y. Yao, X. Liang, Z. Ruan, T. Tian
The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an/CN

Introduction: Lung cancer is the leading cause of cancer-related mortality worldwide. The vinorelbine-cisplatin (NP) regimen has been established as a standard chemotherapy option for advanced non-small cell lung cancer (NSCLC). However, while contemporary first-line treatment paradigms have increasingly incorporated pemetrexed- or taxane-based regimens combined with immune checkpoint inhibitors (ICIs), clinical evidence supporting vinorelbine-based immunotherapy combinations remains scarce. The phase II VinMetAtezo trial provided preliminary insights, demonstrating that metronomic oral vinorelbine combined with atezolizumab, though failing to meet its primary PFS endpoint, maintained an acceptable safety profile with no new toxicity signals. These observations warrant further exploration of vinorelbine-ICI combinations, particularly in the first-line treatment setting where alternative chemoimmunotherapy options are needed. This trial employs a two-stage design to evaluate the efficacy and safety of the NP regimen (vinorelbine plus platinum) in combination with a PD-1 inhibitor, with or without bevacizumab, as a potential first-line therapeutic strategy for metastatic non-squamous NSCLC.

Methods: This multicenter, open-label, dual-cohort trial plans to enroll 87 treatment-naïve patients with metastatic NSCLC lacking actionable driver gene mutations, across 3-5 Chinese centers. Inclusion criteria were: patients with metastatic non-squamous NSCLC without driver gene mutations, has not receive systemic anti-cancer therapy, the occurrence of metastatic disease must be at least 12 months after completion of adjuvant/neoadjuvant treatment, age 18-65 years, ECOG PS 0-1, life expectancy >12 weeks; adequate laboratory-test-documented organ-function results during screening; effective contraception for women of child-bearing potential; available archival tumor tissue or willingness to undergo fresh biopsy, and written informed consent to participate. The main exclusion criteria for both cohorts were: squamous NSCLC, small cell lung, or neuroendocrine cancer; known hypersensitivity to study drugs; currently participating in another clinical trial; received other anti-tumor therapy, major surgery <4 weeks before first dose, lung radiation therapy >30 Gy within 6 months before the first dose, palliative radiotherapy within 7 days before the first dose, live virus vaccination within 30 days before the first dose; active or untreated CNS metastases during screening; uncontrolled pleural effusion, pericardial effusion, ascites requiring recurrent drainage procedures; autoimmune disease; HIV or HBV/HCV positivity; systemic corticosteroid up to 10 mg/day or other systemic immunosuppressant use during the 2 weeks preceding study enrollment; anticipated need for systemic immunosuppressant(s) during the trial; any other severe medical condition that may limit study participation. The exclusion criteria for cohort 2 were: patients with gastrointestinal perforation prior to the first dose or a history of gastrointestinal perforation within 1 year; history of ≥ Grade 2 hemoptysis, laparotomy, thoracotomy, or enterectomy within 28 days prior to the first dose; non-healed wounds; current or recent thromboembolic or cerebrovascular events; hemorrhagic predisposition, coagulation disorders; proteinuria >2+ on dipstick. The study design will be as follows: vinorelbine (60mg/m2 d1, q3w) and cisplatin (75mg/m2 d1, q3w) in combination with Sintilimab (200mg d1, q3w) with/without Bevacizumab (15mg/kg d1, q3w). Patients will be treated until disease progression. Primary endpoint: objective response rate of NP combined with Sintilimab with/without Bevacizumab. Secondary endpoints: efficacy, safety and quality of life. Exploratory endpoint: circulating tumor DNA dynamics and correlation with outcomes.

Keywords: vinorelbine, non-small cell lung cancer, PD-1 inhibitor

P3.18.25 Phase 2 Study of Carboplatin Plus Nab-Paclitaxel Rechallenge for NSCLC With Interstitial Lung Disease: TORG2442/CASTLE Study

T. Itoh[1], G. Saito[1], K. Takahashi[2], Y. Hosomi[3], H. Okamoto[4], T. Suzuki[1]
[1]Graduate School of Medicine, Chiba University, Chiba/JP ,[2]Chiba University Hospital, Chiba/JP ,[3]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/JP ,[4]Yokohama Municipal Citizen's Hospital, Kanagawa/JP

Introduction: Interstitial lung disease (ILD), characterized by inflammation and fibrosis of the pulmonary interstitium, is one of the most common comorbidities in patients with non-small cell lung cancer (NSCLC) and is associated with a poor prognosis. The presence of ILD is considered a risk factor for drug-induced lung injury, and outcomes are particularly poor in cases of acute exacerbation of ILD. Although treatment strategies using agents with a lower risk of ILD exacerbation are warranted, patients with ILD are frequently excluded from pivotal clinical trials, and no standard second-line treatment has been established. The combination of carboplatin and nab-paclitaxel is recognized as a standard first-line regimen, and the platinum rechallenge strategy in NSCLC has been suggested as an effective treatment approach based on pooled analyses. Taken together, rechallenge with carboplatin plus nab-paclitaxel is considered a potentially effective and relatively safe therapeutic option for NSCLC with ILD.

Methods: This multicenter, single-arm, phase 2 study will enroll 32 patients with NSCLC and idiopathic ILD previously treated with carboplatin plus nab-paclitaxel. Key eligibility criteria are as follows: patients aged ≥18 years; those with histologically or cytologically confirmed advanced (unresectable stage III or IV) or recurrent NSCLC; and those diagnosed with idiopathic ILD based on high-resolution computed tomography. Patients must have experienced disease progression after receiving 4 to 6 cycles of first-line chemotherapy (carboplatin plus nab-paclitaxel), with a time interval of ≥ 90 days between the last administration of carboplatin and relapse. Eligible patients must also have measurable lesions according to RECIST v1.1 and an ECOG performance status of 0 or 1. Patients with a history of acute exacerbation of ILD, prior thoracic radiotherapy, steroids use of >10mg/day of prednisolone equivalent within 14 days before registration, or symptomatic central nervous system metastases are ineligible. Patients will receive carboplatin (area under the curve 6, on day 1) and nab-paclitaxel (100 mg/m2, on day 1, 8 and 15) of every 4 weeks for 4 to 6 cycles. Tumor imaging will be performed every 6 weeks from registration. Adverse events will be graded according to CTCAE v5.0. ILD imaging evaluations will be conducted by an independent central review, ensuring the diagnostic quality of ILD, classification of ILD imaging patterns, and accurate diagnosis of acute exacerbation of ILD. The primary endpoint is 3-month progression-free survival without acute exacerbation of ILD rate (3m PFS without AE-ILD rate). Progression-free survival without acute exacerbation of ILD (PFS without AE-ILD) is defined as the time from registration to disease progression, death, or the occurrence of acute exacerbation of ILD. Secondary endpoints include objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), PFS without AE-ILD, safety and tolerability. Patients enrollment will begin in April 2025. This study has been registered in the Japan Registry of Clinical Trials, jRCTs031240743.

P3.18.27 An Exploratory Clinical Study of TROP2 ADC SHR-A1921 Combined With Adebrelimab for Advanced NSCLC After Failure of First-line Standard Therapy

C. Su[1], M. Xie[1], L. Liu[1], C. Zhao[2]
[1]Shanghai Pulmonary Hospital & Thoracic Cancer Institute, Tongji University School of Medicine, Tongji University, Shanghai/CN ,[2]Department of Clinical Research and Development, Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China, shanghai/CN

Introduction: Following first-line standard therapy, nearly all patients with advanced non-small cell lung cancer (NSCLC) experience disease progression due to treatment resistance. There is an urgent need to explore safer and more effective second-line treatment strategies beyond single-agent chemotherapy to address resistance after first-line immunotherapy.Antibody-drug conjugates (ADCs), composed of monoclonal antibodies linked to cytotoxic payloads, represent a novel therapeutic approach. Trophoblast cell-surface antigen 2 (TROP2), a transmembrane glycoprotein, plays a critical role in embryonic development and tumor cell proliferation, invasion, and metastatic dissemination.Combining ADCs with PD-1/PD-L1 inhibitors may yield synergistic efficacy, though such combinations remain underexplored in second-line settings. This study aims to evaluate the efficacy and safety of TROP2 ADC (SHR-A1921) combined with PD-L1 inhibitor adebrelimab in patients with advanced NSCLC who progressed after first-line standard therapy.

Methods: This prospective, single-arm, phase II clinical trial (NCT06480136) enrolls patients with advanced oncogenic driver negative NSCLC (stage IIIB-IV per IASLC 8th edition TNM staging) who had progressed after first-line immunotherapy combined with chemotherapy. Participants will receive SHR-A1921 (3 mg/kg, IV, Q3W) plus adebrelimab (1200 mg, IV, Q3W) until disease progression, intolerable toxicity, withdrawal of consent, or other discontinuation criteria (whichever occurs first). Adebrelimab will be administered for a maximum of 35 cycles or 2 years (whichever comes first), after which patients may continue SHR-A1921 monotherapy until discontinuation criteria are met. The primary objective of this study is to evaluate the efficacy of the combination. Secondary objective is to evaluate the safety. And the exploratory objective is to evaluate the dynamic change of biomarkers during treatment. Enrollment began on July 8, 2024, and the study is ongoing.

Introduction: Pembrolizumab plus chemotherapy is a standard of care, first-line therapy for patients with metastatic non-small-cell lung cancer (NSCLC) with no targetable genetic mutations. Despite advances in treatment for this patient population, there remains an unmet need. Patritumab deruxtecan (HER3-DXd) is an investigational antibody-drug conjugate (ADC) against human epidermal growth factor receptor 3 (HER3), conjugated with a topoisomerase I inhibitor payload, resulting in apoptosis of target cells. HER3 has been shown to be expressed in NSCLC tumors, with an association between HER3 expression and a shorter time to progression. The addition of ADCs to immune checkpoint inhibitors has shown promising antitumor activity. The ongoing phase 1/2 KEYMAKER-U01 umbrella study (NCT04165798) is evaluating investigational agents in combination with pembrolizumab, with or without chemotherapy. We present the study design for KEYMAKER-U01 substudy 01G (NCT06731907), which is evaluating pembrolizumab in combination with HER3-DXd, with or without platinum-based chemotherapy, in previously untreated participants with stage IV NSCLC.

Methods: In this phase 2, rolling-arm, multicenter, open-label, signal-finding substudy, eligible participants are aged ≥18 years with previously untreated stage IV squamous or nonsquamous NSCLC (per American Joint Committee on Cancer v8) with measurable disease per RECIST v1.1 by investigator (verified by blinded independent central review [BICR]) with no EGFR, ALK, or ROS1 alterations, and ECOG PS of 0 or 1. Participants will be randomly assigned 1:2 to Arm 1 and Arm 2, and the number of participants with nonsquamous NSCLC will be limited to 70% per treatment arm. Participants in Arm 1 will receive pembrolizumab 200 mg IV Q3W up to 35 cycles with carboplatin area under the curve 5 mg/ml/min (nonsquamous histology) or 6 (squamous) IV Q3W for 4 cycles, and either paclitaxel 200 mg/m2 IV Q3W or nab-paclitaxel 100 mg/m2 IV QW for squamous histology, or pemetrexed 500 mg/m2 IV Q3W for nonsquamous histology. Participants in Arm 2 will receive pembrolizumab 200 mg IV Q3W up to 35 cycles with HER3-DXd 5.6 mg/kg IV Q3W. Participants can receive HER3-DXd until progressive disease or unacceptable toxicity. Randomization will be stratified by histology (squamous vs nonsquamous) and PD-L1 tumor proportion score (<50% vs ≥50%). The primary objectives are ORR per RECIST v1.1 by BICR, AEs, and treatment discontinuation due to AEs. The secondary objectives are duration of response and PFS per RECIST v1.1 by BICR, and OS. Enrollment for this study will be ongoing globally.

Keywords: Patritumab deruxtecan (HER3-DXd), metastatic non–small-cell lung cancer, antibody-drug conjugate

P3.18.29 NAPISTAR 1-01: An International Phase I/II Trial of the Novel ADC TUB-040 in Advanced/ Metastatic NSCLC Adenocarcinoma

A. Starodub[1], I. Ruiz Gutierrez[2], V. Boni[3], H. Scharpenseel[4], J. Spicer[5], A. Spira[6], E. Wauters[7], J. Wolf[4], L. Ruge[4], Y. Houvras[8], G. Fingerle-Rowson[8], I. Vasconcelos[8], S. Sen[9], I. Eguren Santamaria[2], S. Ochsenreither[10]
[1]The Christ Hospital, Cincinnati/OH/USA ,[2]Clinica Universidad de Navarra, Madrid/ES ,[3]Next Oncology, Madrid/ES ,[4]Center fro Integrated Oncology, University of Cologne, Cologne/DE ,[5]Kings College, London/GB ,[6]Next Oncology, Fairfax/VA/USA ,[7]Department of Pulmonology, UZ Leuven, Leuven/BE ,[8]Tubulis GmbH, Planegg/DE ,[9]Next Oncology, Dallas/TX/USA ,[10]Charite University Hospital, Berlin/DE

Introduction: NaPi2b, encoded by SLC34A2, is a sodium-dependent phosphate transporter that is overexpressed in various cancers, with particularly high levels of expression in non-small cell lung cancer (NSCLC) adenocarcinomas. This clinically validated antigen is targeted by TUB-040, a next-generation antibody-drug conjugate (ADC). TUB-040 combines a NaPi2b-specific, Fc-silenced monoclonal antibody with exatecan, a potent topoisomerase-I inhibitor with a robust bystander effect. Antibody-drug conjugation is via a cleavable dipeptide linker (P5) which enables an optimal, homogeneous and stable drug-to-antibody (DAR) ratio of 8 and prevents non-specific interactions with membranes by increasing hydrophilicity. Preclinical studies demonstrated potent anti-tumor activity, including long-lasting tumor regression at doses as low as 1 mg/kg and durable responses in tumors with low NaPi2b expression.

Methods: NAPISTAR 1-01 (NCT06303505) is an ongoing international (EU, UK, US), open-label, multicenter, Phase I/IIa study investigating the safety, tolerability, and efficacy of TUB-040 in patients with recurrent advanced or metastatic NSCLC adenocarcinoma, including those with actionable genomic alteration (AGA) that progressed after targeted therapy, and separately in patients with platinum-resistant ovarian cancer. TUB-040 is administered intravenously every three weeks (Q3W) as a monotherapy until disease progression or unacceptable toxicity. In Phase I, a stepwise dose-escalation strategy is employed using accelerated titration design (ATD), followed by a Bayesian Optimal Interval (BOIN) model to determine the maximal tolerated dose (MTD) and refine dosing as pre-defined safety parameters are met. The dose-escalation framework includes initial double-dosing steps with a 100% increment over the standard dose, transitioning to modified Fibonacci increments (67%, 50%, and 33% dose increments) with intra-patient escalation permissible at low exposure levels. Phase IIa involves the randomization of patients for dose optimization at two or more doses to further characterize the safety profile and identify the optimal therapeutic dose.

Results: This trial will identify the optimal dose for TUB-040, a first-in-class ADC targeting NaPi2b. TUB-040 offers a novel therapeutic strategy for advanced NSCLC adenocarcinoma patients with limited treatment options. The high prevalence of NaPi2b expression in adeno-NSCLC highlights the potential of TUB-040 to address this significant unmet medical need.

Conclusions:

Keywords: advanced metastatic NSCLC adenocarcinoma, ADC, NaPi2b

P3.18.30 A Phase II Clinical Study of Tafolecimab Combined With Sintilimab in the Treatment of Advanced NSCLC Who Failed the Previous Immunotherapy

M. Xie, L. Liu, C. Su
Shanghai Pulmonary Hospital & Thoracic Cancer Institute, Tongji University School of Medicine, Tongji University, Shanghai/CN

Introduction: Lung cancer has emerged as the malignancy with the highest global mortality rate, exhibiting escalating incidence and mortality worldwide. Immunotherapy represents a transformative breakthrough in oncology, particularly in non-small cell lung cancer (NSCLC), where immune checkpoint inhibitors (e.g., anti-PD-1/PD-L1 antibodies) demonstrate compelling efficacy and manageable safety profiles as monotherapy or combination regimens. However, over 60% of patients experience treatment failure due to acquired resistance despite initial response, with limited therapeutic options post-resistance. Novel strategies are urgently needed to address this clinical challenge.Tafolecimab, a recombinant fully human IgG2 anti-proprotein convertase subtilisin/kexin type 9 (PCSK9) agent, is approved for cardiovascular indications. Emerging preclinical evidence identifies PCSK9 as a potential target to enhance immunotherapy efficacy. Our prior research revealed an inverse correlation between serum PCSK9 levels and immunotherapy outcomes in NSCLC, where elevated PCSK9 predicts inferior responses. This phase II trial investigates the safety and efficacy of Tafolecimab combined with Sintilimab in advanced NSCLC patients after immunotherapy failure.

Methods: This investigator-initiated phase II trial (ChiCTR2400085872) evaluates safety, efficacy, and biomarkers of Sintilimab (200mg, iv, d1, Q3W) plus Tafolecimab (600mg, sc, d1, Q6W) in advanced NSCLC patients with prior immunotherapy failure. Enrolled patients receive combination therapy until disease progression (RECIST 1.1), intolerable toxicity, initiation of new antitumor therapy, withdrawal of consent, loss to follow-up, death, or investigator discretion, whichever occurs first. Sintilimab treatment is capped at 24 months.The primary endpoints are objective response rate (ORR) per RECIST 1.1 and safety profile. Secondary endpoints include progression-free survival (PFS), overall survival (OS), 1-year PFS rate, disease control rate (DCR), and duration of response (DOR).

Keywords: Non-small cell lung cancer, Immunotherapy, combination

P3.18.31 Phase II Study of CBDCA + Nab-PTX + Tremelimumab+Durvalumab for TTF-1 Negative Advanced non-sq NSCLC (WJOG17223L, TURNING)

M. Tachihara[1], T. Miyawaki[2], Y. Sato[3], I. Tanaka[4], H. Kaneda[5], H. Inoue[6], J. Uchida[7], T. Kijima[8], M. Shimokawa[9], I. Okamoto[10], N. Yamamoto[11]

Introduction: Thyroid transcription factor-1 (TTF-1) expression in advanced non-squamous (non-sq) non-small cell lung cancer (NSCLC) has been associated with the efficacy of pemetrexed and PD-1/PD-L1 inhibitor monotherapy. Notably, TTF-1 negative NSCLC demonstrates poor outcomes with platinum + pemetrexed + PD-1/PD-L1 inhibitor therapy, highlighting a critical need for alternative treatments. Given the high unmet need for effective therapies in TTF-1 negative NSCLC, novel treatment strategies are essential. The POSEIDON trial showed that tremelimumab plus durvalumab combined with chemotherapy significantly improved overall survival (OS) and progression-free survival (PFS) versus chemotherapy. We investigate the efficacy and safety of carboplatin (CBDCA) + nab-paclitaxel (nab-PTX) + tremelimumab + durvalumab combination therapy in untreated advanced or postoperative recurrent TTF-1 negative non-squamous (sq) NSCLC.

Methods: This multicenter, single-arm phase II trial enrolls previously untreated advanced or recurrent TTF-1 negative non-sq NSCLC patients aged ≥18 years with ECOG performance status (PS) 0-1. TTF-1 expression is evaluated by immunohistochemical staining of tumor samples at each institute. A specimen is considered TTF-1 negative if none of the tumor cell nuclei exhibit any level of immunoreactivity. Eligible patients have no sensitizing EGFR mutations or ALK rearrangements; stable, treated brain metastases are permitted. The patients receive CBDCA (AUC6, day1) + nab-PTX (100 mg/m2, day1,8,15) + tremelimumab (75 mg/body, day1) + durvalumab (1,500 mg/body, day1) induction therapy for up to four 21-days cycles followed by durvalumab (1,500 mg/body every 4 weeks) until disease progression (PD) or unacceptable adverse events. One additional tremelimumab (fifth dose) is administered at cycle 6/week 16. The primary endpoint is the 12-month PFS rate as assessed by investigators per RECISTv1.1. The secondary endpoints are PFS, OS, objective response rate, and safety. We assumed the threshold of the 12-month PFS rate to be 20% and the expected rate to be 35% with a significant level α=0.05 (one-sided) and power 0.8. The calculated sample size was 54, with a final enrollment target of 57 to account for ineligible patients. Recruitment started in February 2025 at 30 sites in Japan.

Introduction: Currently, immunotherapy in combination with chemotherapy has emerged as the first-line standard treatment for advanced non-small-cell lung cancer (NSCLC) patients with negative driver genes. Nevertheless, for these patients who develop resistance following first-line immunotherapy, the standard second-line treatment remains the chemotherapy regimen centered around docetaxel. There is no established standard recommendation regarding the continuation of immunotherapy in the second-line setting after progression during first-line immunotherapy. Both prospective studies and retrospective real-world data analyses have demonstrated that the overall disease response rate of immunotherapy combined with anti-angiogenesis therapy in the second-line and higher-line settings for the population with first-line immunotherapy resistance ranges from 7% to 30%. This study aims to explore the efficacy and safety of Tislelizumab (Tis) in combination with bevacizumab (Bev) and Nab-paclitaxel (Nab) as a second-line treatment strategy for non-squamous NSCLC patients with resistance to first-line PD-1/L1 inhibitor.

Methods: In this single-arm, prospective phase II study, a total of 46 patients with driver gene-negative NSCLC who have developed resistance following first-line immunotherapy combined with chemotherapy will be recruited. Patients who develop disease progression during the first 2 to 4 cycles of first-line treatment with PD-1/L1 inhibitor in combination with chemotherapy will be excluded. Enrolled patients will receive Tislelizumab (Tis, 200 mg, administered every 3 weeks), combined with Bevacizumab (Bev, 7.5 mg/kg, every 3 weeks) and Nab-paclitaxel (Nab, 125 mg/m^2 on day 1 and day 8, every 3 weeks) for 4 to 6 cycles. Subsequently, they will undergo maintenance therapy with Tis plus Bev until disease progression or the occurrence of intolerable toxicity, with a maximum treatment duration of 2 years. The primary endpoint is the objective response rate (ORR) based on the Recist 1.1 criteria in the intention-to-treat (ITT) population. Secondary endpoints include progression-free survival (PFS), overall survival (OS), disease control rate (DCR), duration of response (DOR), and safety (evaluated according to CTCAE 5.0). The trial recruitment (ChiCTR2500099531) is currently ongoing.

P3.18.33 Intrapleural Anti-PD-1 Antibody for the Treatment of Advanced Non-Small Cell Lung Cancer With Malignant Pleural Effusion

P. Zhan, Y. Cui
Affiliated Hospital of Medical School, Nanjing University, Nanjing/CN

Introduction: The presence of malignant pleural effusion (MPE) remains a challenge in clinical treatment. This study aimed to evaluate the safety and efficacy of intrapleural administration of anti-programmed cell death 1 (PD-1) antibody, specifically targeting patients with advanced non-small cell lung cancer (NSCLC) complicated by MPE.

Methods: From May 2019 to December 2023, a total of 16 advanced NSCLC patients with MPE were enrolled. Each patient received a single intrapleural dose of 100 mg of sintilimab. The primary outcome was safety, while secondary outcomes included the proportion of participants who achieved successful pleurodesis by day 35 and day 70 post-intervention; median pleural progression-free survival (mPPFS); the objective response rate (ORR) of extra-pleural tumor at both day 35 and day 70.

Results: Among the 16 patients, the proportion of participants with successful pleurodesis at day 35 was 75.0% (12/16), which decreased to 56.3% (9/16) by day 70. The mPPFS was 10.4 weeks (95% CI: 7.6-13.3 weeks). The ORR of extrapleural tumors at day 35 was 12.5%, with 12.5% (2/16) of patients achieving partial remission (PR), 81.3% (13/16) maintaining stable disease (SD), and 6.3% (1/16) experiencing disease progression (PD). As for safety, the treatment-related adverse events (TRAEs) were well-tolerated. However, 93.8% (15/16) patients experienced treatment-emergent adverse events (TEAEs). The incidence rate of grade 3 TEAEs was 25.0% (4/16), and no grade 4 TEAEs occurred in any patients.

Conclusions: Intrapleural injection of anti-PD-1 antibody demonstrates promising efficacy and a tolerable safety profile as a novel therapeutic strategy for managing MPE in advanced NSCLC.$$graphic_{A677B7CF-5659-4B5B-9F32-996ACC7741C1}$$

P3.18.34 TACTI-004, a Phase 3 Trial of Eftilagimod Alfa Plus Pembrolizumab (P) + Chemotherapy (C) vs Placebo + P + C in 1St Line NSCLC

M. Sebastian[1], I. Nordman[2], Y. Ürün[3], P.J. Voon[4], D. Isla[5], K. Vera[6], F. Orlandi[7], B. Sansar[8], S. Winckels[9], C. Mueller[9], F. Triebel[10]
[1]Universitätsklinikum Frankfurt, Frankfurt am Main/DE ,[2]Calvary Mater Newcastle, Waratah/AU ,[3]Cebeci Hastanesi, Istanbul/TR ,[4]Hospital Umum Sarawak, Kuching/MY ,[5]University Hospital Lozano Blesa, Zaragoza/ES ,[6]Hospital Británico de Buenos Aires, Buenos Aires/AR ,[7]Orlandi Oncología, Providencia, Santiago/CL ,[8]Mahamana Pandit Madan Mohan Malaviya Cancer Centre and Homi Bhabha Cancer Hospital, Tata Memorial Centre, Varanasi/IN ,[9]Immutep GmbH, Berlin/DE ,[10]Immutep SAS, Orsay/FR

Introduction: Eftilagimod alfa (E), an antigen presenting cell activator, binds to a subset of MHC class II molecules to mediate T cell (CD4/CD8) recruitment/activation. Prior studies in first line (1L) non-small cell lung cancer (NSCLC) (TACTI-002 [NCT03625323]: combining E + pembrolizumab (P); INSIGHT-003 [NCT03252938] combining E with chemotherapy + P [SoC]) showed encouraging efficacy results across all PD-L1 strata & excellent safety profiles. TACTI-004 is a double-blinded, randomized, placebo-controlled phase 3 study testing E + SoC vs. placebo + SoC in 1L NSCLC patients (pts).

Methods: Approximately 756 pts with 1L NSCLC will be enrolled, irrespective of PD-L1 status, & randomized 1:1 to receive either E + SoC or placebo + SoC. The dual primary endpoint (EP) is overall survival & progression-free survival (RECIST 1.1). Secondary EPs include ORR, disease control rate, duration of response, quality of life, safety & biomarkers. Pts will receive 30 mg E SC q2w for 24 weeks, then q3w and P IV at 200 mg (30 min) q3w both for up to 2 yrs. Chemotherapy choice will be histology-dependent: non-squamous NSCLC pts will receive IV cisplatin (75 mg/m2) or carboplatin (AUC 5 or 6) + pemetrexed (500 mg/m2) q3w for 3 mo, then maintenance pemetrexed q3w. Squamous NSCLC pts will receive carboplatin (AUC 5 or 6) + paclitaxel (175 or 200 mg/m2) q3w for 3 mo.Imaging will be performed q6w until week 18, q9w until week 54 & q12w thereafter. Testing for PD-L1 (22C3) & genetic alterations will be prospectively assessed.Key inclusion criteria: Adults diagnosed with measurable advanced/metastatic (A/M) NSCLC (squamous or non-squamous), not amenable to curative treatment nor locally available oncogenic driver mutation-based 1L therapy. Treatment-naïve for systemic therapy (previous palliative radiotherapy for A/M disease acceptable). Expected survival >3 months & ECOG 0 or 1. Tumour tissue must be available for PD-L1 central testing. Pts may not have tumours with EGFR mutations nor ALK or ROS1 translocations. Stable brain metastasis is acceptable.

Keywords: Advanced/Metastatic NSCLC, Immunotherapy, Chemotherapy

Introduction: In the United States, squamous histology accounts for approximately 30% of all non-small-cell lung cancers (NSCLCs), with squamous metastatic NSCLC (mNSCLC) associated with a poor prognosis. In this population, immunotherapy targeting programmed cell death-1/programmed cell death ligand-1 (PD-1/PD-L1) represents the standard of care, with the most common first-line (1L) treatment approach being platinum-based chemotherapy combined with anti-PD-1/PD-L1 immunotherapy. Inhibition of the co-inhibitory T cell immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domain (TIGIT) pathway is being investigated in combination with PD-1/PD-L1 blockade to increase immunotherapy efficacy in NSCLC, as well as other cancer types. Rilvegostomig is a monovalent, bispecific, humanised IgG1 monoclonal antibody targeting both PD-1 and TIGIT receptors that shows antitumor response with a manageable safety profile in NSCLC based on preliminary results (Hiltermann TJN, et al. J Thorac Oncol 2024. Abs OA11.03). ARTEMIDE-Lung02 (NCT06692738) is a phase 3, randomised, double-blind, multicentre study that will assess the efficacy and safety of rilvegostomig versus pembrolizumab, both in combination with platinum-based doublet chemotherapy, as 1L treatment for participants (pts) with squamous mNSCLC.

Methods: Approximately 880 pts will be randomised 1:1 to either Arm A: rilvegostomig + chemotherapy (carboplatin + paclitaxel or nab-paclitaxel) intravenous (IV) every three weeks (Q3W) for 4 cycles followed by rilvegostomig IV Q3W, or Arm B: pembrolizumab + chemotherapy IV Q3W for 4 cycles followed by pembrolizumab IV Q3W. Eligible pts will have histologically confirmed squamous mNSCLC not amenable to curative treatment, tumours expressing PD-L1 (TC ≥1%), no documented mutations in oncogenes with an approved 1L therapy available, and an Eastern Cooperative Oncology Group performance status of 0 or 1. Dual primary endpoints are progression-free survival (Response Evaluation Criteria in Solid Tumors v1.1 by blinded independent central review) and overall survival. Additional endpoints include safety/tolerability and biomarkers. Enrolment is planned across approximately 350 sites in 25-30 countries.

Keywords: Rilvegostomig, Metastatic squamous non-small cell lung cancer, Bispecific antibody

P3.18.36 Peripheral Immune and Hormonal Signatures Associated With Sex Differences in NSCLC Response to Checkpoint Inhibition

S. Hermann[1,2], M. Aykac[1], B. Resuli[1,2], M. Freiwan[1], M. Arredondo Lasso[1], R. Kiefl[1], C. Schneider[3], S. Kobold[4], A. Tufman[1,2]
[1]Department of Internal Medicine V, LMU University Hospital, Munich/DE ,[2]German Center for Lung Research (DZL), Munich/DE ,[3]Division of Surgery, LMU University Hospital, Munich/DE ,[4]Department of Clinical Pharmacology, LMU University Hospital, Munich/DE

Introduction: Immune checkpoint inhibitors (ICIs) have markedly improved outcomes in non-small cell lung cancer (NSCLC), yet their efficacy varies by sex. Recent research has highlighted sex-based differences in immune function and ICI efficacy, with potential explanations including hormonal variances and distinct inflammatory profiles between sexes. The ALICE (alloimmunization and alloantibodies in male and female NSCLC patients treated with ICIs) study is a prospective, translational cohort study examining gender differences in response to checkpoint inhibition in NSCLC. This branch of the ALICE study aims to investigate the interplay between estrogen signaling and cytokine dynamics in shaping immune exhaustion, tumor progression, and therapeutic response.

Methods: Male and female patients with NSCLC treated with ICI were included in a prospective cohort. Blood and tumor samples were collected for HLA profiling, HLA antibodies, immune cell subpopulations, hormone levels and cytokine profiles. This interim analysis presents hormone levels in the first subcohort of ALICE patients in correlation with gender, tumor diagnosis and response to checkpoint inhibition. The interim analysis includes 59 patients with confirmed diagnosis of NSCLC in disease stage I-IV and current or previous ICI treatment. Peripheral blood samples were collected to measure circulating estrogen concentrations and to profile inflammatory markers using a 15-plex cytokine panel (targeting: IFNγ, IL-1α, IL-1β, IL-2, IL-4, IL-5, IL-6, IL-10, IL-12p70, IL-13, IL-15, IL-17A, IL-23, TNFα, TNFβ). The main goal is to examine potential associations between hormone and cytokine levels and objective response to ICI treatment. Secondary analyses will assess how these biomarkers relate to clinical parameters such as sex, disease stage, and tumor progression. Progression-free survival (PFS) will be evaluated via Kaplan-Meier estimates and log-rank testing, with Cox proportional hazards modeling to explore predictors of immune response variability following ICI therapy.

Results: This first interim analysis of the ongoing prospective ALICE study includes 59 patients with histologically confirmed NSCLC, comprising 27 females and 32 males. The majority of patients had adenocarcinoma (n=47), while 8 had squamous cell carcinoma and 4 had other histologies, including adenosquamous carcinoma. Participant enrollment and biospecimen collection are ongoing. Final analyses will be conducted upon completion of target accrual in both male and female cohorts to enable adequately powered sex-specific comparisons. In this interim cohort, circulating estrogen levels in female patients were uniformly low, consistent with postmenopausal status. Unexpectedly, two male patients—one with adenocarcinoma and one with adenosquamous carcinoma—demonstrated markedly elevated estrogen levels. These findings warrant further investigation into the potential immunological or tumor-intrinsic implications of aberrant hormone profiles in male NSCLC patients receiving immune checkpoint inhibitors.

Conclusions: This interim analysis of estrogen levels and cytokine profiles during checkpoint inhibition provides a deeper understanding of sex-dependent immune-inflammatory-hormonal signatures which could lead to more effective gender-based medicine strategies. Sex related differences in the immune system and hormone levels influence the response to ICI-therapy and may account for some gender-specific differences in treatment success. These findings could reveal individualized immunotherapy treatment strategies for patients suffering from NSCLC.

P3.18.37 A Phase 3 Trial of First-Line MK-3475A (Subcutaneous Pembrolizumab) for Stage IV NSCLC With PD-L1 TPS =50%

T-E. Ciuleanu[1], R.A. Ramírez Fallas[2], T. Göksel[3], S.J. Kim[4], G. Song[4], S. Zhang[4], B. Halmos[5]
[1]Institutul Oncologic Prof Dr Ion Chiricuta and University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca/RO ,[2]Private Practice, Guatemala City/GT ,[3]Ege University Faculty of Medicine, EgeSAM-Ege University Translational Pulmonary Research Center, Izmir/TR ,[4]Merck & Co., Inc., Rahway/NJ/USA ,[5]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx/NY/USA

Introduction: First-line treatment for patients with stage IV non-small-cell lung cancer (NSCLC) with a PD-L1 tumor proportion score (TPS) ≥50% and no targetable genetic alterations includes intravenous (IV) administration of the anti-PD-1 monoclonal antibody (mAb) pembrolizumab. However, evidence suggests that patients prefer subcutaneous (SC) versus IV administration of anticancer therapy, mainly due to reductions in clinic time and improved comfort with the SC administration route. MK-3475A is pembrolizumab with the permeation enhancer berahyaluronidase alfa (MK-5180), a variant of human hyaluronidase developed and manufactured by Alteogen Inc., for SC administration ("pembrolizumab SC"). We present the study design of MK-3475A-F84 (NCT06698042), a phase 3, randomized, active-controlled, open-label study of pembrolizumab SC in participants (pts) with previously untreated stage IV NSCLC and PD-L1 TPS ≥50%.

Methods: Eligible pts are aged ≥18 years with previously untreated histologically or cytologically confirmed stage IV (per American Joint Committee on Cancer v8) squamous or nonsquamous NSCLC with PD-L1 TPS ≥50%; no EGFR, ALK, or ROS1 alterations; and measurable disease per RECIST v1.1 as assessed by the investigator. Additional eligibility criteria include an ECOG PS of 0 or 1 and provision of an archival tumor sample or newly obtained core or biopsy of a nonirradiated tumor. Pts are randomized 1:1 to either pembrolizumab SC 790 mg or pembrolizumab IV 400 mg Q6W for ≤18 cycles or until PD, unacceptable toxicity, or pt/physician decision. Randomization is stratified by ECOG PS (0 vs 1), histology (squamous vs nonsquamous), and region (East Asia vs North America/Western Europe/Australia/New Zealand vs rest of world). The dual primary objectives are to compare model-based pembrolizumab cycle 1 area under the curve 0-6 weeks (AUC0-6wk) and steady-state (cycle 3) trough concentration (Ctrough) for pembrolizumab SC vs pembrolizumab IV Q6W; noninferiority will be evaluated with the noninferiority margin of 0.8. Secondary objectives include exposure (cycle 1 maximum concentration [Cmax] and Ctrough, and steady state [cycle 3] Cmax and AUC0-6wk) of pembrolizumab SC vs pembrolizumab IV Q6W, anti-pembrolizumab antibody levels, cycle 1 and steady-state (cycle 3) Ctrough of pembrolizumab SC vs pembrolizumab IV Q3W, ORR, PFS, and duration of response (each per RECIST v1.1 by blinded independent central review), OS, safety, and pt-reported outcomes. Recruitment is ongoing.

Keywords: pembrolizumab SC, anti-PD-1, NSCLC

Introduction: Immunotherapies targeting programmed celldeath-1 (PD-1) and its ligand PD-L1 have transformed the treatment of 1Lmetastatic NSCLC (mNSCLC). However, in a subset of patients with PD-L1-low(i.e. TC <50%) or PD-L1-negative (i.e. TC <1%) disease, anti-PD-(L)1therapies alone or in combination with CT are associated with shorter overallsurvival (OS) than in patients with PD-L1 TC ≥50% disease regardless of NSCLChistology. Dual inhibition of PD-(L)1 and CTLA-4has shown survival benefit in patients with PD-L1-low and PD-L1-negative mNSCLCand is used in clinical practice to address the poorer prognosis of thesepatients. Achieving further efficacy improvements with monospecific CTLA-4 inhibitors at higher treatment doses isclinically restrained by toxicity. Volrustomig (MEDI5752) is a monovalent,PD-1/CTLA-4 bispecific, humanized IgG1 monoclonal antibody engineered tospecifically inhibit PD-1 with increased CTLA-4 blockade on PD-1-positiveactivated T cells compared to PD-1-negative T cells. Data from the first-in-humanphase 1/2 study (NCT03530397) showed evidence of T-cell activation andexpansion of new and existing T-cell clones at pharmacodynamic levels exceedingthose clinically feasible with coadministered anti-PD-1 and anti-CTLA-4monospecific antibodies. Encouraging antitumor activity and a manageable safetyprofile were reported in patients with mNSCLC who received 1L volrustomig 750mg with pemetrexed + carboplatin every 3 weeks (Q3W), including those withPD-L1 TC <1% disease. The phase 3, two-arm, randomized, multicenter,open-label eVOLVE-Lung02 study (NCT05984277) will evaluate the efficacy of 1Lvolrustomig plus CT versus pembrolizumab plus CT in patients with PD-L1 TC<50% NSCLC.

Methods: Eligibility criteria include age ≥18 years; ECOG PS 0/1; histologically or cytologically documented squamous or non-squamous stage IV NSCLC not amenable to curative surgery or radiation; PD-L1 TC expression <50%; wild-type EGFR, ALK, ROS1; absence of genomic alterations in other actionable driver oncogenes (e.g. NTRK, BRAF, RET, MET); no prior systemic therapy for mNSCLC or immunotherapy. Exclusion criteria include prior immunotherapy; cardiac disease including but not limited to cardiomyopathy, heart failure, and uncontrolled hypertension; symptomatic brain metastases; and spinal cord compression. Approximately 1200 patients will be randomized 1:1 to receive histology-specific CT (squamous: paclitaxel plus carboplatin; non-squamous: pemetrexed plus carboplatin + pemetrexed maintenance) in combination with either volrustomig or pembrolizumab 200 mg Q3W for 4 cycles; after this volrustomig (Q3W) or pembrolizumab (200 mg Q3W or 400 mg Q6W where locally approved) will be administered until completion of 24 months of treatment or disease progression, or other discontinuation criteria are met. Randomization will be stratified according to histology (squamous vs non-squamous), PD-L1 (TC <1% vs 1-49%), smoking status (never vs former/current), and region (Asia vs rest of world). Primary endpoints are progression-free survival (PFS) per RECIST v1.1 by blinded independent central review and OS in the PD-L1 TC <1% population. Key secondary endpoints are PFS and OS in all randomized patients; other secondary endpoints include objective response rate, duration of response, PFS2 (progression after starting first subsequent therapy or death), safety and tolerability, patient-reported outcomes (including NSCLC Symptom Assessment Questionnaire on disease-related symptoms), pharmacokinetics, and immunogenicity. Enrollment is ongoing at approximately 26 sites in 25 countries/regions.

Introduction: Programmed cell death-1 (PD-1)/programmed death ligand-1 (PD-L1) inhibitors have improved overall survival of patients with metastatic NSCLC without driver mutations (as first-line monotherapy or in combination with anti-Cytotoxic T-Lymphocyte-Associated Protein 4 [CTLA-4], or in combination with platinum-based doublet agents or as second-line therapy after chemotherapy). However, a significant number of patients do not respond to these immune checkpoint inhibitors or demonstrate disease progression after an initial response. While CTLA-4 is a recognized immunotherapy target in solid tumors, no current anti-CTLA-4 antibodies, including ipilimumab and tremelimumab have demonstrated efficacy as monotherapies to date in NSCLC. Gotistobart (ONC-392/BNT316) is a humanized anti-CTLA-4 mAb with a novel mechanism of action that uniquely preserves CTLA-4 immune checkpoint activity by avoiding lysosomal degradation. A favorable safety profile and anti-tumor activity were previously demonstrated in the first-in-human clinical study (PRESERVE-001) of gotistobart in PD-(L)1 resistant metastatic NSCLC (Kai He et al., JCO 2023;41, 9024-9024).

Methods: PRESERVE-003 (NCT05671510) is a two-stage, randomized, open-label, active-controlled, Phase 3 study of gotistobart versus docetaxel for the treatment of patients with metastatic NSCLC after prior progression on a PD-(L)1 inhibitor. A total of 691 patients will be enrolled, including 213 patients in Stage 1 and 478 patients in Stage 2. In the ongoing Stage 2 of the pivotal study, 478 patients with a histologically or cytologically confirmed diagnosis of metastatic squamous NSCLC will be randomized 1:1 to receive either gotistobart 6 mg/kg Q3W with 2 loading doses of 10 mg/kg Q3W or docetaxel 75 mg/m2 Q3W. Randomization will be stratified by presence of brain metastases (yes or no), ECOG score (0 or 1), and region (US or ex-US). The primary endpoint is overall survival (OS), which will be assessed in the intent-to-treat (ITT) population. OS will be estimated using a Cox Proportional Hazards model, stratified by stratified by the randomization stratification factors, to calculate for the hazard ratio and its 95% confidence intervals (CIs). Kaplan-Meier estimates of median OS will be presented by treatment arm, along with two-sided 95% CIs. Secondary endpoints include objective response rate and progression-free survival based on RECIST 1.1, and safety.

P3.18.40 KRAS Peptide Vaccine Combined With Chemotherapy, Nivolumab and Ipilimumab in Advanced KRAS Mutated Non-Small Cell Lung Cancer

R.J. Keogh, S. Scott, B. Levy, C. Hann, V. Lam, J. Murray, J. Feliciano, A. Pabani, V. Anagnostou, N. Zaidi, J. Brahmer, E. Jaffee, K.A. Marrone
Johns Hopkins University School of Medicine, Baltimore/MD/USA

Introduction: KRAS-mutant non-small cell lung cancer (NSCLC) represents a distinct biologic subtype of lung cancer, accounting for around 30% of cases, that has been historically difficult to treat. While some patients with KRAS-mutated tumors derive sustained clinical benefit from immune checkpoint blockade (ICB), others have tumors that appear to have worse clinical outcomes for complex reasons, including co-mutations in certain genes such as STK11 and KEAP1. While chemo-immunotherapy is the most aggressive option for frontline therapy in these patients, many are unable to develop a durable anti-tumor immune response. Given KRAS is an oncogenic driver and less likely to be immunologically edited, it is a prime target for neoantigen-specific vaccination to induce a more effective immune response. In preclinical and early clinical trial data, our group has demonstrated the benefit of combining targeted synthetic peptide vaccines with ICB and adjuvant stimulants in solid tumors. The current study amendment aims to determine the safety and immunogenicity of a novel vaccine in combination with chemotherapy and dual ICB for patients with metastatic KRAS-mutant NSCLC.

Methods: This is a therapeutic amendment to a single institution, phase I trial which will evaluate a pooled mutant-KRAS peptide vaccine in combination with platinum-doublet chemotherapy and nivolumab and ipilimumab in the treatment-naïve metastatic setting. The vaccine consists of poly-ICLC adjuvant admixed with pooled synthetic long peptides (SLPs) corresponding to six common mKRAS subtypes: G12D, G12R, G12V, G12A, G12C, and G13D. Eligible patients must have the presence of a vaccine-targeted KRAS mutation, measurable disease and tumor amenable to biopsy. Treatment is divided into a lead in phase with two cycles of platinum-doublet chemotherapy combined with ipilimumab and nivolumab followed by a priming, boost and maintenance phase (Figure 1). The primary endpoint of the study is to evaluate the safety of administering a mutant KRAS peptide vaccine in combination with chemotherapy and ipilimumab and nivolumab in patients with advanced KRAS-mutant NSCLC. The secondary objectives will be to evaluate efficacy endpoints, and the impact of predicted KRAS mutations on mutant KRAS specific T cell responses in the peripheral blood. Correlative studies will apply multi-omic approaches to identify markers of response and resistance in tumor and plasma samples. The study has enrolled 5 patients to treatment with the combination of ipilimumab and nivolumab with KRAS-mutant vaccine and we will now procced to enroll additional patients to the amendment described herein.

P3.18.41 A Phase II Study of Second-Line Cadonilimab, Bevacizumab and Docetaxel in Patients With Advanced NSCLC

J.C. Duan[1], B. Cao[2], W. Guo[3], B. Sun[1], L. Liu[1], J. Wang[1]
[1]Cancer Hospital, Chinese Academy of Medical Sciences, Beijing/CN ,[2]Peking University Third Hospital, Beijing/CN ,[3]Shanxi Provincial Cancer Hospital, Taiyuan/CN

Introduction: The second-line treatment options are highly limited for patients with advanced or metastatic non-small cell lung cancer(NSCLC) who have progressed after first-line checkpoint inhibitors(CPI) combined with chemotherapy. Later-line standard treatment recommended by NCCN guidelines are mono-chemotherapy. However, the efficacy is limited with an ORR of 14% -17%, median PFS of 4.0-5.4 months, and OS of 10.5-12 months. Cadonilimab is a humanized immunoglobulin G1 bispecific antibody that simultaneously targets PD-1 and CTLA4. Considering the complex tumor microenvironment after immune resistance, the triplet-regimen of cadonilimab with bevacizumab and docetaxel may exert better anti-tumor effects. Thus, this study aimed to assess the safety and efficacy of the triplet-regimen for the treatment of advanced non-squamous NSCLC without sensitizing EGFR/ALK/ROS1 mutations progressed on CPI.

Methods: AK104-IIT-017 is a single-arm, open-lable, multi-center, phase II trial. Key inclusion criteria are: 1) patients with histologically or cytologically confirmed stage IIIB/IIIC or IV non-squamous NSCLC without sensitizing EGFR/ALK/ROS1 mutations; 2) progressed on not more than one PD-1/L1 inhibitor and one platinum-based chemotherapy (combined or sequential, regardless of sequence); 3) at least two cycles of PD-1/L1 inhibitor (with or without concurrent chemotherapy) with clinical benefits (PFS≥3 months). Other main inclusion criteria include age ≥18 years old, Eastern Cooperative Oncology Group (ECOG) performance status of 0 to 1, and adequate organ function. All patients will be simultaneously adminstrated with cadonilimab 10mg/kg Q3W, bevacizumab 7.5mg/kg Q3W, and docetaxel 60 mg/m2 Q3W. Patients will use triplet-regimen for 4 cycles, with continuous maintenance of treatment with cadonilimab and bevacizumab until disease progression, intolerable toxicity, or other reasons. The primary endpoint is 6-month progression-free survival (PFS) rate according to Investigator Assessment (IA). Secondary endpoints include overall survival(OS), PFS, overall response rate(ORR), disease control rate(DCR), duration of response(DoR),etc. We also plan to explore the clinical significance of gene mutations and immunotherapy-related biomarker changes and their correlations with efficacy. Simon's 2-Stage Design is adopted, assuming a 6-month PFS rate of 30% under the null hypothesis and 50% under the assumption that the triplet-regimen is effective. A sample size of 44 patients is required to achieve 80% power at a two-sided significance level of 5%, considering a dropout rate of 10%. All participants would be enrolled simultaneously at three centers in China. So far, one participant has been enrolled. The trial was registered at ClinicalTrials.gov (NCT06793813) and is actively recruiting.

Keywords: bispecific antibody, anti-angiogenesis, later-line combination therapy

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.42 Camrelizumab Combined With Chemotherapy and Local Consolidative Therapy for Untreated Oligometastatic NSCLC With PD-L1 Expression <

L.P. LIN[1], H.J. Bao[1], X. Luo[1], J.F. Guo[2], P.F. Chen[3], C.J. Deng[1], H.R. Su[1], F.X. Huang[1], X.L. Cao[1], J.Z. Hu[1]
[1]Panyu Central Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]Ho Yin Memorial Hospital, Southern Medical University, Guangzhou/CN ,[3]Guangdong Qifu Hospital, Guangzhou/CN

Introduction: In recent years, PD-1/PD-L1 immune checkpoint inhibitors have gained widespread application in the treatment of advanced non-small cell lung cancer (NSCLC), demonstrating significant therapeutic efficacy. Nevertheless, the efficacy of these inhibitors varies among patients with different PD-L1 expression levels. Oligometastatic non-small cell lung cancer (NSCLC) is an intermediate stage between localized and widely metastatic disease. Although local consolidative therapy for oligometastatic NSCLC has demonstrated some benefits, the value of its combination with immunotherapy requires further investigation. This study aims to evaluate the efficacy and safety of camrelizumab combined with chemotherapy and local consolidative therapy in untreated driver-gene-negative and PD-L1 <50% oligometastatic NSCLC patients.

Methods: This prospective, single-arm, phase II study plans to enroll 35 patients aged 18-75 years with pathologically confirmed NSCLC, stage IV oligometastatic disease (≤3 organs and ≤5 metastatic lesions), PD-L1 expression<50%, no driver gene alterations, and no prior systemic treatment for recurrent/metastatic disease. The treatment regimen consists of camrelizumab 200 mg intravenously every 3 weeks plus investigator-chosen chemotherapy for 4-6 cycles, followed by local consolidative therapy (radiotherapy or ablation) .Three weeks after the end of local therapy, maintenance therapy with camrelizumab is initiated, and for non-squamous NSCLC patients, pemetrexed is added to the regimen. The primary endpoint is progression-free survival (PFS). Secondary endpoints include objective response rate (ORR), overall survival (OS), duration of response (DoR), disease control rate (DCR), and safety.Treatment cycles and assessments are scheduled every 3 weeks, with imaging evaluations every 2 cycles during induction and every 3 cycles during maintenance. Safety follow-up occurs 30 days post-treatment, and survival follow-up continues every 2 months. Data analysis will use descriptive statistics, Kaplan-Meier estimation for survival endpoints, and Clopper-Pearson method for response rates.

P3.18.43 A Phase II Study of IDH1 Inhibitor Combined With Serplulimab and Docetaxel in Previously Treated Advanced NSCLC (ChiCTR2400086196)

S. Zhang, Q. Wang, L. Liu, Y. Wu, C. Su
Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Lung cancer remains the leading cause of cancer-related mortality worldwide, with non-small cell lung cancer (NSCLC) accounting for approximately 85% of all lung cancer cases. Over 50% of patients present with advanced disease at diagnosis, and 30-60% of early-stage NSCLC patients experience recurrence after surgery. Although the combination of PD-1/PD-L1 inhibitors and chemotherapy has become the standard first-line therapy for driver mutation-negative advanced NSCLC, most patients progress within 8-10 months. Second-line therapeutic options remain limited: docetaxel demonstrates modest efficacy (objective response rate [ORR] 6-11%; median overall survival [mOS] 5-10 months), while PD-1 inhibitors (e.g., tislelizumab) show improved survival outcomes (ORR 21.9% vs. 7.0%; mOS 17.2 vs. 11.9 months compared to docetaxel). Despite these advances, there remains an urgent need for alternative treatment strategies.Emerging evidence highlights the oncogenic role of isocitrate dehydrogenase 1 (IDH1) in NSCLC progression. Despite low mutation rates (2.01%) in NSCLC, wild-type IDH1 promotes tumor stemness and chemotherapy resistance via enzyme activity-independent serine biosynthesis. Our preclinical studies reveal that IDH1 overexpression drives cancer-associated fibroblast (CAF) activation an enhances TGF-β/CXCL12 secretion, fostering an immunosuppressive “cold” tumor microenvironment. This IDH1-mediated immunosuppressive niche may contribute to immunotherapy resistance, suggesting that IDH1 inhibition could restore immune sensitivity.TQB3454, a novel IDH1 inhibitor, exhibits superior preclinical safety and efficacy compared to AG-120 (ivosidenib). In previous clinical trial ,TQB3454 demonstrated manageable toxicity. Based on these findings, we hypothesize that combining TQB3454, serplulimab, and docetaxel may reverse immunosuppression and enhance antitumor efficacy , thereby overcoming therapeutic resistance in pretreated NSCLC.

Methods:

Design: Single-center, single-arm phase II trial (ChiCTR2400086196).Population:Patients with histologically confirmed locally advanced/metastatic NSCLC,without actionable driver mutations, progression after systemic therapy.Intervention:TQB3454 (600 mg oral QD),Serplulimab (4.5 mg/kg IV Q3W),Docetaxel (60 mg/m^2 IV Q3W).Endpoints: Primary: ORR (RECIST v1.1) and safety (CTCAE v5.0). Secondary: DCR, DOR, PFS, OS.Target accrual: 39 patients. MiniMax two-stage design (α=0.05, power=80%) with H0: ORR=7% (historical docetaxel) vs. H1: ORR=20%.Statistical Design: Survival endpoints analyzed by Kaplan-Meier method.

P3.18.44 Oral Metronomic Vinorelbine and PD-1 Inhibitors in Elderly Patients With Non-Small Cell Cancer

M. Guan, Q. Shi
Anhui Chest Hospital, Hefei/CN

Introduction: Immune checkpoint inhibitors have greatly changed the landscape of non-small-cell lung cancer treatment with a significant improvement in survival. There are multiple challenges in the treatment of elderly patients with lung cancer. However, elderly patients are rarely included in clinical studies. We conducted an open-label, non-randomised, phase 2 study to evaluate the efficacy and safety of oral metronomic vinorelbine and PD-1 inhibitors in elderly patients with unoperable, locally advanced or metastatic non-small-cell lung cancer.

Methods: Patients received oral metronomic vinorelbine 40mg every week(20mg for patients over 80 years old), combined with PD-1 inhibitors every 3 weeks. The primary end point was objective response rate (ORR), and the second end points included disease control rate (DCR), progression-free survival (PFS), and safety.

Results: Of the 16 patients enrolled in this study, 12 patients received oral metronomic vinorelbine and PD-1 inhibitors as first-line treatment. The ORR was 31.25% and the DCR was 75%. Median PFS was eight months (95% CI 0-30.651). Median OS was not reached. The median PFS was longer in patients with PD-L1 TPS ≥1% than <1% (not reached versus 5 months(95%CI 0.766-9.234), P=0.046). The most common treatment-related adverse event was immune-related hypothyroidism (31.25%, 5/16) and endocrinopathies (18.75%, 3/16). Only one patient experienced grade 3 or higher adverse event, which were liver function impairment.It was considered to be related to concomitant administration of anti-tuberculosis drugs. No grade 5 treatment-emergent adverse events or death were reported.

Conclusions: The combination of oral metronomic vinorelbine and PD-1 inhibitor is efficient, safe and convenient as treatment for elderly patients with unoperable, locally advanced or metastatic non-small-cell lung cancer.

P3.18.45 A Multi-Cohort, Phase II Study of SHR0302 Combined With PD-1/PD-L1 Inhibitior for Treatment Naïve or Acquired Resistant to Immunology NSCLC

X. Zhang, L. Liu, L. Wang, J. Zhao, J. Wu, C. Su
Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Recent studies showed that the dysregulated activation of the JAK/STAT pathway, which leads to the prolonged release of IFN-γ, is a significant contributor to the resistance to immune checkpoint inhibitors in cancer immunotherapy. Preclinical and clinical studies have demonstrated that the combination of JAK inhibitors with PD-1 immunotherapy can reverse or delay onset of immunotherapy resistance by modulating the JAK/STAT pathway in Hodgkin's lymphoma and non - small cell lung cancer (NSCLC). SHR0302, being a highly selective JAK1 inhibitor, has shown excellent clinical benefits by effectively inhibiting the JAK/STAT pathway, leading to its approval for the treatment of Ankylosing Spondylitis in China. Preclinical studies also show that the combination of SHR0302 and PD-L1 inhibitor has synergistic potentials for anti-tumor effect in resistant to-immune checkpoint blockade patients. Thus, we conducted a phase 2 clinical trial evaluating SHR0302 combined with PD1/PD-L1 inhibitors as treatment-naïve or acquired resistant to first-line checkpoint inhibitor NSCLC patients.

Methods: Patients will be enrolled into two cohorts. Cohort 1 enrolled first-line metastatic non-small cell lung cancer (NSCLC), who will be administered a combination of anti-PD-1 and SHR0302 in the maintenance treatment after non-PD from 4-6 cycles of anti-PD-1 and platinum-based chemotherapy. Cohort 2 enrolled NSCLC whose disease progressed due to acquired resistance to first-line PD-1 inhibitor, and they will be administered with a combination of Adebrelimab (PD-L1 inhibitor) and SHR0302. Acquired resistance is defined as documented initial objective response (partial or complete response by RECIST or WHO) to therapy or significant and durable (> 6 months) clinical benefit (stable disease defined by RECIST or WHO). Both cohorts will be treated until patients experienced disease progression, intolerable toxicity, or met the criteria for discontinuation of the trial drug. The primary endpoint of this trial is progression - free survival (PFS), while the secondary endpoints include objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety.

P3.18.46 Ivonescimab Plus Platinum-Doublet Chemotherapy as First-Line Therapy for Locally Advanced/Metastatic SMARCA4-Deficient NSCLC

Z. Liu[1], J. Li[1], Y. Diao[1], F. Li[1], D. Wang[1], J. Zheng[1], C. Hong[1], J. Liu[2], J. Sun[3], Y. Li[1], Y. Liang[1]
[1]Liaoning Cancer Hospital&Institute, Shenyang/CN ,[2]School of Graduate, Dalian Medical University, Dalian/CN ,[3]China Medical University, Shenyang/CN

Introduction: SMARCA4 deficient non-small cell lung cancer (SMARCA4 -dNSCLC) is a rare primary malignant epithelial tumor originating from the lungs.The incidence of SMARCA4-dNSCLC is about 5% -10%, and it is more common in young or middle-aged male smokers. SMARCA4-dNSCLC grows rapidly, metastasizes quickly, and is insensitive to chemotherapy, targeted drugs, and immunotherapy. Currently, there is no standardized treatment plan.Ivonescimab is a global first-in-class anti-PD-1/VEGF bi-specific antibody, can exert a synergistic effect synergistic effects of vascular endothelial growth factor(VEGF) inhibitors and immune checkpoint inhibitors and may achieve better anti-tumor effects in advanced NSCLC.

Methods: This is a prospective, single arm, exploratory study.Eligible participants are adults aged 18 to 75 years and Histologically or cytologically confirmed, locally advanced (stage IIIB) or metastatic (stage IV) SMARCA4 -dNSCLC that cannot be completely resected by surgery or treated by radical concurrent/sequential chemoradiotherapy (according to the 9th edition of the the International Association for the Study of Lung Cancer, ninth Edition);Group performance status score of 0 or 1 with at least 1 measurable lesion (per Response Evaluation Criteria in Solid Tumors [RECIST], version 1.1). Medication regimen:Ivonescimab 20mg/kg D1 + Albumin-Bound Paclitaxel 100mg/m^2 D1/D8/D15 + Carboplatin AUC 5 D1.Q3W for 4-6 cycles.Followed by maintenance therapy with ivonescimab 20mg/kg Q3W.Until disease progression or unacceptable toxicity occurs, or until the 24-month study completion, whichever comes first. Primary endpoint: PFS assessed based on RECIST v1.1. Secondary endpoints: ORR, DoR, DCR, TTR, OS assessed based on RECIST v1.1 and safety assessment. Exploratory endpoints: Health-related quality of life (HRQoL) assessmen.

P3.18.47 ATTEND: Randomized Phase III Trial of Tislelizumab and Chemotherapy With or Without Diphenhydramine in Advanced Non-Small Cell Lung Cancer

L. Liu, M. Shen, Y. Wang, Y. Xiong, S. Li, L. Zhou, J. Zhang, Z. Hui, W. Du, X. Ren
Tianjin Medical University Cancer Institute and Hospital, Tianjin/CN

Introduction: Despite significant advancements in the treatment of advanced Non-Small Cell Lung Cancer (NSCLC), long-term survival rates continue to be unsatisfactory. While immuno-chemotherapy has been established as a first-line therapy for advanced NSCLC, secondary resistance typically emerges within a few months, posing a critical challenge that urgently requires to be addressed in clinical practice. Histamine, a metabolite of histidine, is released by mast cells and plays a role in allergic reactions, tissue damage, and tumor immunotherapy. Research has demonstrated that the concurrent use of non-steroidal anti-inflammatory drugs can significantly enhance the objective response rate in patients treated with nivolumab. Additionally, the co-administration of aspirin has been shown to lower the mortality rate among patients receiving immunotherapy. Furthermore, the H1 receptor antagonist loratadine has been found to improve survival outcomes for NSCLC. Retrospective studies have indicated that combining immunotherapy with diphenhydramine may not only synergistically boost clinical efficacy but also reduce the incidence of immune-related adverse events. Based on these findings, this prospective study will evaluate the safety and efficacy of diphenhydramine combined with tislelizumab and chemotherapy as the first-line treatment of advanced NSCLC.

Methods: The ATTEND trial is an open-label, multicenter Phase III study that includes patients with Stage IIIB/C NSCLC who are unable to undergo radical surgery or radiotherapy, as well as those with metastatic NSCLC. Patients are randomized (1:1) to receive either tislelizumab (200 mg) plus platinum-based doublet chemotherapy (pemetrexed 500 mg/m^2 for non-squamous cell carcinoma or albumin-bound paclitaxel 260 mg/m^2 for squamous cell carcinoma) every 3 weeks, with or without diphenhydramine (20 mg qd IM on day 0-2). A total of 430 evaluable patients will be enrolled to receive anticancer treatment until disease recurrence or intolerable toxicities. The primary endpoint is progression-free survival. Secondary endpoints include objective response rate, overall survival, and toxicity profile. The ATTEND trial commenced in December 2024, and enrollment is ongoing across 19 centers in China.

P3.18.48 Phase II Clinical Trial of Trilaciclib in Combination With PD-1 Inhibitor and Chemotherapy as First-Line Treatment for (NSCLC)

Y. Liang[1], Z. Liu[1], J. Li[1], Y. Diao[1], D. Wang[1], J. Zheng[1], C. Hong[1], J. Liu[2], J. Sun[3], Y. Li[1], F. Li[1]
[1]Liaoning Cancer Hospital & Institute, Cancer Hospital of Dalian University of Technology, Shenyang/CN ,[2]School of Graduate, Dalian Medical University, Dalian/CN ,[3]China Medical University, Shenyang/CN

Introduction: This is an exploratory clinical trial evaluating the efficacy and safety of Trilaciclib in combination with PD-1 monoclonal antibody and first-line chemotherapy in patients with advanced non-small cell lung cancer. In the study, Major inclusion age ≥18 years old , and the histology and cytology confirmed late drive gene mutation negative non-small cell lung cancer, all subjects who meet the enrollment criteria will receive Trilaciclib combined chemotherapy and PD-1 monoclonal antibody as the first-line treatment according to the study plan. Trilaciclib will be used before each chemotherapy cycle and will be treated with chemotherapy for 4-6 cycles. Trilaciclib should also be discontinued after chemotherapy. Imaging evaluation was performed every 2 cycles during treatment. The primary endpoint was progression-free survival (PFS), and the key secondary endpoints were antitumor efficacy (ORR, DCR, OS, etc.) and bone marrow protection efficacy (incidence of grade 3 neutropenia during chemotherapy; Incidence of ≥ grade 3 thrombocytopenia; Incidence of grade 3 anemia, etc.), safety and tolerability.

Methods: Medication plan is Trilaciclib 240mg/m2 intravenously for 30 minutes and administered within 4 hours before chemotherapy; Pembrolizumab 200mg Q3W; Or Camrelizumab 200mg Q3W; Or Tislelizumab 200mg Q3W; Or Sintilimab 200mg Q3W; Or Toripalimab 240mg Q3W;Pemetrexed (non-squamous cell carcinoma) is 500mg/m2 Q3W;Paclitaxel Albumin-bound (squamous cell carcinoma) is 260mg/m2 Q3W;Carboplatin is AUC=5, up to 750mg Q3W; At present, this study has passed the Medical Ethics Committee of Liaoning Cancer Hospital, and has completed registration in the Chinese Clinical Trial Registry, The registration number is ChiCTR2500098340.It is expected to take 12 months to complete the enrollment and 24 months to complete the study.

P3.18.49 Efficacy and Safety of Tislelizumab Combined With Tofacitinib and Docetaxel for NSCLC After Failure of First-Line Immunotherapy

W. Xie, L. Cao, J. Zhang
The First Affiliated Hospital of USTC, Hefei/CN

Introduction: Immune checkpoint inhibitors (ICIs), either as monotherapy or in combination, have significantly improved outcomes in patients with driver gene-negative advanced non-small cell lung cancer (NSCLC). However, disease progression is inevitable in most patients, after which options are limited. Overcoming the inherent poor antigenicity and immunosuppressive tumor microenvironment post-immunotherapy may represent a critical strategy for achieving durable responses to ICIs. Recent evidence suggests that Janus kinase inhibitors (JAKi) may enhance antitumor immunity, and combination with ICIs could potentially overcome resistance to prior immunotherapy and restore antitumor immune responses. This study aims to evaluate the efficacy and safety of tislelizumab (a PD-1 inhibitor) in combination with tofacitinib (a JAK inhibitor) and docetaxel, with the goal of optimizing rechallenge strategies in patients with ICI-resistant NSCLC.

Methods: This is an open-label, single-arm, prospective, multicenter phase II trial designed to assess the efficacy and safety of tislelizumab in combination with tofacitinib and docetaxel as second-line treatment for patients with advanced NSCLC who experienced disease progression after first-line immunotherapy. Eligible patients will receive tofacitinib orally at a dose of 5 mg daily, followed by tislelizumab (200 mg) and docetaxel (75 mg/m2) intravenously at day 8 and then every 3 weeks for 2 years or until progression. The primary endpoint is the objective response rate (ORR) as assessed by the investigator using RECIST 1.1 criteria. Secondary endpoints include progression-free survival (PFS), 6-month PFS rate, disease control rate (DCR), duration of response (DoR), overall survival (OS), and safety. Exploratory objectives will focus on identifying potential biomarkers through blood, urine, and tumor tissue analyses. Adverse events will be monitored throughout the trial and graded according to the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0.

P3.18.50 Induction Tislelizumab With Chemotherapy Followed by Surgery and Radiotherapy in Stage III-N3 Unresectable NSCLC (HURRICAN

A. Li, J. Yu, A. Yu, H. Liu
Cancer Hospital of China Medical University, Liaoning Cancer Hospital & Institute, Shenyang/CN

Introduction: The current standard of care for patients with unresectable locally advanced non-small cell lung cancer (NSCLC) is concurrent chemoradiotherapy (CRT) followed by immunotherapy consolidative. However, up to 30% of patients are ineligible for immunotherapy consolidation. Furthermore, intrathoracic local recurrence remains the predominant mode of treatment failure. Therefore, optimizing local control is a critical priority, particularly for more advanced N3 lymph nodes involvement (part of IIIB and IIIC) patients. To address these challenges, preliminary investigations have explored surgical intervention following immunotherapy-based conversion therapy in N3 patients. However, the feasibility of radical surgery for N3 disease remains constrained. In response, this study aims to evaluate a comprehensive treatment strategy integrating surgery and hypofractionated radiotherapy following induction immunotherapy and chemotherapy, with subsequent immunotherapy consolidation. The objective is to optimize individualized treatment selection, improve local control, and ultimately enhance long-term survival outcomes.

Methods: This is a prospective, multicenter, single arm phase 2 clinical trial enrolling 30 newly diagnosed stage III NSCLC patients with N3 lymph-node metastasis (T1-4N3M0, AJCC 9th edition). Mainly eligible patients must be negative for sensitive gene mutations, treatment-naive for systemic or local therapy, aged ≥18 years, and have an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1, with at least one measurable lesion according to RECIST 1.1 criteria at baseline. Key exclusion criteria include invasion of critical structures such as the aorta, trachea, esophagus, or heart by the primary tumor or metastatic lymph nodes, as well as the presence of Pancoast tumors. Following induction therapy with 3-4 cycles of Tislelizumab combined with platinum-based chemotherapy, patients without disease progression will be evaluated by a multidisciplinary team (MDT) and assigned to treatment strategies based on eligibility and patient preference. Patients deemed eligible to surgery will receive standard lung cancer resection (excluding total pneumonectomy), including removal of the primary tumor, ipsilateral hilar, and ipsilateral mediastinal lymph nodes, followed by hypofractionated chemoradiotherapy targeting N3 metastatic lymph nodes. Patients ineligible for or unwilling to undergo surgery will receive definitive conventional CRT. After completion of local treatment, all patients will continue Tislelizumab maintenance therapy until radiographic disease progression, unacceptable toxicity, or completion of one year of treatment. The primary endpoint is the 1-year event-free survival rate (1y-EFS rate). Secondary endpoints include EFS, overall survival (OS), surgical conversion rate, time to distant metastasis (TTDM), time to local recurrence (TTLR), adverse events (AEs), and the impact of the integrated treatment approach on patient-reported outcomes (PROs). Exploratory analyses will be conducted to identify predictive and prognostic biomarkers using tumor tissue and blood samples collected at multiple time points during the study.

P3.18.51 Anlotinib Combined With PD-1 Blockade and Platinum Doublet Chemotherapy for PSC as First Line Treatment

Y. Wang, Q. Zhao, L. Miao
Nanjing Drum Tower Hospital, Nanjing/CN

Introduction: Pulmonary sarcomatoid carcinoma (PSC) is a unique, highly invasive pulmonary malignancy with a poor prognosis, representing approximately 0.5% of all malignant lung cancers. Many retrospective clinical trials demonstrated good response to imunnotherapy, and ORR was about 30-60%. In this trial, we try to demonstrate the efficacy and safety of Penpulimab combined with anlotinib and platinum doublet chemotherapy as first line treatment for PSC.

Methods: The study included patients with histologically confirmed sarcomatoid carcinoma of the lung; who had not received systemic therapy previously; with measurable lesions (according to RECIST 1.1 criteria); ECOG score 0-1; and aged ≥18 years. The treatment regimen included albumin-bound paclitaxel (100 mg/m^2, d1, d8, d15/q3w or 260mg/m2 d1/q3w), carboplatin (AUC=5, d1/q3w), anlotinib (12 mg, po, qd, d1-14/q3w), and penpulimab (200 mg, d1/q3w) for 4 cycles, following penpulimab and anlotinib for maintenance therapy until progression of disease(PD) or intolerable toxicity. The primary endpoint is PFS, and secondary endpoint included ORR, OS, DCR and safety.

Results: Till March 20, 2025, we enrolled 5 patients. All 5 patients can be evaluated. The ORR is 80% (4/5), and DCR is 100% (5/5). Any grade AE is 100%. The incidence of adverse events at any level is 100%, mainly decreased white blood cells, hypertension, decreased neutrophils, skin reaction of hands and feet, stomatitis, weight loss, and rash.The incidence of adverse events above grade 3 is 40%, mainly increased hypertension, stomatitis, and decreased white blood cells.

Conclusions: Anlotinib combined with PD-1 blockade and platinum doublet chemotherapy is efficacious and AE can be manageable as first line treatment for PSC.$$graphic_{09237E65-9163-43D9-8B75-0AA065617818}$$$$graphic_{18E045F6-7A79-4B06-B56B-DD3E9089524A}$$

P3.18.52 Phase 3 Trial ResQ201A of NAI Plus Tislelizumab and Docetaxel Vs. Docetaxel Monotherapy for Advanced or Metastatic NSCLC Resistant to ICI Therapy

S. Reddy[1], L. Sender[1], R. Blanton[1], A. Malhotra[1], K. He[2], D. Morgensztern[3], J. Wrangle[4], A. Greystoke[5], M. Vincent[6], D. Breadner[6], T. Weitz[1], P.R. Spilman[1], P. Bhar[1], H. Zhang[1], P. Soon-Shiong[1], L. Drusbosky[1]
[1]ImmunityBio, Inc., Culver City/CA/USA ,[2]The Ohio State University Comprehensive Cancer Center, Columbus/OH/USA ,[3]Washington University, St. Louis/MO/USA ,[4]Medical University of South Carolina, Charleston/SC/USA ,[5]Newcastle University, Newcastle/GB ,[6]London Health Sciences Centre, London/ON/CA

Introduction: Immune checkpoint inhibitors (ICIs) that target PD-1 or PD-L1 are approved for use as monotherapy and in combination with chemotherapy in advanced NSCLC. Unfortunately, a majority of patients experience progressive disease with limited treatment options, warranting better options following progression on an ICI. Findings from Phase 2 studies [Wrangle Lancet Oncol. 2018;19(5):694-704; and J. Thorac. Oncol. 2024; 19(10) Suppl.] have demonstrated the potential for the IL-15 receptor superagonist nogapendekin alfa inbakicept (NAI; or N-803) as a novel lymphocyte stimulating agent (LSA) to enhance ICI efficacy, prolonging progression-free survival (PFS) and overall survival (OS) when used in combination with an ICI. ResQ201A is specifically informed by the trial QUILT3.055 wherein median OS was prolonged at 14.3 months overall, and further prolonged to 15.8 months in the 80% of participants wherein NAI increased or maintained absolute lymphocyte counts (ALC) > 1200, and to 21.1 months in those with ALC ≥ 1500. In ResQ201A, monotherapy docetaxel, standard 2nd line therapy for NSCLC, is being compared to combination therapy with NAI, anti-PD-1 tislelizumab [Wang 2021 JAMA Oncol 7], and 2 cycles of docetaxel. NAI, acting as LSA that proliferates and activates NK and T cells, is anticipated to contribute to the efficacy of docetaxel plus tislelizumab therapy in ICI-resistant NSCLC and prolong survival as shown in QUILT 3.055 when administered without chemotherapy.

Methods: In this randomized, open-label phase 3 trial ResQ201A (NCT06745908), up to 462 participants are being enrolled 2:1 in an experimental arm to receive NAI, tislelizumab, and docetaxel or a control arm to receive docetaxel monotherapy. Participants are stratified based on histology, presence of actionable genomic alterations, and geographical region. Experimental arm treatment consists of two 3-week cycles NAI [SC 1.2 mg], tislelizumab [IV 200 mg] plus docetaxel [IV 75 mg/m2] followed by repeated 3-week cycles of NAI (1.2 mg) and tislelizumab (200 mg) without chemotherapy; control arm treatment consists of repeated 3-week cycles with docetaxel (IV 75 mg/m2). Key inclusion criteria are: age ≥ 18 years, ability to provide informed consent, pathologically-confirmed stage IV NSCLC with acquired resistance to an ICI (PD after an initial response or stable disease (SD) (≥ 6 mo. duration) to a single line of anti-PD-(L)1 with or without anti-CTLA-4 or chemotherapy, ECOG performance status of 0 to 2, and measurable tumor lesions according to RECIST v1.1. Key exclusion criteria are: systemic autoimmune disease, history of organ transplant, and positive actionable genomic alterations (AGA) such as ALK AGA. The primary efficacy endpoint is OS by Kaplan-Meier with treatment arm comparison based on the stratified log-rank test and OS hazard ratio (and 95% CI) summarized based on the stratified Cox proportional hazard model, both stratified by the randomization strata. Secondary efficacy endpoints are the immune disease control rate (iDCR - iCR + iPR + iSD [≥ 2 months]) per iRECIST; progression-free survival (iPFS), overall response rate (iORR) and duration of response (iDOR). Safety is assessed by AEs and SAEs graded using the NCI CTCAE v5.0.

P3.18.53 Phase 3 Clinical Trial ResQ201A of N-803 (NAI), Tislelizumab and Docetaxel Vs. Docetaxel Monotherapy for Advanced NSCLC Resistant to ICI Therapy

P.R. Spilman[1], S. Reddy[1], L. Sender[1], A. Malhotra[1], R. Blanton[1], M. Vincent[2], D. Breadner[2], T. Weitz[1], P. Bhar[1], H. Zhang[1], P. Soon-Shiong[1]
[1]ImmunityBio, Inc., Culver City/CA/USA ,[2]London Health Sciences Centre, London/ON/CA

Introduction: This is a description of the phase 3 clinical trial ResQ201A-NSCLC (USA: NCT06745908 and EU: 2025-521221-32-00) for people with advanced or metastatic nonsmall cell lung cancer (NSCLC). A phase 3 clinical trial looks at how well a possible new treatment works, as well as its side effects, in many people. The participants in this trial have NSCLC and have previously received a type of immunotherapy called an 'immune checkpoint inhibitor' (or ICI) for which the therapy stopped working overtime. ICIs block proteins that prevent immune cells from actively killing tumor cells. In this study, an ICI called tislelizumab will be used with a new treatment called nogapendekin alfa inbakicept (NAI) that is very good at activating immune cells called natural killer and T cells. It is thought these 2 treatments together with docetaxel - a standard chemotherapy used for NSCLC - will be more effective than docetaxel alone. Tislelizumab has already been approved by the U.S.A. FDA for 2 types of esophageal cancer and NAI has already been shown to be effective for a particular type of bladder cancer, for which it was approved by the FDA in 2024.

Methods: The trial is open label, which means the people running the trial and the participants receiving treatment in the study will know the treatment received. Up to 462 participants will be enrolled and assigned to either the group (or 'arm') that receives the experimental combination of the 3 treatments or to the 'control' arm, where they would receive docetaxel alone. In the experimental arm, participants will receive two 3-week cycles of NAI (1.2 mg) by subcutaneous injection, tislelizumab (200 mg) by intravenous (IV) infusion, and docetaxel (75 mg/m2) also by IV, followed by repeated 3week cycles of only NAI and tislelizumab at the same dosage. Participants in the control arm will receive repeated 3-week cycles of docetaxel alone (IV 75 mg/m2). Participants must be at least 18 years of age, be able to understand what will happen on the study (informed consent). and have stage 4 NSCLC that was previously treated with an ICI that either was not effective or that became less effective over time. Participants need to be relatively healthy (ECOG score of 0 to 2). Tumors will be scanned by CT or MRI and measured using systems called RECIST v1.1 and immune RECIST. People who have immune diseases, are receiving treatment after an organ transplant, or who have a genetic alteration termed 'ALK' cannot participate in the study. An important objective is the time a participant survives, called 'overall survival. This will be analyzed using a statistical method called KaplanMeier. Important assessments are changes in the tumor size, if any, and how long it lasts, referred to as the disease control rate, the objective response rate, and progression-free survival. Determination of safety is very important, therefore vital signs and changes in laboratory tests will be recorded, as well as adverse events (AEs) of all severity using the NCI CTCAE v5.0 system.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.54 Increasing the Dosing Interval of Osimertinib in Patients With EGFR-Mutated Advanced NSCLC (OSI-SAVE Study Design)

M. van den Bos[1], S.L. van der Zeeuw[2], G.D.M. Veerman[1], M.S. Paats[1], E. Oomen- de Hoop[1], M-R.B.S. Crombag[2], L.E.L. Hendriks[3], M.A. van der Drift[4], A.J. van der Wekken[5], I. Bahce[6], W.K. de Jong[7], E.F. Smit[8], J. Remon[9], D. Planchard[9], V.F. Surmont[10], R.H.J. Mathijssen[1], I.H. van der Sijs[2], A-M.C. Dingemans[1]
[1]Erasmus MC Cancer Institute, University Medical Center, Rotterdam/NL ,[2]Erasmus University Medical Center, Rotterdam/NL ,[3]Maastricht University Medical Center+, Maastricht/NL ,[4]Radboud University Medical Center, Nijmegen/NL ,[5]University of Groningen, University Medical Center Groningen,, Groningen/NL ,[6]Amsterdam UMC, Location VU Medical Center, Cancer Center Amsterdam, Amsterdam/NL ,[7]University Medical Center Utrecht, Utrecht/NL ,[8]Leiden University Medical Center, Leiden/NL ,[9]Gustave Roussy, Villejuif/FR ,[10]Ghent University Hospital, Ghent/BE

Introduction: Osimertinib, a third-generation tyrosine kinase inhibitor (TKI), is approved as a first-line treatment for locally advanced or metastatic epidermal growth factor receptor (EGFR)-mutated non-small cell lung cancer (NSCLC). At the registered dosage of 80 mg once daily (QD), up to 98% of patients experience adverse events, most frequently diarrhea and rash, while severe toxicity occurs in up to 34% of cases. Phase 2 studies suggest that reducing the dose to 40 mg QD maintains efficacy while decreasing toxicity. Given osimertinib's half-life of 44 hours, extending the dosing interval to 80 mg every other day (QOD) is pharmacokinetically justifiable, as it provides an area under the curve (AUC) equivalent to that of 40 mg QD. This adjusted dosing regimen could reduce adverse events without compromising therapeutic effectiveness. Furthermore, a non-daily regimen will reduce the cost of osimertinib by approximately €3,000 per patient per month in Europe. Given a median progression-free survival (mPFS) of 18.9 months, this could yield substantial savings.

Objective: The primary objective of this trial is to investigate the effectiveness of osimertinib 80 mg QOD compared to the registered 80 mg QD regimen. The primary endpoint is PFS defined as the time from randomisation to clinical or radiological disease progression. Secondary endpoints include overall survival, patient-reported toxicity, quality of life, the cumulative incidence of central nervous system (CNS) metastases and economic assessment. Exploratory endpoints include pharmacokinetics, pharmacogenetics, and circulating tumor DNA.

Methods: This international, randomized controlled, non-inferiority trial (EU trial number: 2024-514693-47-00) will enroll 383 patients to achieve 80% power with a 10% non-inferiority margin. Eligible patients must have received osimertinib 80 mg QD, with or without platinum-pemetrexed chemotherapy, for at least three months to treat EGFR-mutated (exon 19 deletion or L858R), locally advanced or metastatic NSCLC. Secondly, they must have demonstrated a radiological response to treatment. Patients with baseline CNS metastases will be excluded. Patients will be randomized in a 1:1 ratio to receive either osimertinib 80 mg QOD or continue 80 mg QD, with or without chemotherapy, and will be monitored in routine clinical care for up to two years.

Relevance: This is the first large-scale clinical trial to determine whether increasing the dosing interval of osimertinib in NSCLC patients is both safe and effective. If non-inferiority is demonstrated, the results will provide robust evidence to support the adoption of osimertinib 80 mg QOD as a standard-of-care regimen.

P3.18.55 A Phase II Study of Repotrectinib in ROS1-Positive Non-Small Cell Lung Cancer Patients With Active Brain Metastasis - REPOSE

T. Füereder[1], B. Kiesewetter[2], G.L. Banna[3], J. Perez-Escuredo[4], J.A.G. Martinez[4], A.M. Molina[4], F. Slebe[4], A. Grisold[5], A.S. Berghoff[1], M. Preusser[1]
[1]Department of Medicine I, Division of Oncology, Medical University of Vienna, Vienna/AT ,[2]Medical University of Vienna, Vienna General Hospital, Vienna/AT ,[3]Portsmouth Hospitals University NHS Trust, Portsmouth/GB ,[4]MEDSIR, Barcelona/ES ,[5]Department of Neurology, Medical University of Vienna, Vienna/AT

Introduction: A subset of patients with metastatic NSCLC (mNSCLC) have tumors that harbor driver genetic alterations, including ROS1 rearrangements, which are detected in 0.9-2.6% of mNSCLC cases. ROS1-targeted tyrosine kinase inhibitors (TKIs) have transformed the disease course. However, given that up to 50% of patients develop brain metastases (BM), and current treatment options are limited for overcoming acquired resistance, novel ROS1 inhibitors with enhanced intracranial (IC) efficacy are needed. Preclinical studies reported that repotrectinib, a next-generation ROS1 inhibitor, is a highly selective ROS1 inhibitor with favorable properties for enhanced intracranial activity. The TRIDENT-1 (NCT03093116) study reported meaningful IC activity of repotrectinib in patients with advanced solid tumors harboring ROS1, or NTRK1-3 rearrangements and asymptomatic BM. The limited treatment options for patients with BM, particularly those with symptomatic lesions, and the promising IC overall response rate (ORR) observed in TRIDENT-1 underscore the need for further research.

Methods: REPOSE (NCT06315010) is an international, multicenter, open-label, single-arm, phase II trial using Simon's two-stage design in patients with mNSCLC with ROS1 fusion and active BM. Eligible adult patients must have histologically proven advanced NSCLC with ROS1 fusion and untreated or progressing BM after local treatment, with no immediate indication for neurosurgery or radiotherapy. Prior anti-ROS1 therapy is not allowed. Participants must have at least one measurable brain lesion (≥10 mm) confirmed by T1-weighted, gadolinium-enhanced MRI, meeting RANO-BM criteria. There is no limit on prior chemotherapy, immunotherapy, or non-ROS1 TKI therapy. ECOG performance status must be ≤2, with adequate bone marrow and organ function.Twenty patients will be enrolled to receive repotrectinib 160 mg orally once daily for 14 days, then twice daily until unacceptable toxicity, disease progression, death, or discontinuation for any reason. The first stage includes 10 patients, expandable to 20 in the second stage.The primary endpoint is IC-ORR at any time, based on the best CNS response per RANO-BM criteria. Main secondary endpoints include ORR (RECIST v1.1 for extracranial (EC)/overall lesions), clinical benefit rate, disease control rate, time to response, duration of response, best tumor burden change and progression-free survival (RANO-BM for IC lesions, RECIST v1.1 for EC/overall lesions), overall survival (OS), neurological function (NANO scale), patient reported outcomes, and safety (NCI-CTCAE 5.0). The sample size follows Simon's two-stage design. An IC-ORR ≥50% is the alternative hypothesis, while ≤20% is unmeaningful (null hypothesis). The design has a 10% one-sided type I error rate and 93.8% power to reject the null hypothesis. The study will stop for futility if <2 (20%) intracranial responses occur in stage 1 (N=10). The primary endpoint is met if ≥7 of 20 patients show intracranial responses. Primary analysis will use Koyama & Chen's (2008) methods. Enrollment is expected to take 17 months. The steering committee will decide on continuation based on efficacy and safety. Trial activation is expected in April 2025 for Spain and Austria, and in June 2025 for Germany, with about 15 sites across the three countries.Clinical Trial Identification: NCT06315010Support and funding: Bristol-Myers Squibb (BMS)

P3.18.56 EGFR-Mutated Lung Cancer in Randomized Investigator-Initiated Study (ERIS): A National Phase III Trial From the Swedish Lung Cancer Study Group

M. Jönsson[1], F. Rosengren[1], A. Karlsson[1], J. Staaf[1], S. Isaksson[1], G. Grubb[2], J. Isaksson[3], U. Mager[4], M. Johansson[5], A. Vikström[6], E. Broström[7], D. Agterhuis[8], J. Sundh[9], N. Carlson[10], B. Bergman[11], S. Ekman[12], M. Planck[1]
[1]Lund University, Lund/SE ,[2]Skane University Hospital, Lund/SE ,[3]Gävle Hospital, Gävle/SE ,[4]Halland's Hospital, Halmstad/SE ,[5]University Hospital of Umeå, Umeå/SE ,[6]University Hospital, Linköping/SE ,[7]Uppsala University Hospital, Uppsala/SE ,[8]Falu Hospital, Falun/SE ,[9]Örebro University Hospital, Örebro/SE ,[10]Central Hospital Kristianstad, Kristianstad/SE ,[11]Sahlgrenska University Hospital, Gothenburg/SE ,[12]Karolinska Institute, Stockholm/SE

Introduction: Advanced EGFR-mutated non-small cell lung cancer (NSCLC) should be treated with a tyrosine kinase inhibitor (TKI) in first line. Current Swedish guidelines recommend either a third-generation inhibitor, osimertinib, or one of the second-generation EGFR-inhibitors, afatinib or dacomitinib. Given differences in complexity of resistance at tumor progression during treatment with these agents (that have not yet been compared in a head-to-head trial), the optimal sequence of EGFR-inhibitors is still under debate. In this nation-wide randomized trial, ERIS, we will evaluate progression free survival, total time on TKI treatment, overall survival, tumor responses, adverse effects, quality-of-life, and molecular profiles in blood and tumor samples aimed for improving treatment decisions and management of resistance mechanisms.

Methods: The main inclusion criteria is advanced EGFR-mutated NSCLC accepted for first-line treatment with an EGFR-TKI. Exclusion criteria include e.g. presence of second primary malignancy without radical treatment option. Study participants are randomized to second or third generation EGFR-inhibitor, i.e. afatinib/dacomitinib or osimertinib. Randomization is stratified according to occurrence of CNS metastases and according to EGFR mutation type. Cross-over to osimertinib in second line is recommended in the event of T790M-positive progression during treatment with a second-generation inhibitor. Choice of regimen in all subsequent lines of treatment is made by the local investigators. The study includes a structured assembling of clinical data, tumor evaluation, and laboratory tests. The longitudinally sampled blood and tumor tissue will be used for explorative analyses on the DNA, RNA, and protein level. An inclusion of minimum 200 patients over a three year-period in Sweden is planned and the study will end 36 months after the last inclusion.

Results: At abstract submission, a total of 82 patients at 11 different hospitals in Sweden have been randomized.

Conclusions: There is a need to identify who will benefit most from second vs. third generation EGFR-TKI:s in first line. Early treatment prediction and monitoring through biomarkers may lead to more individualized treatment. In ERIS, we address these questions by randomization between osimertinib and dacomitinib/afatinib and by longitudinal sampling of blood and tumor tissue.

Introduction: Epidermal growth factor receptor (EGFR) mutations are the predominant drivers of NSCLC. While EGFR tyrosine kinase inhibitors (TKIs) are the primary treatment for EGFR-mutant NSCLC patients, resistance inevitably develops, leading to disease progression. JIN-A02, a novel 4th generation EGFR-TKI, intended for oral administration, selectively and reversibly binds to EGFR mutations, including the C797S and/or T790M mutation that causes resistance to 3rd generation of EGFR-TKIs. Preclinical studies with EGFR C797S and/or T790M mutated cell lines and C797S+ xenograft mice model showed that JIN-A02 inhibits cell and tumor growth in a dose dependent manner and exhibits high selectivity over wild-type EGFR. Moreover, JIN-A02 has been shown to penetrate the blood-brain barrier and exhibit anti-tumor activity in an intracranial tumor model. This phase 1/2 study is designed to evaluate the safety and anti-tumor activity of JIN-A02 in EGFR-mutant NSCLC patients.

Methods: JIN-A02 is under evaluation in Phase 1/2, multicenter, an open-label trial (NCT05394831) for subjects with advanced NSCLC harboring C797S and/or T790M mutation as a monotherapy. The primary objective is to assess safety, tolerability, pharmacokinetics, and anti-tumor effect for determining the recommended phase 2 dose (RP2D) of JIN-A02. Inclusion criteria are that the subject (≥ 18 years) must have advanced or metastatic NSCLC showing progressive disease post-treatment with approved standard EGFR-TKIs and/or platinum-based anticancer chemotherapy, with ECOG status 0 or 1.The study consists of 3 parts: dose escalation (Part A), dose exploration (Part B), and dose expansion (Part C). In Part A, JIN-A02 is administered orally once daily from 12.5 mg, and at least 3 subjects are recruited per cohort conducted over 28 days cycles to evaluate the maximum tolerated dose. Dose escalation between cohorts is made at up to twice the prior dose level. Dose-limiting toxicities (DLTs) are assessed over 21 days. Part B aims to further evaluate JIN-A02 safety to determine the RP2D using two preliminary effective dose levels from Part A. In Part C, subjects are divided into 5 cohorts based on the EGFR mutation status (both or single positive for C797S and T790M), and the anti-tumor activity of JIN-A02 is evaluated according to RECIST v1.1 at the RP2D.

Results: As of April 01, 2025, Part A is still in progress at Cohort 6 of 300 mg daily. A total of 20 subjects received JIN-A02 over 6 dose levels and 4 subjects are still on study treatment (2 subjects with 150mg, 2 subjects with 300mg). No DLT has been reported in any of these 6 cohorts in Part A. Three patients with EX19DEL/T790M/C797S exhibited partial responses (50 mg OD, 100 mg OD, and 300 mg OD, respectively). The median duration of response among these responders was 414 days (range: 106 days - 539 days). Of these, the patient on 300 mg showed a sustained response with shrinkage of lung (-39.7%) and brain lesions (-19.4 %). Furthermore, in the ctDNA analysis of this patient, C797S and EX19DEL mutations were completed cleared and more than 90% of T790M mutation was cleared after JIN-A02 treatment.

Conclusions: Further dose escalation is warranted to comprehensively assess both safety and anti-tumor efficacy of JIN-A02.

Keywords: NSCLC, EGFR, C797S

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.58 Trastuzumab Deruxtecan + Pembrolizumab as First-Line Treatment in HER2-Overexpressing, PD-L1 Tps <50% NSCLC (DESTINY-Lung06)

P. Janne[1], C-C. Zhou[2], E.F. Smit[3], E. Felip[4], K. Goto[5], W.N. William Jr.[6], C. Abe[7], Q. Zhou[7], T. Kamio[7], K. Pereira[7]
[1]Dana-Farber Cancer Institute, Boston/MA/USA ,[2]East Hospital Affiliated to Tongji University, Shanghai/CN ,[3]Leiden University Medical Center, Leiden/NL ,[4]Vall d'Hebron University Hospital & Vall d'Hebron Institute of Oncology (VHIO), Barcelona/ES ,[5]National Cancer Center Hospital East, Kashiwa/JP ,[6]Grupo Oncoclínicas, São Paulo/BR ,[7]Daiichi Sankyo, Inc., Basking Ridge/NJ/USA

Introduction: Non-small cell lung cancer (NSCLC), driven by diverse molecular alterations, is the leading cause of cancer-related deaths globally. Human epidermal growth factor receptor 2 (HER2) overexpression (immunohistochemistry score [IHC] 3+ or IHC 2+) occurs in ~13%-20% of patients with NSCLC and is associated with poor prognosis. Programmed death ligand 1 (PD-L1) is expressed in ~60%-70% of patients with NSCLC and predicts immunotherapy response. Pembrolizumab + platinum-based chemotherapy is a first-line treatment option for patients with HER2-overexpressing nonsquamous NSCLC without actionable genomic alterations (AGAs), regardless of PD-L1 expression. However, survival outcomes are modest in patients with PD-L1 tumor proportion score (TPS) <50%. Additionally, no first-line HER2-directed therapies are approved for HER2-overexpressing NSCLC, highlighting an unmet medical need. Trastuzumab deruxtecan (T-DXd), a HER2-directed antibody-drug conjugate, has shown efficacy in HER2-overexpressing tumors. DESTINY-Lung01 was conducted to investigate T-DXd in patients with previously treated HER2-overexpressing NSCLC. Findings from DESTINY-Lung01, DESTINY-PanTumor02, and DESTINY-CRC02 led to the approval of TDXd monotherapy as the first tumor-agnostic HER2-directed therapy for unresectable/metastatic HER2-positive (IHC 3+) solid tumors after prior systemic treatment and no satisfactory alternative treatment options. Preclinical evidence suggests T-DXd enhances antitumor immunity and may have synergistic effects with immune checkpoint inhibitors. Preliminary data from the phase 1b DS8201-A-U106 trial showed encouraging efficacy with T-DXd + pembrolizumab (confirmed objective response rate [ORR], 54.5%) in immuno-oncology treatment-naive patients with HER2-expressing NSCLC, supporting a larger phase 3 investigation of this treatment combination. DESTINY-Lung06 aims to enhance first-line standard-of-care, immuno-oncology by replacing standard chemotherapy with TDXd + pembrolizumab for patients with HER2 overexpressing, PD-L1 TPS <50% NSCLC.

Methods: DESTINY-Lung06 (NCT06899126) is a global, open-label, randomized, phase 3 trial designed to evaluate the safety and efficacy of T-DXd + pembrolizumab versus platinum-based chemotherapy + pembrolizumab in patients with HER2-overexpressing, PD-L1 TPS <50%, unresectable/metastatic, nonsquamous NSCLC. Patients (≥18 years) should have centrally confirmed HER2 overexpression and PD-L1 TPS <50% and no known AGAs that have locally available therapies targeting their AGAs in the first-line advanced/metastatic setting. Patients should have an Eastern Cooperative Oncology Group performance status of 0 or 1, left ventricular ejection fraction ≥50%, and not have received prior systemic anticancer therapy in the metastatic setting. Patients with a history of myocardial infarction, interstitial lung disease/pneumonitis, or other lung-specific illnesses will be excluded. The primary endpoint is progression-free survival (PFS) by blinded independent central review (BICR). The key secondary endpoint is overall survival. Additional secondary endpoints include investigator-assessed PFS, ORR and duration of response by BICR and investigator assessment, safety, and patient-reported outcomes. Approximately 686 patients will be randomized 1:1 to receive T-DXd 5.4 mg/kg + pembrolizumab 200 mg every 3 weeks (Q3W) or pemetrexed 500 mg/m2 + platinum-based chemotherapy (cisplatin 75 mg/m2 or carboplatin AUC 5 mg/mL/min) + pembrolizumab 200 mg Q3W. Randomization will be stratified by prior neoadjuvant/adjuvant therapy (yes vs no), smoking history (ever smoked vs never smoked), PD-L1 expression (TPS <1% vs 1%-49%), and HER2 IHC expression (IHC 3+ vs non-3+).

Keywords: non–small cell lung cancer, HER2-overexpressing, trastuzumab deruxtecan

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.59 Resistance Mechanisms and Sequential Therapies Following 1St Line Lorlatinib in ALK+ NSCLC: A Real-World Study (LORES CTONG2501)

S. Lu, z. Li, Z. Chen, Z. Zhou, X. Ai, Y. Yu, Y. Yang, X. Niu
Shanghai Chest Hospital, Shanghai Jiaotong Juniversity School of Medicine, Shanghai/CN

Introduction: Lung cancer remains the leading cause of cancer-related mortality worldwide, with non-small cell lung cancer (NSCLC) accounting for the majority of cases. Approximately 3-7% of NSCLC patients harbor anaplastic lymphoma kinase (ALK) gene rearrangements. ALK-positive NSCLC is characterized by unique molecular features and a high propensity for brain metastases, contributing to suboptimal clinical outcomes. Lorlatinib, a third-generation ALK tyrosine kinase inhibitor (TKI), has demonstrated unprecedented progression-free survival (PFS) and intracranial efficacy in first-line treatment of locally advanced and metastatic ALK-positive NSCLC. Despite its effectiveness, resistance to lorlatinib inevitably emerges in some cases, and the mechanisms underlying resistance in real-world populations after first-line use are poorly characterized. Furthermore, evidence guiding sequential therapies post-lorlatinib progression is limited. This study aims to address these critical gaps by prospectively investigating resistance mechanisms and evaluating the clinical utility of subsequent treatment strategies in a real-world cohort, thereby informing personalized therapeutic approaches, optimizing patient management and improving overall survival.

Methods: This is a multicenter, prospective, observational real-world study enrolling approximately 100 adults with locally advanced/metastatic ALK-positive NSCLC who progressed after first-line treatment with lorlatinib. Patients will be recruited from 10 sites in China. Key inclusion criteria include histologically or cytologically confirmed NSCLC, ALK gene rearrangement confirmed by approved tests, and documented disease progression after first-line lorlatinib treatment. Exclusion criteria include prior treatment with other ALK-TKI and concurrent participation in other interventional clinical studies. The primary objective is to explore the resistance mechanisms to first-line lorlatinib. Secondary objectives include evaluating the efficacy and safety of sequential treatment strategies post-lorlatinib progression. Resistance mechanisms will be investigated using next-generation sequencing (NGS) of circulating tumor DNA (ctDNA) and tissue biopsy DNA and RNA (when feasible). If possible, the detection of stereo-seq(RNA) will be further carried out. Patients will be followed up for 24 months to assess the outcomes of post-progression therapies. Descriptive statistical analyses will be conducted, and Kaplan-Meier curves will be used to summarize time-to-event variables.

Introduction: The French National Cancer Institute has proposed funding for research networks focused on cancers with poor prognosis. The COALA network, dedicated to oncogene-addicted lung adenocarcinoma, received funding of 3 M€ in 2024 for a period of five years, with the goal of improving the prognosis of this group of patients. One of the main challenges in thoracic oncology is to increase the survival of patients with oncogenic addiction. A better understanding of tumor biology has allowed the development of targeted therapies that are highly effective in terms of response rates and progression-free survival without being able to definitively eradicate the disease. The objective of COALA is to bring together physicians, surgeons, biologists, computer scientists, mathematicians and sociologists from 15 expert centers in France. By enhancing our understanding of treatment resistance and identifying strategies to overcoming it, the network aims to offer patients a better prognosis.

Methods: Our aim is to radically improve the outcome of oncogene-addicted lung cancer by setting up a national network with the following goals: - Overcome the molecular resistance to targeted therapies in highly oncogene-addicted lung cancer (EGFR, ALK, ROS1, BRAF V600E) with a focus on the residual disease. - Improve the targeting of hard-to-treat alteration (KRAS, MET, HER2) or emergent biomarkers (BRAF nonV600, NRG1). - Address the role of the immune and non-immune environment in molecularly characterized lung cancer to refine the role of immunotherapy and non-targeted agents. - Extend our findings and hypotheses on early-stage lung cancer to improve the potential to radically cure oncogene-addicted NSCLC. - Address the sociological aspect of building such a network including multiple partners. - Harmonize and organize all the clinical and biological databases to fuel all the projects. - Create a consortium around the theme including patients, academic and industrial partners. - Develop specific clinical trial based on our preclinical findings - Disseminate the knowledge to inform the community and to recruit more researchers to this cause, enabling French research on lung cancer to cross new boundaries. The COALA network aims to bring together expert teams in France to focus on this ambitious integrated research project. Our goal is to identify new vulnerabilities in resistance mechanisms to targeted therapy. The objective is to implement our therapeutic strategies, particularly to target residual disease and significantly improve the prognosis of lung cancer associated with oncogenic addiction, in both advanced and early stages.

Introduction: Adagrasib is a potent, orally available, small molecule covalent KRASG12C inhibitor that has received accelerated/conditional approval as monotherapy in the United States, European Union, and United Kingdom for patients with previously treated KRASG12C-mutated locally advanced/metastatic NSCLC based on results from the phase 1/2 KRYSTAL-1 study. Adagrasib further demonstrated significant improvements in progression-free survival (PFS) and objective response rate (ORR) compared with docetaxel in the phase 3 KRYSTAL-12 study in patients with KRASG12C-mutated advanced/metastatic NSCLC previously treated with chemotherapy and immunotherapy. For patients with previously untreated KRASG12C-mutated advanced/metastatic NSCLC, the standard of care remains immunotherapy with or without chemotherapy. However, in patients with advanced NSCLC (not selected for KRAS mutation status), this first-line approach results in a median PFS of 6-9 months and a 5-year overall survival (OS) rate of approximately 20% (de Castro G, et al. J Clin Oncol 2022; Garassino MC, et al. J Clin Oncol 2023). Adagrasib is currently being evaluated in the first-line setting in combination with pembrolizumab, a PD-1 inhibitor, vs pembrolizumab monotherapy in patients with KRASG12C-mutated advanced/metastatic NSCLC and PD-L1 ≥50% in the phase 3 portion of the KRYSTAL-7 study (NCT04613596), following promising results from the phase 2 portion of the study (ORR, 59%; median PFS, 27.7 months; Garassino MC, et al. ELCC 2025). First-line adagrasib is also being evaluated in combination with pembrolizumab and chemotherapy in the single-arm, phase 2 KRYSTAL-17 study (NCT05609578). The phase 3 KRYSTAL-4 study (NCT06875310) aims to evaluate the efficacy and safety of first-line adagrasib in combination with pembrolizumab and chemotherapy vs placebo with pembrolizumab and chemotherapy in patients with KRASG12C-mutated advanced/metastatic non-squamous NSCLC, regardless of PD-L1 expression level.

Methods: KRYSTAL-4 is a randomized, double-blind, placebo-controlled, phase 3 study of adagrasib plus pembrolizumab and platinum-doublet chemotherapy vs placebo plus pembrolizumab and platinum-doublet chemotherapy in patients with treatment-naïve, locally advanced/metastatic non-squamous NSCLC with a KRASG12C mutation (detected in tumor tissue and/or circulating tumor DNA centrally or locally using a sponsor-approved test). Patients may have any level of tumor PD-L1 expression (determined centrally or locally using a sponsor-approved immunohistochemistry test). Patients with stable and asymptomatic brain metastases, including untreated brain metastases (≤20 mm in diameter), are eligible for inclusion. Randomization (1:1) will be stratified according to tumor PD-L1 expression (<1% vs 1-49% vs ≥50%) and presence of brain metastases (yes vs no). Patients will receive adagrasib 400 mg or placebo orally BID (until disease progression or unacceptable toxicity), pembrolizumab 200 mg intravenously Q3W (up to a total of 24 months), and pemetrexed 500 mg/m2 (until disease progression or unacceptable toxicity) plus cisplatin 75 mg/m2 or carboplatin AUC 5 mg/ml/min intravenously Q3W (four cycles). The study has dual primary endpoints of PFS (per RECIST v1.1 according to blinded independent central review [BICR]) and OS. Secondary endpoints include ORR and duration of response per RECIST v1.1 according to BICR, PFS according to investigator assessment, safety, and patient-reported outcomes. Intracranial efficacy and investigator-assessed PFS2 will also be evaluated as exploratory endpoints.

Introduction: ROS1 gene fusions, oncogenic alterations that result in constitutive activation of the ROS1 kinase domain leading to dysregulated cell differentiation, proliferation, and survival, occur in ~2% of patients with non-small cell lung cancer (NSCLC). Patients with ROS1+ NSCLC tend to be female, younger, never-smokers, diagnosed at an advanced stage, and have adenocarcinoma. Crizotinib, a tyrosine kinase inhibitor (TKI) approved by the US Food and Drug Administration (FDA) for ROS1+ NSCLC in 2016, transformed clinical outcomes (objective response rate [ORR], 72%; median progression-free survival [PFS], 19.3 months; Shaw et al, Annals of Oncology 2019) for patients with ROS1+ NSCLC; however, ~50% of crizotinib-treated patients developed central nervous system (CNS) metastases, and ~30%-40% developed the acquired resistance mutation G2032R. Taletrectinib, an oral, potent, CNS-active, selective, next-generation, ROS1 inhibitor, has shown high and durable responses and favorable safety in patients with ROS1+ NSCLC. In the pooled analysis of the two pivotal phase 2 clinical trials, taletrectinib demonstrated a high confirmed ORR (cORR) in both TKI-naive (n=160; 88.8%) and TKI-pretreated (n=113; 55.8%) patients. Among TKI-naive patients, median duration of response (DOR) was 44.2 months and median PFS was 45.6 months. In crizotinib- or entrectinib-pretreated patients, median DOR and PFS were 16.6 and 9.7 months, respectively. Intracranial-ORR was 76.5% in 17 TKI-naive patients and 65.6% in 32 TKI-pretreated patients. Taletrectinib is active against the most common acquired resistance mutation to crizotinib, G2032R (n=13; cORR, 61.5%). In December 2024, the US FDA granted Priority Review of the New Drug Application for taletrectinib for advanced ROS1+ NSCLC; a Prescription Drug User Fee Act goal date of June 23, 2025, was assigned.

Methods: TRUST-III (NCT06564324) is a phase 3, open-label, head-to-head trial evaluating the efficacy and safety of taletrectinib vs crizotinib in an estimated 138 patients with locally advanced or metastatic ROS1+ NSCLC (Figure). Adults without prior ROS1-targeted TKI will be randomized 1:1 to receive taletrectinib or crizotinib. Patients will be stratified by the presence of baseline CNS metastases and prior use of chemotherapy. Taletrectinib 600 mg (recommended phase 2 dose) will be administered once daily; crizotinib 250 mg will be administered twice daily. Patients will be treated in 28-day cycles until disease progression or unacceptable toxicity. The primary endpoint is PFS per RECIST v1.1 by blinded independent review committee. Key secondary endpoints include ORR; PFS per investigator; overall survival; safety and tolerability; and patient-reported outcomes of health-related quality of life. This trial is currently enrolling.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.63 Phase 1 Study of FHND5071, a Novel Selective RET Inhibitor, in RET Fusion-Positive Advanced NSCLC

B. Han[1], T. Chu[1], D. Yuan[2], Y. Zhu[2]
[1]Shanghai Chest Hospital, Shanghai/CN ,[2]Jiangsu Chia Tai Fenghai Pharmaceutical Co. Ltd., Nanjing/CN

Introduction: FHND5071 is a novel, oral, selective RET inhibitor that demonstrates strong tissue and brain penetration. In preclinical studies, FHND5071 exhibited significantly higher tumor and brain tissue exposure: the AUC_{0-t} of FHND5071 in tumor tissue was approximately 28-time higher than that of selpercatinib, and its brain concentration was ~33-time higher at 4 hours post-dose. These favorable distribution characteristics translated into robust antitumor activity and CNS efficacy in the ongoing Phase 1 multi-center, open-label trial (NCT05818917).

Methods: Eligible patients (≥18 years) with histologically or cytologically confirmed advanced RET fusion-positive non-small cell lung cancer (NSCLC) who had progressed after standard therapy or had no available standard treatment options were enrolled in dose escalation (40-400 mg QD) and dose expansion cohorts (160 or 240 mg QD). FHND5071 was administered orally QD in continuous 28-day treatment cycles. A total of 48 NSCLC patients were enrolled (N=15 in dose escalation; N=33 in dose expansion). At baseline, 29% (14/48) had brain metastases and 77% (37/48) had received prior treatment. One enrolled patient did not receive study drug and was excluded from the intent-to-treat (ITT) population.

Results: Among the ITT population (N=47), ORR was 68.1% (32/47; 95% CI: 53.6-80.1), and the DCR was 89.4% (42/47; 95% CI: 77.4-96.0). In the pooled high-dose group (≥240 mg, N=27), the ORR was 70.4% (19/27). The median DoR was not reached (95% CI: 11.0-NE), with 68.8% (22/32) of responders still on treatment at cutoff. Median PFS was also not reached (95% CI: 12.8-NE) with a censoring rate of 59.6%. Among 14 patients with baseline brain metastases, 4 had measurable brain metastases. All 4 pts achieved brain metastases shrinkage after the treatment, with reduction of 100%, 85.7%, 48.3% and 32.5% respectively. The CNS ORR reached 100%, consistent with its high brain tissue penetration observed preclinically. Two dose-limiting toxicities (DLTs) were reported in the 400 mg dose group (N=6) during the dose-escalation phase, including one case of Grade 3 proteinuria and one case of Grade 3 elevation in alanine aminotransferase (ALT) and aspartate aminotransferase (AST); both events resolved with supportive care. No treatment-related Grade ≥3 adverse events (TRAEs) occurred in ≥10% of patients. Among Grade ≥3 treatment-emergent adverse events (TEAEs), infectious pneumonia was the only event occurring in ≥10% of patients (5/47, 10.6%).

Conclusions: FHND5071 demonstrated robust antitumor activity, including meaningful intracranial responses. The compound's strong CNS efficacy, along with its manageable safety profile supports its continued development as a promising therapy for patients with RET fusion-positive advanced NSCLC.

P3.18.64 Phase 1 Study to Evaluate the Safety and Tolerability of CVHNLC Plus Pembrolizumab in Patients With Squamous NSCLC

B. Besse[1], B. Schmitt-Bormann[2], M. Falk[2], O. Schönborn-Kellenberger[3], V. Denninger[4], S.D. Koch[4], T. Seibel[2], F. Lehmann[2], P. Codó[2], P. Tyan[2], U. Gnad-Vogt[5]
[1]Gustave Roussy Cancer Campus, Villejuif/FR ,[2]CureVac SE, Wiesbaden/DE ,[3]Cogitars GmbH, Heidelberg/DE ,[4]CureVac SE, Tübingen/DE ,[5]CureVac SE, Weisbaden/DE

Introduction: Programmed cell death protein 1 (PD-1) or PD-ligand 1 (PD-L1) blockade has become an important pillar of standard treatment for patients with metastatic squamous cell non-small cell lung cancer (sqNSCLC). However, the overall prognosis remains poor for these patients, highlighting a high unmet need for new treatment options. Messenger ribonucleic acid (mRNA)-based cancer immunotherapies represent a promising strategy to increase the therapeutic efficacy of immune checkpoint blockade. CVHNLC is an LNP-encapsulated mRNA-based cancer immunotherapeutic encoding eight tumor-associated antigens expressed in sqNSCLC. Our study will assess the safety and tolerability of CVHNLC plus pembrolizumab in patients with sqNSCLC.

Methods: CV-HNLC-001 is a first-in-human, phase 1, dose-finding, open-label trial of CVHNLC in patients with advanced sqNSCLC. The trial comprises a dose-escalation part (Part A) of first-line pembrolizumab maintenance treatment plus CVHNLC followed by an optional dose-expansion part (Part B) of first-line treatment of CVHNLC in combination with pembrolizumab and platinum-based chemotherapy. In Part A, patients with histologically confirmed metastatic stage IV sqNSCLC will be eligible if they have received 3-6 months of treatment with pembrolizumab either as monotherapy or in combination with ≥2 cycles of platinum-based chemotherapy as first-line treatment, with no documented disease progression and eligible for pembrolizumab maintenance therapy. CVHNLC doses between 100 µg and 400 µg will be investigated, guided by a Bayesian Logistic Regression Model. Patients will initially receive 4 weekly intramuscular injections of CVHNLC followed by 3-weekly injections plus pembrolizumab for up to 12 months or until disease progression or undue toxicity. The primary endpoint of Part A includes the number of dose-limiting toxicities and incidence of treatment-related and -emergent adverse events; secondary endpoints include overall response rate per RECIST 1.1, progression-free survival, duration of response, and disease control rate. Exploratory endpoints include antigen-specific immune responses against the encoded antigens, changes in cytokine/chemokine profiles and other biomarker signals detectable in peripheral blood. At the end of Part A, an independent Data and Safety Monitoring Board will recommend the CVHNLC dose for Part B.

Introduction: Lung cancer remains the leading cause of cancer-related mortality worldwide, with previously treated non-small cell lung cancer (NSCLC) patients representing a significant unmet medical need. In this setting, after patients have received platinum-based chemotherapy and/or immune checkpoint inhibitors, docetaxel monotherapy is often the main stay of treatment, with reported objective response rates (ORRs) of 9.2% to 14.7%, median progression-free survival (mPFS) of 3.0 to 4.5 months, and median overall survival (mOS) of 9.1 to 11.8 months across multiple studies. RAS mutations occur in approximately 30% of NSCLC cases, with non-G12C variants making up 60% of these mutations. The majority of these are G12X mutations (such as G12D, G12V, etc.), for which there are currently no approved targeted therapies. Daraxonrasib (RMC-6236) is an oral, RAS(ON) multi-selective, tri-complex inhibitor of GTP-bound mutant and wild-type RAS. In an ongoing Phase 1 monotherapy trial (NCT05379985), daraxonrasib at 120-220 mg daily showed manageable safety and preliminary efficacy in patients with NSCLC. As of a September 30, 2024 data cutoff (N=73), Grade ≥ 3 treatment-related adverse events (TRAEs) reported in ≥2 patients included rash (n=5, 7%), vomiting (n=2, 3%), and anemia (n=2, 3%), with no Grade 4 or Grade 5 TRAEs. In 40 patients with RAS G12X-mutant NSCLC, previously treated with immunotherapy and platinum-based chemotherapy, treatment with daraxonrasib at 120-220 mg resulted in a confirmed ORR of 38%, median duration of response (DOR) of 15.1 months (95% CI: 11.1, Not Estimable [NE]), mPFS of 9.8 months (95% CI: 6-12.3), and a mOS of 17.7 months (95% CI: 13.7-NE). These preliminary results provide strong rationale for the continued development of daraxonrasib in patients with previously treated, locally advanced or metastatic, RAS-mutant NSCLC.

Methods: RASolve 301 is a global, multicenter, open-label, randomized Phase 3 study (NCT06881784) designed to evaluate the efficacy and safety of daraxonrasib compared to docetaxel in patients with previously treated, locally advanced or metastatic, RAS-mutant NSCLC. Patients are randomized 1:1 to receive either docetaxel or daraxonrasib. Key eligibility criteria include histologically confirmed NSCLC, age ≥ 18 years, ECOG performance status of 0 or 1, previous treatment with an anti-PD(L)-1 agent and platinum-based chemotherapy, and a documented RAS mutation based on local testing. Eligible RAS mutations are defined as nonsynonymous mutations in KRAS, NRAS, or HRAS at codons 12, 13, or 61 (G12, G13, or Q61). Key exclusion criteria include untreated central nervous system metastases, prior RAS-directed therapy, or the presence of an actionable driver mutation for which an approved targeted therapy is available. The dual primary endpoints are PFS and OS in patients with RAS G12X mutations excluding G12C (G12X-C). Secondary endpoints include PFS and OS in patients with all RAS mutations, ORR per RECIST v1.1, DOR, time to response, quality of life, safety and tolerability, and further characterization of daraxonrasib's pharmacokinetic profile. The study will enroll approximately 420 patients globally across North America, Europe, and Asia.

Keywords: metastatic NSCLC, RAS inhibition, daraxonrasib (RMC-6236)

P3.18.66 Preliminary Safety and PK of the MET-TKI Do-2 in Advanced Solid Tumors With MET Aberrations: Phase I Study

T.P.S. Perera[1], H. Prenen[3], R. Galot[4], A. Cortot[5], A. Swalduz[6], B. Dekeyser[3], P. de Bruijn[7], F. Zammit[8], J-P. Machiels[8], B. Delafontaine[9], S. Rottey[9], I. Desar[10], M. Paats[11], B. Sikkema[12], F. Wastelin[1], c. Ahlin[1], J. Verweij[1], C. van Herpen[10], D. Robbrecht[7]
[1]DeuterOncology, Liege/BE ,[3]University Hospital Antwerp, Antwerp/BE ,[4]Institut Roi Albert II Cancer Center, Brussels/BE ,[5]University of Lille, Lille/FR ,[6]Centre Leon Berard, Lyon/FR ,[7]Erasmus MC Cancer Institute, Rotterdam/NL ,[8]Cliniques universitaires Saint-Luc, Brussels/BE ,[9]Ghent University Hospital, Ghent/BE ,[10]Radboud University Medical Center, Nijmegen/NL ,[11]Department of Respiratory Medicine, Rotterdam/BE ,[12]Erasmus MC Cancer Institute, Rotterdam/BE

Introduction: DO-2 is a potent (0.2nM Kd) highly selective (>3000 fold vs 450+ kinases tested), deuterated MET Tyrosine Kinase Inhibitor that was designed to have 'fast on' and 'fast off' binding kinetics. The resulting short residence times requires drug exposure to be above a threshold for MET inhibition. Here, we report the safety pharmacokinetics (PK) and preliminary efficacy data from the dose escalation phase (Part 1) of the first-in-human phase 1 trial of DO-2 in patients with advanced solid tumors harboring MET aberrations.

Methods: Eligible patients with tumors harboring proven MET activating mutations or MET amplification (≥10 copies) received DO-2 once (QD) or twice (BID; 4hr interval) daily orally, under fasting conditions. The primary endpoint was safety and tolerability; secondary objectives included PK of DO-2, the primary metabolites DO-5 and M3 and anti-tumor activity according to RECIST 1.1. Dose-escalation followed a Simon stage 3 accelerated titration design starting at 5mg QD, enrolling one patient per cohort until grade 2 toxicity. Thereafter, dose-escalation followed a "3+3" design. Blood samples for PK were collected pre-dose and at multiple time points post-dose on days 1 and 22. The dose limiting toxicity (DLT) observation period was 4 weeks. Response assessment was performed every 8 weeks.

Results: Thus far, 26 evaluable cancer patients have been included at ten dose levels (5, 10, 20, 40, 60 and 80 mg QD and 20+20, 30+30, 40+20 and 40+40mg BID). There were 19 exon14 skipping mutant and 3 MET amplified (>10fold) Non-Small Cell Lung Cancer (NSCLC) patients 1 ovarian, 1 rectal and 1 gastroesophageal cancer with MET Amp (>10fold) and 1 renal cancer with another MET mutation. The pre-clinically determined DO-2 exposure (AUC0-24; >1000ng.h/ml) and target Time over Threshold (ToT; 160ng/ml) were reached with all the BID dosing levels tested. Treatment Related Adverse Events were mainly grade 1 or 2, with grade 3 adverse events (18%) being limited to 2 cases of nausea, and 1 each of reversible creatinine increase, fatigue and vomiting. No peripheral oedema, expected with MET inhibition, was seen. Anti-tumor activity included one confirmed partial response (cPR), a disease control rate (DCR) at week 8 of 76% in all the 21 fully evaluable patients and 100% in the six evaluable 1st line exon14 skipping mutant NSCLC patients. One patient without RECIST target lesions had complete resorption of malignant pleural effusion and related symptoms after 20wks. This patient remains on treatment (65wks +) with no reported adverse events of note.

Conclusions: DO-2 was well tolerated with an expected safety profile and no drug-induced edema as typical for other MET inhibitors. The dose for the expansion cohort will be selected based on all available data after review by the safety evaluation team.Based on the promising DCR and DOR, the expansion cohort will recruit patients with locally advanced, treatment naïve unresectable or metastatic NSCLC MET exon 14 skip who are ineligible for standard of care treatment.

P3.18.67 First-In-Human Phase I/II Trial of PFL-002/VERT-002 in Locally Advanced or Metastatic Solid Tumors Including NSCLC With MET Alterations

J. Mazieres[1], M. McKean[2], M. Brandao[3], C-C. Lin[4], G. Ruiter[5], S.M. Lin[6], B. Jean[7], A. Laurans[7], Y. Wang[7], C. Fabre[7]
[1]Toulouse University Hospital, Toulouse/FR ,[2]Sarah Cannon Research Institute at Tennessee Oncology, Nashville/TN/USA ,[3]Institut Jules Bordet, Hôpital Universitaire de Bruxelles, Brussels/BE ,[4]National Taiwan University Hospital, Taipei/TW ,[5]Netherlands cancer institute, Amsterdam/NL ,[6]Yonsei Cancer Center, Yonsei University College of Medicine, Seoul/KR ,[7]Institut de Recherche Pierre Fabre, Toulouse/FR

Introduction: Non-small cell lung cancer (NSCLC) represents 85% of lung cancer cases, with 47% to 55% diagnosed at Stage IV. Around 2% to 4% of NSCLCs have MET exon 14 (METex14) skipping alterations, the median Overall Survival (OS) is 8 to 11 months without MET inhibitor treatment. Although approved MET TKIs are efficacious in NSCLC with METex14 mutation, they have limited efficacy in NSCLC with MET amplification. Moreover, the safety profile has limitations that affect treatment tolerance. Therefore, there is still a high unmet medical need in patients with solid tumors including NSCLC with MET alterations, more specifically those with de novo MET amplification, in the absence of approved or suitable therapies. VERT-002 is a monoclonal antibody targeting the MET receptor. Unlike classical antagonistic antibodies inducing target internalization, VERT-002 has a unique mechanism of action based on the enhancement of MET ECD intrinsic shedding, inducing near complete profound MET degradation, thus, leads to loss of MET signaling and eventual death of tumor cells, whose survival has become dependent on MET signaling, termed “MET-addiction”.In addition, VERT-002 has demonstrated anti-tumor activities in relevant tumor models in vitro and in vivo. These observations make VERT-002 an interesting therapeutic development candidate for the treatment of MET-altered tumors.

Methods: PFL-002 (NCT06669117) is an open-label, first-in-human (FIH) Phase I/II trial designed to evaluate the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), preliminary antitumor activity and efficacy of VERT-002. The trial consists of 3 parts: In Part 1, patients with solid tumors, including NSCLC with MET alterations, will be enrolled to reach up to 30 evaluable patients. The Bayesian Optimal Interval (BOIN) design will guide the dose escalation to determine the MTD (or the MAD if the MTD cannot be reached) based on the safety data of VERT-002. In Part 2, safety, anti-tumor activity, PK and PD of VERT-002 will be further characterized. In Part 2a, up to 20 patients with NSCLC harboring METex14 mutation will be enrolled and treated at a dose where safety is acceptable, and activity may be expected. In Part 2b, up to 90 evaluable patients with NSCLC harboring METex14 mutation and/or MET amplification will be randomized to 2 or 3 doses. The Part 2 main goal is to define VERT-002 recommended phase 2 dose (RP2D).Part 3 will be added at the end of Part 2 once sufficient data will be available to support its design. Dose level 1 has been completed without DLT. Enrollment to dose level 2 began in December 2024.

Introduction: Activating mutations of the epidermal growth factor receptor (EGFR) gene occur in 15-20% of non-small-cell lung cancer (NSCLC) patients (pts). About 7-18% pts develop resistance due to EGFR C797X mutations after treatment with third-generation EGFR TKI, often presenting with brain metastases. There is a need for new treatments in this setting, including inhibitors selective for these resistance mutations. PFL-241/STX-241, an orally bioavailable fourth generation EGFR targeted, brain-penetrant small-molecule inhibitor addressing C797X mutations, may provide benefit in NSCLC patients (pts) progressing after third-generation EGFR TKI treatment. Preclinical studies show that PFL-241/STX-241 has activity against double mutants (EGFR ex19del/L858R mutation founder mutations and acquired C797X resistance). PFL-241/STX-241 is highly selective for EGFR mutants over wild-type, and has brain penetrance comparable to osimertinib. In in vivo double mutant models, PFL-241/STX-241 has demonstrated tumor regression supporting further clinical exploration.

Methods: PFL-241 is a First-In-Human (FIH) open label, international, multicenter phase I/II trial designed to evaluate the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), preliminary anti-tumor activity and efficacy of PFL-241/STX-241. The trial is comprised of 3 Parts: Part 1 Dose Escalation, Part 2 Dose Optimization for Recommended Phase 2 Dose (RP2D) selection, and Part 3 Dose Expansion at RP2D. In Part 1, successive cohorts of pts with locally advanced or metastatic NSCLC who have previously progressed on a third generation EGFR TKI at any line of treatment, will be treated with PFL-241/STX-241, administered orally as single agent, until the Maximum Tolerated Dose (MTD) or Maximum Administered Dose (MAD) is reached. In Part 2, pts with locally advanced or metastatic NSCLC harboring C797X mutation who have previously received a third generation EGFR TKI at any line of treatment, will be randomly assigned in a 1:1 ratio into at least 2 dose cohorts to receive PFL-241/STX-241 at OBD and MTD to identify the RP2D. Part 3, will assess the efficacy of PFL-241/STX-241 at the RP2D. PFL-241 is approved for enrollment in 5 countries globally with 10 actively recruiting patients

P3.18.69 Efficacy and Safety of Befotertinib Plus Icotinib in Advanced NSCLC With Uncommon EGFR Mutations: A Phase II Study (Icombine)

X. Hou[1], K. Liu[1], T. Qin[2], L. Lin[3], X. Yang[4], Z. Lin[5], Y. Xie[6], Q. Bu[7]
[1]Sun Yat-Sen University Cancer Center, Guangzhou/CN ,[2]Shenshan Medical Center, Memorial Hospital of Sun Yat-Sen University, Guangzhou/CN ,[3]Panyu Central Hospital Affiliated to Guangzhou Medical University, Guangzhou/CN ,[4]Guangdong Provincial Hospital of Traditional Chinese Medicine, Guangzhou/CN ,[5]Jiangmen Central Hospital, Jiangmen/CN ,[6]Guangzhou Chest Hospital, Guangzhou/CN ,[7]First Affiliated Hospital of Guangxi Medical University, Nanning/CN

Introduction: EGFR mutations, one of the most common driver mutations in non-small cell lung cancer (NSCLC), are present in up to 51.4% of Asian NSCLC patients. The advent of targeted therapies has significantly improved survival outcomes for NSCLC patients. However, current targeted therapies are predominantly indicated for or investigated in patients harboring classical EGFR mutations, such as exon 19 deletions (19Del) and L858R (exon 21). Although uncommon EGFR mutations (accounting for 10-15% of EGFR-mutant NSCLC, such as G719X, L861Q, and S768I) show partial efficacy to approved EGFR tyrosine kinase inhibitors (TKIs) like afatinib and osimertinib, the optimal therapeutic strategy for these mutations remains undetermined, with no consensus in clinical practice. Preclinical and clinical evidence has shown that combining first-/second- and third-generation EGFR-TKIs may delay resistance (e.g., osimertinib plus gefitinib demonstrated an 88.9% objective response rate [ORR] in phase I/II trials), but such strategies remain unexplored in uncommon mutations. Befotertinib, a third-generation TKI approved for classical EGFR mutations, has demonstrated superior progression-free survival (median PFS: 22.1 vs. 13.8 months) compared to icotinib. This study investigates the novel combination of befotertinib and icotinib to address unmet therapeutic needs in NSCLC patients with uncommon EGFR mutations.

Methods: This prospective, phase II, single-arm trial (NCT06517953) employs a Simon's optimal two-stage design to evaluate the efficacy and safety of befotertinib combined with icotinib in treatment-naïve advanced NSCLC patients harboring uncommon EGFR mutations (G719X, L861Q, or S768I). In Stage I, eight patients receive befotertinib 75 mg once daily (QD) plus icotinib 125 mg three times daily (TID). Dose escalation of befotertinib to 100 mg QD will occur after the first 21-day cycle if no grade ≥2 thrombocytopenia or grade ≥2 headache (per CTCAE v4.03) is observed; otherwise, the dose remains at 75 mg. If ≥2 patients achieve an objective response, the trial will proceed to Stage II, enrolling an additional 15 patients (total evaluable N=23). Treatment continues until disease progression, intolerable toxicity, or patient withdrawal. The primary endpoint is ORR assessed by RECIST v1.1, with secondary endpoints including PFS, disease control rate (DCR), overall survival (OS), and safety evaluations (incidence and severity of adverse events). Recruitment for this trial is currently ongoing.

Results: The clinical trial is ongoing.

Conclusions: The clinical trial is ongoing.

Keywords: Uncommon EGFR mutations, Befotertinib, Icotinib

P3.18.70 Combination of Osimertinib and Carotuximab for Advanced, EFGR-Mutated Non-Small Cell Lung Cancer Patients

K. Sankar, N. Bhowmick, M. Thiruvalluvan, B. Waissengrin, E.M. Posadas, M. Tighiouart, K. Reckamp
Cedars-Sinai Medical Center, Los Angeles/CA/USA

Introduction: CD105 is a transmembrane receptor found on non-small cell lung cancer (NSCLC) cells that promotes bone morphogenic protein (BMP) signaling and inhibits transforming growth factor-beta (TGF-β). Inhibition of epidermal growth factor (EGFR) with tyrosine kinase inhibitors (TKIs) like osimertinib and gefitinib were found to further promote CD105 expression. In mouse models, the suppression of BMP signaling downstream of CD105 by a monoclonal neutralizing antibody, carotuximab (ENV105), was found to restore osimertinib sensitivity. Although carotuximab was originally developed as an anti-angiogenic agent due to its known expression in proliferative endothelial cells, the studies demonstrated no clinical benefit. However, together with the preclinical findings and an acceptable safety profile suggested that carotuximab may support sensitivity in patients with EGFR mutant NSCLC developing resistance to osimertinib in a synthetic lethality strategy. We initiated a phase I trial with osimertinib and carotuximab in advanced EGFR mutant NSCLC to evaluate the ability of CD105 inhibition to overcome resistance to osimertinib safely.

Methods: This phase I study (NCT05401110) will assess safety and tolerability and RP2D of carotuximab and osimertinib in patients with recurrent or metastatic NSCLC with EGFR activating mutations. In part 1, dose escalation, the RP2D, toxicity and tolerability of the combination will be assessed by adverse events as graded by CTCAE 5.0. The number of dose-limiting toxicities (DLTs) experienced within the first two treatment cycles will be assessed to determine the RP2D. Dose escalation will use an adaptive Bayesian design. In part 2, we will evaluate 2 patient cohorts: those with progressive disease on osimertinib or other prior EGFR (TKIs) (n = 25) and those receiving front line osimertinib for less than 12 weeks with detectable ctDNA (n = 25). Patients must have finished chemotherapy at least three weeks or radiotherapy at least two weeks before enrollment. A history of interstitial lung disease, small cell lung cancer histology, as well as recent thrombotic and/or cardiovascular events are exclusion criteria. Carotuximab is given through an intravenous infusion once a week for the first 4 weeks, then every 2 weeks at a dose based on dose-finding study, and osimertinib 80 mg is given orally once daily. Secondary objectives include assessment of objective response rate, duration of response, progression free survival and disease control rate. Exploratory endpoints are included to identify companion biomarkers in tumor tissue, circulating DNA and extracellular vesicles. Clinical trial information: NCT05401110. Support for this trial has been provided by the William and Anna Tenenblatt Foundation and the Cancer Clinical Trials Office of Cedars-Sinai Cancer Center.

P3.18.71 CA240-0007: BMS-986504 With Anti-PD-1 or Chemotherapy as Treatment for Advanced Solid Tumors With Homozygous MTAP Deletion

K. Leventakos[1], J.T. Henry[2], P.A. Jänne[3], J. Rodón[4], D. Richards[5], K.P. Papadopoulos[6], R. Zuniga[7], K.C. Arbour[8], A. Wozniak[9], C.D. Chin[9], A. Mazzei-Abba[9], B. George[10]
[1]Mayo Clinic, Rochester/MN/USA ,[2]Sarah Cannon Research Institute at HealthOne, Denver/CO/USA ,[3]Dana-Farber Cancer Institute, Boston/MA/USA ,[4]The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[5]Texas Oncology, Tyler/TX/USA ,[6]START Center for Cancer Research, San Antonio/TX/USA ,[7]New York Cancer & Blood Specialists, New York/NY/USA ,[8]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[9]Bristol Myers Squibb, Princeton/NJ/USA ,[10]Medical College of Wisconsin, Milwaukee/WI/USA

Introduction: BMS-986504 selectively binds to the PRMT5-MTA complex, which represents a synthetic lethal target in MTAP-deletion (MTAP-del) cancer cells, while sparing MTAP-wild-type cells. CA240-0007 (NCT05245500) is a phase 1/2 multiple expansion cohort trial of BMS-986504 in patients with advanced, unresectable or metastatic solid tumors with homozygous MTAP-del. Preliminary antitumor activity has been shown in multiple advanced solid tumors with BMS-986504 monotherapy. Based on emerging preclinical data, combining BMS-986504 with standard of care treatment (anti-programmed death-1 [PD-1] or chemotherapy [chemo]) is expected to increase efficacy in advanced solid tumors. Phase 1b combination substudies from the dose escalation and expansion phases will evaluate the safety, pharmacokinetics (PK), and clinical activity of BMS-986504 with anti-PD-1 treatment or chemo.

Methods: BMS-986504 will be evaluated with anti-PD-1 treatment in MTAP-del non-small cell lung cancer and other solid tumors, and with chemo in pancreatic ductal adenocarcinoma (PDAC). Eligibility criteria for the combination substudies will meet all enrollment criteria specified for the phase 1/1b parts of the main study but with specific criteria for the substudies. Patients with measurable disease are eligible. Patients with active brain metastases or carcinomatous meningitis, select cardiac abnormalities, or prior PRMT5 or MAT2A inhibitor treatment will be excluded. Exclusion criteria for these respective substudies differ based on prior treatment history, comorbidities, and recently or currently administered concomitant medications. Exclusion criteria specific to the BMS-986504 with anti-PD-1 treatment substudy include lung radiation (> 30 Gy) within 6 months before the first treatment dose, active or prior documented autoimmune disease, immunosuppressant use within 28 days before the first treatment dose, history of primary immunodeficiency or allogeneic transplant, or receipt of a live vaccine within 30 days before the first treatment dose. Exclusion criteria specific to the PDAC substudy include a history of select lung diseases, connective tissue disorders, peripheral artery disease, chronic leukemias, or the ongoing need for warfarin or for a treatment known to inhibit or induce cytochrome P450 3A4 or 2C8 that cannot be switched to an alternative treatment prior to study entry. Treatment will begin with BMS-986504 400 mg QD with anti-PD-1 Q3W in solid tumors or BMS-986504 200 mg QD with chemo in PDAC. Starting doses of BMS-986504 are based on safety, preliminary antitumor activity, and potential dose-dose interactions. Evaluation of subsequent dose levels will be in accordance with the Modified Toxicity Probability Interval-2 method. The substudy objectives include safety, clinical activity, PK, and recommended phase 2 dose of BMS-986504 in combination regimens. Further substudies with BMS-986504 combination regimens are planned. The combination substudies are currently recruiting, and approximately 155 patients will be enrolled across all substudies.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.72 Liquid Biopsy Guided Addition of Chemotherapy With TKI in Advanced EGFR Mutated NSCLC (LiquiACT)

P.S. Malik[1], K. Prabhash[2], V. Noronha[2], S. Khurana[1], D. Pushpam[1], A. Sharma[1], D. Jain[1], O.A. Shetty[2]
[1]All India Institute of Medical Sciences, New Delhi, New Delhi/IN ,[2]Tata Memorial Centre, Mumbai/IN

Introduction: Combination of tyrosine kinase inhibitors (TKIs) with chemotherapy is emerging as a new standard of care for the treatment of EGFR mutated non small cell lung cancer (NSCLC) which has shown to improve progression-free survival but at the cost of higher toxicity. Baseline ctDNA positivity, failure to clear ctDNA at 3 weeks after TKI and presence of co-existing TP53 mutations have been considered poor risk factor for TKI monotherapy. Whether we can avoid the addition of chemotherapy and associated toxicities in patients who do not have these high risk features, is largely unknown. In this study, we aim to evaluate if the risk adapted ctDNA guided addition of chemotherapy to TKI is non-inferior to TKI- chemotherapy combination in EGFR mutated advanced NSCLC

Methods: This is an open label, multicentric, phase 3, randomized control trial including patients 18 years of age and above, having advanced NSCLC with sensitizing EGFR mutations and ECOG PS 0 and 1. Patients with treated and asymptomatic brain metastasis are allowed. Patients are being randomized in 1:1 ratio to receive either TKI of physician choice (osimertinib or gefitinib) with platinum based chemotherapy or TKI of physician's choice for 3 weeks and addition of chemotherapy at 4th week only in cases with any of the risk factors namely baseline ctDNA positive status, failure to clear ctDNA at 3rd week sample or presence of TP53 co-mutations. Patients without any of the risk factors in the experimental arm are being continued on TKI as monotherapy. The primary end point is 2-year overall survival rates. The secondary end points are toxicity profiles, Quality of life assessed by EORTC QLQ-C30 and LC13 questionnaires, progression free survival and cost analysis. This is a non-inferiority trial. Assuming that the 2 year OS rates in the control group (TKI+ chemotherapy) are 60% and hazard ratio defining non-inferiority margin of 1.3, with 5% alpha and 90 percent power we will require 321 patients for this study over 2 years. Expecting a 10% drop outs due to loss to follow up, total number required will be 354 (177 in each arm). Enrolment in the study has been started in March 2025.

Introduction: Gocatamig (MK-6070; HPN328) is a delta-like ligand 3 (DLL3)-targeted T-cell engager. Ifinatamab deruxtecan (I-DXd) is an antibody-drug conjugate (ADC) comprising a B7-H3 monoclonal antibody covalently linked to a potent topoisomerase I inhibitor. Both DLL3 and B7-H3 are highly expressed on the cell surface of small cell lung cancer (SCLC). Gocatamig monotherapy has shown manageable safety and encouraging antitumor activity in participants with SCLC that is relapsed or refractory after one or more prior lines of platinum-based chemotherapy. I-DXd monotherapy has been well tolerated and shown promising efficacy as second- or later-line treatment in participants with extensive-stage (ES) SCLC. The distinct mechanisms of action and minimally overlapping toxicities of gocatamig and I-DXd suggest that their combination may enhance efficacy yet remain tolerable.

Methods: The 6070-002 study (NCT06780137) is an ongoing, open-label, multicenter two-part study. Adults ≥18 years old with ES SCLC and ECOG PS 0 or 1 who had prior platinum-based chemotherapy (with or without PD-(L)1 inhibitors) are eligible. Part 1 includes a safety run-in phase of different dosing schedules of gocatamig combined with I-DXd, as well as I-DXd alone, followed by a dose-expansion phase. Target doses and schedules of gocatamig and I-DXd in part 1 will be determined based on the findings of the ongoing 6070-001 study (NCT04471727). Participants will be allocated to treatment arms during the dose-expansion phase using an interactive response technology if more than one cohort is enrolling at the same time. Part 2 consists of a Japan-only arm, in which participants receive gocatamig monotherapy. The primary objectives are to evaluate safety and tolerability (parts 1 and 2), including the incidence of adverse events (AEs), dose-limiting toxicities, and treatment discontinuations due to AEs, and to evaluate the objective response rate per RECIST v1.1 (part 1). Secondary objectives are to evaluate duration of response and progression-free survival per RECIST v1.1 (part 1) and to characterize the pharmacokinetics and immunogenicity of gocatamig plus I-DXd combination therapy (part 1), I-DXd monotherapy (part 1), and gocatamig monotherapy (part 2). The 6070-002 study will enroll participants in Australia, Chile, China, Israel, Japan, the Republic of Korea, Spain, Türkiye, and the United States of America.

Introduction: BNT327 is an investigational anti-PD-L1 x VEGF-A bispecific antibody (bsAb) that is designed to restore effector T-cell function by binding PD-L1, while localizing VEGF-A neutralization within the tumor microenvironment, leading to tumor growth inhibition. BNT324/DB-1311 is an investigational topoisomerase-I-inhibitor-based anti-B7H3 antibody-drug conjugate (ADC) with a cleavable linker and a drug-to-antibody ratio of ~6.

We hypothesize that combining BNT327 and BNT324/DB-1311 will improve efficacy since targeting VEGF-A can facilitate ADC penetration, which in turn can increase sensitivity to PD-L1 inhibition. Moreover, B7H3, an immune checkpoint protein, is overexpressed in tumor tissues and promotes tumor progression through immune-dependent and nonimmune pathways. In preclinical in vivo models, BNT327+BNT324/DB-1311 demonstrated superior anti-tumor effects compared to each drug alone. Encouraging early efficacy results and safety profile have been reported separately for BNT327 and BNT324/DB-1311 in both small-cell lung cancer (SCLC) and non-small-cell lung cancer (NSCLC); the combination is anticipated to improve patient outcomes with a manageable safety profile.

Unconfirmed ORR is reported. TRAEs reported in BNT327 studies are related to BNT327 and/or chemotherapy.
DCR, disease control rate; EGFRm, epidermal growth factor receptor mutated; mo, month; NR, not reported; NSCLC, non-small-cell lung cancer; nsq, non-squamous; ORR, overall response rate; mOS, median overall survival; mPFS, median progression-free survival; SCLC, small-cell lung cancer; sq, squamous; TRAE, treatment-related adverse events.

Methods: This global Phase 1b/2, open-label, two-part multicohort trial will evaluate efficacy, safety, pharmacokinetics, and the recommended Phase 2 dose (RP2D) of BNT324/DB-1311+BNT327 (NCT06892548). Inclusion criteria include: ≥18 years, ECOG PS 0-1, histologically or cytologically confirmed advanced/metastatic SCLC or NSCLC.

In Part 1, patients with SCLC or NSCLC will receive BNT324/DB-1311+BNT327 using a Bayesian optimal interval dose escalation (BOIN) design. Three dose levels with be explored for BNT324/DB-1311 (DL0, DL1, DL2) and 2 dose levels for BNT327 (DL0, DL1). Part 1 primary endpoint is safety, including dose-limiting toxicities to determine RP2D.

Part 2 will consist of 7 Cohorts (2 for dose optimization [DO] and 5 for signal-seeking), with Cohort-specific enrollment criteria: • non-squamous NSCLC, without actionable oncogenic alterations (AGA negative), any PD-L1 expression, treatment-naïve for advanced/metastatic disease (DO Cohort 1) • SCLC, post-chemotherapy +/- immunotherapy (DO Cohort 2) • non-squamous NSCLC, AGA negative, post-chemotherapy +/- immunotherapy (Cohort 3) • squamous NSCLC, AGA negative, treatment-naïve for advanced/metastatic disease (Cohort 4) • squamous NSCLC, AGA negative, post-chemotherapy +/- immunotherapy (Cohort 5) • non-squamous NSCLC, AGA positive, post-TKI (Cohort 6) • ES-SCLC, treatment-naïve (Cohort 7). Both DO Cohorts 1 and 2 will randomize patients 1:1 to RP2D vs a lower-dose combination (RP2D−1) and Cohorts 3-7 will receive RP2D until disease progression or up to 24 months (BNT327 monotherapy may continue for 12 additional months). Part 2 primary endpoint is safety and ORR in DO Cohorts 1&2 to determine the optimal dose, and ORR in Cohorts 3-7. Enrollment is ongoing.

P3.18.75 Tislelizumab in Combination With EP/EC Chemotherapy and Sequent Anlotinib Followed by Radiotherapy as First-Line Treatment for ES-SCLC

Z. Liu, Z. Liu, J. Zhou
Jiangxi Cancer Hospital, Nanchang/CN

Introduction: The combination of immunotherapy with chemotherapy has greatly improved the efficacy of first-line treatment for extensive-stage SCLC(ES-SCLC) patients, but compared to NSCLC, the benefits are still relatively limited. Therefore, the exploration of how to expand the benefits of immunotherapy for SCLC is ongoing. Adding anti-angiogenic to the foundation of immunotherapy combined with chemotherapy can further improve the prognosis of patients with ES-SCLC. Additionally, previous studies have shown that after induction therapy, the addition of thoracic radiation therapy (TRT) following remission leads to an increase in survival rates and a significant reduction in the recurrence rate of thoracic lesions. Therefore, this study aims to explore the efficacy and safety of first-line treatment for ES-SCLC with Tislelizumab in combination with the EP/EC chemotherapy and sequential Anlotinib followed by radiotherapy.

Methods: This was an open-label, single-arm, phase 2 trial. Eligible patients were aged 18 years or older with histologically or cytologically documented untreated ES-SCLC (VALG staging). Patients received induction treatment with Etoposide (100mg/m2, d1-3) and Carboplatin (AUC 5, d1) or Cisplatin (75 mg/m2, d1) plus Tislelizumab (200 mg, d1) and Anlotinib(10mg, d1-14) of each 21-day cycle, for 4 cycles. Subsequently, investigators assessed patients who were suitable for radiotherapy (a total dose of 50Gy-51Gy for the primary chest lesion, and 30Gy or 45-50Gy for brain metastases). Patients suitable for radiotherapy include those with Complete Response (CR), Partial Response (PR), and those with Stable Disease (SD) whom the investigators deem likely to benefit from the treatment. During the maintenance treatment, patients will receive Tislelizumab in combination with Anlotinib until disease progression. The primary endpoint is the Progression-Free Survival (PFS) as assessed by the investigators according to RECIST v1.1. The Secondary endpoints were 6-month PFS rate, OS, 1-year OS rate and ORR. Safety was assessed in the intention-to-treat population. This study is registered with medicalresearch.org.cn, PID: 241871, and is ongoing.

P3.18.76 Efficacy and Safety of Cross-Line Adebrelimab Combined With Apatinib and Nab-Paclitaxel in Recurrent Small Cell Lung Cancer

F. Kou[1], H. Wu[1], Q. Wang[2], Z. Ren[3], X. Mu[1], C. Yu[1], Y. Liu[2], Y. Wang[2], T. Chen[2], C. Li[3], H. Ma[3], Y. Tang[4]
[1]Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou/CN ,[2]Nanyang Second People's Hospital, Nanyang/CN ,[3]Nanyang Central Hospital, Henan Province, Nanyang/CN ,[4]Cancer Hospital of Dalian University of Technology, Liaoning Cancer Hospital & Institute, Liaoning/CN

Introduction: Treatment options for relapsed small cell lung cancer (SCLC) remain limited, with second-line standard regimens (e.g., topotecan) demonstrating an objective response rate (ORR) of <25% and a median overall survival (OS) of 6-8 months. The CAPSTONE-1 study established adebrelimab combined with carboplatin and etoposide as the first-line standard of care for patients with extensive-stage SCLC in China. However, the clinical value of continuing immune checkpoint inhibitors (ICIs) beyond progression after first-line immunotherapy remains unclear. Here, we present the first evaluation of effectiveness and safety of cross-line adebrelimab (i.e., continued use after progression on first-line immunotherapy) combined with apatinib (a VEGFR-2 inhibitor) and nab-paclitaxel in relapsed SCLC.

Methods: This prospective, multicenter, single-arm study enrolled patients with histologically confirmed relapsed SCLC who progressed after first-line adebrelimab combined with chemotherapy. Key eligibility criteria included age ≥18 years, ECOG performance status 0-1, at least one measurable disease per RECIST v1.1, and progression-free survival (PFS)≥3 months for first-line treatment. Patients received induction therapy comprising adebrelimab (1200 mg q3w), apatinib (250 mg qd), and nab-paclitaxel (200 mg/m^2 q3w) for 2-4 cycles, followed by maintenance therapy with adebrelimab and apatinib until disease progression or intolerable toxicity. The primary endpoint was ORR, the secondary endpoints included PFS, OS, disease control rate (DCR),duration of response and safety assessed by CTCAE v5.0.

Results: Between December 10, 2023 to February 12, 2025, 12 patients were included (median age 61.5 years [range 48-74], 4 [33.3%] with ECOG PS 1, 3 [25.0%] with brain metastasis, 2 [16.7%] with liver metastasis, 6 [50.0%] with first-line PFS ≥6 months). As of March 25, 2025, the median follow-up was 6.4 months (95% CI: 3.2-9.5). Among the 12 patients, 10 were evaluated, the unconfirmed ORR was 66.7% (8/12; 95% CI: 34.1-89.7%) and DCR was 83.3% (10/12; 95% CI: 54.4-99.5%). The median PFS was 6.2 months (95% CI: 4.9-7.5). Treatment- related adverse events (TRAEs) of any grade were reported in 9 (75.0%) patients, and grade 3 or worse TRAEs occurred in 5 (41.7%) patients. The most common grade 3 or worse TRAEs were neutropenia and decreased white blood cell count.

Conclusions: Cross-line adebrelimab combined with apatinib and nab-paclitaxel showed promising efficacy and manageable safety in relapsed SCLC, providing a novel treatment strategies for post-immunotherapy progression.

P3.18.77 Efficacy and Safety of Adebrelimab Plus Irinotecan Liposome in ES-SCLC After First-Line Therapy: A Phase II Study (AIPATH)

Y. Wang[1], Y. Shang[2], D. Sun[3], Z. Wang[4], Y. Zhao[5], L. Wang[1], L. Jing[1]
[1]The Fourth Hospital of Hebei Medical University, Shijiazhuang/CN ,[2]Affiliated Hospital of Hebei University, Baoding/CN ,[3]Chengde Central Hospital, Chengde/CN ,[4]Tangshan People's Hospital, Tangshan/CN ,[5]Cangzhou Central Hospital, Cangzhou/CN

Introduction: Platinum-based chemotherapy or immunochemotherapy is the standard first-line treatment for extensive-stage small-cell lung cancer (ES-SCLC). Despite inducing significant tumor responses, most patients experience disease progression. Second-line options, mainly traditional chemotherapy, offer limited survival benefit. This study evaluates the efficacy and safety of adebrelimab combined with irinotecan liposome (II) in ES-SCLC patients after progression on first-line therapy.

Methods: This multicenter, multicohort prospective phase II trial in China enrolls ES-SCLC patients aged 18-75 years with histologically or cytologically confirmed diagnoses, Eastern Cooperative Oncology Group (ECOG) performance status 0-1, progression after first-line treatment with etoposide and platinum-based chemotherapy, at least one measurable, non-irradiated target lesion per RECIST version 1.1, a life expectancy ≥ 12 weeks, and adequate organ function. Exclusion criteria include clinically significant brain or meningeal metastases, and interstitial pneumonia. Patients are stratified into two cohorts: cohort A (prior immune checkpoint inhibitors) and cohort B (no prior immune checkpoint inhibitors), with 30 patients each. All patients receive adebrelimab 1200 mg plus irinotecan liposome (II) 100 mg/m2 intravenously every 3 weeks until disease progression and/or intolerable toxicity. Primary endpoint is objective response rate.Secondary endpoints include overall survival (OS), 6-month OS rate, progression-free survival (PFS), duration of response (DOR), disease control rate (DCR), and safety. Exploratory endpoints include biomarker analysis, quality of life assessments, and long-term survivor characteristic.Trial registration: ChiCTR2400089170.

P3.18.78 A Prospective Study of Lurbinectedin Plusivonescimab Assecond-Line Treatment for Extensive-Stage Small Cell Lung Cancer

F. Zhou[1], C. Zhou[1]
[1]Shanghai East Hospital, Shanghai/CN

Introduction: Extensive-stage small cell lung cancer (ES-SCLC) is a highly aggressive malignancy with limited therapeutic options. Patients undergoing second-line and subsequent systemic therapies typically have a survival of only 4-5 months. Lurbinectedin, a novel chemotherapy agent, has been approved for the treatment of adult patients with metastatic SCLC with disease progression during or after platinum- based chemotherapy. Recent advances in immunotherapy and anti-angiogenic therapies have shown promise for improving patient outcomes. Preliminary data from two phase 1/2 single-arm studies (2SMALL and LUPER) have demonstrated significant anti-tumor activity of lurbinectedin in combination with immunotherapy as second-line treatment for ES-SCLC. Ivonescimab (AK112), a bispecific antibody against programmed cell death protein 1 (PD-1) and vascular endothelial growth factor (VEGF), has shown potential in improving survival when combined with chemotherapy in ES-SCLC. This study aims to evaluate the efficacy and safety of lurbinectedin combined with ivonescimab (AK112) in patients with ES-SCLC who have progressed after first-line chemoimmunotherapy.

Methods: This is a prospective, multi-center, open-lable, single arm phase 2 clinical trial. Key inclusion criteria include: 1) patients with histologically or cytologically confirmed ES-SCLC; 2) disease progression on or after first-line immunotherapy combined with platinum-based chemotherapy; Other main inclusion criteria include aged 18-75 years, Eastern Cooperative Oncology Group (ECOG) performance status of 0 to 1, at least one measurable lesion according to Response Evaluation Criteria in Solid Tumours (RECIST) v1.1 and adequate organ function. The study consists of two phases: a safety run-in phase and an expansion phase. All participants will be simultaneously adminstrated with lurbinectedin 3.2 mg/m^2 every three weeks (Q3W) and ivonescimab (AK112) 20 mg/kg Q3W until disease progression or intolerable toxicity. The safety run-in phase will initially enroll 6 participants. If the treatment is deemed safe and tolerable, the study will proceed to the expansion phase. Our study aims to enroll a total of 53 participants. Sample size calculations were based on a power of β=0.8 and a two-sided significance level of α=0.2, with the 6-month progression-free survival (PFS) rate estimated at 32.9% under the null hypothesis of ineffectiveness and 45% under the alternative hypothesis of effectiveness, considering 10% dropout rate. The primary efficacy endpoint is the 6-month PFS rate, while secondary endpoints include objective response rate (ORR), median PFS, duration of response (DOR), disease control rate (DCR), and overall survival (OS). Safety will be evaluated based on the incidence and severity of adverse events (AEs) graded according to the NCI-CTCAE v5.0. Exploratory analyses will include biomarkers assessments of PD-L1 expression, tumor mutational burden (TMB), and immune cell infiltration in tumor tissues and plasma samples. In conclusion, this study aims to provide valuable insights into the efficacy and safety of lurbinectedin combined with ivonescimab (AK112) as the second-line treatment for ES-SCLC, potentially offering a new therapeutic option for patients. The trial has been registered at www.chictr.org.cn.

P3.18.79 Contralateral Esophageal-Sparing Technique Reduces High-Grade Esophagitis in Locally Advanced Small Cell Lung Cancer

M. Hu, Y. Xu
Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Acute esophagitis, especially grade 3 or higher, is a major limiting toxicity in the concurrent chemoradiotherapy for locally advanced small cell lung cancer (LS-SCLC) , which can severely impact patient quality of life and treatment outcomes. The primary objective of this study was to evaluate whether the contralateral esophageal-sparing technique (CEST) could reduce the incidence and severity of high-grade esophagitis in LS-SCLC patients. The secondary objectives included assessing esophageal dose-volume parameters and overall treatment efficacy.

Methods: This single-center, prospective, randomized controlled trial enrolled 70 eligible LS-SCLC patients with tumors a within 1 cm of the esophagus. They were randomly assigned to the standard therapy group (CON) and the CEST group in a 1:1 ratio. All eligible patients received concurrent chemoradiotherapy (45 Gy radiotherapy in 30 fractions, twice-daily for 3 weeks with chemotherapy). In the CEST group, the CE was contoured as an avoidance structure with specific dose-volume constraints (CE maximum dose < 42 Gy, V36 < 0.5 cc, V30 < 3.5 cc). Acute esophagitis (AE) events were graded in line with the RTOG acute toxicity grading system. Ethical approval was obtained, and all patients provided informed consent.

Results: In this study, 70 patients were recruited (34 in CEST group, 36 in CON group). Eventually, 62 patients (31 in each group) were included in the analysis due to patient withdrawals and incomplete radiotherapy. In the CEST group (n=31), the incidence of acute esophagitis was 19.4%, and no cases of grade 3 or higher adverse events (AE) were observed. In the CON group (n=31), the incidence rate was 83.9%, including 4 cases (12.9%) of grade 3 AE. Dosimetric analysis revealed that the median maximum esophageal dose in the CEST group was 38.0 Gy, which was significantly lower than that in the CON group (47.8 Gy). The CEST group had better volume parameters, such as V45 of 0 cc, V36 of 0.01 cc, and V30 of 0.30 cc, compared to the CON group's 3.15 cc, 7.88 cc, and 9.31 cc, respectively (all P < 0.01). For treatment efficacy, analyses of progression-free survival (PFS) and overall survival (OS) showed no significant differences between the two groups (all P>0.05).

Conclusions: This study shows that the application of CEST in LS-SCLC patients can significantly reduce the incidence and severity of acute esophagitis, making it worthy of further clinical promotion. CEST helps improve the quality of life for patients undergoing concurrent chemoradiotherapy and may optimize treatment standards.$$graphic_{5060127F-EE3D-48CC-B655-447DEEED8184}$$

Introduction: There are limited options for the treatment of extensive-stage small cell lung cancer (ES-SCLC) that has progressed after platinum-containing therapy with or without anti-programmed cell death protein (ligand) 1 (anti-PD-[L]1) therapy. Due to the toxicities and poor clinical outcomes associated with the current fully approved standard of care (SOC), topotecan, there remains an unmet need for novel agents in this patient population. Sacituzumab govitecan (SG), a Trop-2-directed antibody-drug conjugate, has demonstrated encouraging antitumor activity and manageable safety as a second-line treatment for ES-SCLC in the open-label, phase 2 TROPiCS-03 study. At a median study follow-up of 12.3 months in TROPiCS-03, investigator-assessed objective response rate (ORR) per Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST v1.1) was 42% and median overall survival (OS) was 13.6 months. Neutropenia (44%) and diarrhea (9%) were the most common grade ≥3 treatment-emergent adverse events (TEAEs), and no TEAEs led to discontinuation of SG; one treatment-related TEAE led to death. EVOKE-SCLC-04 (NCT06801834) is a global, multicenter, randomized, open-label, phase 3 study evaluating the efficacy and safety of SG versus SOC (topotecan or amrubicin [Japan only]) in previously treated patients with ES-SCLC.

Methods: Key eligibility criteria for EVOKE-SCLC-04 include age ≥18 years, confirmed SCLC diagnosis, Eastern Cooperative Oncology Group Performance Status score of 0-1, measurable disease per RECIST v1.1, disease progression after 1 prior line of platinum-containing therapy with or without anti-PD-(L)1 therapy, and no untreated central nervous system (CNS) metastases and/or carcinomatous meningitis. Patients will be randomized 1:1 to either SG (10 mg/kg on Days 1 and 8) or SOC: topotecan (1.5 mg/m2 daily on Days 1-5) or amrubicin (40 mg/m2 daily on Days 1-3) administered as intravenous infusion in 21-day cycles, until progressive disease as assessed by blinded independent central review (BICR) per RECIST v1.1, unacceptable toxicity, or death. Randomization will be stratified by chemotherapy-free interval (≥90 vs <90 days), CNS involvement (yes vs no), geographic region (East Asia vs non-East Asia), and prior anti-PD-(L)1 therapy (yes vs no). The primary endpoints are ORR as assessed by BICR per RECIST v1.1 and OS. Secondary endpoints include progression-free survival, duration of response, patient-reported outcomes (time to first deterioration in shortness of breath and physical functioning), and safety/tolerability. This study is open and actively recruiting as of February 2025 and is planning to enroll 695 patients from approximately 200 sites globally.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.81 A Phase II Study of First-Line Sintilimab Combined With Anlotinib and Platinum-Based Chemotherapy in Unresectable MPM

J.C. Duan[1], R. Wan[1], X. Wu[1], K. Fei[1], X. Ren[2], Z. Wang[1], J. Xu[1], Y. Guo[2], X. Wu[2]
[1]Cancer Hospital, Chinese Academy of Medical Sciences, Beijing/CN ,[2]Shanxi Provincial Cancer Hospital, Taiyuan/CN

Introduction: Malignant pleural mesothelioma (MPM) remains an aggressive thoracic malignancy with limited therapeutic advancements. Current first-line platinum-pemetrexed chemotherapy demonstrates modest efficacy (objective response rate (ORR) 20-40%, median overall (OS) 12-18 months). Recent studies have explored the role of anti-angiogenic agents and immune checkpoint inhibitors in MPM. BEAT-meso trial showed that the addition of atezolizumab to chemotherapy-bevacizumab result in a significant improvement in PFS (9.2 versus 7.6 months, HR 0.72, p = 0.0021); however, it did not translated into a significant increase in median OS (20.5 versus 18.1 months, p = 0.14). Anlotinib, a multi-target tyrosine kinase inhibitor, potently inhibits VEGFR2/KDR, along with PDGFRβ and C-kit, showing promising anti-tumor activity in various malignancies. Previous studies suggested that compared to bevacizumab, Anlotinib demonstrate both anti-angiogenses and regulation of cell proliferation, along with the modulation of immunosuppressive tumor microenvironment (TME). Sintilimab, a fully humanized IgG4 PD-1 monoclonal antibody, has demonstrated efficacy and manageable safety in advanced lung cancer, suggesting its potential in MPM. Building on these findings, this trial investigates the novel combination of sintilimab, anlotinib, and platinum-based dual-agent chemotherapy, hypothesizing synergistic effects through PD-1 blockade, VEGF pathway inhibition, and chemotherapy-induced immunogenic modulation.

Methods: This single-arm, open-label, phase II trial enrolls treatment-naïve patients aged ≥18 years with histologically confirmed unresectable or advanced MPM (stage IIIB/IV), ECOG 0-1, and measurable lesions per mRECIST 1.1. Key exclusion criteria include prior systemic therapy for advanced disease (excluding platinum-containing adjuvant therapy >6 months prior), active autoimmune diseases, and uncontrolled CNS metastases. Patients receive sintilimab 200mg IV (D1, Q3W), anlotinib 12mg PO (D1-14, Q3W), pemetrexed 500mg/m^2 IV (D1, Q3W), and cisplatin 75mg/m^2/carboplatin AUC5 IV (D1, Q3W) for 4-6 cycles, followed by sintilimab/anlotinib/pemetrexed maintenance until disease progression or intolerable toxicity. The primary endpoint is investigator-assessed ORR per mRECIST 1.1. Secondary endpoints include duration of response(DOR), disease control rate(DCR), progression-free survival (PFS), OS, and safety (NCI-CTCAE v5.0). Using a Simon two-stage design, 29 patients will be enrolled across two Chinese centers, taking into account an approximately 20% dropout rate. In the first stage, 13 participants would be recruited. If the number of responders among these 13 participants was less than 5, the study would be terminated. Otherwise, the enrollment would continue. We also plan to explore predictive biomarkers through serial blood samples detection and tumor tissue analysis. The trial was registered at ClinicalTrials.gov (NCT05188859) and is actively recruiting. As of March 27th , 2025, 8 patients have been enrolled.

Results: Between September 1, 2024, and March 27, 2025, 8 patients were enrolled in the study. Of these, 5 were evaluable for efficacy, with 3 achieving partial response (PR) and 2 stable disease (SD), resulting in an ORR of 60% and a DCR of 100%. Treatment-related adverse events (TRAEs) included 1 patient discontinuing anlotinib due to pulmonary embolism, 1 requiring dose reduction to 8 mg for intestinal obstruction, and 1 reducing to 10 mg for diarrhea.

Conclusions: No conclusions to report for this trial in progress abstract.

Introduction: Thymic epithelial tumors (TETs) are rare tumors, with an incidence of 0.15 per 100,000 person-years. In Switzerland, the number of diagnosis has increased in recent years, particularly in women, according to data from our national cancer registry. Due to their rarity, management of TET patients should include dedicated multidisciplinary discussion at expert centers. Diagnosis is often delayed, preventing curative treatments. Furthermore, due to a high interobserver variability and limited pathology expertise diagnostic changes often occur upon review at specialized centers. Treatment protocols are based on retrospective series, expert opinion, and a limited number of prospective trials, emphasizing the importance of expert centers and multidisciplinary teams (MDT) for optimal care.

Methods: THETIS is a Swiss national network that includes the following Swiss cities and regions: Ticino, Lausanne, Geneva, Baden, Bern, St Gallen, Lucerne, Chur, Basel, Winterthur, Thurgau, Zurich and Fribourg. Key components include regular MDT discussions for all confirmed or suspected TET cases to ensure accurate diagnosis and management, and pathological review for standardizing diagnostic practices. The network will develop evidence-based treatment guidelines to uniform management across Switzerland. Furthermore, we will start a multi-center, ambispective observational study aiming at collecting clinical, epidemiological, and biological data on TETs in Switzerland. The registry will include data for all patients treated in the participating centers, focusing on diagnosis (imaging techniques, histology, clinical staging), treatment history (systemic therapies, radiotherapy, surgery), and patient outcomes. A data warehouse will integrate clinical data with biological samples, such as tumor biopsies, enabling translational research and informing future clinical trials. Clinical data will be collected prospectively during MDT and retrospectively from patients electronic charts. Relevant information will be entered into a dedicated electronic Case Report Form (eCRF), using validated software (5DBase® or Redcap®) for remote data collection, ensuring compliance with data protection, access control, and traceability standards. The database will be based on datasets from ITMIG (www.itmig.org). The TETHIS registry will enable the identification of epidemiological trends, treatment outcomes, and therapy effectiveness for TETs. Integrating clinical data with biological samples potentially uncovers novel biomarkers for diagnosis, prognosis and novel therapies. MDT discussions and expert reviews will improve diagnostic accuracy, ensuring timely and appropriate treatment. Additionally, treatment guidelines will ensure consistent, high-quality care across Switzerland. TETHIS network is a collaborative effort to improve the diagnosis, treatment, and research for thymic malignancies in Switzerland. We will collaborate with international research networks, including ITMIG and Euracan, to enhance global research, broaden access to clinical trials, and support novel therapies. Ultimately, it will provide a valuable resource for clinical trials and informed decision-making in TET treatment, eventually improving patient outcomes. We will present number of cases discussed and activities implemented during the first months following network activation.

TUESDAY, SEPTEMBER 9, 2025 - 10:00 - 11:30

P3.18.83 Efficacy and Safety of Ivonescimab Plus Chemotherapy for Recurrent/Metastatic Thymic Carcinoma: A Phase II Study (iThyme)

X. Hou, M. Liu, K. Liu, X. Chen, L. Zhang
Sun Yat-Sen University Cancer Center, Guangzhou/CN

Introduction: Thymic carcinoma (TC) is a rare malignancy with an increasing incidence in Asia. Despite surgical resection being the cornerstone for early-stage disease, advanced or metastatic thymic carcinoma poses significant therapeutic challenges. Platinum-based chemotherapy is the current standard of care, yet its efficacy is limited with response rates ranging from 30% to 60%. Emerging evidence suggests that dual targeting of immune checkpoints and angiogenesis may enhance antitumor activity. Ivonescimab, a novel bispecific antibody targeting PD-1 and VEGF, has demonstrated promising results in non-small cell lung cancer. This study aims to evaluate the efficacy and safety of ivonescimab in combination with chemotherapy as a first-line treatment for recurrent or metastatic thymic carcinoma.

Methods: This prospective, single-arm, Simon' s two-stage phase II study (NCT06750952) enrolls patients with histologically confirmed, untreated, unresectable TC. Key inclusion criteria: ECOG PS 0-1, measurable lesions (iRECIST), and adequate organ function. Patients receive ivonescimab (20 mg/kg, intravenously every 3 weeks) in combination with paclitaxel (175 mg/m^2) or albumin-bound paclitaxel (260 mg/m^2) and carboplatin (AUC 5) for 4-6 cycles, followed by maintenance therapy with ivonescimab until disease progression or unacceptable toxicity. The primary endpoint is the 6-month progression-free survival rate (PFS6m). Secondary endpoints include PFS, overall response rate (ORR), disease control rate (DCR), duration of response (DoR), overall survival (OS), and safety assessments. Exploratory biomarker analyses will assess tumor tissue and blood samples. Using Simon' s optimal design (α=0.05, β=0.20), 8 patients are enrolled in Stage I; if ≤3 progressions occur by 6 months, Stage II proceeds to total 24 patients. Success is defined as ≤10 progressions at 6 months in the full cohort.

Results: The clinical trial is ongoing.

Conclusions: The clinical trial is ongoing.

Keywords: Thymic carcinoma, Ivonescimab, Chemotherapy

Introduction: With a median age at diagnosis of 70, lung cancer is a major public health issue for older adults worldwide. Surgery plays a crucial role in the treatment of most patients with non-metastatic lung cancer. However, patients often face postoperative challenges such as pain, fatigue, reduced pulmonary function, and diminished physical capabilities. Despite the importance of these issues, there are limited data on how to best improve the functional recovery of older adults after lung cancer surgery, and few interventions specifically address the needs of older patients and their family caregivers (FCGs). This pragmatic comparative effectiveness trial aims to assess whether telephone-based physical-activity coaching, provided both before and after surgery, offers greater benefits than physical-activity self-monitoring without coaching for older adults and their FCGs.

Methods: SR2204 is a phase 3, multi-center, randomized comparative effectiveness trial. 382 older adults (aged 65 and above) with a lung cancer diagnosis and planned surgical resection, along with their family caregivers (FCGs), will be recruited prior to surgery and randomly assigned to one of two groups: telephone-based physical activity coaching or physical activity self-monitoring without coaching. Participants in the coaching group engage in 5 telephone sessions with rehabilitation coaches (1 before and 4 after surgery), receive an intervention resource manual, and are provided with a wristband pedometer. Those in the self-monitoring group are given physical activity guidelines from the American Society of Clinical Oncology (ASCO) and wristband pedometers. All participants are evaluated prior to surgery (baseline), at discharge, and at 30-, 60-, and 180-days post-discharge. The primary outcome measure is the change in 6-minute walk distance at 30 days after discharge compared to baseline. Secondary endpoints include geriatric assessment, lower extremity function, self-reported physical function, self-efficacy, and quality of life. The trial is open to enrollment at 12 sites throughout the United States. Enrollment commenced on January 10, 2024. The trial has enrolled 118 patient participants at the time of submission, among whom 64% enrolled along with FCGs in the study. Clinical trial information: NCTN06196008.

Introduction: A healthier lifestyle could have avoided >1,600,000 lung-cancer-related deaths in 2019. Lifestyle interventions have a positive impact on the natural history of lung cancer across all disease stages. However, solid clinical evidence of the impact of lifestyle interventions on hard clinical endpoints in early-stage disease is currently lacking. The STARLighT study builds on the hypothesis that implementing a structured lifestyle intervention together with systemic treatment would significantly improve clinical outcomes in patients with early-stage lung cancer while substantially improving patients' quality of life. The primary aim of the STARLighT trial is to test the impact of a structured and evidence-based lifestyle intervention delivered by a telemedicine platform on pathological complete response (pCR) in patients undergoing neoadjuvant treatments and on disease-free survival (DFS) in patients undergoing adjuvant therapies. We expect that a tailored lifestyle intervention will result in a higher pCR rate and longer DFS in patients in the neoadjuvant or adjuvant setting, respectively, thereby potentially increasing cure rates in early NSCLC.

Methods: A master clinical protocol will be set up to evaluate the lifestyle intervention in different cohorts of patients diagnosed with non-oncogene addicted with early-stage non-small cell lung cancer (NSCLC), stages IB to IIIA. COHORT A will accrue 46 patients undergoing neoadjuvant chemo/immunotherapy and exploit a single-arm phase II design to detect an increase in the proportion of pCR from 20% to 40%; COHORT B will accrue 278 patients undergoing physician's choice of adjuvant treatment and exploit a 1:1 randomized controlled design to detect an increase in 2-year DFS rates from 55% to 70% in the control and experimental arms, respectively. All patients in COHORT A will receive a personalized physical exercise intervention thrice a week, tailored nutritional counseling by a skilled dietitian, and immunonutrients, two bottles/day. The intervention in COHORT A will last for the entire neoadjuvant treatment period. In COHORT B, whereas patients randomized in the controls will receive the current standard of care and dedicated educational health material, those allocated in the experimental arm will undergo physical exercise twice a week, nutritional counseling, and oral supplementation (whey protein, 20 gr/day). The intervention for the COHORT B will last 6 months. Translational studies will encompass baseline assessment of genomic and transcriptomic features and longitudinal assessment of circulating immuno-inflammatory profiles and tumor microenvironment composition, to be correlated with clinical and lifestyle data to build a comprehensive predictive model.

Introduction: Neutropenia represents a frequently observed dose-limiting toxicity of chemotherapy, with its severity and persistence significantly influencing treatment efficacy. In non-small cell lung cancer (NSCLC) management, while high-risk febrile neutropenia (FN) chemotherapy remains relatively uncommon, real-world data indicate suboptimal utilization of granulocyte colony-stimulating factor (G-CSF) prophylaxis among patients with risk factors receiving intermediate-risk FN regimens. This study aims to evaluate the clinical effectiveness and safety profile of efbemalenograstim alpha in maintaining absolute neutrophil count (ANC) levels during chemotherapy cycles for NSCLC patients undergoing intermediate-risk FN treatment protocols with coexisting risk factors.

Methods: This randomized, multicenter, exploratory clinical study (NCT06143735)enrolled non-small cell lung cancer (NSCLC) patients undergoing intermediate-risk febrile neutropenia (FN) chemotherapy with additional risk factors. Participants were stratified into two groups: the primary prophylaxis arm (Group A) received subcutaneous efbemalenograstim alfa (20 mg) within 48±4 hours after each chemotherapy, starting from the first cycle, while the secondary prophylaxis arm (Group B) initiated treatment only if grade ≥3 neutropenia (CTCAE v5.0) occurred in the preceding cycle. All patients were required to receive at least 4 cycles of platinum-based chemotherapy. The primary objective was to compare the incidence of grade ≥3 neutropenia during the first chemotherapy cycle between primary and delayed secondary prophylaxis strategies. The secondary objectives included FN incidence, grade ≥3 neutropenia during other chemotherapy cycles, and adverse events or serious adverse events. Here,we present, after the first analysis, the updated results of Guard-03.

Results: As of March 31, 2025, 53 subjects were enrolled (median age: 69 years; 64.15% with ECOG 0-1; 90.57% male), with 35 assigned to Group A and 18 to Group B . The incidence of grade ≥3 neutropenia during the first treatment cycle was 23.08% (6/26) in Group A versus 64.71% (11/17) in Group B. Febrile neutropenia (FN; defined per CTCAE v5.0 as ANC <1.0×10^9/L with single temperature >38.3°C [101°F] or sustained temperature ≥38°C [100.4°F] for >1 hour) occurred in 1 and 2 patients in Groups A and B, respectively. Safety analysis showed 11 patients (28.2%) experienced TRAEs (4 cases [10.3%] with pain symptoms such as ankle soreness or neuropathic pain), while 23 patients (59.0%) developed grade ≥3 AEs, predominantly chemotherapy-related.

Conclusions: Efbemalenograstim alfa demonstrated promising clinical efficacy in the prophylactic management of chemotherapy-induced neutropenia, reducing the risk of infection and enhancing patients' quality of life.

Lee Moffitt Cancer Center & Research Institute, Tampa/FL/USA ,[15]Stanford Division of Oncology & Stanford Cancer Institute, Stanford/CA/USA ,[16]Stanford Cancer Center, Stanford/CA/USA ,[17]UCLA Jonsson Comprehensive Cancer Center, Santa Monica/CA/USA

Introduction: Mesothelin (MSLN) is commonly overexpressed in lung cancer, with minimal expression in normal tissues. Unacceptable toxicities, including death, have limited MSLN-targeted programs. A2B694 is an autologous, logic-gated Tmod chimeric antigen receptor T cell (CAR T) therapy designed to improve tumor selectivity and decrease toxicity by integrating an MSLN CAR T activator with a human leukocyte antigen (HLA)-A*02 blocker. Loss of heterozygosity (LOH) may provide a means to target tumors instead of normal cells.

Methods: EVEREST-2 (NCT06051695) is a first-in-human, open-label, phase 1/2 study evaluating the safety and efficacy of A2B694 in patients with recurrent or metastatic cancers with MSLN expression (non-small cell lung cancer [NSCLC], colorectal cancer, pancreatic cancer, ovarian cancer, and mesothelioma) and tumor-associated HLA-A*02 LOH. Eligible patients are identified in the master prescreening study, BASECAMP-1 (NCT04981119). BASECAMP-1 enrollees have their leukapheresis product cryopreserved. When clinically appropriate, A2B694 is manufactured on demand and administered after lymphodepletion. The primary objective of phase 1 is to evaluate the safety and tolerability of A2B694 and identify a recommended phase 2 dose. The phase 2 primary objective is to assess overall response rate.

Results: As of 6 March 2025, 5 patients were enrolled in phase 1: 4 women/1 man, median age 59 years, 4 non-Hispanic White, 1 Hispanic. Tumor types included ovarian cancer (Patients 1-3), pancreatic cancer (Patient 4), and NSCLC adenocarcinoma (Patient 5). A2B694 doses were 0.5×108 (n=1), 1×108 (n=3), and 2×108 (n=1) cells. Lymphodepletion was well-tolerated by all patients, with no clinically significant cytopenias. All patients had ≥1 adverse event, most commonly decreased appetite (n=3; 1 serious) and fatigue (n=3). There were no dose-limiting toxicities, cytokine release syndrome, or related neurotoxicity noted, and no new safety signals after ≤8.9 months of follow-up. A2B694 was detected post-infusion in peripheral blood in all treated patients (Figure) and present in a tumor biopsy in 1 patient (Patient 4) 42 days (D) post-infusion. Patient 5 has KRAS G12V/STK11 co-mutated NSCLC adenocarcinoma that progressed on carboplatin, pemetrexed, and pembrolizumab. They achieved a partial response at D90 post-infusion and continue on observation. Patients 1-3 had stable disease at D28 and progressive disease by D90 and Patient 4 had progressive disease at D28.

Conclusions: A2B694 has manageable safety and tolerability in patients with advanced solid MSLN-expressing tumors with tumor-associated HLA-A*02 LOH. The dose-escalation phase continues to enroll patients. All patients exhibited CAR T expansion, and there is an ongoing partial response in a patient with NSCLC.

EP.01.01 Exercise Training Modalities in Patients With Lung Cancer: A Protocol for Systematic Review and Network Meta-Analysis

Y. Zhang
Gansu Provincial Maternal and Child Health Hospital, LanZhou/CN

Introduction: Lung cancer is a common malignancy and a major cause of cancer-related deaths worldwide, ranking high in terms of morbidity and prevalence. Exercise is a well-established recovery aid for many chronic respiratory conditions and lung cancer. However, it is difficult to determine the superiority of different exercise training modalities using randomised controlled trials (RCTs) or pairwise meta-analyses. Our Bayesian network meta-analysis (NMA) aimed to compare the impact of different perioperative exercise training modalities on lung function, exercise capacity, adverse events, health-related quality of life and mortality in patients undergoing lung cancer surgery, including preoperative and postoperative patients.

Methods: We will perform a comprehensive literature search using PubMed, EMBASE, Cochrane Library and Web of Science, from inception to May 2022, to identify studies that potentially provide data regarding exercise training modalities for patients with lung cancer. We will assess the risk of bias according to the Cochrane risk-of-bias tool and certainty of evidence for the main outcomes using the Grading of Recommendations Assessment, Development and Evaluation framework. Pairwise meta-analyses will be conducted using a random effects model and Stata software, and the NMA will be analysed using R software.

Results: We will focus on the following outcomes of interest: ► Lung function (eg, volumes and diffusing capacity). ► Exercise capacity (measured either by the 6min walk test or peak oxygen consumption during a maximal incremental exercise test). ► Adverse events. ► Quality of life, determined using the Medical Outcomes Study Short Form 36 General Health Survey, the European Organization for Research and Treatment of Cancer Quality of Life, the Functional Assessment of Cancer Therapy-Lung scale or HRQoL. ► Mortality.

Conclusions: Different exercise training modalities will be considered in our systematic review, including aerobic, strengthening, breathing and combined exercises. Supervised, unsupervised or a combination of both exercise sessions will be considered. Aerobic exercise will be defined as a regimen that contains aerobic components. Aerobic components include, but are not limited to, walking, cycling, yoga (only yoga that meets the definition of aerobic exercise), jogging and swimming.26 Strengthening exercise will be defined as a regimen consisting of some type of progressive resistance to increase muscle strength, endurance or power, which includes, but is not limited to, bench press, seated row, shoulder press, leg press and weight strength.27 Breathing exercises will be defined as a broad range of respiratory strategies, including, but not limited to, pursed-lip, abdominal and thoracic breathing exercises. Combined aerobic and resistance training (combined exercise) will be defined as performing an aerobic training programme plus a resistance training programme to ensure an adequate dose of each type of exercise.

Keywords: Exercise training modalities, lung cancer

EP.01.02 Long-Term Survival After Curative Surgery for Stage I-III NSCLC Patients in British Columbia, 2005-2021: A Population-Based Study

Y. Chen[1], T. Chang[2], P. Cao[3], C. Ho[2,4], R. Meza[1,4]
[1]British Columbia Cancer Research Institute, Vancouver/BC/CA ,[2]British Columbia Cancer, Vancouver/BC/CA ,[3]Purdue University, West Lafayette/IN/USA ,[4]University of British Columbia, Vancouver/BC/CA

Introduction: Lung cancer remains the leading cause of cancer-related mortality worldwide. In British Columbia (BC), Canada, curative-intent surgical resection is the cornerstone treatment for stage I-III non-small cell lung cancer (NSCLC). Real-world data on long-term survival across demographic and clinical subgroups is essential to measure the impact of adopting novel treatment modalities and early detection interventions. Here, we evaluated overall survival (OS) among stage I-III NSCLC patients diagnosed from 2005 to 2021 who underwent curative-intent surgery in BC, to characterize patterns of survival before the implementation of the provincial lung cancer screening program in 2022.

Methods: We conducted a population-based retrospective cohort study using data from the BC Cancer Registry. We included patients aged 40-80 at diagnosis, with stage I-III NSCLC, who received curative-intent surgery between 2005 and 2021. Demographic (age, sex) and clinical (stage, histology, year of diagnosis) variables were obtained. Kaplan-Meier methods estimated OS probability (with 95% confidence intervals, CIs) at 12, 36, and 60 months. We used Fine and Gray's subdistribution hazard model to estimate sub-hazard ratios (sHRs) for lung-cancer-specific mortality by prognosis factors, accounting for the competing risk of death from other causes. The University of British Columbia Research Ethics Board approved this study.

Results: A total of 3,614 patients met inclusion criteria (57.8% female; mean age at diagnosis 67.3 years). Overall, 12-, 36-, and 60-month OS estimates were 93.2% (CI 92.7-93.7), 80.2% (CI 79.1-81.3), and 68.6% (CI 67.1-70.2), respectively. Females had higher OS than males (60-month OS 72.4% vs. 63.5%). By stage, 60-month OS was 76.0% for stage I, 57.5% for stage II, and 50.9% for stage III. Adenocarcinoma demonstrated the most favorable OS (60-month OS 71.3%), while squamous cell carcinoma (58.9%) fared the worst. Patients diagnosed in later years experienced higher 60-month OS than those diagnosed in 2005-2009 (49.9%). In competing risk analysis, earlier years of diagnosis were associated with higher risk of lung-cancer-specific death (2005-2009: sHR=3.27, CI=2.48 to 4.31; 2010-2013: sHR=1.90, CI=1.55 to 2.34; 2014-2017: sHR=1.44, CI=1.17 to 1.77) compared to 2018-2021, after adjusting for age, sex, stage, and histology.

Conclusions: Survival after curative-intent surgery for stage I-III NSCLC has improved in BC over time, with early stage, adenocarcinoma histology, and female sex associated with better prognosis. Future analyses will explore how treatment modality has driven these improvements. Our findings provide a benchmark for future assessments of the BC lung cancer screening program's impacts on lung cancer mortality and survival.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.03 Young Patients With Non-Small Cell Lung Cancer in Poland - a Comprehensive Epidemiological, Molecular and Prognostic Analysis

M. Knetki-Wróblewska[1], B. Tomasik[2], L. Grono[2], W. Bortnowski[2], B. Sobocki[2], M. Sekuła[3], J. Chwatko[3], M. Krzakowski[1]
[1]Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw/PL ,[2]Medical University of Gdansk, Gdansk/PL ,[3]Medical Univeristy in Warsaw, Warsaw/PL

Introduction: The incidence of non-small cell lung cancer (NSCLC) in Young Caucasian Patients (<50 years) is low, and knowledge clinical features, molecular landscape, and treatment outcomes is still incomplete. This study presents the clinicopathological, molecular characteristics, and survival of young-onset NSCLC in a real-world setting in two cancer centres in Poland.

Methods: Patients aged 18 to 50 years with a diagnosis of NSCLC who were treated between 2010 and 2023 were identified using electronic medical records. The included patients were reviewed for demographics including age, sex, smoking history, histology, molecular analysis, staging, treatment history, and survival data. Survival was analysed using the Kaplan-Meier method.

Results: Of 234 included Caucasian patients, the median age was 42.8 years, 55% (n = 129) were female, 38% (n = 90) were never smokers. Most of the patients had adenocarcinoma (74%, n = 173) and presented metastatic disease (73%, n = 171). In patients with non-squamous metastatic NSCLC (n = 130), next-generation sequencing (NGS) was performed in 60% (n = 78). Molecular aberrations were found in 79% (n = 62) of the patients, which is a significantly higher percentage than in the general population of patients. Among them in the majority (n = 47, 76%) molecular targeted therapy was introduced. Median overall survival (OS) in metastatic NSCLC was 17.6 months (95% CI 14.7-21.1 months), with a higher median overall survival in those with a targeted therapy option (23.6 months) compared to those without (12.9 months; p < 0.001). In patients with non-metastatic NSCLC, median OS was 81.1 months (95% CI 77.3-152.9 months).

Conclusions: Young Caucasian patients with NSCLC have predominantly advanced stage adenocarcinoma and exhibit a high prevalence of actionable molecular aberrations. Integration of NGS and targeted therapies significantly influences treatment outcomes, highlighting the need for personalised approaches in this rare population.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.04 Features, Demographics and Treatment Profiles of Primary Lung Cancer Cases in Nigeria: The Largest Single Centre Report in West Africa

M. Adewole[1,2,3], A. Sowunmi[2,4], N. Adedewe[4], E. Aje[4], I. Ariyo[4], O. Aremu[5], O. Odupitan[2], R. Osarogiagbon[6], U. Anazodo[1,7], J. Gee[3], F. Dako[1,3]
[1]Medical Artificial Intelligence Laboratory, Lagos/NG ,[2]College of Medicine, University of Lagos, Lagos/NG ,[3]University of Pennsylvania, Philadelphia/PA/USA ,[4]NSIA LUTH Cancer Center, Lagos/NG ,[5]College of Medicine, Lagos State University, Lagos/NG ,[6]Baptist Cancer Center, Memphis/TN/USA ,[7]Montreal Neurological Institute, McGill University, Montreal/QC/CA

Introduction: Lung cancer leads the cancer incidence and mortality chart globally, yet it is not among the top 10 cancer cases in Nigeria. This is likely due to underdiagnosis, partly due to similar clinical presentations to endemic diseases such as tuberculosis, as well as limited infrastructure for robust data storage and analysis. This study aims to unravel lung cancer in Nigeria by examining the database of cases treated at a leading comprehensive cancer center in Lagos, the most populous city in West Africa.

Methods: Primary lung cancer cases treated at the Centre between 2019 and 2024 were retrospectively reviewed. Patient data, including demographics, tumor characteristics, medical imaging, comorbidities and histological subtypes, diagnosis and treatment options, were analyzed.

Results: The search revealed 175 confirmed cases (Scan QR Code to see study cohort demographics table). The average patient age was 59 years (range: 27 - 85), of which 49.7% were females and Adenocarcinoma the most common histological subtype (57.1%). Only 4% of cases presented at an early stage (I and II). Despite lung cancer's strong global association with tobacco use, 14.9% of cases had a history of smoking, suggesting the possible role of environmental and genetic factors. Cross modality imaging was available to 77% of the patients for diagnosis. Radiotherapy was provided to 31% of patients, most of which for palliative intent. Immunohistochemistry testing was performed in 14.3% of cases, while 8% of patients received immunotherapy, reflecting limited access to advanced molecular diagnostics and targeted therapies. Representative CT images of the cases are shown in Figure 1.

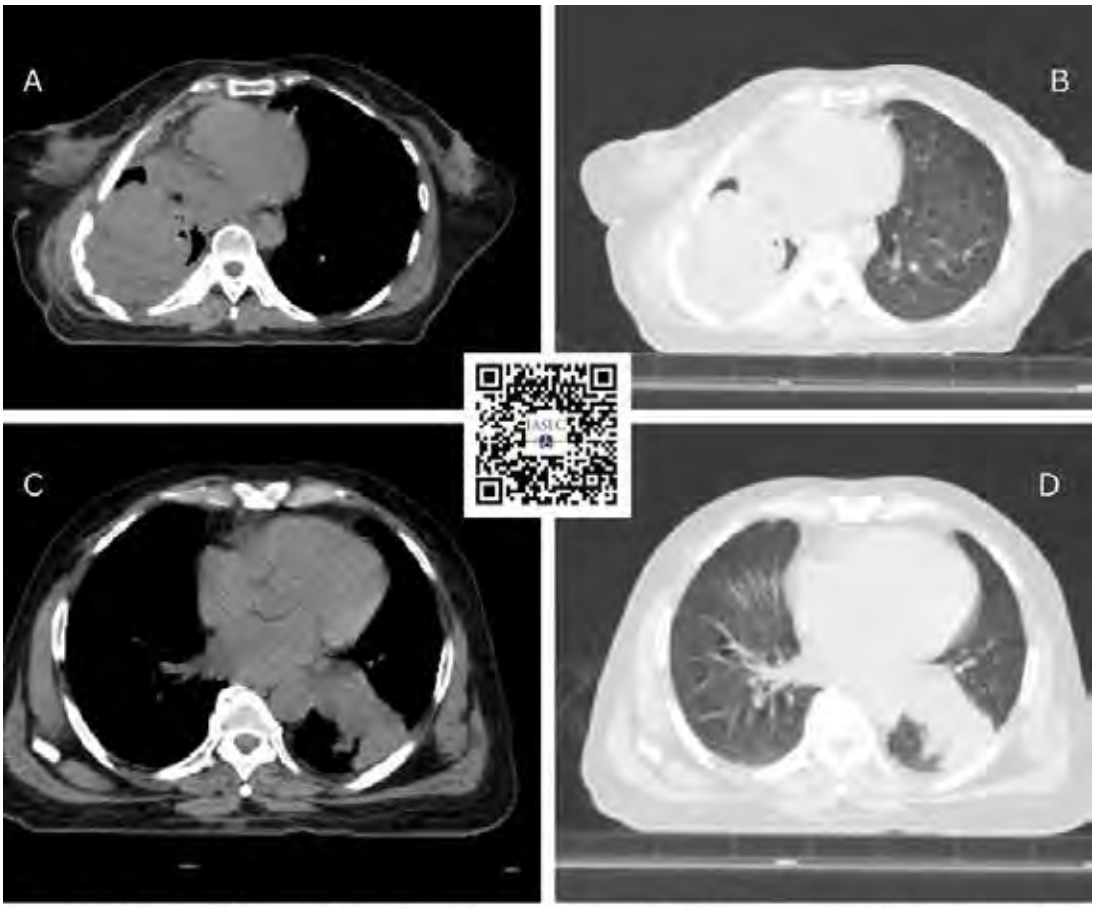

Figure 1: Study Cohort Sample CT Images (A and C in soft tissue window, B and D in lung window). A and B shows right lung mass with associated atelectasis and pleural effusion. C and D demonstrate left lower lobe mass with associated atelectasis. Scan the QR code to see the full demographic table

Conclusions: This study, representing the largest single center lung cancer report from West Africa, highlights a predominance of late-stage lung cancer presentation and heavy reliance on palliative care in Nigeria. Importantly, lung cancer in this cohort showed a weak association with smoking, with nearly equal male and female representation, differing from global patterns. Defining and targeting high-risk groups and improved understanding of cancer biology in African populations is needed to improve regional and global lung cancer outcomes.

[1]São Paulo State University (Unesp), Medical School, Botucatu/BR ,[2]Clinical Hospital of Botucatu Medical School, Botucatu/BR ,[3]Fundação Getúlio Vargas, São Paulo/BR ,[4]Universidade Nove de Julho, Bauru/BR ,[5]Faculdade de Medicina de Catanduva, Catanduva/BR ,[6]Universidade do Oeste Paulista, Jaú/BR

Introduction: Understanding the clinical pathway of cancer patients is fundamental for optimizing the management of tracking programs and driving strategies for improving clinical outcomes within the public healthcare system. The purpose of this study has been to map the clinical pathways of patients treated by the Inspire Program, in Botucatu, Brazil, analyzing the healthcare flows and identifying critical factors that directly impact the efficiency and the results in lung cancer care.

Methods: This retrospective study analyzed patient data who were treated by the Inspire Program, implemented in Botucatu, São Paulo, Brazil in the period from January 2023 to October 2024. The program focuses on early diagnosis and treatment of chronic respiratory conditions, especially focused on vulnerable populations, integrated between primary care and specialized networks. The information was extracted from clinical and administrative records, ranging from demographic, smoking history, diagnostic exams, treatment performed, and clinical outcomes. The clinical flows were analyzed by process mining, generating detailed maps that revealed the frequency of transitions, the temporal efficiency between steps and critical factors that directly impacted the quality of patient care for lung cancer patients.

Results: The data analysis revealed that the patients' mean age was 63.5, with (62.5%) female gender predominance, and with a mean tobacco load of 79 packs/year, indicating a significant history of smoking. Most patients were diagnosed with an advanced stage of cancer (37.5% in stage IV). Before beginning treatment, the most common activities included primary healthcare (17.8%), laboratory exams (13.4%), and miscellaneous medical care (12.2%). After diagnosis, laboratory exams were the most common (22.91%), radiotherapy (16.59%), and primary healthcare (9.16%) as the most frequent interventions. An analysis of the clinical pathways demonstrated differences based on the staging of the disease: patients in the initial stages were mainly treated with thoracic surgery, while those whose stages were locally advanced and advanced were treated with combined radiotherapy, chemotherapy, and multidisciplinary support, including palliative and nutritional care.

Conclusions: This study mapped the clinical pathways of patients with lung cancer treated by the Inspire Program, revealing the complexity of treatment pathways and emphasizing the importance of specialized and multidisciplinary interventions.

Introduction: Lung cancer in individuals under 50 years presents distinct clinical characteristics and poses unique diagnostic and therapeutic challenges. This study aims to evaluate the demographic profile, molecular characterization and survival outcomes in young lung cancer patients in India

Methods: This retrospective study included consecutive patients from community oncology centres diagnosed Lung cancer NSCLC (age ≤50) between March 2018 and September 2024. Progression-free survival and overall survival were calculated using the Kaplan-Meier analysis

Results: A total of 2281 patients were diagnosed with lung cancer, of whom 297(13%) were young patients(age ≤ 50 years); among them, n=83 were classified as very young (age≤40 years), and n=214 were aged between 41 and 50 years. The median age at presentation was 45 years(IQR 40-48), with a M:F of 1.14:1 and distribution by stage was 3.4%(n=10) in stageI/II, 17.2%(n=51) in stageIII, and 77.8%(n=231) in stageIV. Among the cohort, smoking history was reported in 32.2% of males and 13.7% of females(p<0.001). The cohort comprised 90.9% of Non-small cell lung cancer(NSCLC) cases, with adenocarcinoma being the predominant subtype (84.1%). Most common sites of metastasis were bone(134/231), brain(75/231), lymph nodes(52/231), and liver (49/231). Molecular testing was performed in 66.3%(197/297) of patients, out of which Next-generation sequencing(NGS) was done in 104/197 patients wherein 45.2% were comprehensive NGS panel and 54.8% were short NGS panel while 93/197 were tested by Polymerase chain reaction(PCR) method. Actionable molecular alterations(EGFR/ALK/ROS1) were detected in 55.3%(109/197) of tested patients, with EGFR mutations in 40.6%(80/197), ALK rearrangement in 12.7%(25/197), and ROS1-rearrangement in 5.1%(10/197), while Tumor mutational burden(TMB) >10 Mut/Mb was reported in n=4/197. Prevalence of ALK rearrangement was significantly higher in patients ≤ 50 years (12.7%) compared to overall cohort of lung cancer patients (5.6%)p<0.001. Among the 44.7%(88/197) of patients with EGFR/ALK/ROS1 wild-type, PD-L1 expression was 1-49% in 27 patients and >=50% in 8 patients. Mutational alterations were identified in 36.1% of males and 38.8% of females(P=0.624), with a similar distribution across both genders. The median overall survival(mOS) of the cohort was 38.1 months(95 % CI 32.0- 44.1) with a median follow-up duration of 21.3 months(95% CI: 17.1-25.5). The mOS for the very young cohort(age≤40 years) was 24.2 months (95%CI: 2.2-46.5). Survival analysis was limited to stage IV patients to evaluate the impact of driver mutations and targeted therapy, showed a significantly improved mOS of 49 months(95%CI: 34.7-63.2) in those who received targeted therapy compared to 17.2 months(95%CI: 11.4-22.9) in those who did not(p=0.000). Additionally, mOS was longer in females at 57.2 months (95%CI: 29.9-84.5) compared to 32.9 months in males(95%CI: 19.8-46.1)(p=0.114)

Conclusions: This study provides valuable insights into the clinical characteristics and survival outcomes of young lung cancer patients in Western India, with a distinct focus on the very young population (≤ 40 years). The findings emphasize the unique disease biology in this subgroup, highlighting the importance of early molecular profiling and personalized treatment strategies to improve outcomes in this demographic

EP.01.07 Lung Cancer in Young: A Descriptive Study From Thoracic Oncology Clinic in Northern India

S. Chougale, P.K. Singh, A. Ahuja, G. Arya
Pandit Bhagwat Dayal Sharma Post Graduate Institute of Medical Sciences, Rohtak/IN

Introduction: Lung cancer has been considered as disease of the old. However, there has been a steady rise in lung cancer incidence among younger population throughout the globe. Young lung cancer patients exhibit unique risk factors, molecular traits, and clinical behaviour. In this study we intended to study the clinico-demographic characteristics of young lung cancer patients from northern India.

Methods: This was a retrospective study including lung cancer patients under 45 years of age (at the time of diagnosis) and attending the thoracic oncology clinic in a tertiary care hospital in northern India. Data on demographics, smoking-history, histology, stage, treatment, laboratory investigations and survival (overall survival- OS) were collected.

Results: Between January 2022 and March 2025, a total of 844 patients were registered in the clinic. Among them, 52 patients (6.2%) were younger than 45 years (with 17 below 36 years of age). Males constituted 67% (n=35) of this cohort, and overall mean age was 38.5±6.5 years. A history of smoking was present in 60% (n=31, all current smokers) with mean pack years of 11.9±4.1. The majority cases were diagnosed through ultrasound-guided-biopsy, followed by endobronchial biopsy. Non-small cell lung carcinoma was the predominant histological type (83%, n=43), with adenocarcinoma (n=21) being the most common subtype, followed by squamous cell carcinoma (n=12). Most patients had an Eastern-Cooperative-Oncology-Group (ECOG) performance status of 1 at presentation (48.1%). At diagnosis, 63.5% of patients had metastatic disease. 24 patients were classified as stage IVa, while 11 patients (each) had stage IIIc and IVb disease. Financial constraints prevented most patients from undergoing comprehensive molecular testing. 17 adenocarcinoma patients had data of basic (EGFR-mutation/ALK-rearrangement/ROS1-rearrangement) molecular-analysis available: 6 had EGFR mutations, 8 harboured ALK rearrangements, and 3 showed no targetable genetic alterations. Only 5 of 14 eligible patients received targeted therapy. All remaining patients were treated with chemotherapy and radiation as appropriate. Using Kaplan Meier Survival analysis, OS was found to be significantly higher in never-smokers compared to smokers (15±0.9 versus 8±1.5 months; p<0.05). Survival outcomes were also better in females compared to males (p=0.046). OS was also lower in patients who had an haemoglobin of less than 9gm/dl at the time of presentation (12±1.4 versus 4±2.2 months; p=0.041). However, OS was independent of histological subtype, ECOG and albumin levels.(figure 1)

Conclusions: Majority young lung cancer cases often presented late and genetic alterations especially ALK-rearrangement were common. Smoking and presence of anaemia contributed significantly to survival outcomes.

EP.01.08 Lung Cancer in Elderly Patients: Insights From a Community Oncology Setting in Western India

K. Chaudhari[1], D. Pal[2], M. Randive[3], K. Jobanputra[2], A. Joshi[2], V. Maniar[2], P. Kalaskar[2], K. Joshi[2], U. Maheshwari[2], D. Morzaria[2], P. Kendre[2], A. Pathan[4], R. Dave[4], M. Mekha[4], N. Bayas[2], S. Bhosale[2], K. Tamkhane[2], N. Shirsi[4], R. Puranik[4], T. Patil[4]
[1]MOC Cancer Care & Research Centre, Indore/IN ,[2]MOC Cancer Care & Research Centre, Mumbai/IN ,[3]MOC Cancer Care & Research Centre, Nagpur/IN ,[4]MOC Cancer Care & Research Centre, Pune/IN

Introduction: Lung cancer remains a major cause of cancer-related deaths, with elderly patients facing unique clinical challenges. This study addresses the limited data on lung cancer outcomes in elderly patients (≥80 years) in Western India, focusing on survival trends, treatment patterns, and the impact of molecular mutations in community oncology settings.

Methods: This retrospective study included consecutive patients from community oncology centres diagnosed Lung cancer NSCLC (age ≥80) between March 2018 and September 2024. Baseline characteristics including patient demographics, disease stage, and treatment modalities were retrieved from the EMR. Progression-free survival and overall survival were calculated using the Kaplan-Meier analysis

Results: A total of 2281 patients were diagnosed with lung cancer, of whom 189 patients who were aged ≥80 years were analyzed and found to have Median age of 82 years (IQR: 81-85) with M:F ration being 2:1. Distribution by stage is as follows, stage I/II - 6.9% (n=12), stage III - 22.8% (n=43), and stage IV - 69.3% (n=131), while the Common metastatic sites included bone (61/131), brain (22/131), liver (22/131) and lymph nodes (17/131). The cohort comprised of 82% Non-small cell lung cancer (NSCLC) cases, with adenocarcinoma being the predominant subtype (72.3%). Molecular testing was performed in 57.7% of patients, with EGFR mutations being the most common (31.1%), followed by KRAS (9.7%), TP53 (8.7%), MET (3.9%), RET, ROS1, PIK3CA (1.9% each) and BRAF, ALK, and HER2 (each 0.97%). PD-L1 testing was conducted in 38% of patients, with PD-L1 expression of 1-49% observed in 27 of 72 cases and ≥50% in 12 of 72 cases. The Median overall survival (mOS) of the cohort was 10.3 months (95% CI: 6.7-13.9) with median follow up time of 32.8 months (95% CI: 25-40.5). Patients with identified mutations had significantly improved mOS (14.95 months) compared to non-mutated patients (7.3 months) p<0.001. Mutation-positive patients in this subgroup also had improved survival outcomes 14.95 months (95% CI: 12.1-16.9) compared to 4.7 months in non-mutated patients (95% CI: 0.1-9.2) p = 0.025. Among 189 patients, 52.9% (100/189) received first-line treatment, with mutations detected in 42% (42/100); among these, 80.9% (34/42) received TKI, 14.2% (6/42) chemotherapy, and 4.7% (2/42) a combination of chemotherapy and TKI. Among mutation-negative patients (58/100), 10.3% (6/58) had PD-L1 expression of 1-49%, 8.6% (5/58) had ≥50% expression, and 45.4% (5/11) received immunotherapy

Conclusions: Elderly lung cancer patients (≥80 years) are known to have poor survival and lesser prevalence of actionable mutation however, targeted treatment with respect to these molecular aberrations can help to improve survival in this subset of patients

EP.01.09 NSCLC Epidemiology and Survival in Denmark, Finland, and Norway: A Decade of Real-World Insights From the LANDSCAPE Study

A. Knuuttila [1], E. Urbanska[2], J.L. Hansen[3], O. Hölsä[4], T. Ågesen[5], R.H. Petersen[6], Å. Helland[7]
[1]Helsinki University Hospital, Helsinki/FI ,[2]Department of Oncology, Rigshospitalet, Copenhagen/DK ,[3]Institute of Health and Society, University of Oslo,, Oslo/NO ,[4]Medaffcon Oy, Espoo, Finland, Espoo/FI ,[55] Trude Ågesen Medical Evidence Scientific Lead AstraZeneca Nordics, Oslo, Norway trude.agesen@astrazeneca.com, Oslo/NO ,[6]Copenhagen University Hospital, Rigshospitalet,, Copenhagen/DK ,[7]Oslo University Hospital, OSLO/NO

Introduction: Despite comparable healthcare systems and cancer care, Nordic countries have different overall survival (OS) rates in lung cancer. Healthcare registries enable for longitudinal, population-based, lung cancer studies with real-world data to examine survival variations in Nordic populations. Here we describe a NSCLC population and survival rates in non-metastatic and metastatic settings in Denmark, Finland, and Norway to better understand differences in course of disease in the Nordic region and provide insights for improved lung cancer management.

Methods: This observational study was conducted in three Nordic countries (January, 2011-December, 2022). In Denmark and Norway, NSCLC cohorts were established by linking nationwide, population-based healthcare registries. The Finnish NSCLC cohort comprised patients from the Helsinki and Uusimaa (Helsinki University Hospital data lake) regions (~30% overall NSCLC population). The study population included patients with NSCLC during the study period. Demographic data were summarized at NSCLC diagnosis (index date). Annual 1-, 3-, 5-year survival estimates were reported by country and metastatic status at diagnosis (M0, no metastases; M1, metastases). Age-standardized survival analyses were conducted to determine median OS by metastatic status.

Results: Analysis cohorts comprised 45,298 (Denmark), 6,986 (Finland), and 25,480 (Norway) patients with NSCLC aged, 70 years on average (standard deviation ~ 9.5 years) at time of diagnosis across all countries and metastatic status. Approximately 50% (Denmark), 55% (Finland), and 55% (Norway) of respective cohorts were male. During the study period, 1-, 3-, and 5-year survival numerically improved for M0 and M1 in all countries (Figure 1). One-year survival increased between 2011-2022 from 66.2%, 63.6%, and 69.5% to 79.8%, 71.2%, and 80.9% (M0 group), and from 23.1%, 23.7% and 25.9% to 31.5%, 30.0% and 36.9% (M1 group) in Denmark, Finland and Norway, respectively, with similar trends for 3- and 5-year survival. Median survival times during the study period for the M0 group were 35, 28, and 44 months in Denmark, Finland, and Norway, respectively. In the M1 group, median OS was 6 (Denmark), 5 (Finland), and 7 (Norway) months.

Conclusions: Survival rates for NSCLC patients improved over this decade-long, observational study in Denmark, Finland, and Norway at 1-, 3-, and 5-years' follow-up and by metastatic status. The large survival differences in patients with and without metastases at diagnosis highlight the need for early diagnosis and prevention metastatic disease to improve outcomes. These data enable additional research on NSCLC-care management in patient subgroups for further insights that may guide future healthcare decisions.

Keywords: Survival, epidemiology, NSCLC

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.10 Young Onset Lung Cancer: Clinical, Pathologic and Molecular Profile From a Tertiary Care Centre in Indi

K. Borda
All India Institute of Medical Sciences (AIIMS), New Delhi, New Delhi/IN

Introduction: Lung cancer in young patients is a rare entity. This subset of patients may have a biologically distinct behaviour compared to their older counterparts. Studies done so far in this age group have a higher proportion of females and adenocarcinomas on histology. A higher frequency of positive family history and driver mutations have also been observed. Data is scarce in this population especially in the Indian setting.

Methods: Records of lung cancer patients aged ≤40 years and gender and smoking status matched patients aged ≥ 60 years, registered at Lung Cancer Clinic at AIIMS New Delhi and NCI Jhajjar between 01/01/2018 and 30/07/2024 were collected and analysed. Clinical, pathologic, molecular, treatment and outcome details were collected

Results: Records of 201 young onset lung cancer cases and gender and smoking status matched late onset lung cancer cases were analysed. In the young onset group median age at presentation was 36 years (20-40) and 66 years (60-83) in the late onset group. Adenocarcinoma was the most common histology in both groups. In the young onset group, 115 patients (57.21%) were males and 85 patients (42.79%) were female and majority were non-smokers (81.59%). In the late onset group prevalence of comorbidities was significantly higher (15.92% vs 44.27%, p < 0.001). Young patients were more likely to present with metastatic disease (92.04% vs 84.08%; p= 0.014), higher number of metastatic sites (2 vs 1; p< 0.001), brain metastases (41.08% vs 18.34%; p<0.001), adrenal metastases (18.92% vs 11.24%; p= 0.049) and ALK rearrangement positivity (26.98% vs 8.76%; p< 0.001). There was no difference in PFS1, TKI-PFS or OS between the age groups. In the young onset group metastatic disease was associated with a detrimental outcome (HR = 5.38; p= 0.002) and TKI use was associated with a better outcome (HR = 0.41; p = 0.008).

Conclusions: In conclusion, younger lung cancer patients exhibited a higher prevalence of metastatic disease, particularly brain and adrenal metastases, and a greater frequency of ALK mutations, while older patients had more comorbidities but fewer metastatic sites. Despite these differences, performance status was comparable across age groups. Although younger patients showed a higher prevalence of driver mutations, this was not statistically significant. The use of tyrosine kinase inhibitors (TKIs) significantly improved survival outcomes in both age groups, emphasizing the importance of targeted therapies in lung cancer management regardless of age.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.11 Impact of Demographics and Smoking on Driver Gene Mutations Development in Non-Small Cell Lung Cancer (NSCLC)

T.I. Khallad, A.A. Bani Mustafa, M.N. Ibrahim
Jordan University of Science and Technology, Irbid/JO

Introduction: Lung cancer is the most common type of cancer. Non-small cell lung cancer (NSCLC), is known to have a variety of genetic mutations. Behavioral and demographic factors cause an increased risk of development of driver gene mutations, including KRAS, EGFR, ERBB2, and ALK, which leads to a higher incidence of lung cancer. This study aims to explore the impact of smoking, sex, race, and ethnicity on the development of driver mutations in non-small cell cancer patients.

Methods: We queried the AACR Project GENIE BPC NSCLC v2.0 dataset and included 537 patients diagnosed with stage I-III NSCLC. We tested for significant associations using Chi-square test. Effect sizes were measured using Cramer V and Phi coefficients. A p-value of <0.05 was considered statistically significant.

Results: A total of 537 patients diagnosed with NSCLC were included, with a median age of 68.2 years (35.5-87.5). The majority were female (55.7%) and White (86.6%), with 93.5% identified as non-Hispanic. Smoking status was significantly associated with EGFR mutations ($p<0.001$, Cramer V = 0.333, moderate association) but not with KRAS, ERBB2, or ALK mutations. Female sex was significantly associated with EGFR mutations ($p=0.006$, phi = 0.118); but no significant associations were observed for ERBB2, KRAS, or ALK mutations. White race was significantly associated with EGFR ($p<0.001$, Cramer V = 0.192) and ERBB2 mutations ($p=0.003$, Cramer V = 0.171), both indicating small associations, while no associations were found for KRAS or ALK mutations. Ethnicity showed no significant association with any of the studied mutations: ERBB2, KRAS, EGFR, or ALK.

Conclusions: This study showed significant association between smoking, female sex and white race and the development of EGFR, but not with KRAS, ALK or ERBB2 gene mutations. However, ethnicity had no correlation to the occurrence of any of the studied driver gene mutations. These findings highlight the role of demographics and lifestyle factors in development of driver mutation in non-small cell lung cancer, emphasising the need for personalised approaches in risk assessment and treatment.

Keywords: NSCLC, Epidemiology, Genetic mutations

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.12 A Causal Machine Learning Approach for the Prediction of Immune-Related Adverse Events in Lung Cancer Patients Receiving Immunotherapy

F. Reid[1], J. McPhelim[2], M. Simpson[2], F. Dong[1], R. Maguire[1]
[1]University of Strathclyde, Glasgow/GB ,[2]NHS Lanarkshire, Bothwell & Uddingston/GB

Introduction: Immune-Related Adverse Events [irAEs] are a diverse set of toxicities associated with immunotherapy affecting multiple organ systems, ranging in severity from mild to life-threatening. Whilst awareness of irAE incidence is growing, current research gaps mean that risk factors are often not well understood. Although RCTs are viewed as the gold standard for clinical evidence, they must generally exclude individuals with comorbities, certain lifestyle factors, concomitant medication, and other characteristics commonly present in real-world populations, limiting their generalisability. Meanwhile, observational studies which include individuals with these characteristics are limited by challenges in establishing causality. These shortcomings contribute to uncertainty in facilitating shared decision making between provider and patient as well as human factors such as considerations around Quality of Life, with irAEs being a common concern for both parties. In clinical practice, decisions must be based on explainable reasoning, not only correlations found by associative black-box models. Therefore, this research aims to bridge the gap between RCTs, observational studies, and clinical practice by utilising State-of-the-Art machine learning models capable of efficiently discovering causal relationships in observational data, aiming towards actionable decision support for both clinicians and patients regarding irAEs. We apply these methods to a retrospective clinical dataset of patients with lung cancer who received immunotherapy, incorporating detailed records of treatment history, demographics, irAEs, laboratory results, comorbidities, and concomitant medications.

Methods: To identify potential causal relationships between observational variables and the development of irAEs, we apply a machine learning framework based on causal discovery methods. These approaches are underpinned by well-established statistical theory and allow us to move beyond traditional association-based models, enabling the identification of variables which may play a causal role in the onset of irAEs. The causal outputs of the models are represented by a causal Directed Acyclic Graph (DAG), which makes interpretability intuitive.

Results: To validate our approach, we tested our proposed model on synthetic datasets with known ground truth, finding that it consistently outperformed existing state-of-the-art causal discovery methods as measured by Structural Hamming Distance.

On real-world data, combination chemotherapy was found to be a causal factor influencing irAE incidence, as well as patient gender. Other logically-sound causal relationships were found, such as between Primary Site and Surgery Type. Causal effects downstream from irAEs included haemoglobin, Billirubin, White Blood Count, Random Glucose, and Random Cortisol counts, all of which can be affected by the action of specific irAEs on various organs.

However, many spurious relationships were also found by our model, such as an indication that Surgery Type can affect a patient's Age Group.

Conclusions: Preliminary application of our causal discovery model to a dataset of lung cancer patients treated with immunotherapy reveals some promising findings consistent with clinical expectations. However, the dataset is currently limited in size and completeness, restricting predictive accuracy for both causal and associative models. These initial findings should be viewed as exploratory. Data collection is ongoing, and updated analyses based on more complete data will be presented at the Conference, allowing more robust conclusions to be drawn.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.13 Lung Cancer Burden in Latin America and the Caribbean, 1990-2021: A Comprehensive Analysis

P.S. Gupta[1], K. Dudhat[2], G. Singh[3], S. Kotnani[4]
[1]Kiran Multi-Super speciality hospital, Surat/IN ,[2]International American University College of Medicine,St. Lucia, St. Lucia/LC ,[3]St Vincent's medical center, Quinnipiac university, Bridgeport Ct/CT/USA ,[4]Rutgers Monmouth Medical Center, New Jersey/NJ/USA

Introduction: Lung cancer remains a leading cause of cancer-related morbidity and mortality globally. In Latin America and the Caribbean (LAC), the epidemiological transition and rising exposure to risk factors such as tobacco use have contributed to a changing burden. This study aims to quantify and analyze trends in incidence, mortality, and disability-adjusted life years (DALYs) attributable to lung cancer in LAC from 1990 to 2021.

Methods: Utilizing global burden of disease 2021 methodology, focusing on 33 countries in the LAC region, we estimated age-standardized rates (ASR) per 100,000 population for incidence, mortality, and DALYs. Trends were evaluated using estimated annual percentage change (EAPC), stratified by sex and country.

Results: Between 1990 and 2021, the number of new lung cancer cases in LAC increased from 52,400 to 108,900, representing a 107.7% rise. However, the ASR of incidence showed a modest increase from 14.8 to 15.6 per 100,000 (+5.4%). Mortality ASR declined slightly from 13.2 to 12.6 per 100,000 (−4.5%), with a significant reduction in males (EAPC −0.6%) but a marginal increase in females (EAPC +0.3%). The total DALYs rose from 1.3 million to 2.4 million, largely driven by population aging. Countries like Cuba and Uruguay had the highest incidence rates in 2021 (above 25 per 100,000), while countries like Guatemala and Haiti had the lowest (below 8 per 100,000).

Conclusions: While age-standardized mortality rates have decreased slightly, the overall burden of lung cancer in LAC has increased due to population growth and aging. Gender-specific trends suggest progress among males, but emerging concerns among females. Strengthening tobacco control, early detection strategies, and access to care is essential to reduce the growing health and economic burden in this region.

EP.01.14 Pulmonary Pure Ground-Glass Nodule Follow-Up During Pregnancy and Lactation: A Case Repor

B. liang, Q. Cai, T. Zhang
The Fifth Affiliated Hospital, Southern Medical University, Guangzhou/CN

Introduction: The prevailing consensus advocates observation as the primary management strategy for pure ground-glass nodules (pGGNs) until morphological alterations necessitate surgical intervention. However, significant controversy persists regarding special populations, particularly concerning the pre-gestational resection of pGGNs in young women. The central debate focuses on whether dynamic hormonal fluctuations during pregnancy and lactation might influence nodular progression. We present a case of a 31-year-old woman with a left upper lobe pGGN followed through pregnancy and lactation.

Methods: A previously healthy 31-year-old woman was incidentally found to have a 6-mm pGGN in the left upper lobe during a routine health examination in February 2023. The lesion had a CT attenuation of -570 HU (Figure). Given the absence of concerning features, active surveillance was recommended. She subsequently conceived in 2023, gave birth in 2024, and breastfed for nearly one year. In 2025, a follow-up chest CT was performed to assess any changes in the nodule.

Results: Follow-up CT in 2025 showed that the nodule remained 6 mm in size but exhibited increased attenuation, with a CT value of -450 HU (Figure). A multidisciplinary team (MDT) discussion suggested two options: surgical resection or continued surveillance. The patient opted for continued follow-up rather than immediate surgery. No new solid components or significant dimensional changes were observed during the latest evaluation.

Conclusions: Hormonal fluctuations during pregnancy and lactation have been linked to significant changes in certain malignancies, but their impact on pGGN progression remains unclear. In this case, despite prolonged exposure to hormonal changes, the nodule remained stable in size, with only a mild increase in attenuation. While surgical resection was considered, the patient chose close monitoring instead. Long-term follow-up is required to further elucidate the natural history of pGGNs in pregnancy and lactation.

EP.01.15 Gender Disparities in Survival Outcomes of "Minimally Invasive Lung Squamous Cell Carcinoma"

Y. Ma[1], J. Ye[1], J. Liu[1], X. Chen[1], Z. Li[1], W. Lv[1], W. Xu[2], Y. Yang[1], L. Wang[1], S. Hu[3], J. Hu[1,4]
[1]The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/CN ,[2]Sanmenwan Branch, the First Affiliated Hospital, Zhejiang University School of Medicine, Sanmen/CN ,[3]Department of Thoracic Surgery, the Second Affiliated Hospital of Nanchang University, Nanchang/CN ,[4]Key Laboratory of Clinical Evaluation Technology for Medical Device of Zhejiang Province, Hangzhou/CN

Introduction: Lung cancer exhibits marked gender disparities in both incidence and survival outcomes. Females demonstrate a higher incidence of lung adenocarcinoma (LUAD), while males are higher of lung squamous cell carcinoma (LUSC). Male patients exhibit poorer survival outcomes compared to females in both pathological types. Survival outcomes vary across pathological types: patients with LUSC show inferior survival outcomes relative to LUAD. The refinement of pathological classification in LUAD has enabled more precise treatment approaches, but LUSC still lacks similarly refined subclassifications. The study aims to investigate gender-stratified survival outcomes in LUSC patients with tumors ≤3 cm in diameter and invasion depth ≤5 mm (The study defines such LUSC as "minimally invasive LUSC"). The findings may contribute to refining the LUSC classification system and the precision of therapeutic strategies.

Methods: Surveillance, Epidemiology, and End Results (SEER) database is an authoritative database in the United States that provides detailed data on cancer incidence, survival, and treatment. Based on the SEER database, the study analyzed 654 cases of "minimally invasive LUSC" diagnosed between 2018 and 2020. The study performed life table analysis, Kaplan-Meier analysis, and univariate and multivariate Cox regression analysis, while adjusting for confounding factors, to assess the patients data. The nomogram was constructed to guide the prognosis judgment.

Results: The survival analysis showed that male patients (n = 374) with "minimally invasive LUSC" exhibited a shorter survival period than female patients (n = 280). In univariate analysis, the study found that gender, laterality, primary site, stage, and chemotherapy were potential factors influencing patients' survival. The results of multiple Cox regression analysis demonstrated an increased risk of death in males compared to females (HR = 1.40), especially in the groups of 60-69 years (HR = 2.09), middle lobe (HR = 2.28), moderate differentiation (HR = 2.31), single tumor (HR = 1.61), postoperative systemic therapy (HR = 5.89) and chemotherapy (HR = 3.16). Based on receiver operating characteristic (ROC) curve analysis, the area under the curve (AUC) value for the survival prognostic model developed in this study was 0.73.

Conclusions: The study proposes the concept of "minimally invasive LUSC" firstly and reveals that male patients with such LUSC exhibit a worse prognosis compared to females, thereby contributing to refining the pathological classification framework of LUSC. It is a retrospective analysis utilizing the SEER database with relatively limited sample size, so our center is prospectively collecting supplementary cases to be incorporated into future research.

Figure1. Survival curves of "minimally invasive LUSC" of different genders

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.16 Differential Effect of Neoadjuvant Therapy in Locally Advanced Non-Small Cell Lung Cancer Based on Sexis

A. Rybkin[1], K. Becht[1], N. Wells[1], J.B. Long[1], P. Soulos[1], B.J. Slotman[2], L. Marignol[3], H.S. Park[1]
[1]Yale, New Haven/CT/USA ,[2]Amsterdam University Medical Center, Amsterdam/NL ,[3]Trinity College Dublin, Dublin/IE

Introduction: Patients with locally advanced non-small cell lung cancer (LA-NSCLC) experience disease progression rates of 60-70% at 2 years despite numerous modern approaches to treatment. This highlights the need for predictive biomarkers to identify at-risk patients and improve patient selection. Prior laboratory and clinical research suggests that sex may be a possible predictive and prognostic biomarker for survival in lung cancer, particularly following radiotherapy (RT). In this study, we seek to investigate sex as a biomarker for overall survival (OS), progression-free survival (PFS), and pathologic complete response (pCR) in patients receiving neoadjuvant chemotherapy (chemo), chemo-RT, or chemo-immunotherapy (IO) prior to surgery for LA-NSCLC.

Methods: We accessed the NSCLC data in the Flatiron Health Research Database. Adults (age ≥ 18) with stage II-IIIA NSCLC diagnosed from 1/1/2019 to 3/4/24 and treated with neoadjuvant chemo, chemo-RT, or chemo-IO, with chemotherapy consisting of at least two cycles of a platinum doublet. First, we analyzed OS, PFS, and pCR in males versus females using Cox proportional hazards regression in the entire cohort. We analyzed these outcomes based on treatment within subgroups of sex and based on sex within subgroups of treatment. We conducted Fine-Gray competing risk analysis for PFS.

Results: Our cohort consisted of 150 patients, including 62 females and 88 males with similar characteristics except for higher proportion of squamous cell histology in males. Most (62%) received chemo-IO (n=93), followed by 22% with chemo alone (n=33), and 16% with chemo-RT (n=24). Among those receiving chemo-RT, females had significantly higher OS (HR 0.085, 95% CI 0.009-0.725, p=0.006) and borderline significantly higher PFS (HR 0.247, 95% CI 0.055-1.104, p=0.051) than males. Males receiving chemo-RT had significantly worse OS than those getting chemo alone (HR 5.721, 95% CI 1.321-24.781, p=0.009). These differences were not observed in females. On cumulative incidence analysis, an increased hazard of death and not progression was observed in males undergoing chemo-RT. These results were maintained when adjusting the Cox models for histology, with males undergoing chemoRT having worse OS than those getting chemo alone (HR 5.424, 95% CI 1.023-24.462, p=0.0278). Despite higher pCR rates among males (29.5% versus 27.4%), multivariable analysis did not indicate an association between sex or treatment type with pCR.

Conclusions: In this cohort of patients with LA-NSCLC undergoing neoadjuvant therapy before surgery, males who received chemo-RT have significantly lower OS than females. Furthermore, treatment of males with chemo-RT results in significantly worse OS when compared to chemo alone, without significant differences in other subgroups. Further research is needed to test the hypothesis that sex may be a biomarker for increased radiation toxicity following neoadjuvant therapy for LA-NSCLC

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.17 Association Between Cigarette Smoking History and Germline Rare Variant Burden in a Cohort of Lung Cancer Patients

S. Saini[1], V. Tran[1], H. Rowbotham[1], C. Nichols[2], N. Litterman[2], S. Aslibekyan[1]
[123]andMe, Inc., Sunnyvale/CA/USA ,[2]Troper Wojcicki Philanthropies, Los Altos/CA/USA

Introduction: Lung cancer is the global leading cause of cancer-related mortality. While cigarette smoking is the strongest risk factor, incidence of lung cancer among persons who have never smoked cigarettes is increasing, highlighting the etiologic role for other environmental and genetic risk factors. Most large-scale genetic studies of lung cancer to date have focused on common germline genetic variants, while the role of rare variants remains understudied. This study compared germline rare variant burden among 23andMe Lung Cancer Genetics Study participants with and without a history of cigarette smoking.

Methods: 1220 individuals diagnosed with lung cancer provided informed consent to participate in the study and were genotyped on a custom chip that included 1023 rare (minor allele frequency <0.001) coding (frameshift, missense, and stop-gain) variants in 45 genes previously implicated in germline genetic susceptibility to lung cancer. Data on lung cancer diagnosis, cigarette smoking, and other relevant covariates were collected via web-based surveys. Smoking history was defined as self-report of either current smoking or of a lifetime total of at least 100 cigarettes smoked. Associations between rare germline variants and smoking history were assessed using Fisher's exact test as well as logistic regression adjusted for age, sex, and ancestry principal components. A Poisson regression was fit to compare the counts of rare germline mutations between individuals with and without a history of smoking, adjusted for age, sex, ancestry principal components, and genotyping chip version.

Results: Among the 1010 consented 23andMe Lung Cancer Genetics Study participants who provided exposure data, 536 (53%) had self-reported a history of cigarette smoking. Of the 1023 rare SNPs, 56 had the variant allele in the study sample. A nominal association was observed between the history of smoking and a missense variant in the RET gene (rs77724903, Fisher's exact test p=0.05). However, none of the rare variants was associated with smoking history after adjustment for age, sex, and ancestry principal components. Further, the counts of rare variant mutations were not statistically different between individuals with and without a history of smoking (β= 0.03, p-value= 0.67).

Conclusions: Our findings do not support a significant difference in rare germline variant burden by history of cigarette smoking. Future larger-scale studies including individuals without cigarette smoking history may be able to detect associations with specific rare variants that can elucidate lung cancer etiology in that population.

Keywords: genetics, rare variants, smoking

EP.01.18 Family History of Lung Cancer in Lung Cancer in Never-Smokers, a Matched Case-Control Study

H.S. Kwak[1], J. Lee[2], C-M. Choi[1], Y.J. Jung[1], H.R. Kim[1], J.H. Hwang[2], J-Y. Lee[2], H.K. Kim[2], W. Ji[1]
[1]Asan Medical Center, Seoul/KR ,[2]Samsung Medical Center, Seoul/KR

Introduction: Lung cancer in never-smokers (LCINS) accounts for over 50% of newly diagnosed lung cancer cases in East Asia. However, current lung cancer screening programs are based on high-risk smokers, and risk factors for lung cancer among never-smokers are not well established.

Methods: This was a multicenter, case-control study matching on age and sex in never-smokers. Case patients were diagnosed with non-small cell lung cancer (NSCLC) between 2016 and 2020 in tertiary centers in South Korea, while control individuals underwent opportunistic chest CT screening with negative findings in the same center's health screening department during the same period. The clinical characteristics of case patients and risk factors for NSCLC were analyzed.

Results: The number of case patients and matched control individuals was 3,000 each, totaling 6,000. The median age of the study population was 60 years, and females accounted for 81.1%. Among case patients, the adenocarcinoma subtype was the most common form of NSCLC (95.0%). The mutation rates of epidermal growth factor receptor (EGFR) and anaplastic lymphoma kinase (ALK) were 63.1% and 3.3%, respectively. In multivariable logistic regression models, a first-degree family history of lung cancer (adjusted odds ratio [aOR]: 1.21; 95% confidence interval [CI]: 1.02-1.45; P = 0.032) and chronic lung disease (aOR: 2.95; 95% CI: 2.42-3.61; P < 0.001) were significant risk factors for NSCLC. In a subgroup analysis by age, a family history of lung cancer remained a significant risk factor among individuals younger than 60 years (aOR: 1.47; 95% CI: 1.14-1.90; P = 0.003) but not in those older than 60 years (aOR: 1.01; 95% CI: 0.79-1.30; P = 0.913). In the sex-stratified analysis, this association remained significant in males (aOR: 1.63; 95% CI: 1.04-2.60; P = 0.036) but not in females (aOR: 1.15; 95% CI: 0.95-1.40; P = 0.148).

Conclusions: A first-degree family history of lung cancer and a history of chronic lung disease were significant risk factors for NSCLC in never-smokers. Among younger individuals and males, the risk associated with a first-degree family history of lung cancer was more pronounced. Further studies are needed to identify high-risk groups among never-smokers and to expand lung cancer screening programs beyond smokers to include never-smokers.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.19 Characteristics of Lung Cancer in Never- and Light-Smokers: A Retrospective Study From Greece

G. Gomatou, I. Kotsantis, A. Kyriazoglou, M. Anastasiou, A. Pantazopoulos, M. Moutafi, N. Gavrielatou, E. Zazas, A. Boulouta, C. Caglar, M. Roumpoutsou, T. Frantzi, L. Gkaralea, A. Kalfoutzou, A. Sofis, A. Psyrri, P. Economopoulou
Attikon University Hospital, Athens/GR

Introduction: Lung cancer (LC) in never- and light-smokers accounts for 10-20% of all LC cases. Recent studies estimate that its incidence is rising worldwide. However, clinicopathologic and molecular data of patients with LC with no/light smoking history are scarce and do not reflect the heterogeneity of demographic and molecular features of different populations worldwide.

Methods: This is a retrospective study enrolling all patients with LC from the Oncology Unit of a tertiary academic hospital in Athens between 2010-2024. Medical records were reviewed to identify never-smokers (<100 cigarettes during lifetime) and light-smokers (<5 cigarettes/day). Demographic, clinicopathologic and molecular data were recorded. Air quality index (AQI) was searched in https://www.iqair.com/.

Results: We identified 67 cases of never- and light- smokers with LC in a total of 1280 LC patients (prevalence= 5.2% n=67/1280, never-smokers=39, light-smokers= 28, mean age±SD=69.1±12.0). Females constituted 64.1% (25/39) of never smokers. Professional exposure (silica dust and radon) was reported in 4.47% (3/67) of patients and 10.5% (7/67) had family history of at least one first-degree relative with LC. AQI of the patients' residence was moderate (51-100) in 53.7% and good (0-50) in 46.3% of the cases. Adenocarcinoma subtype was diagnosed in 83.5% of the patients; other subtypes included squamous (n=4), LCNEC (n=2), adenosquamous (n=1), NOS (n=1) and SCLC (n=1). The TNM stage at initial diagnosis was stage I in 4.5% (3/67), stage II in 10.5% (7/67), stage III in 15.0% (10/67) and stage IV in 70.1% (47/67) of the patients. There were 20.9% of the patients who were initially diagnosed with stage IVA due to malignant pleural or pericardial effusion or pleural metastases. PD-L1 expression (TPS) was available in 38 patients and was negative (<1%) in 21, low (1-49%) in 12 and high (>50%) in 5 patients. NGS was available in 15 patients and PCR testing of main driver genes in 31 patients. Oncogenic alterations were identified in 21 patients and were: EGFR exon 19 del/L858R point mutations (n=11), EGFR exon 20 insertion (n=1), ERBB2 amplification (n=1), RET fusion (n=1) and KRAS G12 mutations (n=7, 6 light-smokers/1 never-smoker).

Conclusions: Our data validate the need for multicenter national registries of never- and light-smokers with LC to identify the distinct characteristics of this subgroup in different patient populations.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.20 Non-Smoking Lung Adenocarcinoma: Implications for Predominant Growth Patterns, Tumor Heterogeneity and Prognosis

E. Rolf[1], B. Niedermaier[1,2], M. Allgäuer[2,3], L.V. Klotz[1,2], M.A. Schneider[2,4], M.E. Eichhorn[1,2], H. Winter[1,2]
[1]Department of Thoracic Surgery, Thoraxklinik, Heidelberg University Hospital, Heidelberg/DE ,[2]Translational Lung Research Center Heidelberg (TLRC-H), Member of the German Center for Lung Research (DZL), Heidelberg/DE ,[3]Institute of Pathology, Heidelberg University Hospital, Heidelberg/DE ,[4]Translational Research Unit, Thoraxklinik, Heidelberg University Hospital, Heidelberg/DE

Introduction: In pulmonary adenocarcinoma, several growth patterns can be discriminated, including lepidic, acinar, papillary, micropapillary, solid, and complex glandular. The individual tumor composition and occurrence of the different growth patterns is associated with significant differences in prognosis. Patients with predominantly lepidic tumors have a favorable long-term survival compared to patients with solid- or micropapillary-predominant tumors. Smoking is the main risk factor for the development of lung adenocarcinoma, but it remains unknown if smoking-associated and non-smoking lung adenocarcinomas differ in respect to the occurrence of different growth patterns.

Methods: This retrospective cohort study included 501 patients with pathologic stage I non-mucinous pulmonary adenocarcinoma who underwent curative surgery with complete resection (R0) between 2010 and 2020. Differences between patients with a history of smoking and non-smokers were analyzed by Chi-Square test and Mann-Whitney U test. Patient survival was determined using the Kaplan-Maier method with log-rank test.

Results: 403 (80.4%) patients were active or former smokers, 98 (19.6%) non-smokers. Non-smokers were significantly more likely to be female (75.5%, p<0.001). The median age of never-smokers at the time of surgery was 69.8 years compared to 65.8 years for smokers (p< 0.001). Based on the current IASLC grading system, non-smokers had a higher proportion of tumors with favorable tumor grading (grade 1: 19.4% vs. 9.9%; grade 3: 26.5% vs. 41.9%; p = 0.003). The T-stage did not differ significantly between the groups. Lepidic-predominant tumors were almost twice as common in non-smokers as in smokers (19.4% vs. 10.4%, p = 0.042). The opposite was true for solid-predominant tumors (6.1% vs. 14.1%, p = 0.042). The median follow-up time was 61 months. We observed a trend for favorable 5-year recurrence-free survival in non-smokers at 80.3% vs. 72.5% in smokers (p = 0.104; log-rank test).

Conclusions: Smoking status has a significant influence on tumor heterogeneity and the occurrence of different growth patterns within adenocarcinoma. Non-smokers develop the disease at an older age, have more lepidic tumor components, lower tumor grade and tend to have better recurrence-free survival. Further studies with a larger patient cohort are necessary to validate the results shown here and to clarify the biological basis of the different tumor proportions in non-smokers.

Keywords: lung adenocarcinoma, non-smokers, growth pattern

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.21 Mapping Persistent and Irreversible Arsenic Effects on Lung Epithelium Using Integrated Transcriptome and Methylome Analysis

M. Erkan, K. Whelan, J. Salsman, A. Wallace, G. Dellaire, V.D. Martinez
Dalhousie University, Halifax/NS/CA

Introduction: Arsenic, a well-established environmental carcinogen, contaminates underground water sources worldwide and poses a significant public health threat through chronic low-dose exposure. In Nova Scotia (Canada), elevated arsenic levels in drinking water, particularly in rural well water systems, are believed to contribute to the province's rising lung cancer incidence, even among non-smokers. Arsenic undergoes biotransformation in the body through methylation processes, which paradoxically can both detoxify arsenic and generate reactive intermediates that alter DNA methylation patterns and disrupt epigenetic regulation, leading to aberrant gene expression. Despite substantial evidence connecting arsenic exposure to lung carcinogenesis, the molecular mechanisms and early biomarkers of damage remain poorly understood. Our research aims to identify specific biomarkers of early arsenic-induced molecular damage using lung models exposed to environmentally relevant arsenic concentrations that mirror those found in Nova Scotia's high-risk regions.

Methods: We established an in vitro experimental system using human bronchial epithelial cells (HBECs), a key target of arsenic-induced carcinogenesis. These cells were systematically exposed to relevant concentrations of sodium arsenite (0.08µM and 2µM) to represent both low and moderate-high exposure levels observed in human populations. Cells underwent treatment following a controlled exposure protocol with treatment cycles of 48-96 hours between passages over a period extending up to 12 days, creating a chronic exposure model. We included experimental groups where arsenic was removed to assess recovery dynamics and irreversible molecular changes. Both DNA and RNA were isolated from treated cells to enable characterization using next-generation sequencing, with a comprehensive coverage of the transcriptome and assessment of DNA methylation patterns. This approach allows for the detection of alterations in methylation profiles, subtle (likely tissue-specific) changes in gene expression, and alternative splicing events potentially relevant to arsenic-induced carcinogenesis.

Results: The first cohort of 18 samples has been successfully sequenced and processed through our analytical pipeline. Data quality assessment and normalization procedures are currently being completed for differential expression analysis using DESeq2. Our initial focus is identifying arsenic-induced persistent gene expression changes that develop in response to exposure and are maintained throughout the treatment period, with particular attention to expression changes occurring in regions with differential methylation patterns. Subsequent phases will investigate irreversible molecular changes by removing arsenic after exposure and allowing cells to grow. Additionally, we will co-treat cells with arsenic-chelating agents to identify arsenic-dependent molecular alterations specifically and distinguish them from general stress responses. We will validate identified molecular signatures in human lung tumors from individuals in high-arsenic regions using the Nova Scotia Lung Tumour Biobank (the largest lung tumor biobank in Canada), and in lung organoids to evaluate chronic exposure effects in a more complex lung model.

Conclusions: Identifying specific biomarkers of arsenic-induced lung damage will contribute to developing prevention strategies and early detection methods for arsenic-related lung cancer. The molecular signatures we characterize may serve as screening biomarkers for high-risk populations, addressing a significant public health concern in Nova Scotia and globally.

Keywords: Arsenic, bioinformatics, molecular damage

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.22 The Effectiveness of Offering Repeated Co-Located, Opt-Out Smoking Cessation Support Within Lung Cancer Screening

R.L. Murray[1], D. Baldwin[2], K. Brain[3], P. Crosbie[4], S. Quaife[5], R. Thorley[1], H. Copeland[6], R. Gabe[5], N. Hancock[6], C. Marshall[6], S. Rogerson[7], I. Simmonds[6], M. Callister[7]
[1]University of Nottingham, Nottingham/GB ,[2]Nottingham University Hospitals NHS Trust, Nottingham/GB ,[3]Cardiff University, Cardiff/GB ,[4]University of Manchester, Manchester/GB ,[5]Queen Mary University of London, London/GB ,[6]University of Leeds, Leeds/GB ,[7]Leeds Teaching Hospital NHS Trust, Leeds/GB

Introduction: The UK National Screening Committee has recommended the implementation of targeted lung cancer screening with integrated smoking cessation service provision. The Yorkshire Enhanced Stop Smoking (YESS) study showed the acceptability and efficacy of a co-located stop smoking service (SSS) comprising NRT/e-cigarettes and behavioural support delivered on an opt-out basis to all eligible smokers attending for baseline lung cancer screening within the Yorkshire Lung Screening Trial (YLST), however the impact of offering SSS for subsequent screening rounds is unknown.

Methods: In March 2021 YLST commenced its second round of screening, two years after individuals had attended for their baseline screen, as well as re-inviting those who had not responded to their baseline invitation in the previous round. Stop smoking support was offered on the same basis as delivered in YESS (behavioural support plus nicotine replacement therapy/vapes/pharmacotherapies for up to 12 weeks). Here we report preliminary analyses of the uptake of this offer, and self-reported quit rates at 4 and 12-weeks post attendance at screening.

Results: Of 1498 current smokers eligible for SSS, 1138 (76.0%) were attending for their second screening visit. Of re-attendees, 864 (75.9%) accepted a consultation with a smoking cessation practitioner (SCP): 498 (57.6%) had received SSS in the previous round, 306 (35.4%) had declined in the previous round, and 60 (6.9%) had not been eligible. Of the 360 attending for the first time, 297 (82.5%) accepted an SCP consultation. Overall, 843 of the 1161 (72.6%) individuals meeting the SCP accepted ongoing SSS. Of those accepting ongoing SSS, 25.7% reported abstinence from smoking at 4 weeks, (14.5% of all eligible smokers) and 37.0% reported abstinence from smoking at 12 weeks (20.8% of all eligible smokers) (similar to overall quit rates seen during the first round of screening in YLST).

Conclusions: Co-located, opt-out, specialist stop smoking support was shown to be effective during a second screening round, with good engagement and encouraging 4 and 12 week quit rates.

Keywords: Smoking cessation, Lung cancer screening

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.23 Tobacco Smoking, Quit Attempts and Vaping Among an Online Sample of South African Cancer Survivors

L. Ayo-Yusuf[1],[2], K. Kali[1]
[1]University of Pretoria, Pretoria/ZA ,[2]Sefako Makgatho Health Sciences University, Pretoria/ZA

Introduction: Studies have demonstrated that tobacco smoking may negatively affect cancer survivors' health and survival, including raising the risk of having poor cancer treatment outcomes, developing subsequent primary cancer, and having cardiovascular and respiratory comorbidities. Smoking cessation is therefore a priority in caring for cancer survivors who smoke. With limited access to smoking cessation services, the use of e-cigarettes or vaping has been promoted as a cessation aid in South Africa, and elsewhere. However, only limited information is available on quitting behaviour and use of e-cigarettes among cancer survivors in South Africa and low- and middle-income countries in general. This study therefore sought to describe quit attempts and intention to quit smoking and pattern of e-cigarette use among a population of self-identified cancer survivors who currently smoke cigarettes.

Methods: Methods: This was a secondary analysis of data obtained from an online sample of 13,675 South African adults aged ≥18 years, including 381 cancer survivors (self-reported having been diagnosed with cancer). The online survey conducted in 2021 during the COVID-19 pandemic used a non-probability sampling, but an appropriate weight was applied to the sample to provide a more representative sample of the South African population. Information collected included participants' diagnosis of cancer and other potential comorbidities (asthma, hypertension and diabetes), ever tobacco and e-cigarette use and sociodemographic characteristics.

Results: Of the cancer survivors, 84.2% were older than 45 years and 65.2% were males. 74.8% have greater than high school education but 40.2% were not employed. Of the cancer survivors, 15.7% (95%CI=10.2- 23.4) currently smoke cigarettes and 1.3% (0.8 - 2.3) currently use e-cigarettes. Of those who smoke, 50.7% reported having attempted to quit in the past 12 months while only 44.5% contemplate quitting in the coming 6 months. Of those who have ever attempted to quit in the past, 50% reported using cold-turkey, 16.3% reported using one or a combination of approved cessation aids (counselling/NRT/medication), while only 2.2% reported using e-cigarettes as cessation aid. Of the participants, 10.2% reported having been diagnosed with a mental health condition, while 11.5% reported a chronic respiratory disease as comorbidity.

Conclusions: This study showed that tobacco smoking is prevalent among South African cancer survivors, but the use of e-cigarettes or vaping remains uncommon, highlighting the urgent need to provide smoking cessation services to this priority population with significant comorbidities.

Keywords: Cigarette smoking, Vaping, cancer survivor

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.24 Determinants Influencing Smoking Cessation Implementation in an Oncology Setting: Canadian Healthcare Provider Perspectives

I. DeVuono[1], W.K. Evans[2], A. Coroiu[3], M. Chaiton[1], S. Veldhuizen[1], L. Zawertailo[1], O. Melamed[1], L. Eng[4], M. George[2], M. Halligan[5], C. Silverman[5], S. Hussain[1], P. Selby[1]
[1]Centre for Addiction and Mental Health, Toronto/ON/CA ,[2]Ontario Health (Cancer Care Ontario), Toronto/ON/CA ,[3]McGill University, Montreal/QC/CA ,[4]Princess Margaret Hospital, Toronto/ON/CA ,[5]Canadian Partnership Against Cancer, Toronto/ON/CA

Introduction: Smoking after a cancer diagnosis contributes to adverse health outcomes, including the risks of second primary cancers and cancer recurrence, poorer treatment responses, and increased treatment-related toxicities. For individuals with cancer, quitting smoking increases survival and reduces risk of recurrence and second primaries. In Canada, Ontario Health recommends SC support (SCS) to all individuals with cancer. However, an implementation gap remains in the provision of SCS within Ontario regional cancer centres (RCCs). Our qualitative study aimed to identify determinants influencing the implementation of SCS in oncology settings through semi-structured interviews with healthcare providers (HCPs) at four of the 14 Ontario RCCs.

Methods: Our study was conducted at the Centre for Addiction and Mental Health in collaboration with Ontario Health (Cancer Care Ontario), the Canadian Partnership Against Cancer, and patient advisors. Ontario Health employed purposive sampling to select participating RCCs, ensuring diversity in centre parameters and patient populations served. Snowball sampling was used to recruit adult, patient-facing HCPs in the RCCs. Semi-structured interviews were framed using the Consolidated Framework for Implementation Research (CFIR), which explores multiple factors affecting the implementation of evidence-based practice, including aspects related to the intervention itself, the individuals involved, the implementation process, and the inner and outer settings. Interviews were conducted virtually and HCPs were compensated with a 30 Canadian dollar gift card. Thematic analysis guided our data analysis, deductively using CFIR, and inductively as new themes emerged.

Results: Of the 27 HCPs who participated in our study, 41% were radiation therapists, 15% each were registered dental hygienists and registered nurses, 11% were registered practical nurses, and 19% were physicians, nurse practitioners, social workers, and advanced practice nurses. HCPs were generally experienced in providing SCS to patients, as 74% of providers had 5-14 years of experience. From the HCP perspective, five themes emerged: 1. Patient engagement with SCS is shaped by both clinical and personal factors, including their cancer stage, cancer type, age, quit motivation, and perceived stigma. 2. HCPs tailored SCS based on the patient's context, sometimes avoiding the discussion in response to poor prognosis, emotional distress, or resistance. 3. Empathy is critical to providing smoking cessation support, yet training gaps leave HCPs feeling unprepared. 4. The 3As (Ask, Advise, and Act) approach to smoking cessation presents challenges with advising and acting, alongside mixed perceptions of the opt-out referral model. 5. System-level constraints, including limited HCP time, lack of continuity in patient care, unclear prescribing roles for varenicline and bupropion, insufficient communication about RCC's performance metrics and lack of feedback on impact of SCS on patients referred for SC.

Conclusions: These findings highlight the complex interplay of patient-level, interpersonal, and structural factors that influence the provision of SCS in oncology settings. Addressing these challenges will require a multifaceted approach, including tailored interventions, enhanced HCP training, and system-level changes to better integrate smoking cessation support into oncology settings.

EP.01.25 Identifying Effective Strategies to Support Smoking Cessation in Ontario Cancer Care Settings: A Consensus-Building Approach

N. Minian[1], A. Coroiu[2], M. Chaiton[1], S. Veldhuizen[1], L. Zawertailo[1], O. Melamed[1], L. Eng[3], M. George[4], M. Halligan[5], C. Silverman[5], S. Hussain[1], P. Selby[1], W.K. Evans[6]
[1]Centre for Addiction and Mental Health, Toronto/ON/CA ,[2]McGill University, Montreal/QC/CA ,[3]Princess Margaret Hospital, Toronto/ON/CA ,[4]Ontario Health (Cancer Care Ontario), Toronto/ON/CA ,[5]Canadian Partnership Against Cancer, Toronto/ON/CA ,[6]McMaster University and Ontario Health (Cancer Care Ontario), Hamilton/ON/CA

Introduction: In 2012, Cancer Care Ontario introduced a smoking cessation (SC) program in its 14 regional cancer centers. The program targeted patients receiving ambulatory cancer care who were recent or current tobacco users. Despite the presence of a guiding framework for SC in Regional Cancer Centers, and numerous initiatives to disseminate the growing body of literature demonstrating that smoking cessation after a cancer diagnosis improves treatment outcomes, reduces complications, and enhances survival rates, program delivery and performance has varied widely amongst treatment centers. Of greatest concern is the variability in the performance metric 'Percentage of current or recent tobacco users who accepted referral to SC support" ' where some centers perform exceptionally well, others struggle to reach target (30%) This study, supported by the Canadian Cancer Society Research Institute, aimed to identify the most viable implementation strategies to support smoking cessation within Ontario's cancer treatment facilities.

Methods: To establish consensus on feasible and impactful strategies to address the observed variability, we conducted a modified Delphi panel, a structured consensus-building methodology, engaging a diverse panel of oncology HCPs and individuals with lived cancer and tobacco use experience. We conducted two rounds of rating 13 potential implementation strategies previously identified in systematic reviews as effective in facilitating SC within oncology settings. In Round 1, 15 panelists (10 HCPs, 5 patients) rated each strategy on a five-point scale (1 = Very Low Likelihood of Success; 5 = Very High Likelihood of Success). Strategies were categorized based on consensus levels: "Appropriate" (≥70% agreement on high likelihood of success), "Inappropriate" (<50% agreement), and "Partial Consensus" (between 50% and 69%). Strategies lacking consensus advanced to Round 2, during which panelists reviewed summarized feedback from Round 1 before re-rating the most promising strategies.

Results: In Round 1, no strategy achieved full consensus as Appropriate. On the other hand, four strategies were deemed Inappropriate: 1. Adding electronic medical record alerts for smoking cessation counselling. 2. Distributing smoking cessation pamphlets. 3. Posting educational materials for staff. 4. Providing real-time feedback to HCPs. Seven strategies fell into the partial consensus category, requiring further discussion. In Round 2, 12 panelists (9 HCPs, 3 patients) reassessed these strategies, incorporating feedback from Round 1. Four strategies achieved full consensus as viable for implementation: 1. Revising clinical roles to establish expectations for HCPs to offer smoking cessation referrals. 2. Increasing the number of smoking cessation champions within regional cancer centres. 3. Distributing free smoking cessation medication onsite at cancer centres. 4. Mailing free SC medication directly to patients' homes.

Conclusions: This consensus-building study highlights the importance of stakeholder engagement in identifying contextually appropriate SC strategies. While some commonly employed approaches were deemed unlikely to succeed, the panel identified four strategies with strong potential for implementation in Ontario's cancer treatment facilities. These findings will inform future efforts to integrate evidence-based smoking cessation support into oncology care.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.26 Achievements and Future Directions of Tobacco Control in Lung Cancer Prevention in China

X. Zhi
Chinese Association on Tobacco Control and Health, Beijing/CN

Introduction: As the largest tobacco consumer globally, China faces persistently high incidence and mortality rates of lung cancer. Recent years have witnessed significant progress in lung cancer prevention through legislative actions, health education, and multi-dimensional tobacco control strategies. This study synthesizes China's achievements in tobacco control and their impact on lung cancer epidemiology and early detection.

Methods: We analyzed national policy documents, epidemiological data, and clinical studies (2023-2025) to evaluate the effects of tobacco control measures (e.g., public smoking bans, increased tobacco taxes, health campaigns) and the integration of low-dose computed tomography (LDCT) screening.

Results: 1. Policy Effectiveness: Adult smoking rates decreased by 14.2% compared to 20154, with a 35% reduction in public smoking in Beijing post-implementation of the 2015 smoking control ordinance10. Nationwide smoke-free legislation now covers 78% of public spaces5. 2. Early Detection: LDCT combined with AI improved early-stage lung cancer detection to 80%, achieving a 5-year survival rate near 100% post-surgery10. Revised 2024 guidelines lowered the screening age threshold to 45, targeting high-risk non-smoking women10. 3. Public Awareness: Health education campaigns via social media and science popularization projects (e.g., the 2025 "Scientific Tobacco Control, Shared Health" initiative) increased public awareness of smoking risks to 92%15. 4. Integrated Medicine: Traditional Chinese medicine (TCM) reduced chemotherapy-induced side effects, enhancing patient compliance16.

Conclusions: China's multi-faceted tobacco control strategies and technological innovations have effectively mitigated lung cancer risks and improved early diagnosis. Sustained integration of policy, healthcare, and societal resources is crucial to achieving the "Healthy China 2030" goals.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.27 Gender and Tobacco Use Status Shape Support for Endgame Strategies in India

D. Aden
AIIMS, New Delhi/IN

Introduction: In India, where tobacco use remains a leading public health concern, there is limited research on public preferences and support levels for tobacco endgame strategies and policies aimed at eliminating tobacco use. Furthermore, the interaction between gender and tobacco use status in shaping these support levels remains unexplored. This study aimed to assess preferences for various tobacco endgame strategies and examine support levels among Indian adults, with a focus on the interactive effects of gender and tobacco use status

Methods: A cross-sectional survey was conducted using a convenience sample of 250 Indian adults,for 2 years between 2022 and 2024, 45.3% of whom were female. Participants were asked how much they agreed or disagreed upon use of standardised packaging,type of tobacco and bans on minors. Preferences for tobacco endgame policies were assessed across demographic variables using chi-square tests. Levels of support were compared by gender and tobacco use status using bootstrapped regression models, adjusting for relevant covariates.

Results: Policy preferences varied significantly across subgroups.Overal , 55 % of adults(63% of and 47% of women $p < 0.001$)showed preference for standardized packaging. 69% of female participants favored nicotine reduction strategies. There were 51.2% of never, 59.4% of past ,25.3% of current smokers($p < 0.001$) were supportive of taxation measures, import bans, bans for both minors and adults, and flavor bans. Overall, never and past tobacco users expressed significantly greater support for endgame policies compared to current users. Notably, among males, those who had never used tobacco or had quit demonstrated higher support levels than their currently using counterparts.

Conclusions: he findings suggest that strong support for tobacco endgame strategies among never and former tobacco users, particularly among males, suggests a favorable climate for advancing such policies in India. These findings can guide targeted advocacy and policy formulation.Perceived difficulties in gaining public support should not impede the introduction of rigorous tobacco control measures needed to achieve a tobacco-free India.

Keywords: Tobacco endgame, smokers, targeted advocacy

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.28 Changes in Respiratory Function in a Patient Undergoing Two Lung Resections

N. Hiraiwa, H. Yamato, E. Okura, Y. Takeuchi, M. Okumura
NHO Osaka Toneyama Medical Center, Toyonaka city, Osaka prefecture/JP

Introduction: Owing to recent advancements in CT imaging and lung cancer treatment, opportunity of detecting new pulmonary lesions after lung cancer surgery has become increasingly common. We investigated changes in postoperative pulmonary function in patients undergoing repeated lung resections.

Methods: A total of 86 patients underwent pulmonary resection twice at our institution between January 2010 and December 2024. Among them, 35 patients received pulmonary function test one year after the second surgery. Predicted postoperative pulmonary function was calculated assuming a 3% decrease for partial resection, while segmentectomy and lobectomy were calculated based on the number of resected subsegments. In order to compare the difference between predicted and actual pulmonary function, the discrepancy (%) was analyzed by Pearson's correlation coefficient analysis.

Results: There were ten patients who underwent lobectomy for both surgeries and 17 patients who underwent one lobectomy and one sub-lobar resection, and 8 patients who underwent limited resection for both surgeries. Indication for lung resection was primary lung cancer, metastatic tumor, and lymph node involvement. The number of cases in which actual values exceeded predicted values was 32 for VC and 31 for FEV1.0%. The mean discrepancy between actual and predicted values was 42.7% for VC and 43.1% for FEV1.0% in the group that underwent two lobectomies, 26.6% for VC and 36.1% for FEV1.0% in the lobectomy and sub-lobar resection group, and 10.9% for VC and 86.0% for FEV1.0% in the group that underwent two sub-lobar resections. The Pearson's correlation coefficients between the discrepancy of actual versus predicted values and the extent of lung resection were 0.665 for VC and 0.787 for FEV1.0%, with both of P-values being <0.001. There were 20 past or current smokers and using a t-test to compare the discrepancy in pulmonary function between smokers and non-smokers, no significant difference was found.

Conclusions: These findings suggest that in cases of two-stage lung resection, the greater the volume of lung resected, the smaller the decline in postoperative pulmonary function relative to predicted values. Additionally, smoking history does not contribute to this discrepancy. Further studies with a larger sample size are expected to provide more insights into postoperative pulmonary function.

Keywords: Postoperative Respiratory Function, Repeated Lung Resection

EP.01.29 Association of the Cholesterol-Modified Prognostic Nutritional Index With the Survival After Lung Resection for Elderly Patients With NSCLC

Y. Matsui, K. Takami
NHO Osaka National Hospital, Osaka/JP

Introduction: Malnutrition has been considered a prognostic predictor of various diseases. Several nutritional indicators, including the prognostic nutritional index (PNI), and neutrophile-lymphocyte ratio (NLR), C-reactive protein-albumin ratio (CAR), the controlling nutritional status (CONUT) and are known as an independent prognostic predictor for non-small cell lung cancer (NSCLC). Furthermore, high cholesterol levels have been reported to increase the risk of cancer as well as cardiovascular and cerebrovascular disease and intensify tumor aggressiveness. Recently, the cholesterol-modified PNI (CPNI), which was proposed as a new nutritional assessment based on PNI, has shown greater predictive accuracy for overall survival (OS) in breast and liver cancer patients than other indices, but the association with this in patients with NSCLC is unknown. The purpose of this study was to verify the effectiveness of CPNI in determining the nutritional status and predicting OS in elderly patients with NSCLC, comparing it with several previously proposed nutritional indicators.

Methods: This retrospective single-center study enrolled 181 patients aged 75 years or older with first-episode NSCLC patients who underwent curative lung resection from April 2006 through December 2021. All data used in this study were preoperative. With respect to the cut-off values for each factor, including BMI, CPNI, PNI, NLR, CAR, and CONUT, those with standard values were statistically analyzed at those values, and those without were calculated based on ROC curves. The association between baseline characteristics, including the blood collection items, histology, pathological stage, nutritional indexes and OS was examined using Kaplan-Meier curves and Cox proportional hazard regression models.

Results: 97 patients (53.6%) were male, and the most common histology was adenocarcinoma in 140 patients (77.3%). The median follow-up period was 61 months. During follow-up, 79 patients (43.6%) died and 40 patients (22.1%) recurrenced. Univariate and multivariate analysis showed that patients with high CPNI had lower OS than those with low CPNI (p<0.0001 and 0.004, respectively). In addition, male (HR 2.28, 95% CI 1.08-4.82, p=0.0306), low BMI (HR 1.97, 95% CI 1.21-3.20, p=0.0063), pathological stage (≥II) (HR 1.92, 95% CI 1.12-3.28, p=0.017), and pleural invasion (HR 1.99, 95% CI 1.14-3.48, p=0.016) were also significant predictors of OS. Among evaluated analyzed objective nutritional assessments, CPNI demonstrated the greatest prognostic predictive power for predicting OS.

Conclusions: CPNI may be a new instrument for evaluating nutritional status and forecasting survival in elderly NSCLC patients who underwent lung resection, potentially offering advantages over other several previously proposed objective nutritional assessments.

Introduction: Lung cancer is the leading cause of cancer-related deaths in females, with incidence rates declining more slowly in women than in men. While smoking remains the primary risk factor, it does not fully explain the increasing burden of lung cancer in women. Emerging evidence suggests that reproductive factors, including hormonal fluctuations, metabolic disorders, and family history of cancer and their interaction, may influence lung cancer susceptibility. However, the risk factors and their interaction remain poorly understood, particularly across diverse populations. To address this gap, we conducted a case-control study using the All of Us Research Program cohort to explore the complex interplay between these factors and lung cancer risk in adult females.

Methods: Using de-identified data from the All of Us Research Program, we conducted an age-matched case-control study to investigate the association between sociodemographic, reproductive, and metabolic disorders and family history with lung cancer risk in adult females. We identified cases and controls using SNOMED-CT codes and applied a 1:1 stratification (n=5,500) to ensure statistical power. Descriptive statistics, chi-square tests, and two-sample t-tests were used to compare characteristics between cases and controls. Multivariable logistic regression was performed to assess the likelihood of lung cancer occurrence, adjusting for potential confounders.

Results: Lung cancer patients had a mean age of 67.9 years (SD ± 11.9) and a BMI of 28.9 (SD ± 7.1). Non-Hispanic Whites comprised 63.4%, followed by non-Hispanic Blacks (14.5%) and Hispanics (12.2%). Overweight individuals had lower odds (adjusted OR = 0.78, p = 0.0003), while obesity was insignificant. Smoking increased the risk (adjusted OR = 1.28, p = 0.0023), but alcohol had no effect. Postmenopausal bleeding (adjusted OR = 1.59, p < 0.001) and menopause (adjusted OR = 1.47, p < 0.001) were significant, while estrogen use was borderline (p = 0.063). Smoking interactions with estrogen use (p = 0.043) and menopause (p < 0.001) increased risk, as did menopause in Asians (adjusted OR = 2.12, p = 0.001). Hyperlipidemia (adjusted OR = 1.62, p < 0.001) and hypothyroidism (adjusted OR = 1.65, p < 0.001) were significant, with hyperlipidemia-smoking interaction further increasing risk (adjusted OR = 1.71, p < 0.001). Breast (adjusted OR = 0.84, p = 0.038) and ovarian (adjusted OR = 0.61, p = 0.007) cancer family history were protective. Risk increased with smoking in lung cancer family history (adjusted OR = 1.94, p = 0.03), breast cancer family history with hypothyroidism (adjusted OR = 1.64, p = 0.0038), and postmenopausal bleeding with family history of breast (adjusted OR = 1.82, p = 0.017) or lung cancer (adjusted OR = 2.10, p = 0.033).

Conclusions: Beyond smoking, factors such as sociodemographic factors, reproductive history, metabolic conditions, and family history of lung, breast, or ovarian cancer and their interactions contribute to risk. Identifying these factors can improve early detection and prevention strategies for female lung cancer.

EP.01 RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL

EP.01.31 Vaping, Smoking and Lung Cancer in Adults Under Age 50: A Case-Control Study

M. Bittoni, S. Diriye, D. Carbone, R. Harris
The Ohio State University, Columbus/OH/USA

Introduction: Lung cancer in young adults (under 50 years of age) is increasingly recognized as a distinct clinical entity with potentially unique risk factors. While nicotine exposure through electronic delivery systems (vaping) has been associated with vaping-related lung injury, its contribution to lung cancer risk in younger populations remains largely unexplored. We examined the association between vaping, cigarette smoking, and lung cancer risk in young adults in a case-control study conducted at The Ohio State University Medical Center.

Methods: Electronic medical records from the James Cancer Hospital and Solove Research Institute were analyzed, focusing specifically on patients under 50 years of age with newly diagnosed, pathologically confirmed lung cancer during 2013-2021. A total of 256 lung cancer cases were compared to 2,946 controls without cancer matched to the cases by age, gender, race, and year of ascertainment. Unconditional logistic regression analyses were performed to estimate odds ratios (OR) with 95% confidence intervals for vaping, smoking, and lung cancer in this younger population.

Results: Among individuals under 50 years of age, the distribution of cigarette smoking and vaping differed dramatically between cases and controls. Traditional smokers who did not vape made up 69.9% of cases and 22.3% of controls, OR=5.1 (95% CI: 3.8-6.9, p<0.0001). Most notably, 7.8% of cases both vaped and smoked compared to only 1.6% of controls, with an OR=7.8 (95% CI: 4.2-14.5, p<0.0001) for those who both smoked and vaped versus OR=3.0 (95% CI: 2.2-4.2, p<0.0001) for those who smoked only. Thus, younger adults who both vaped and smoked had an 8-fold increased risk of lung cancer compared to non-smokers, and approximately 2.6 times higher risk than those who only smoked.

Conclusions: Our findings suggest an increased risk of lung cancer among young adults who both vape and smoke compared to those who only smoke. While smoking alone remains a significant risk factor, the addition of vaping appears to further accelerate carcinogenesis in younger populations. These results highlight the potentially harmful synergistic effect of vaping and smoking in young adults and underscore the importance of targeted preventive strategies for both habits. Further research is needed to confirm these results and to elucidate biological mechanisms that may contribute to heightened lung cancer risk among those who combine vaping with cigarette smoking.

EP.02.01 Investigating the MET Exon 14 Interactome in Lung Adenocarcinoma

S.A. Okun[1], D. Lu[2], W. Lockwood[1]
[1]BC Cancer Research Institute, Vancouver/BC/CA ,[2]Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Lung cancer is the leading cause of cancer death worldwide, with lung adenocarcinoma (LUAD) being the most common subtype. In 3-4% of cases, LUAD patients present with mutations in the hepatocyte growth factor receptor (MET) resulting in skipping of exon 14 (METex14); these mutations may be associated with a worse prognosis and a more invasive phenotype. Exon skipping affects receptor degradation, leading to increased receptor half-life and subsequent hyperactivation of downstream signaling pathways which contribute to METex14's transforming potential. While targeted therapies against METex14 have been developed, patient response is poor, necessitating the development of more robust treatment strategies. Our lab has previously demonstrated that METex14 preferentially drives KRAS signaling, hyperactivating the RAS-MAPK signaling pathway relative to its wildtype counterpart. Disruption of signaling through this pathway impeded cell proliferation and colony formation in a METex14-addicted model, while KRAS activation restored cell viability following treatment with MET inhibitors. The increased reliance upon the RAS-MAPK pathway by METex14 compared to the wildtype receptor suggests that this mutant displays altered affinity for downstream effectors which results in differences in signaling activity.

Methods: To investigate, cell lines overexpressing either V5-tagged wildtype or mutant receptor were made; overexpression is inducible following treatment with doxycycline. Lysates from these cell lines were then collected and used for co-immunoprecipitation, followed by mass spectrometry, to identify binding partners which preferentially interact with METex14 and contribute to its oncogenic potential.

Results: Interactors were identified for both the wildtype and mutant receptor, including both known and novel interactors. The interactome comprised various proteins involved in facilitating MET signaling. Effectors mediating Ras activation were also detected and found to preferentially interact with the mutant form of MET.

Conclusions: Together, this work will lead to a better understanding of METex14 signaling, as well as elucidate potential vulnerabilities which can be exploited therapeutically in combination with METex14 targeted therapies to improve patient prognosis.

Keywords: Lung Adenocarcinoma, Interactome, MET

EP.02.02 YB-1 Is a Survival Factor for Mesothelioma-Associated Fibroblasts

M. Pinós[1,2], M. Hashim[1], A. Ries[1], C. Pirker[1], L. Koszik[1], B. Mosleh[1], K. Sinn[1], M.A. Hoda[1], K. Schelch[1], B. Döme[1], W. Berger[1], M. Grusch[1]
[1]Medical University of Vienna, Vienna/AT ,[2]University of Barcelona, Barcelona/ES

Introduction: Pleural mesothelioma (PM) is a rare malignancy mainly caused by the inhalation of asbestos fibers, with a poor outcome due to a long latency period with nonspecific initial symptoms, leading to late diagnosis. Moreover, treatment options are limited and show a relatively low efficacy, resulting in a median survival of less than 12 months. PM is characterized by a lack of oncogenic mutations, suggesting that the signals driving growth and migration of pleural mesothelioma cells (PMCs) are mainly induced by the tumor microenvironment (TME). Over the last decades, cancer-associated fibroblasts (CAFs) have gained attention for their ability to promote pro-oncogenic traits such as proliferation, migration, invasiveness, and therapy resistance. It has been previously demonstrated that mesothelioma-associated fibroblasts (Meso-CAFs) induce PMCs proliferation and migration through the secretion of signaling molecules. Additionally, Y-box binding protein 1 (YB-1) has emerged as a key pro-oncogenic and multifunctional protein involved in multiple hallmarks of cancer, promoting tumor growth and metastasis in multiple cancer types. Recent studies demonstrated that YB-1 inhibition in PMCs significantly reduces their malignant traits and enhances cisplatin sensitivity. The aim of the present study is to investigate the role of YB-1 in Meso-CAFs and determine whether this molecule is one of the main TME signals driving PMCs malignancy.

Methods: YB-1 depletion was achieved by treating cells with the specific inhibitor SU056 or by siRNA. Cell proliferation was assessed using SYBR Green staining. YBX-1 RNA levels and Meso- CAF differentiation markers (ELN and CTGF) were analyzed by qRT-PCR. YB-1 protein expression and phosphorylation were quantified via western blot. The stimulatory effect of Meso-CAFs on YB-1 expression in PMCs was evaluated by treatment with conditioned media. Cell migration and cell fate were assessed by live cell videomicroscopy, followed by single-cell tracking and image analysis.

Results: YB-1 targeting siRNA treatment was able to achieve a strong reduction of YBX-1 mRNA and protein levels in Meso-CAFs. SU056 resulted in a more moderate reduction of YB-1 protein without an effect on mRNA. Both methods of YB-1 targeting decreased the viability and migration capacity of Meso-CAFs and resulted in an increase of cell death. In contrast, no consistent regulation of the Meso-CAF differentiation markers ELN and CTGF levels by YB-1 targeting was observed. Treatment with Meso-CAF-conditioned medium had only a minimal effect on YB-1 expression in PMCs.

Conclusions: YB-1 plays a key role for the survival of Meso-CAFs. Targeting YB-1 with specific drugs, such as SU056, or via knockdown may thus not only reduce growth, migration, and invasion of PMCs directly, as previously demonstrated, but also indirectly by removing the stimulating effect of Meso-CAFs on PM growth, potentially resulting in a more pronounced overall treatment efficacy.

EP.02.03 Investigating the Therapeutic Potential of DUSP4/6 Inhibition in Lung Adenocarcinoma

A. Subramaniam[1], D.A. Farnsworth[1], F.D. Johnson[2], W.W. Lockwood[1], F. Naznin[1]
[1]BC Cancer Research Institute, Vancouver/BC/CA ,[2]The Netherlands Cancer Institute, Amsterdam/NL

Introduction: Lung cancer (LC) is the principal cause of cancer mortalities due to limited treatment options with curative potential. Non-small cell lung cancer (NSCLC), of which lung adenocarcinomas (LUADs) are the predominant variant, make up around 80% of all LC cases. The epidermal growth factor receptor (EGFR) and Kirsten rat sarcoma virus (KRAS) oncogenes are often mutated within this subtype. Resistance eventually develops to all current therapeutics for EGFR and KRAS-mutated LUADs, highlighting a need for novel treatment options. KRAS and EGFR mutations promote oncogenesis by activating the mitogen activated protein kinase (MAPK) signalling pathway and its key effectors, the extracellular signal regulated kinases (ERK1/2). We have previously demonstrated that excessive activation of ERK1/2 can also be toxic to cancer cells. The dual specificity phosphatases (DUSP) 4 and 6 negatively regulate ERK signalling, and their inhibition has been proposed as a strategy to hyperactivate ERK and induce cancer cell death. However, combined inhibition of DUSP4 and 6 has not been evaluated in LUAD. This project aims to investigate the effects of DUSP4/6 knockout in drug sensitive and drug resistant cell lines to evaluate the therapeutic potential of DUSP4/6 inhibition in LUAD.

Methods: Using CRISPR and RNAi, we depleted DUSP4 and DUSP6 in LUAD cell lines, including models that are sensitive and resistant to common targeted therapies. Clonogenic assays were conducted to determine the impact of DUSP deletion on cell proliferation and viability, as well as changes in sensitivity to targeted therapies including osimertinib and trametinib. A kinase translocation reporter assay and Western blots assessed the impact of gene knockout on ERK activity.

Results: Findings show that combined knockout of DUSP4/6 impairs LUAD cell viability and induces ERK hyperactivation. Certain drug resistant LUAD cell lines were more sensitive to combined knockout than their parental counterparts.

Conclusions: Given the challenges of resistance to targeted therapies in LUAD, novel approaches are urgently needed. This study demonstrates that DUSP4/6 knockdown can overcome drug resistance, supporting the potential for therapies targeting DUSP4/6 as a viable treatment strategy.

EP.02.04 Identification of a Novel Immunotherapy Target in EGFR-Mutant Lung Cancer Resistant to Immune Checkpoint Inhibitors

K. Nitanai
Asahikawa Medical College, Asahikawa/JP

Introduction: Immunotherapy is the standard of care for non-small cell lung cancer (NSCLC). However, EGFR-mutant lung cancer exhibits high resistance to immune checkpoint inhibitors (ICIs). This resistance has been attributed to low PD-L1 expression and low tumor mutation burden (TMB). Recently, an immunosuppressive tumor microenvironment (TME) has been proposed as a contributing factor, but the mechanisms underlying this phenomenon remain unclear. This study aims to identify novel therapeutic targets for ICI therapy in EGFR-mutant lung cancer.

Methods: We analyzed The Cancer Genome Atlas (TCGA) and Cancer Cell Line Encyclopedia (CCLE) databases to compare gene expression between EGFR-mutant and non-EGFR-mutant lung cancers, identifying a significantly upregulated gene, "Gene X," in EGFR-mutant lung cancer. Further analysis of the EGFR-mutant lung cancer cell line HCC2279, which harbors an exon 19 deletion, revealed bimodal expression of Gene X, leading to the classification of high-expression (X-High) and low-expression (X-Low) groups. To investigate the functional role of Gene X, we conducted RNA sequencing (RNA-seq) in X-High and X-Low groups. Additionally, we co-cultured HCC2279 cells with NK92 cells and compared protein X knockout in X-High cells to control groups. To further assess immune cell dynamics, we utilized a three-dimensional microfluidic system to evaluate NK cell migration towards tumor spheroids in response to Gene X modulation.

Results: Enrichment analysis revealed that X-Low cells exhibited higher enrichment of interferon and inflammatory markers, suggesting increased immunogenicity. In co-culture experiments with NK92 cells, X-knockout HCC2279 cells exhibited increased granzyme B levels, indicating enhanced NK cell activity. Furthermore, in the microfluidic assay, X-knockout HCC2279 cells significantly accelerated NK-92 cell migration towards tumor spheroids from the side channel, further supporting the role of Gene X in immune modulation.

Conclusions: These findings suggest that Gene X expression in EGFR-mutant lung cancer contributes to an immunosuppressive tumor microenvironment by modulating NK cell recruitment and activation. Targeting Gene X may serve as a novel immunotherapeutic approach for overcoming ICI resistance in EGFR-mutant lung cancer.

EP.02.05 Three-Dimensional Visualization of Spreading Tumor Cell Through Air Spaces (STAS) Using High Resolution Phase-Contrast Imaging Method

E. Yi[1], N. Sunaguchi[2], J.H. Lee[1], Y. Kang[1], S-J. Seo[3], S. Lee[1]
[1]Korea University Anam Hospital, Seoul/KR ,[2]Nagoya University, Nagoya/JP ,[3]Daegu Catholic University Medical Centre, Seoul/KR

Introduction: The presence of spreading tumor cell through air spaces (STAS) above the edge of tumor margin inside lung cancer has been proved to be one of important prognostic factors for recurrence. However, there still no definite diagnostic tools for the detection of STAS unless proceeding precise pathologic examination. Synchrotron radiation phase-contrast tomography techniques applying specially designed crystal optics could be an optimal imaging method for visualizing STAS from lung cancer samples. The aim of this study is to visualization of STATS over the edge lung adenocarcinomas using synchrotron radiation tomography apply analyzer-based optics for identification of STAS over the edge of lung adenocarcinoma, therefore, enhancing three-dimensional comprehension of invasive mechanism.

Methods: Parts of human lung cancer tissue harvested from a patient who underwent surgical resection for curative purpose were used to acquire high resolution phase-contrast CT using synchrotron radiation. The experiment was performed using analyzer-based optic devices configured at Photon Factory BL 14B affiliated in High Energy Accelerator Research Organization in Japan. Obtained images were reconstructed to three-dimensional tomography. Segmentation was also performed. Used specimen was made to a formalin-fixed Paraffin Fixed block, sliced and stained with hematoxylin and eosin (H&E) for conventional light-microscopic examination

Results: Parts of human lung cancer tissue harvested from a patient who underwent surgical resection for curative purpose were used to acquire high resolution phase-contrast CT using synchrotron radiation. The experiment was performed using analyzer-based optic devices configured at Photon Factory BL 14B affiliated in High Energy Accelerator Research Organization in Japan. Obtained images were reconstructed to three-dimensional tomography. Segmentation was also performed. Used specimen was made to a formalin-fixed Paraffin Fixed block, sliced and stained with hematoxylin and eosin (H&E) for conventional light-microscopic examination

Conclusions: Synchrotron radiation phase-contrast tomography imaging techniques applying analyzer-based optics are useful for achieving higher resolution enough to visualize the actual three-dimensional characteristics of STAS. This approach has the potential to establish a fundamental framework for 3D virtual histopathology as an imaging-based diagnostic tool for lung cancer.

EP.02.06 Natural Multiple Serine Synthase Inhibitors Modulate Tumor Microenvironment Polarization and Inhibit the Growth of Lung Cancer

M. Liu, C. Su
Tongji University School of Medicine, Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Cancer cells exhibit a high level of metabolic activity and strongly rely on exogenous amino acid resources, especially serine and glycine. The Chinese herb Pinellia ternata has been reported to improve cellular lipid metabolism, regulate cellular immunity, and possess anti-tumor properties. In this study, we reported that the nano-therapeutic drugs prepared from Pinellia ternata simultaneously inhibited multiple serine synthesis enzymes and targeted both tumor cells and macrophages in the tumor microenvironment and declined the growth of lung cancer.

Methods: Pinellia exosomes were extracted by ultracentrifugation and detected by electron microscopy. In pinellia exosomes treated THP1 macrophages, the M1 and M2 cellsubtye markers were detected by Q-PCR. In pinellia exosomes treated lung cancer cells, cell proliferation, cell apoptosis and cell cycle were detected by CCK8 and flow cytometry. The regulated gene expression and signaling pathway by pinellia exosomes were detected by transcriptome sequencing.

Results: Electron microscopy examination showed that pinellia exosomes were vesicles with spherical and bilayer membrane structures. It was unexpectedly found that Pinellia exosomes simultaneously caused decrease expressions of multiple serine synthesis-related genes PHGDH, PSAT1, and PSPH in macrophages, the members of the JAK/STAT signaling pathway were regulated by serine synthesis enzyme genes. Further studies showed that Pinellia exosomes inhibited lung cancer growth by promoting M1 polarization of tumor-associated macrophages through affecting serine synthesis, and also had a direct inhibitory effect on lung cancer cells, especially in lung cancer cells with high expression of PHGDH, PSAT1, and PSPH genes.

Conclusions: Natural Chinese herbal medicine Pinellia exosomes inhibit the expression of serine synthesis-related genes, exert dual effects on lung cancer cells and macrophages in the tumor microenvironment, thereby suppress lung cancer growth. This provides a new approach for tumor treatment by combining natural Chinese herbal medicine with modern nanotechnology.

EP.02.07 Enhancing Alectinib Efficacy in ALKPositive Non-Small Cell Lung Cancer by Targeting Mtor

H. Madhi[1], H.A. Serhan[1], R. Mercer[1], L. Bao[1], X. Cheng[1], N.M. Merrill[1], S.R. Pine[2], D.R. Camidge[2], S.D. Merajver[1], A. Qin[1], M.B. Soellner[1]
[1]University of Michigan, Ann Arbor/MI/USA ,[2]University of Colorado, Aurora/CO/USA

Introduction: Alectinib, a powerful ALK tyrosine kinase inhibitor (TKI), has greatly enhanced treatment outcomes for patients with ALK-positive non-small cell lung cancer (NSCLC). However, a major challenge is the inevitable development of resistance, with nearly 50% of cases driven by the activation of parallel signaling pathways, such as the mTOR pathway. The mTOR pathway, a central regulator of key cellular processes of cell growth, metabolism, and survival plays a pivotal role in tumor progression and cellular adaptation to therapeutic pressure. Given the important role of mTOR in promoting tumor survival, integrating mTOR inhibition with Alectinib holds potential to optimize treatment efficacy and impact of ALK-targeted therapies. This combination approach holds potential not only to optimize outcomes for patients with advanced ALK-positive NSCLC but also to broaden the impact of ALK-targeted therapies by combating therapeutic resistance.

Methods: ALK-rearranged cancer cell lines CUTO8, CUTO9, CUTO29.1, CUTO39, CUTO41, CUTO43, CUTO46, DFCI032, NCI-H2228, NCI-H3122, SNU2292, SNU2535, and EA2 were treated with Alectinib alone or in combination with Everolimus. Cell viability was assessed using a 3D Cell-titer Glo viability assay and a BioTek BioSpa Live Cell Analysis System. Synergistic interactions were quantitatively evaluated using the Chou-Talalay method.

Results: The combination of Alectinib and Everolimus demonstrated strong synergistic effects, significantly reducing cell viability across all tested ALK-rearranged NSCLC cell lines, demonstrating increased sensitivity when mTOR was co-targeted. This profound synergy suggests that dual inhibition effectively disrupts key oncogenic adaptive signaling pathways that contribute to tumor cell plasticity that favors survival and proliferation. The observed reduction in cell viability was not only consistent across multiple ALK-rearranged NSCLC models, but also exhibited a greater magnitude of effect compared to Alectinib monotherapy, reinforcing the therapeutic potential of this combination approach from the onset of treatment.

Conclusions: These findings provide strong evidence that mTOR inhibition is a promising strategy to enhance the effectiveness of Alectinib, potentially overcoming some resistance mechanisms in ALK-positive non-small cell lung cancer (NSCLC) and enhancing Alectinib efficacy. Taken together, these studies in multiple cell models provide a strong rationale for further in vivo validation and clinical exploration to improve outcomes for patients.

EP.02.08 Exploratory Effect of Cisplatin on Autophagic Pathway in Human Lung Adenocarcinoma Cell Line

D. DIKSHA[1,2], P. Gupta[2], S. Shivani[2], R. Dhingra[2], H.N. Yadav[2], K.K. Inampudi[2], S. Singh[2], S.C. Yadav[2], T.G. Jacob[2], P.S. Malik[2]
[1]All India Institute of Medical Sciences, New Delhi/IN ,[2]All India Institute of Medical Sciences, DELHI/IN

Introduction: Cisplatin, an antineoplastic agent acts through various mechanisms like apoptosis, DNA damage and cell cycle arrest. Recently, cisplatin was found to induce autophagy, a cell recycling pathway in breast, prostate, pancreatic and oral cancer. This study aims to determine the effect of cisplatin on autophagic pathway in human lung adenocarcinoma (A549) cell line.

Methods: Cell viability assay was performed at 7.5-250 µM cisplatin against A549 cell line (NCCS, Pune) at 24 h, 48 h and 72 h and half - maximal inhibitory concentration (IC50) was determined. Cell cytotoxicity assay and cell cycle analysis were performed using flow cytometry. Additionally, reactive oxygen species (ROS) and nitric oxide (NO) levels were determined. Hoechst staining was performed using confocal microscopy. Autophagy - related protein 5 (ATG5) and sequestosome 1 (SQSTM1) were determined using Western blotting. Additionally, sequestosome 1 was semi-quantitatively determined using immunofluorescence. Ultrastructural changes in A549 cells were determined using transmission electron microscopy (TEM).

Results: IC50 of cisplatin at 24 h, 48 h and 72 h were 43.6 µM, 19.8 µM and 9.6 µM, respectively. At 20 µM there was 11.9 fold increase in early apoptotic cells and 3.8 fold increase in late apoptotic cells ($p<0.0001$). At 40 µM, there was 11.9 fold increase in early apoptotic cells and 6.9 fold increase in late apoptotic cells ($p<0.0001$). Cisplatin caused arrest in G2M phase of cell cycle as compared to control cells ($p<0.0001$). Mean fluorescence intensity (MFI) of ROS was higher in cisplatin treated groups as compared to control [cisplatin 20 µM: 13.8 ± 0.4 ($p=0.0003$), cisplatin 40 µM: 24.2 ± 2.1 ($p=0.0002$), control: 4.4 ± 1.3] but NO release was lower in cisplatin treated groups compared to the control group [cisplatin 20 µM: 15.1 ± 0.6 ($p <0.0001$), cisplatin 40 µM: 15.1 ± 0.6 ($p <0.0001$), control: 24.2 ± 0.5]. Using Hoechst staining, there was increase in the MFI in the cisplatin treated groups as compared to the control group 7 ($p <0.0001$). There was downregulation of proteins, ATG5 and SQSTM1 in the cisplatin treated groups. Additionally, decrease in MFI of SQSTM1 was observed in cisplatin treated groups as compared to the control group [cisplatin 20 µM: 7017.5 ± 5048.3 ($p=0.001$), cisplatin 40 µM: 4467.6 ± 2245.4 ($p <0.0001$), control: 22073.9 ± 12715.6] using immunofluorescence. On electron microscopy, increased number of autophagosomes and residual bodies were observed in cisplatin treated groups as compared to the control group.

Conclusions: Cisplatin, an anticancer drug, was observed to downregulate key proteins involved in autophagic pathway leading to increased accumulation of autophagosome and residual bodies in cisplatin treated groups. It implies that autophagy plays a crucial role in the anticancer activity of cisplatin in human lung adenocarcinoma. Hence, further studies with autophagy inducer and inhibitor will help in elucidating the conclusive effect of cisplatin activity through autophagic pathway.

EP.02 TUMOR BIOLOGY – PRECLINICAL BIOLOGY

EP.02.09 Deciphering CD47-Mediated Platelet-Tumor Crosstalk and Its Role in NSCLC Metastasis

A. Lau[1,2], Z. Rousseau[1,2], W. Ma[2], R. Hoshi[1,2], M. Lodyga[2], H. Ni[1,2], K.L. Thu[1,2]
[1]University of Toronto, Toronto/ON/CA ,[2]Keenan Research Centre, St. Michael's Hospital, Toronto/ON/CA

Introduction: CD47 is overexpressed and associated with poor prognosis in non-small cell lung cancer (NSCLC). Most studies of CD47 in cancer have focused on its role in promoting tumor immune evasion, although we and others have found that it influences cancer metastasis. Since platelets can promote tumor cell dissemination and they can bind to other cells through homotypic CD47 interactions, we aimed to investigate the hypothesis that CD47 promotes NSCLC metastasis through interactions with platelets.

Methods: CRISPR/Cas9 was used to knockout (KO) CD47 in murine (LLC) and human (H1299) NSCLC models. The effects of CD47 KO on cancer cell binding to platelets after co-incubation and platelet activation induced by cancer cell supernatants in vitro were measured by flow cytometry. Binding assays utilized GP1b-b and CMFDA as markers for platelets, while JON/A and Pac-1 were used as activation markers. An in vivo study to assess the influence of platelets on cancer metastasis was performed using the LLC model. Luciferase-tagged LLC cells were intravenously delivered into mice by tail vein injections, and platelet depletion was achieved using an anti-GPIb antibody administered by intraperitoneal injection every 3 days. Metastasis to the lungs was monitored using bioluminescence imaging of mice to detect luciferase activity. RNA-sequencing (RNA-seq) data for LLC cells sorted from wildtype and CD47 KO tumors grown in mice was also analyzed to investigate how CD47-associated transcriptomic changes might influence platelet-mediated metastasis.

Results: In vitro assays revealed decreased binding of platelets to LLC cells with CD47 KO compared to wildtype controls. Results for H1299 cells were variable and additional replicates are needed to confirm the trend towards reduced platelet binding to CD47-deficient cells in this model. Supernatants from LLC and H1299 cells with CD47 KO exhibited a reduced ability to activate platelets relative to supernatants from cells with wildtype CD47. In vivo, platelet depletion did not affect metastasis of wildtype LLC cells to the lungs, but CD47 KO together with platelet depletion completely abolished metastasis. Gene set enrichment analyses on RNA-seq data for cancer cells isolated from LLC tumors revealed that genes downregulated in CD47 KO relative to wildtype tumors were significantly enriched for coagulation pathways. Moreover, several genes encoding factors that bind to platelet receptors were upregulated in CD47 KO relative to wildtype cells.

Conclusions: Our findings suggest that CD47 regulates lung cancer cell interactions with platelets, which could affect the ability of lung cancer cells to metastasize and/or contribute to other hallmarks of cancer influenced by platelets. As such, CD47 blockade could antagonize lung tumor growth and progression through multiple mechanisms. Future experiments will include studies to characterize platelet activating factors secreted by wildtype and CD47 KO cells, and in vivo experiments to understand the effects of platelet depletion on cancer cell metastasis in additional NSCLC models.

Introduction: Clinical trials using KRASG12C inhibitors as monotherapies have exhibited brief responses. It has been identified that EGFR is involved in a dominant resistance mechanism to KRASG12C inhibitors in colorectal cancer. Therefore, targeting EGFR activation with cetuximab, a key component of the adaptive resistance mechanism, is of significant interest. Notably, in KRASG12C-mutant lung cancer patients, fulzerasib plus cetuximab attained an 80% response rate (KROCUS).

Beyond its role in oncogenic signalling, KRAS has been implicated in the remodelling of aspartate metabolism and the urea cycle, directly affecting the expression of argininosuccinate synthetase 1 (ASS1) and fumarate accumulation. Interestingly, in colorectal cancer, specific KRAS mutations can lead to ASS1 overexpression, facilitating cell proliferation and generating key intermediates of the TCA cycle, such as fumarate. These findings suggest that ASS1 expression and fumarate levels could serve as key prognostic biomarkers in different cancer types.

In this study, we evaluated the synergistic effects of fulzerasib or sotorasib (KRASG12C inhibitors) in combination with cetuximab in KRAS-mutant lung cancer cell lines, along with analysis of RAS signaling rebound. In addition, identification of a wide range of proteins and assessment of fumarate levels.

Methods: A panel of KRAS G12C-mutant cell lines, including H358, H23, H2122, H1792, H2030 and Mia-PaCa-2 were used. Reagents, antibodies, cetuximab and sotorasib were purchased. Fulzerasib was provided by Genfleet. Cell viability was assessed by MTT. The following primary antibodies were used for western blot analysis: EGFR Y1068, HER3 Y1289, FASN, EphA2 S897, YAP Y357, MIG6, ASS1, ERK1/2 T202/Y204, MRAS and Hsp90. Fumarate levels were quantified using a spectrophotometric kit.

Results: The IC50 values for both fulzerasib and sotorasib were notably low in H358, H2122, and Mia PaCa-2 cells, whereas they were high in H2030 cells and moderately elevated in the H23 cell line. The combination with cetuximab enhanced cytotoxicity. H358 cells showed a high synergistic effect, with a combination index of 0.53 when paired with fulzerasib. Other cell lines exhibited slightly synergistic effects (values below 1), while H23 cells showed an additive response.Western blot analysis revealed that the ERK1/2 rebound, typically induced by fulzerasib or sotorasib alone, was effectively abolished in H358 cells. Suppression of ERK1/2 resulted in attenuation of YAP Y357 phosphorylation. ASS1 expression appeared to increase more substantially in the more resistant cell lines, H23 and H2030, following treatment with sotorasib or fulzerasib. In contrast, ASS1 expression levels remained largely unaffected in H358 by KRASG12C inhibitors treatment. Fumarate levels seem to be higher in H358 compared to more resistant cell lines. Fulzerasib and sotorasib seem to increase levels of fumarate in a similar extent.

Conclusions: Cetuximab combined with fulzerasib or sotorasib inhibits cell viability in H358 cell line, preventing ERK1/2 rebound and YAP1 activation. Levels of ASS1 in H358 cells were stable before treatment. In contrast, ASS1 levels were low and upregulated after sotorasib treatment in H23 cells. Low ASS1 expression is shown to harbour a poor prognosis. Further research could clarify the relevance of ASS1 and fumarate as a biomarker and therapeutic target.

Keywords: Fumarate, ASS1, KRASG12C inhibitors

EP.02 TUMOR BIOLOGY – PRECLINICAL BIOLOGY

EP.02.11 Clinical and Biological Significance of Cystathionine Gamma-Lyase in Pulmonary Adenocarcinoma

Y. Kataoka, D. Ishihara, K. Shibata, M. Yoden, T. Shiratori, K. Ueda, K. Okamoto, Y. Kawaguchi, K. Teramoto, J. Hanaoka
Shiga University of Medical Science, Otsu/JP

Introduction: Cystathionine gamma-lyase (CTH) is an enzyme that catalyzes endogenous hydrogen sulfide and involved in physiological processes, such as cell proliferation and migration. However, the significance of CTH expression in lung adenocarcinoma remains unclear. This study aimed to evaluate CTH expression in invasive pulmonary adenocarcinoma and clarify its prognostic significance in patients.

Methods: CTH expression was analyzed by immunohistochemistry to evaluate its clinicopathological significance in 103 patients with p-Stage IA-IIIA invasive pulmonary adenocarcinoma who underwent surgical resection between 2016 and 2021. To clarify the role of CTH expression, the effects of CTH knockdown in human lung adenocarcinoma cell lines ABC-1 and VMRC-LCD were examined using proliferation, scratch, and invasion assays. To investigate the involvement of CTH in tumor cell aggressiveness, growth factor antibody array was performed.

Results: In patients with p-Stage IA-IIIA invasive pulmonary adenocarcinoma, CTH expression in tumor cells was significantly associated with tumor recurrence ($p = 0.014$), histological subtype ($p < 0.001$), and microvessel invasion ($p = 0.001$). Patients with higher CTH expression levels had significantly lower relapse-free survival rates than those with lower CTH expression levels ($p = 0.005$). In vitro assays, the CTH knockdown did not affect the proliferative activities of A549, ABC-1, and VMRC-LCD cells. The migratory and invasive activities of these tumor cells were significantly reduced by CTH knockdown. The growth factor antibody array revealed that the protein level of platelet-derived growth factor-A (PDGF-A) was significantly decreased by CTH knockdown in tumor cells.

Conclusions: CTH promotes tumor cell motility via PDGF-A expression in pulmonary adenocarcinoma. In p-Stage IA-IIIA invasive pulmonary adenocarcinoma, CTH expression could serve as a predictor of tumor recurrence.

Keywords: Pulmonary adenocarcinoma, Cystathionine gamma-lyase

EP02.12 Identifying Acquired Resistance Mechanisms to Sotorasib in G12C Lung Adenocarcinoma (LuAD) Cell Lines (CL)

M.C. Cucurtull Salamero[1,2], M. Saigi Morgui[3], E. Pros[4], P. Navajas-Chocarro[4], M. Domenech Viñolas[3], A. Hernández[3], A. Notario[3], M. Sánchez-Cespedes[4]
[1]Institut Català d'Oncologia, Badalona/ES ,[2]B-ARGO, Badalona/ES ,[3]Institut Català d'Oncologia, B-ARGO, Badalona/ES ,[4]Josep Carreras Leukaemia Research Institute (IJC), Badalona/ES

Introduction: KRAS mutations are responsible for approximately 20% of lung adenocarcinomas (LuAD). Most of these mutations consist of a glycine to cysteine transversion at codon 12 (G12C), trapping KRAS on its GTP-bound active state and consequently activating downstream singnaling pathways. The first effective strategies are G12C inhibitors (sotorasib and adragrasib) that are bound to mutant cysteine, therefore trapping KRAS on its inactive state. Sotorasib and adagrasib trials showed promising response rates but short duration of response (11 and 8 months, respectively). We assessed the possible mechanisms of acquired resistance to sotorasib and tried to identify possible strategies to overcome this resistance.

Methods: To generate sotorasib-resistant models we selected two different commercial lung cancer cell lines (H355 and H2030) and exposed them to increasing doses of sotorasib. We characterized the parental cancer cells and the derived-resistant genetically and molecularly by exome (WES) and RNA sequencing and performed analysis of signaling pathways and of the KRAS activation status by western-blot and RAS assay test. We also exposed the resistant cells to a SHP2 inhibitor (TNO155) and to a MEK inhibitor (trametinib), with and without sotorasib, and determined efficacy using cell viability and colony formation assays. We also tested these drug combinations in other commercial and in a patient-derived lung cancer cells with a KRASG12C mutation.

Results: The H2030 cells showed partially intrinsic resistance to sotorasib and we couldn't find acquired resistant mechanisms at a genetic level, although there were changes in gene expression. Three of the H358 derivate resistant cells showed KRAS G12C amplification. One model harbored a secondary G12V mutation. AKT activation was present in two models. TNO155 was not effective in overcoming resistance but trametinib was. One of the resistant models was addicted to sotorasib as drug combinations weren't effective without sotorasib.

Conclusions: Mutant allele amplification and secondary KRAS nonG12C mutations could be on target acquired resistance mechanisms. AKT pathway activation could be an off-target resistance mechanism. SHP2i could be synergic in combination with sotorasib in partially resistant cell lines.

Keywords: KRAS, sotorasib, resistance

Introduction: In the evolving landscape of treatment for resectable lung cancer patients, better understanding of tumor biology is necessary. We have previously identified proteins associated with survival in surgically resected stage I-III lung adenocarcinoma (LUAD) patients. We sought to perform proteomic analysis in resected stage I LUAD patients to determine 1) proteins associated with recurrence and 2) whether there are shared proteins compared with our previously identified survival-associated proteins.

Methods: From our retrospective database of resected LUAD between 2016-2022, we selected pathologic stage I patients. We then selected 10 early recurrent cases (recurrence within 3 years of surgery) and 10 cases with long disease-free interval (more than 3 years). Laser microdissection was used to selectively harvest tumor epithelium from the formalin-fixed, paraffin-embedded LUAD tumor tissues, which were analyzed using a quantitative proteomics workflow employing tandem mass tags and high-resolution liquid chromatography-tandem mass spectrometry. Significant proteins were then compared with previously identified survival-associated proteins.

Results: Among the 10 early recurrent cases, the median age was 70.5, and 2 were females. By procedure, 6 received wedge resections and 4 received lobectomies. By stage, there were 6 stage IA2 and 4 IA3. By morphology, there were 6 acinar, 2 papillary, 1 lepidic, and 1 solid. Among the long disease-free interval cohort, the median age was 74, and 2 were females. By procedure, 5 received wedge resections and 5 received lobectomies. By stage, there were 1 stage IA1, 6 IA2, and 3 IA3. By morphology, there were 4 solid, 3 acinar, 2 mucinous, and 1 uncategorized. Between the two cohorts, we identified 880 proteins that were significantly altered ($p<0.05$). We then compared these to the 1041 significantly ($p<0.05$) altered proteins associated with survival in stage I-III LUAD in our previous study. We identified 109 proteins that are shared between the two studies that are highly quantitatively correlated (correlation ~0.8, $p<0.0001$, Figure 1).

Conclusions: Our study identified proteins significantly associated with recurrence in resected stage I LUAD patients. Furthermore, some of these proteins are shared with our previously identified proteins associated with survival in stage I-III LUAD. Current and future work will focus on pathway analysis and performing similar analysis on preoperative biopsy specimens.

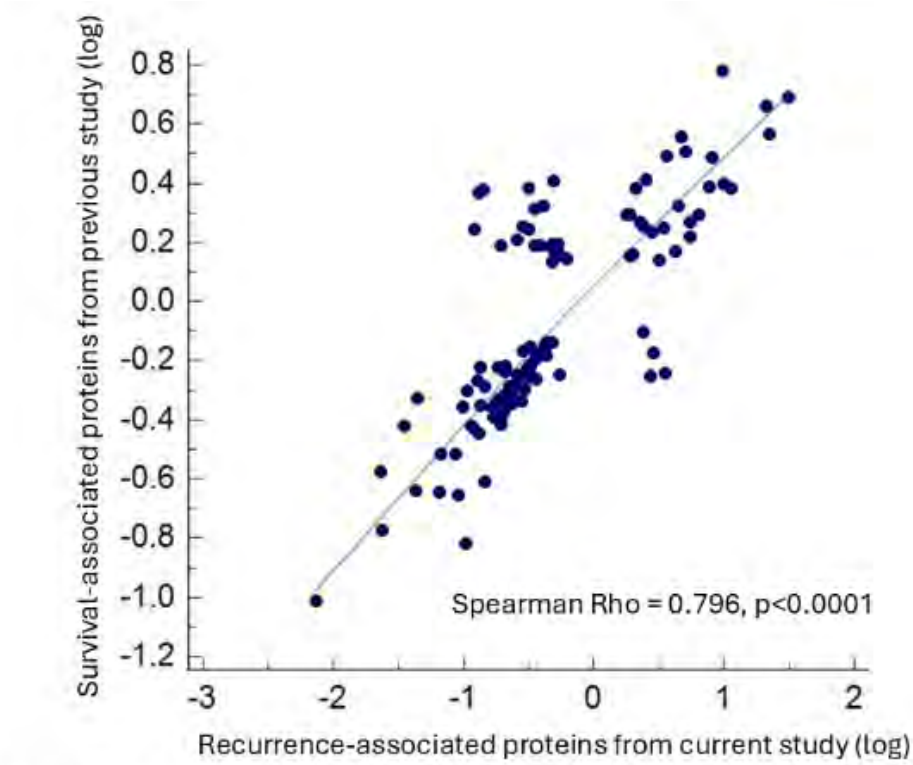

Figure 1. Correlation of recurrence-associated proteins from stage I lung adenocarcinoma and survival-associated proteins from previous study in stage I-III lung adenocarcinoma

EP.03.02 An Integrating Multiomic Approach to Chart the Tumor Immune Microenvironment Associated to Immunotherapy Response in Non-Small Cell Lung Cancer

F.T. Gallina, N. Porciello, G. Frisullo, L. D'Ambrosio, M.M. Rosado, R. TAJE', V. Balzano, G. Campo, F. Di Modugno, B. Palermo, F. Goeman, F. De nicola, L. Landi, F. Cappuzzo, P. Visca, P. Nisticò
IRCCS National Cancer Institute Regina Elena, Rome/IT

Introduction: The organization and composition of the Tumour Immune Microenvironment (TIME) are crucialdeterminants of patient clinical outcomes. This evidence highlights the importance of profiling cellidentity, functionality, and tissue architecture for the development of novel and more effectivetherapeutic strategies. Distinct TIME subtypes have been characterized, each exhibiting uniquefeatures that influence tumour invasiveness, modulate immune responses, and impact theeffectiveness of therapeutic interventions. Among these, a TIME enriched in tertiary lymphoidstructures (TLS), ectopic lymphoid hubs where B and T cells interact to produce high-affinityimmune responses and durable immune memory, has recently emerged as a prognostic andpredictive biomarker of responsiveness to immune checkpoint blockade (ICB) therapy.Concurrently, cancer-associated fibroblasts (CAFs), a highly heterogeneous and dynamic cellularcomponent of the TIME, have gained increasing interest for their pivotal role in shaping TIMEarchitecture, influencing tumor progression, and modulating immune cell functionality. Ourprevious work has shown that, in CAFs, the high expression of hMENA, an actin cytoskeletonregulator, modulates the expression of Lymphotoxin β Receptor (LTβR) and secretion of CXCL13,critical initiators of TLS development. Furthermore, we identified a gene signature, includinghMENA, fibronectin, and LTβR, that is predictive of response to ICB in NSCLC and is associatedwith the presence of a TLS-enriched TIME.

Methods: We collected tumor, adjacent non-tumor tissue, and peripheral blood from six treatment-naïveNSCLC patients who underwent curative surgery in our Institute. Patients who later recurred andreceived ICB were classified as good or poor responders. We integrated spatial transcriptomics, by10X Visium, and single-cell RNA sequencing (scRNA-seq) to in-depth profile the composition andfunctionality of patients' TIME and focused on TLS maturation, also in relation to surroundinghMENA-expressing CAFs

Results: By integrating publicly available single-cell atlases of T and B cells, and the in-house generatedCAF atlas with our spatial transcriptomic datasets, we identified key TIME programs likelyassociated to clinical response to ICB therapy. Comparative analysis between ICB responder andnon-responder patients revealed significant differences in TLS cellular composition and maturationstages. Specifically, NSCLC patients with a good response to ICB exhibited a higher TLSmaturation score, also characterized by an increased abundance of activated and germinal center Bcells, along with antibody-secreting plasma cells. Additionally, integrating the lung CAF single-cellatlas with spatial transcriptomic data highlighted a higher presence of immunosuppressive hMENA-overexpressing CAFs within and around TLS in poor ICB responders compared to good responders,suggesting that hMENA-expressing CAFs may hinder the formation of fully functional antitumorTLS. In parallel, ongoing scRNA-seq profiling of peripheral lymphocytes aims to uncover systemicimmune signatures that could further aid in stratifying patients based on their likelihood to benefitfrom ICB.

Conclusions: Our findings emphasize the value of combining complementary spatial and single-celltranscriptomic technologies to uncover predictive biomarkers of ICB response in NSCLC and toreveal novel mechanisms of immune evasion, critical for developing more precise and effectiveimmunotherapeutic strategies

EP.03.03 Tumor Heterogeneity Consisting of SCLC With RB1 Exon 19 Deletion and L718V Mutation-Positive Adenocarcinoma in EGFR-TKI Resistant Lung Cancer

S. Kakuto[1,2], K. Uchibori[3], E. Miyauchi[2], M. Nishio[3], H. Sugiura[2], R. Katayama[1]
[1]The Cancer Chemotherapy Center, Japanese Foundation For Cancer Research, Tokyo/JP ,[2]Department of Respiratory medicine, Tohoku University Graduate School of Medicine, Miyagi/JP ,[3]The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo/JP

Introduction: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) are widely used as targeted therapies for EGFR-positive non-small cell lung cancer (NSCLC). However, acquired resistance, such as secondary mutations and histological transformation to small cell lung cancer (SCLC), remains a significant clinical challenge. In this study, we investigated the mechanisms of resistance to osimertinib by analyzing sequential biopsy specimens obtained over time following the development of resistance.

Methods: We established cell lines from cancerous pleural effusions and mediastinal lymph node biopsies obtained from patients with EGFR L858R mutation-positive lung cancer who had been treated with osimertinib at the time of disease progression. EGFR and other gene mutations, as well as gene expression profiles, were analyzed using RNA sequencing and whole-exome sequencing. In addition, we assessed the drug sensitivity of the established cell lines and examined the effects of the drugs on cell proliferation signaling pathways by Western blot analysis.

Results: The patient-derived cell lines JFCR330-4 and JFCR330-7, established from pleural effusions after the development of resistance to osimertinib, were classified as lung adenocarcinoma. Both L858R and L718V mutations in the EGFR gene were identified in these lines. In contrast, JFCR330-5, which was established from mediastinal lymph node biopsy specimens, exhibited characteristics of SCLC, and harbored only the EGFR L858R mutation. Cell viability assays and Western blot analyses demonstrated that JFCR330-4 and JFCR330-7 were resistant to osimertinib but showed high sensitivity to afatinib, a second-generation EGFR-TKI. Notably, JFCR330-7 cells exhibited partial sensitivity to gefitinib, whereas they were resistant to erlotinib, which shares a high degree of structural similarity with osimertinib. RNA sequencing revealed that genes regulated by ASCL1, as well as synaptic and nervous system-related genes, were enriched in JFCR330-5, which had undergone small cell transformation. Both RNA sequencing and whole-exome sequencing detected TP53 mutations in all cell lines derived from this patient. However, only in JFCR330-5 was a deletion of exon 19 in the RB1 gene identified, suggesting that a DNA region of approximately 10 kb or less, including exon 19, was deleted. Such a single-exon deletion at the DNA level is likely to be missed by next-generation sequencing (NGS) of tumor tissues when a high proportion of nucleic acids are derived from surrounding normal tissues. These subtle genetic alterations may underlie SCLC transformation even in cases lacking obvious RB1 mutations or deletions.

Conclusions: In this case, SCLC transformation and the acquisition of the L718V mutation occurred simultaneously but in distinct tumor sites. In the pleural effusion, the L718V mutation emerged, suggesting that afatinib may be a potential therapeutic option to overcome this resistance. In contrast, in the mediastinal lymph node metastasis, microdeletion of the RB1 gene led to small cell transformation and subsequent drug resistance. These findings highlight the temporal and spatial heterogeneity of resistance mechanisms in EGFR inhibitor-treated lung cancer.

Keywords: SCLC transformation

EP.03 TUMOR BIOLOGY – TRANSLATIONAL BIOLOGY

EP.03.04 PD-L1-Regulated c-Met Phosphorylation Contributes to MET Amplification in EGFR Mutation NSCLC

D.D-R. Huang[1], C-C. Hsu[2], B-C. Liao[1], W-H. Hsu[2], J.C-H. Yang[1]
[1]National Taiwan University Cancer Center, Taipei/TW ,[2]National Taiwan University Hospital, Taipei/TW

Introduction: Programmed death-ligand 1 (PD-L1) is a well-recognized predictive biomarker for immunotherapy in non-oncogene-addicted non-small cell lung cancer (NSCLC). However, its role in epidermal growth factor receptor (EGFR)-mutant NSCLC remains unclear. Some retrospective analyses suggested that PD-L1 expression is associated with lower response rate and shorter survival to EGFR tyrosine kinase inhibitors. This study aims to investigate the impact of PD-L1 on the signaling pathways in EGFR-mutant NSCLC.

Methods: The regulatory role of PD-L1 was investigated through in vitro manipulation of PD-L1 expression across several EGFR-mutant cell lines, followed by analysis via human receptor tyrosine kinase (RTK) array, Western blotting, protein tyrosine phosphatase (PTPs) activity assays. Anti-PD-L1 antibodies atezolizumab and durvalumab were added to evaluate the location of regulation. In vivo experiments were carried out using xenograft mice implanted with parental, PD-L1 knock-out and PD-L1 overexpression NCI-H1975 cells. Osimertinib was orally administered to the mice until tumor progression to evaluate the impact of PD-L1 on osimertinib resistance. Progression-free survival (PFS) of the mice were compared using log-rank test and plotted on Kaplan-Meier curve. MET copy number variation was assessed by RT-PCR-based TaqMan assay.

Results: In human RTK array screening, c-MET phosphorylation was found to be increased in EGFR-mutant PD-L1 overexpression cells. We found that PD-L1 overexpression upregulated c-MET phosphorylation, while PD-L1 knock-out and knock-down resulted in downregulation of c-MET phosphorylation. Atezolizumab and durvalumab did not reduce c-MET phosphorylation in PD-L1 overexpression cells. Furthermore, we showed that PD-L1 upregulates c-MET phosphorylation by suppressing PTP activity. In xenograft mice, PFS was significantly shorter in mice implanted with PD-L1 overexpression tumor, compared with mice implanted with PD-L1 knock-out and parental NCI-H1975 tumor cells. MET amplification only developed in PD-L1 overexpression, but not in PD-L1 knock-out and parental NCI-H1975 cells, at the time of osimertinib resistance.

Conclusions: In EGFR-mutant NSCLC, PD-L1 regulates c-MET phosphorylation and promotes MET amplification, contributing to osimertinib resistance and shorter survival.

Keywords: programmed death-ligand 1, epidermal growth factor receptor mutation, MET alterations

EP.03.05 The Study on the Mechanism of OM-85 in Regulating the Immune Microenvironment in Early-Stage Lung Adenocarcinoma

M. Sun[1], L. Xie[1], Y. Ni[1], Y. Song[1], J. Yin[1], H. Kong[1], S. Lu[1], X. Wang[1], J. Zhou[1], M. Xiang[2], B-S. Ding[3], C.A. Powell[4], C. Bai[1], Y. Song[1], D. Yang[1]
[1]Zhongshan Hospital Fudan University, Shanghai/CN ,[2]School of Basic Medical Sciences, Fudan University, Shanghai/CN ,[3]West China Second University Hospital, Sichuan University, Chengdu/CN ,[4]Icahn School of Medicine at Mount Sinai, New York/NY/US

Introduction: Early-stage lung adenocarcinoma (LUAD) in clinical practice predominantly manifests as ground-glass pulmonary nodules, exhibiting an incidence rate of 10%-20% in China, with about 5% progressing to invasive malignancy. Current management strategies are restricted to serial CT surveillance or invasive resection, lacking effective pharmacological interventions. OM-85 Broncho-Vaxom (BV), a standardized bacterial lysate with documented immunomodulatory capacity, was investigated for its therapeutic potential in remodeling the immune landscape of incipient LUAD, aiming to establish a paradigm for early pharmacological intervention.

Methods: A KrasG12DTgfbr2-/- (KT) genetically engineered mouse model recapitulating human early LUAD pathology was employed. Sixteen age-matched male mice (8-10 weeks) were randomized into two cohorts: Cohort A (vehicle control, PBS oral gavage) and Cohort B (OM-85 treatment). Longitudinal tumor dynamics were quantified via micro-CT volumetry and survival Kaplan-Meier analysis. Multi-parametric immunophenotyping (IHC/IF, flow cytometry) mapped immune infiltrate spatial-kinetic profiles. Systemic and compartmental immune responses were decoded through scRNA-seq of lung parenchyma and cytokine profiling (ELISA: peripheral blood, BALF). Functional validation included NK-tumor co-culture systems and transwell invasion-migration assays.

Results: OM-85 administration conferred significant survival advantage coupled with attenuated tumor burden. scRNA-seq unveiled clonal expansion of CX3CR1+NK cells within tumor niches, exhibiting enriched cytokine-cytotoxic effector pathways. In vitro, OM-85-primed NK cells demonstrated CX3CR1/IFN-γ axis activation, which mediated potent suppression of LKR cell invasiveness. CX3CR1 knockdown abrogated OM-85's anti-tumor efficacy.

Conclusions: OM-85 orchestrates tumor-immune crosstalk by potentiating CX3CR1+NK cell effector functions, characterized by IFN-γ-driven suppression of metastatic priming and stromal remodeling. This study mechanistically deciphers how oral OM-85 administration restrains early LUAD progression via NK-centric immunomodulation, proposing a novel oral immunomodulatory regimen for intercepting premalignant evolution.

Keywords: early-stage lung adenocarcinoma, bacterial lysate products, NK cells

EP.03.06 Blocking JNK Signaling as a Strategy to Fight EGFR-Driven Lung Cancer

L. Shi[1,2,3,4], J. Bossen[2], S. Krauss-Etschmann[1,2], T. Roeder[2]
[1]Research Center Borstel, Leibniz Lung Center, Borstel/DE ,[2]Christian-Albrechts Universität zu Kiel, Kiel/DE ,[3]Linyi People's Hospital, Linyi/CN ,[4]German Center for Lung Research (DZL), Borstel/DE

Introduction: Mutations in the Egfr gene are among the most important drivers of lung tumor development. However, the success of personalized therapies still needs to be improved due to the development of resistance. We comprehensively analyzed the signaling pathways involved in tumor development in a tailored Drosophila model to identify novel intervention stategies.

Methods: In suitable Drosophila models, tumors were induced by constitutive activation of the EGFR receptor, and both tumor volume and survival rate or mean survival time were quantified.

Results: Our research underscores the pivotal role of the EGFR-activated signaling system in tumor growth. Through targeted genetic and pharmacological interventions, we demonstrated the significant contributions of different arms of this system, the canonical MAPK pathway and the PI3K/Akt pathway. The JAK/STAT pathway emerged as a critical factor in cancer cell migration. Notably, JNK inhibition via RNAi or dominant-negative constructs significantly reduced tumor growth (6.92-fold decrease in T6 tracheoblast area, $p < 0.0001$), suppressed proliferation, and promoted apoptosis. Importantly, our findings indicate that the JNK pathway acts as a central coordinator of these signaling pathways, influencing their activation. This aligns with our observation that JNK signaling blockade can be effective in inhibiting tumor growth.

Conclusions: The implications of our findings are promising, a targeted, intelligent combination therapy focusing on different signaling pathways could be a highly effective approach for treating lung tumor patients. Notably, the inclusion of JNK inhibition holds particular potential.

EP.03.07 The Role of Tumour Intrinsic Inflammasome Mutations in Lung Adenocarcinoma

D. Gough
Hudson Institute of Medical Research, Clayton/AU

Introduction: Lung adenocarcinoma (LUAD) is the most common form of lung cancer and the leading cause of cancer related death. In 2017, immune checkpoint inhibitors (ICI)s were approved as part of the front-line LUAD treatment regime. However, only about 20% of non-stratified LUAD patients respond to ICI monotherapy, and predicting the response of individual patients remains challenging. The innate immune system is critical and necessary for maturation and activity of the adaptive immune system and offers opportunities to enhance the response to ICIs. Indeed, the importance of the innate immune cytokine, IL-1b in the development of LUAD was revealed by the phase III CANTOS trial which recorded a staggering 67% and 77% reduction in lung cancer incidence and mortality respectively. However, IL-1b neutralization in patients with existing LUAD failed to meet primary efficacy endpoints. Together this highlights the potential of harnessing the innate immune system in the treatment of LUAD but to do so requires a deep understanding of the inflammatory environment throughout the development of LUAD.

Methods: We combine patient data with autochthonous mouse models of LUAD and spatial transcriptomics to interrogate the importance of the inflammasome in Kras driven LUAD development.

Results: Our data show activating mutations in the inflammasome are prevalent in LUAD, which are accompanied by transcriptomic changes in tumor microenvironment. Tumor intrinsic deletion of the inflammasome significantly delays disease onset.

Conclusions: The inflammasome plays a key role in the development of lung adenocarcinoma and offers a novel therapeutic opportunity.

Introduction: Angiogenesis is a hallmark of disease progression and poor prognosis in non-small cell lung cancer (NSCLC). Ramucirumab, an antiangiogenic antibody that binds the vascular endothelial growth factor receptor (VEGFR), is approved as second line treatment for metastatic NSCLC, in combination with docetaxel. Angiogenic inhibitors function by normalizing tumor vasculature, hence improving drug delivery and immune cell infiltration to the tumor. Tumor Treating Fields (TTFields) are electric fields that disrupt cellular processes critical for cancer cell survival. TTFields therapy, together with immune checkpoint inhibitors or docetaxel, is approved for treatment of metastatic NSCLC following progression on or after platinum-based therapy. In the current study, we examined the effects of TTFields concomitant with docetaxel and anti-VEGFR treatment in an orthotopic NSCLC mouse model.

Methods: C57Bl/6 mice were injected orthotopically with LL/2 lung carcinoma cells, and tumors were allowed to grow for 7 days. The mice were then treated with TTFields (150 kHz) or sham (heat) continuously for 8 days. Vehicle or the murine anti-VEGFR DC101 (10mg/kg) were intraperitoneally administered on days 1, 4, and 7 of treatment. Vehicle or docetaxel (3mg/kg) were intraperitoneally administered on days 2, and 6 of treatment. Overall, there were 6 study groups: control, docetaxel alone, docetaxel plus DC101, TTFields alone, TTFields plus docetaxel, and TTFields plus docetaxel plus DC101. At treatment end, tumors were weighed and analyzed by immunohistochemistry, with anti-CD31 for vessel staining and additional functional markers.

Results: TTFields concomitant with docetaxel and DC101 significantly decreased tumors size relative to all other treatment groups. Tumors from this treatment group also presented with higher levels of apoptosis, as indicative from TUNEL assay. Staining for αSMA and CD8 demonstrated, respectively, that the blood vessels of these tumors were more mature and allowed for increased tumor infiltration of cytotoxic T cells.

Conclusions: TTFields application alongside docetaxel and an anti-VEGFR antibody increased treatment efficacy via normalization of tumor blood vessels, which allowed for increased tumor immune cell infiltration and presumably elevated tumor drug delivery.

EP.03.09 A New Treatment Approach for Non-Small Cell Lung Cancer

A. Suraweera[1], M. Tang[1], S. Samuel[2], D.J. Richard[1], K.J. O'Byrne[1]
[1]Queensland University of Technology, Brisbane/AU ,[2]University of Queensland, Brisbane/AU

Introduction: Lung cancer is the leading cause of cancer related deaths worldwide. Non-small cell lung cancers (NSCLC) account for 85-90% of all lung cancers. Despite recent advances in NSCLC therapies, the majority of patients with advanced disease ultimately relapse. Genomic instability is a hallmark of all cancers. To prevent cancer, cells possess a complex network of signalling pathways called the DNA damage response (DDR), which is involved in the detection, signalling, and repair of DNA. Failure of the DDR leads to cancer and tumorigenesis. Here we provide the first stages of development for a novel DDR-targeting therapeutic for the treatment of NSCLC.

Methods: Molecular dynamics, together with in vitro binding and site directed mutagenesis were used to identify the binding pose regulating chromatin remodelling, that is required for the efficient repair of DNA damage by the DDR. Based on the identified binding pose, we have developed a first-in-class small molecule inhibitor. On-target activity of this small molecule inhibitor was determined using cell viability, DNA repair and apoptosis assays. In vivo validation was additionally performed in a preclinical model of NSCLC.

Results: In-silico molecular dynamics, in vitro binding and site directed mutagenesis identified the binding pose regulating chromatin remodelling, that is required for the efficient repair of DNA damage. Using this data, a small molecule inhibitor was developed. Treatment with the inhibitor induced cell death and apoptosis of NSCLC cells in vitro and significantly reduced tumour growth in a preclinical model of NSCLC.

Conclusions: Our results demonstrate the early stages of development for a novel DDR-targeting therapeutic for the treatment of NSCLC, which would have applicability in the most aggressive and genetically unstable lung cancers.

EP.03.10 Evaluating the Role of the Blood-Brain Barrier in Intracranial Response Rates for Metastatic Lung Cancer

T-Y.U. Chang, D.J. Stewart, P. Wheatley-Price
The Ottawa Hospital, Ottawa/ON/C

Introduction: Lung cancer is the second most common cancer overall and the leading cause of cancer death worldwide, as well as the most common cause of brain metastases (BMs) with reported prevalences of 10-20%.Drug delivery to normal brain tissue is limited by the blood-brain barrier (BBB). For this reason, systemic therapies are thought to be less effective for BMs than other disease sites. Many clinical trials exclude patients with BMs or require them to be stable after localized therapy.There is evidence that the BBB is disrupted in the setting of BMs and substances normally minimally detectible in normal brain tissue can achieve significant concentrations in BMs. This raises the question of whether response rates in lung cancer BMs are significantly different from other sites of disease.

Methods: We conducted a literature search to determine reported intracranial response rates for drugs or combination regimens used to treat metastatic lung cancer, as well as extracranial or overall response rates where available. The predicted penetration of each drug through an intact BBB was evaluated based on its molecular size, chemical properties, affinity for efflux transporters, and testing of cerebrospinal fluid and brain tissue samples in animal models (and human samples, where available), then rated as none (zero), poor (<5% systemic concentrations), low (5-10%), moderate (10-50%), good (50-80%), or excellent (80%-100%+).

Results: We reviewed 31 prospective and retrospective studies from 1989-2025 reporting intracranial response rates to systemic therapies for small cell and non-small cell lung cancer, as well as 10 studies or reviews discussing drug penetration through the BBB. Predicted BBB penetration for different agents ranged from none for monoclonal antibodies to excellent for certain targeted therapies. Across drug classes and lines of therapy, intracranial response rates were generally comparable to, or higher than, extracranial or overall response rates, regardless of predicted brain penetration.

Conclusions: Regardless of predicted brain penetration, systemic agents demonstrated comparable intracranial response rates to extracranial or overall response rates. This has important implications in drug and clinical trial design, suggesting that research should aim for maximum overall response rates rather than increased brain penetration and that the exclusion of patients with asymptomatic, untreated brain metastases from clinical trials is unwarranted.

EP.03.11 Peritumoral B Lymphocyte Mediated Immune Response Is Associated With Survival in Patients With Non-Small Cell Lung Cancer

O. Kose[1], A. Turna[2], M. Agkoc[3], T. Demircan[4], D. Durali[1]
[1]Istanbul Medipol University School of Medicine, Istanbul/TR ,[2]Istanbul University-Cerrahpasa Cerrahpasa Medical Faculty, Istanbul/TR ,[3]Erzurum City Hospital, Erzurum/TR ,[4]Muğla Sıtkı Koçman University School of Medicine, Muğla/TR

Introduction: Tumor-infiltrating immune cells play a significant role in the promotion or inhibition of tumor growth. As an integral component of the tumor microenvironment, tumor-infiltrating B lymphocytes and T lymphocytes exist and play important roles in shaping tumor development. We aimed to evaluate the T cell and B cell mediated immune microenvironment to find an association between survival and certain immune cell subpopulations.

Methods: : A total of 55 patients who underwent surgical resection from October 2018 to July 2023 with the diagnosis of stage IA to IIB non-small cell lung cancer (NSCLC) were enrolled. Samples from tumor, mediastinal lymph nodes, healthy lung tissue and peripheral blood were collected from all patients. Lymphocytes were isolated from the blood and the tumor mass. Different T and B lymphocyte phenotypes and functions were analyzed. Quantitative PCR was used to measure EBI3, IL-12p35 IL-10, LGALS1 and MAF mRNA expression.

Results: The mean age of all patients was 63.7 ± 7.8 years and 47 (85.5%) of them were male. The most common resection type was lobectomy (n=42, 76.3%) and histopathological diagnosis revealed adenocarcinoma in 17 (30.9%) cases. There was no significantly significant difference in terms of total T lymphocyte number and cytotoxicT lymphocytes between healthy tissue and tumor tissue. CD19+ B cells from the tumor tissue showed significantly higher PD-L1 expression(i.e. B regulatory cells) (14.5% ± 2.9%) compared to CD19+ B cells from healthy tissue (HT) and mediastinal lymph nodes (mLN), which exhibited PD-L1 expression levels of 7.0 ± 1.5% and 7.2 ± 1.7%, respectively($p<0.001$). Bregs cells were found to be significantly higher in mediastinal lymph nodes and peripheral blood of the patients with NSCLC. Higher activated T lymphocytes was associated with better survival ($p=0.011$) in mediastinal lymph nodes. In addition, CD3+ PD-L1+ T cells in the tumor($p=0.039$), lower number and activity of Breg cells in peripheral blood($p=0.031$)were significantly associated with better survival(Figure).

Conclusions: The anti-tumor immune response seemed to be closely associated with postoperative oncological outcomes. Particularly regulatory B lymphocytes, appear to play a role in anti-tumor immunity and survival. Future immunotherapeutic strategies may also target B lymphocytes to enhance treatment outcomes

EP.03.12 Sex-Specific Blood-Based Immune Signatures Predict Response to First-Line Immunotherapy in Advanced NSCLC: A Prospective Translational Study

B. Resuli[1], D. Kauffmann-Guerrero[1], M. Aykac[1], S. Hermann[1], M. Arredondo Lasso[1], R. Kiefl[1], P. Mertsch[1], J. Kovacs[1], T. Kauke[1], C. Schneider[1], J. Behr[1], A. Tufman[1]
[1]LMU University Clinic, Munich/DE

Introduction: Immune checkpoint inhibitors (ICIs) targeting the PD-1/PD-L1 axis have emerged as a cornerstone in the management of advanced non-small cell lung cancer (NSCLC) without identifiable actionable oncogenic drivers. Despite these advances, durable responses remain confined to a minority of patients, and PD-L1 expression alone is an insufficient predictive biomarker. Emerging evidence indicates that biological sex may influence antitumor immune responses and modulate the efficacy of ICIs, although the underlying biological mechanisms remain poorly understood.This study aims to investigate sex-specific circulating immune-inflammatory biomarkers associated with response to ICI-based therapy in NSCLC.

Methods: This is a prospective, single-center, observational translational study conducted in a real-world clinical setting. The study plans to enroll 100 patients (50 males, 50 females) with advanced or unresectable, EGFR/ALK-wildtype NSCLC, ECOG performance status 0-2, initiating first-line treatment with either ICI monotherapy or ICI combined with platinum-doublet chemotherapy. Peripheral blood samples are collected at three predefined timepoints: (1) baseline (prior to treatment), (2) first radiologic assessment (approximately 6-9 weeks post-treatment initiation), and (3) radiologically confirmed disease progression. Cytokine profiling is performed using the Q-Plex™ Human Cytokine Inflammation Panel, targeting nine cytokines (IFNγ, IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, TNFα). The primary endpoint is the association between baseline cytokine levels and objective response rate (ORR). Secondary endpoints include progression-free survival (PFS), overall survival (OS), immune-related adverse events (irAEs), and longitudinal cytokine dynamics. All analyses will be stratified by sex to explore sex-specific immune correlates.

Results: As of the current reporting period, patient enrollment and biospecimen collection are ongoing. No clinical or biomarker analyses are available at this time. Cytokine and outcome analyses will be conducted upon completion of enrollment and sufficient follow-up. At this first interim analysis, 35 patients have been enrolled: 15 (43%) female, 28 (80%) with adenocarcinoma histology, 27 (77%) received pembrolizumab plus platinum-based chemotherapy, and 8 (23%) received ICI monotherapy.

Conclusions: This study aims to define sex-specific circulating immune-inflammatory profiles associated with response to first-line immune checkpoint inhibition in advanced NSCLC. By integrating cytokine profiling with longitudinal clinical outcomes in a sex-balanced cohort, the results are expected to contribute to the identification of predictive biomarkers that reflect differential immune dynamics by sex. These findings may ultimately support more refined, biomarker-driven treatment algorithms and promote sex-informed personalization of immunotherapy strategies in routine clinical practice.

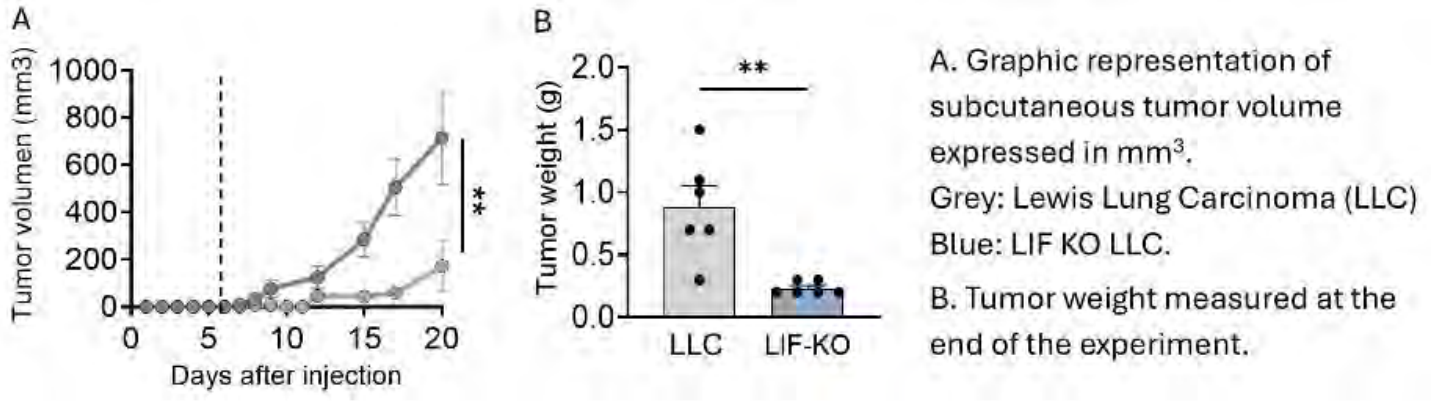
EP.03.13 LIF Is Associated With Poor Prognosis and Participates in Lung Cancer Growth and Implantation in Preclinical Models of NSCLC

C. Muñoz-Pinedo[1], F. Luciano-Mateo[1], S. Hijazo-Pechero[1], F. Jiménez-Hernández[1], S. Plans-Marin[1], L. Collado-Rodríguez[1], D. Palau-Gallinat[1], M. Cruz-Rodríguez[1], E. Nadal[2]
[1]IDIBELL, Hospitalet de Llobregat/ES ,[2]Catalan Institute of Oncology (ICO), Hospitalet de Llobregat/ES

Introduction: LIF is a cytokine with multiple pro-tumorogenic roles. It maintains stemness, immune suppression and promotes cachexia. LIF expression is regulated by oncogenic pathways like KRAS, and it is involved in lung pathologies like fibrosis. We hypothesized that LIF may be a good target against NSCLC.

Methods: LIF mRNA expression was correlated with prognosis using the TCGA dataset and Cox proportional hazards models. A549, SW900, H460, H1299, H2126 cell lines were analyzed in culture. The murine Lewis Lung Carcinoma cell line (LLC) deficient in LIF was generated via CRISPR. LLC were injected subcutaneously or via tail vein in B6 mice. Expression of markers in murine tumors was analyzed by qPCR.

Results: LIF expression was significantly associated with worse overall survival (OS) in LUSC (HR = 1.25 (1.02-1.52)) after adjusting for disease stage. A similar association was observed in LUAD, although not statistically significant (HR = 1.17 (0.97-1.42). We analyzed expression and secretion of LIF in murine LLC and Human NSCLC cell lines. Secreted levels of this cytokine were heterogeneous in several cell lines in culture (25-700 pg/ml) and they were increased by placing cells under glucose starvation or hypoxia (125-1000 pg/ml). LIF-deficient LLC grew in culture at the same rate than the parental cells. However, cells injected subcutaneously in mice developed smaller tumors in the absence of LIF (0.88±0.41g versus 0.23±0.05g). In a subsequent experiment injecting cells through the tail vein, 15 of 20 mice injected with WT LLC developed tumors in the lung, while only 1 out of 20 mice developed tumors with LIF KO LLC cells. Analysis of cytokine and immune markers revealed significantly lower IL-6, neutrophils, E-selectin and CD163 in LIF-low tumors, consistent with less innate immune, pro-tumoral infiltration. Conversely, tumors with basal levels of LIF (WT LLC) displayed more Interferon gamma and CD8, suggesting a higher immune response when LIF is reduced.



Conclusions: LIF, which levels are increased by glucose deprivation and hypoxia, leads to larger tumors, immune suppression and more implantation of Lewis Lung Carcinoma in lungs of mice. Since several drugs targeting LIF or its receptor are being tested in clinical trials, we propose that LIF could potentially be a good target against NSCLC which could improve immune clearance and reduce tumor growth.

EP.03.14 Single-Cell Transcriptome Analysis Revealed an Activated Tumor Immune Microenvironment in KRAS Mutant NSCLC

H. Wang[1,2], K. Xu[1,2], Y. Xu[1,2], C. He[1,2], L. Xu[1,2], H. Tang[1,2], Z. Zhang[1,2]
[1]The First Affiliated Hospital of USTC, Hefei/CN ,[2]University of Science and Technology of China, Hefei/CN

Introduction: Patients with KRAS-mutated(mKRAS) advanced non-small cell lung cancer (NSCLC) have a poor prognosis and immunotherapy is an effective treatment option. High expression of PD-L1 is an underlying mechanism, but the role of the tumor microenvironment(TME) related to immunotherapy has been little studied.

Methods: We enrolled a total of 47 NSCLC patients with KRAS mutations, 20 receiving first-line immunotherapy and 27 receiving first-line chemotherapy, and performed survival analysis. Single-cell RNA sequencing data from 10 mKRAS and 13 wild-type KRAS mutations(wtKRAS) were simultaneously integrated to explore differences in the immune microenvironment.

Results: Among 47 patients with mKRAS NSCLC, the most common KRAS mutation subtypes were G12D and G12C, with mutation rates of 38.30% and 31.91%, respectively(Figure 1A). The median PFS for patients receiving immunotherapy in the first-line setting was 9.10 (95% CI: 7.10-21.30) months, while the median PFS for patients receiving chemotherapy in the first-line setting was 5.63 (95% CI: 3.00-11.00) months, with a P-value of 0.030 and an HR value of 0.467 (95% CI: 0.235-0.928) (Figure 1B). Compared with wtKRAS NSCLC, tumor-infiltrating lymphocytes (B lymphocytes and T lymphocytes) were significantly increased in mKRAS NSCLC(Figure 2A-B). PDCD1, LAG3, and HAVCR2 were significantly enriched in mKRAS NSCLC(Figure 2C). The proportion of Tissue Resident Memory(TRM) CD8+T cell and Naïve CD8+T cell were prevalent in mKRAS NSCLC, while regulatory CD4+ T (Treg) cell was dominant in wtKRAS NSCLC(Figure 2D-E).

Conclusions: Our results offer a comprehension of the single-cell immunological landscape of mKRAS NSCLC. Enrich of CD8+ TRM and lack of CD4+ Treg might be key factors responsible for the active TME of mKRAS NSCLC.

EP.03.15 Chemotherapy Upregulates PD-L1 Expression via cGAS-STING Pathway in Non-Small Cell Lung Cance

M. Khalil[1,2], M. Li[2], N-A. Pham[2], M. Tsao[1,2]
[1]University of Toronto, Toronto/ON/CA ,[2]Princess Margaret Cancer Centre, Toronto/ON/CA

Introduction: Expression of Programmed Cell Death Ligand 1 (PD-L1) is a key albeit incomplete predictive biomarker of response to anti-PD-1/PD-L1 inhibitors. Superior clinical efficacy of PD-1/PD-L1 inhibitors is mainly observed in patients with high PD-L1 tumour expression (KEYNOTE-024, KEYNOTE-042). We hypothesize that approaches modulating PD-L1 expression may prove useful in utility of anti-PD-1/PD-L1 inhibitors. Here we show that chemotherapy can upregulate the expression of PD-L1 through the activation of cGAS-STING pathway in NSCLC.

Methods: NSCLC cell lines including A549, MGH7, HCC4006, H226, H1944, and H2122 were treated with cisplatin at varying doses and time points. CRISPR-Cas9 mediated STING knock-out cell lines were generated and treated with cisplatin. MGH7 and A549 cells were treated with cGAMP (10ug) and poly (dA:dT = dsDNA); activators of STING and cGAS, respectively and ruxolitinib, a JAK1/2 inhibitor. Expression of PD-L1 and markers of cGAS-STING pathway were analyzed by western blot and flow cytometry.

Results: Treatment of NSCLC cell lines including A549, MGH7, HCC4006, H226, H1944, and H2122 with cisplatin showed upregulation in PD-L1 expression in a dose and time dependent manner. In addition to cisplatin, pemetrexed, docetaxel, and gemcitabine also led to PD-L1 upregulation in A549 and MGH7 cell lines. This upregulation in PD-L1 expression was sustained after a 72-hr drug holiday post-treatment. These findings were validated in-vivo in three NSCLC patient-derived xenograft (PDX) models, which also showed PD-L1 protein upregulation after 3, 10, and 17 days of cisplatin treatment. For the mechanistic studies, A549 and MGH7 cell lines were selected due to their diverse baseline expression of PD-L1 with A549 being ~1% positive and MGH7 being ~85% positive. After cisplatin treatment, MGH7 and A549 cells showed an upregulation of the cGAS-STING pathway markers including cGAS, p-STING, p-TBK, and p-H2AX, a marker of DNA damage. When STING knock-out A549 and MGH7 cells were treated with cisplatin, there was no increase in PD-L1 expression as compared to the wild-type cells confirming the role of this pathway in modulating PD-L1 expression. Untreated STING knock-out A549 and MGH7 cells also showed reduced PD-L1 expression as compared to the wild type cells indicating that cGAS-STING pathway regulates PD-L1 expression at baseline. Additionally, treatment of A549 and MGH7 cells with cGAS agonist poly (dA:dT) and STING agonist cGAMP also increased PD-L1 protein expression. When treated with a combination of ruxolitinib (JAK1/2 signalling inhibitor) and cGAMP/poly (dA:dT), PD-L1 upregulation was abrogated suggesting that JAK-STAT pathway works downstream of cGAS-STING signalling to regulate PD-L1 expression.

Conclusions: Cytotoxic chemotherapies used to treat NSCLC patients induce PD-L1 expression via the activation of cGAS-STING pathway in NSCLC. This study also indicates that the chemotherapy treatment alone can possibly contribute to drug resistance by upregulating PD-L1 and promoting immune evasion, emphasizing the need for subsequent anti-PD-1/PD-L1 treatment. Further research is necessary to validate this hypothesis.

EP.03.16 Cell-Specific Fluorescence Lifetime Values in Live Non-Small Cell Lung Cancer Cells

A.L. Russell, L. Mathieson, L.A. Neilson, A.S. Hunt, A.R. Akram
University of Edinburgh, Edinburgh/GB

Introduction: There is a need for early diagnosis in NSCLC. Fluorescence lifetime imaging (FLIM) is a translational technique that measures endogenous autofluorescent decay rates reflecting intrinsic metabolic activity. Fernandes et al1 have shown that fluorescence lifetime values are lower in NSCLC compared to adjacent non-tumour lung. However, the underlying source and heterogeneity of FLIM signals is not known at a cellular level. We utilise FLIM to understand the cell-specific FLIM signals within live tumour and non-tumour lung tissue.

Methods: Fresh NSCLC and adjacent non-tumour lung samples were obtained from consented patients undergoing surgical resection. Samples were digested to single-cell suspensions and used to establish 3D epithelial and tumour organoids as well as 2D cancer associated fibroblast (CAF) cultures. PBMCs were isolated from blood from consented patients. Label-free fluorescence lifetime imaging was performed using a laser scanning confocal microscope (STELLARIS FALCON, Leica Microsystems). Samples were excited at 488nm with an emission range of 498-596nm. FLIM images were analysed using cell-specific ROIs to quantify mean autofluorescence lifetimes.

Results: 10 patient-derived samples were used, encompassing adenocarcinoma, squamous cell carcinoma and pleomorphic cell carcinoma, as well as one non-tumour tissue sample (Figure 1A). FLIM images revealed consistent morphology in CAFs and tumour cells, while PBMCs displayed more varied morphology (Figure 1B-D). Phasor analysis demonstrated similar vector plots across cell types, but greater variance in fluorescence lifetime of PBMCs compared to CAFs and tumour cells. All cell types showed a bi-exponential decay curve fit, with chi-squared values within an optimal range of 0.9-1.6. Following quantification across multiple ROIs and fields of view, tumour cells displayed significantly longer fluorescent lifetimes compared to CAFs, and similarly CAFs demonstrated significantly shorter fluorescence lifetimes compared to PBMCs (p=0.0002 and 0.0124, respectively). Fluorescent lifetimes of tumour cells and PBMCs showed no significant differences (Figure 1F). Interestingly, epithelial cells derived from non-tumour organoids from a single patient demonstrated a significantly higher FLIM signal than tumour cells derived from squamous cell carcinoma and pleomorphic cell carcinoma organoids (mean 3.137ns vs 2.940ns, p=0.0002).

Conclusions: We demonstrate that primary human NSCLC displays cell-specific FLIM signals across patient samples. This forms the basis of enhancing our understanding of the constitutive makeup of FLIM signals in NSCLC. Further work will include increasing data across these cell types, subtyping immune cell populations and quantifying changes to FLIM according to targeted metabolic disruption using immunotherapeutic factors.

EP.03.17 Altered Immune Profile in Lung Cancer Patients With Pneumonitis

P.H. Feng[1],[2], K-Y. Chen[3]
[1]Taipei Medical University, Taipei/TW ,[2]Shuang Ho Hospital, New Taipei City/TW ,[3]National Taiwan University Hospital, Taipei/TW

Introduction: Certain patients receiving immunotherapy experienced various degree of immune-related adverse events (irAEs), and pneumonitis is one of the most concerned irAEs. Clinical risk factors for pneumonitis include squamous cell carcinoma, preexisting interstitial lung disease, chronic obstructive lung disease and elder patients. Other immunological biomarkers of irAEs include elevated activated CD4+ and CD8+ T cells, lower regulatory T cells (Treg) and lower myeloid derived suppressor cells (MDSCs), and result in loss of self-tolerance and active T cells targeting healthy tissues. The real-world data of comprehensive immune profile of patients with pneumonitis irAE is few and we showed the immune profile of two lung cancer patients with pneumonitis.

Methods: We prospectively collected peripheral blood from advance lung cancer patients before receiving immunotherapy. PBMC were isolated and peripheral blood immune cell, including CD4, CD8, NK, NKT and MDSCs, were analyzed by flow cytometry thoroughly.

Results: From Jan 2024 to Dec 2024, seven lung cancer patients were enrolled before receiving immunotherapy. Three patients received adjuvant immunotherapy, and others were received chemotherapy with immunotherapy as advanced lung cancer treatment. Two of seven patients had grade 2 pneumonitis, one receiving adjuvant immunotherapy and another first line chemotherapy with immunotherapy. These two patients with pneumonitis, both had higher activated CD4 and CD8 T cells (CD4+TNF-α, CD4+IFN-γ, CD8+TNF-α+, CD8+IFN-γ+) and less MDSC (CD14+S100A9+). Besides these well-known immune cells, these two patients also had higher CD8+PD-1+ T cells but similar CD4+PD-1+/CD4+TIGIT+/CD8+TIGIT+ level. After using steroid and stop immunotherapy, pneumonitis of both patients was controlled. After stopping immunotherapy, these two patients eventually had disease progression.

Conclusions: Pneumonitis, a relative uncommon but important irAE, is difficult to predict. In this report, we showed that possible biomarker candidates with activated CD4 and CD8 T cells, MDSC, and CD8+PD-1+. Further study of validation is warranted.

Keywords: irAE, pneumonitis, immunotherapy

EP.04 SCREENING AND EARLY DETECTION

EP.04.01 Current Status of Lung Cancer Screening in Latin America

L. Viola[1], E. Tuta Quintero[2], A. Cardona[3], S. Martinez-Jaramillo[3], L. Seijo-Maceiras[4], F. Suárez[5], C. Carvajal[3]
[1]Fundación Neumológica Colombiana - CTIC, Bogotá/CO ,[2]Universidad de La Sabana, Chía/CO ,[3]Centro de Tratamiento e Investigación en Cáncer Luis Carlos Sarmiento Angulo, Bogota/CO ,[4]Servicio de Neumología, Clínica Universidad de Navarra, Proyecto CASSANDRA, Madrid/ES ,[5]Sociedad Chilena de Enfermedades Respiratorias - Servicio de Cirugía, Clínica Santa María, Santiago de Chile/CL

Introduction: Lung cancer is one of the leading causes of cancer-related mortality in Latin America. The implementation of low-dose computed tomography (LDCT) screening programs has been shown to reduce mortality; however, their adoption in the region varies significantly.

Methods: A multicenter forum was organized with the participation of researchers from the included countries. Subsequently, information was updated through discussions with key opinion leaders and screening experts in countries where changes had occurred. Data were collected on centers with LDCT capabilities, diagnostic methods used, national regulations, public policies, structured reporting systems, and the existence of national screening campaigns.

Results: Brazil, Mexico, and Argentina have made the most progress in lung cancer screening, with the existence of both public and private programs. However, only Brazil has national regulations, and Mexico has an active screening campaign. Costa Rica, Colombia, Uruguay, Mexico, Argentina, and Peru use Lung-RADS for standardized reporting. Most countries lack national regulations or public policies supporting screening. Some, such as Chile, Brazil, and Argentina, have developed national consensus guidelines, while Guatemala remains in a preparatory phase. In countries like Nicaragua, Honduras, and El Salvador, screening is primarily based on chest radiography, whereas no documented initiatives exist in Venezuela.

Conclusions: Lung cancer screening in Latin America presents significant disparities. While some countries have made progress in implementing structured programs, most lack regulations and public policies. Strengthening regional cooperation and developing coordinated strategies are essential to improve early detection and reduce the burden of disease in the region.

Screening Priorities in Latin America

1. Education on implementing lung cancer screening programs in low-resource settings for pulmonologists, thoracic surgeons, and nurse navigators.
2. Training radiologists in structured reporting of low-dose chest CT scans.
3. Training leaders on quality indicators in lung cancer screening programs.

Country	Screening Availability	Diagnostic Methods	National screening regulations	Public policies	Structured LDCT reporting system	National screening campaigns
Costa Rica	1 private center	LDCT	No.	No.	LungRADS	No.
Dominican Republic	1 research center	Chest X-ray	No.	No.	No.	No.
Panama	indirect screening	LDCT	No.	No.	No.	No.
El Salvador	4 centers	LDCT	no	No.	No.	No.
Nicaragua	No – 2 private centers with capacity.	Chest X-ray	No.	No.	No.	No.
Honduras	No.	Chest X-ray	No.	No.	No.	No.
Colombia	4 centers (All private)	HR CT	No.	No.	LungRADS.	No.
Brazil	No.	Contrast CT	Yes.	Yes.	No.	No.
Uruguay	5 centers (All private)	LDCT	No.	No.	LungRADS	No.
Guatemala	Yes. Public and private system.	Spirometry	No.	Preparatory phase of a project.	No.	No.
Mexico	1 pilot project.	DLCO	No.	Yes.	LungRADS.	Yes.
Paraguay	No.	LDCT	No	No	No	No
Chile	2 public centers	LDCT	Chilean Screening Consensus.	No	No	No

EP.04.02 Fully-Automated Classification of Parenchymal Low Attenuation-Clusters as Indicators of Pulmonary Emphysema in Lung Cancer Screening

H. Liu[1,2], D. Han[2], M. Heuvelmans[2,3], M. Silva[4], J.W.C. Gratama[5], C. van der Aalst[1], H. de Koning[1], M. Oudkerk[2,6]
[1]Erasmus Medical Center, Rotterdam/NL ,[2]Institute for Diagnostic Accuracy, Groningen/NL ,[3]Amsterdam University Medical Center, Amsterdam/NL ,[4]Department of Medicine and Surgery (DiMeC),University of Parma, Parma, Italy, Parma/IT ,[5]Department of radiology and Nuclear Medicine, Gelre Hospitals Apeldoorn, Apeldoorn/NL ,[6]University of Groningen, Groningen/NL

Introduction: Emphysema, identified as a lung cancer risk factor, can be quantified on low dose CT(LDCT) in lung cancer screening(LCS) programs. Emphysema is commonly assessed by the percentage of Low Attenuation Area(LAA%), yet it lacks precise measurement of emphysema lesion size and number. Advanced LA-cluster analysis systematically distinguishes emphysema regions by size through iterative subtraction. In this study, we aim to optimize the early detection of emphysema by automatic quantification through LA-cluster analysis and compare it with LAA analysis, using a LDCT lung cancer screening dataset.

Methods: A random cohort of 352 consecutive LDCT examinations was selected from a LCS dataset. All scans were evaluated for emphysema by four readers according to the latest Fleischner criteria. Emphysema was automatically quantified by LAA analysis and LA-cluster analysis with thresholds from -940HU to -970HU. AI-based software Aview (Coreline soft, v.42) was used to automatically segment the lungs and for emphysema quantification. LA-clusters were calculated and classified by size below a set of HU thresholds. A range of cluster size from 5.0mm to 9.0mm with 0.5mm intervals were used as the cut-off value in discriminating normal/trace cases versus at least mild cases. Visual score was used as reference for comparison. Spearman's correlation coefficients assessed the correlation between the largest cluster and visual scores, as well as LAA% and visual scores.

Results: The highest agreement between cluster size and visual scores in discriminating normal/trace cases and at least mild cases was observed below -940 HU at 8.5mm, below -950 HU at 7.0m to 8.5mm, below -960 HU at 7.0mm and 7.5mm , and below -970HU at 6.0mm. The corresponding kappa values, ranging from 0.870 to 0.876, demonstrated a very good agreement. For LAA analysis, kappa values ranged from 0.497 to 0.601, indicating moderate agreement. Spearman's correlation coefficients indicated an association between cluster size and visual assessments, ranging from 0.664 to 0.674. Similarly, an association between LAA% and visual assessments was observed, with coefficients ranging from 0.522 to 0.619.

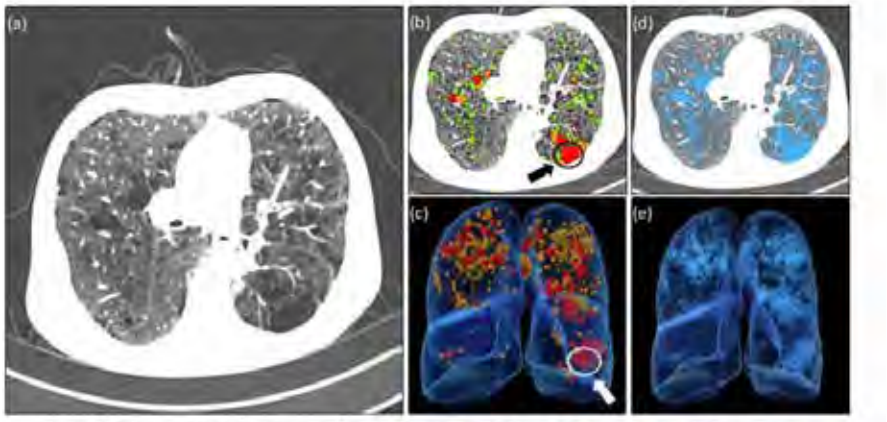

Figure 1 3D reconstructed images with axial CT and MPR views in a severe case with LA cluster analysis and LAA-analysis under -950HU. Figure 1(a) shows original MPR axial image, 1(b) shows the largest masked LA-clusters in an axial view, 1(c) shows 3D reconstructed image with LA-cluster, 1(d)shows masked LAA, and 1(e)shows 3D reconstructed image with LAA. The LA-clusters were masked in different colors based on the cluster diameters: clusters with diameters smaller than 3 mm were colored purple; those with diameters between 3 and 7 mm were colored green; clusters with diameters between 7 and 10 mm were colored orange; and clusters with diameters larger than 10 mm were colored red. The largest LA cluster is indicated by black circles and arrows in the axial images, while the same cluster in the 3D reconstructed images are highlighted with white circles and arrows. The LAA was colored in blue.

Conclusions: Optimal cluster size cut-off varied at different HU thresholds. Higher agreements between visual severity scores and fully-automated LA-cluster size compared to LAA analysis for CT-based emphysema detection suggests the application of LA-cluster analysis has more potential for early emphysema detection in LDCT lung cancer screening.

EP.04 SCREENING AND EARLY DETECTION

EP.04.03 Uptake and Impact of a Framework to Support Implementation of Low-Dose Computed Tomography (LDCT) Screening for Lung Cancer

H. Wilcox, O. Carswell, J. Hooper, E. Wheeler
The Health Policy Partnership, London/GB

Introduction: The Lung Cancer Policy Network is a global network of multidisciplinary experts from the lung cancer and oncology community. In 2023, the Network developed a framework to support the implementation of low-dose computed tomography (LDCT) screening for lung cancer. Since then, the framework and associated online toolkit have supported those involved in the planning and delivery of LDCT screening programmes around the world.

Methods: Development of the framework was informed by a review of peer-reviewed and grey literature from 2010-22, expert interviews and insights from Network members. To further refine the framework, it was applied to five countries where screening implementation is underway: Canada, Poland, South Korea, the UK and the US. To support those applying the framework, the Network has developed an online toolkit that includes policy briefs, videos and a suite of useful materials. These resources are applicable to a wide variety of contexts in recognition of the fact that, whilst not all health systems will be fully 'ready' for lung cancer screening implementation, this should not delay planning for a screening programme. Over the past year, the toolkit has been expanded to include new resources focused on engaging traditionally underserved communities, and a summary guide to support those applying the framework to their regional context. Later this year, the Network will publish case studies and reference documents to support financial planning for screening programmes.

Results: To date, the framework has been downloaded nearly 3,000 times and the toolkit has been used by almost 7,400 people. Application of the framework is already having an impact on the implementation of lung cancer screening programmes: • Initial assessment in Kazakhstan • Progress in Australia • Collaboration with the Asia Pacific Coalition Against Lung Cancer, including a webinar and workshop that used the framework to structure discussions • The launch of a policy brief on screening priorities in the Middle East and Africa that was informed by the framework and supported by a policy call for screening in the region.

Conclusions: To our knowledge, this is the first framework to support the implementation of LDCT screening programmes globally . Since the framework was developed, the Network has been delighted to witness its application to drive policy commitments and support screening implementation in a variety of settings. By expanding application of the framework to more health systems, comprehensive evidence can be generated to inform considerations for implementation and facilitate high-quality, equitable and cost-effective screening around the world.

EP.04.04 A Relative Perspective on Whether Risk-Based Lung Screening Eligibility Prioritize People With Higher Competing Mortality

X. Feng, H.A. Robbins, M. Johansson
Internation agency for research on cancer, LYON/FR

Introduction: Risk-based lung cancer screening is more efficient than categorical eligibility criteria, but concerns have been raised that risk models prioritize individuals with high competing mortality and lower screening benefit. We addressed this question by evaluating the ratio between competing causes of death and lung cancer death as a function of lung cancer risk.

Methods: We analyzed 53,152 participants from the National Lung Screening Trial (NLST) and 400,935 individuals aged 50-80 with a smoking history from 3 cohorts in the Lung Cancer Cohort Consortium (LC3). Within categories of 6-year lung cancer risk by the PLCOm2012 model, we calculated the ratio of other-cause deaths to lung cancer deaths.

Results: Among NLST participants, both lung cancer and other-cause mortality increased with increasing lung cancer risk. The ratio of other-cause to lung cancer deaths was inversely correlated with lung cancer risk (Pearson ρ=-0.55 [95%CI -0.68, -0.38], Figure 1A). The ratios across risk quintiles (lowest to highest) were 5.8, 4.5, 3.1, 2.6, and 2.3. In LC3, the ratio was also inversely correlated with lung cancer risk (Pearson ρ=-0.84 [95%CI 0.89, 0.76], Figure 1B).

Conclusions: We confirm that other-cause mortality increases among people with higher lung cancer risk. However, the ratio between competing and lung cancer death decreases with lung cancer risk. This is in line with the hypothesis that individuals at high lung cancer risk are more likely to benefit from screening, including when considering their risk of death from competing causes. We will extend this analysis to all cohorts from LC3.

EP.04 SCREENING AND EARLY DETECTION

EP.04.05 Lung Cancer Diagnosis Among Screening Participants in the Multi-Health-System Philadelphia Lung Cancer Learning Community

J. Barta[1], C. Shusted[1], C. Saia[2], J. Wainwright[2], C. Erkmen[3], R. Myers[1], R. Wender[2], A. Vachani[2], K. Rendle[2]
[1]Thomas Jefferson University, Philadelphia/PA/USA ,[2]University of Pennsylvania, Philadelphia/PA/USA ,[3]Temple University, Philadelphia/PA/USA

Introduction: Uptake of lung cancer screening (LCS) is reported to be 18-20% among eligible individuals but varies at the national level, state level, and by other geographic measures. Our group has previously demonstrated the feasibility of a citywide, multi-health-system analysis of LCS through a novel research collaboration, the Philadelphia Lung Cancer Learning Community (PLC2). The objective of this follow-up analysis is to examine lung cancer diagnosis among individuals receiving LCS in Philadelphia.

Methods: Individuals eligible for LCS by USPSTF 2021 criteria and who received a low-dose CT (LDCT) chest scan between January 1, 2014 and December 31, 2023 were identified at two PLC2 healthcare systems. The analysis was restricted to Philadelphia residents by geocoding street addresses obtained from the electronic health record (EHR) using ArcGIS. At Jefferson Health patient data were extracted from the prospectively accruing Jefferson LCS Registry, a data repository that includes USPSTF-eligible individuals receiving centralized LCS at multiple health system locations. At Penn Medicine patient data, from the hybrid LCS Program were identified and extracted retrospectively from the EHR using LCS-specific Current Procedural Terminology or Healthcare Common Procedure Coding System codes (71271 or G0297, respectively). At both sites, the first completed LCS was categorized as the baseline LDCT for each screened patient, and baseline characteristics were extracted before or on the baseline LCS date. Background characteristics and lung cancer diagnoses were aggregated among PLC2 sites for descriptive statistical analysis.

Results: During the 10-year study period 10,418 USPSTF 2021-eligible individuals residing in Philadelphia completed LCS, and more than half (54.8%) of baseline LDCTs were completed in 2021, 2022, or 2023. The study cohort was comprised of 52.6% women, as well as 62.8% Non-Hispanic Whites, 25.3% Non-Hispanic Blacks, 3.2% Hispanics, and 4.1% Multiple/Other race and ethnicity. More than half of screened individuals (60.4%) reported a current smoking status, and 87.9% had a smoking history of at least 30 pack-years. The prevalence of additional lung cancer risk factors including diagnosis of chronic obstructive pulmonary disease (31.0%), personal history of cancer (9.0%), and family history of lung cancer (15.5%) was also ascertained. Despite significant differences in prevalence and distribution of lung cancer risk factors among participants at each study site, there was no difference in cancer detection rate between sites (3.5% vs. 3.6%, p=0.75). All individuals were classified by USPSTF-2013 and -2021 eligibility and were assigned a 6-year lung cancer risk using the Prostate, Lung, Colorectal, and Ovarian (PLCOm2012) risk model. All 10,418 individuals were geocoded to one of 374 residential census tracts in Philadelphia.

Conclusions: LCS at PLC2 institutions in Philadelphia can be systematically characterized using a common data model among multiple health systems to examine individual- and neighborhood-level factors. Ascertainment of lung cancer risk and lung cancer diagnosis can help to identify areas for future research and implementation of strategies to guide lung cancer prevention and control across the city.

EP.04 SCREENING AND EARLY DETECTION

EP.04.06 Health Beliefs and Adherence to Lung Cancer Screening in a Diverse, Real-World Population

S. Bhalla[1,2], H.A. Hamann[3], T. Prasad[1], M.A. Mullins[1], S.T. Malone[1], J. Rodriguez[1], M.E. Gwin[1], V. Natchimuthu[2], R.G. Nair[1], L.N. Ibekwe-Agunanna[1], S.J. Craddock Lee[4], D.H. Johnson[1], U. Wahid[1], A. Gao[1], S. Zhang[1], D.E. Gerber[1]
[1]University of Texas Southwestern Medical Center, Dallas/TX/USA ,[2]Parkland Health, Dallas/TX/USA ,[3]University of Arizona, Tucson/AZ/USA ,[4]University of Kansas Medical Center, Kansas City/KS/USA

Introduction: Lung cancer screening (LCS) with low-dose CT (LDCT) remains markedly underutilized. Prior studies suggest that perceptions and attitudes regarding LCS may influence intention to undergo LDCT; however, little is known about these beliefs affect real-world LDCT adherence, especially among vulnerable populations. We examined LCS-related health beliefs and LDCT completion in an urban safety-net healthcare system (Parkland Health, Dallas, Texas).

Methods: English- and Spanish-speaking patients eligible for LCS based on 2013 United States Preventative Services Task Force criteria for whom LDCT had been ordered (but not yet performed) were invited to participate in a survey assessing demographic information, smoking history, and perceptions of lung cancer risk and lung cancer screening. Survey items were adapted from validated measures, including the Lung Cancer Screening Health Belief Scales and the Lerman Breast Cancer Worry Scales, to assess LCS-related beliefs (i.e., perceived risk, benefits, barriers, and self-efficacy) and worry about lung cancer. We evaluated the association between these parameters and LDCT completion using the two-sample T test and Chi-square test.

Results: Among 447 eligible individuals, 411 participated in the survey (including 71% from racial/ethnic minoritized groups), of whom 339 (82%) completed the initial LDCT. Almost half believed that they were at risk for lung cancer in their lifetime, and over 90% believed that LCS would help find lung cancer early. Higher self-efficacy scores and lower perceived barriers scores were associated with LDCT completion (P=0.002 and P=0.004, respectively; Figure 1). Perceived risk and benefit scores were not associated with LDCT completion. Individuals who did not complete the first LDCT were more likely to note fear of lung cancer (33% vs. 17%; P=0.008), stigma related to lung cancer (33% vs. 18%; P<0.001), and worry affecting mood (82% vs. 67%; P=0.02).

Conclusions: In a diverse, real-world lung cancer screening population, most patients believed that LCS helps find lung cancer early, yet approximately 20% of patients did not complete the initial LDCT. Perceived fear, stigma, and worry affecting mood were associated with reduced LDCT completion. These findings offer insight into potentially modifiable factors and future interventions to improve LCS uptake among eligible individuals.

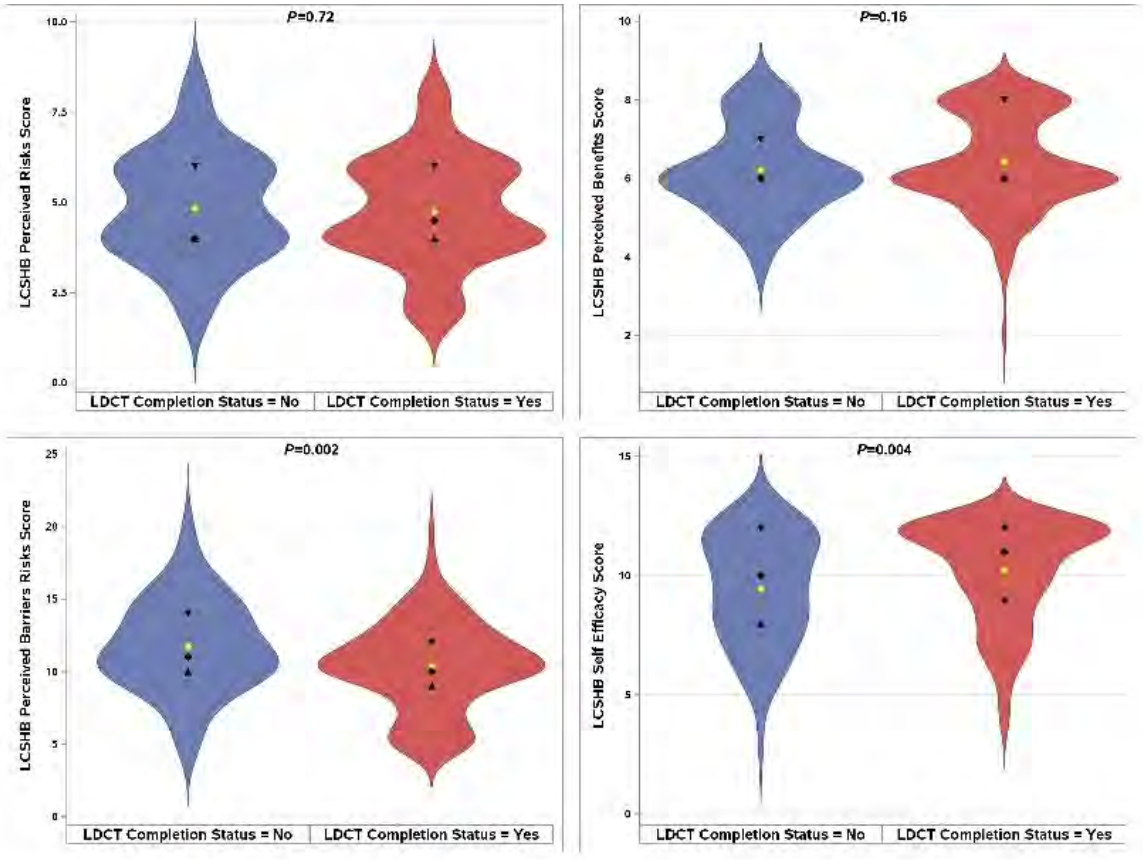

Figure 1: Distribution of Lung Cancer Screening Health Belief (LCSHB) Scale scores based on low-dose CT scan completion status among survey respondents. Violin plots reveal mean (yellow diamond), median (black diamond), and interquartile range (triangles)

EP.04 SCREENING AND EARLY DETECTION

EP.04.07 Participant and Provider Experiences in an Indigenous Focused Trial of Lung Cancer Screening in Aotearoa New Zealan

K. Parker[1], K. Bartholomew[1], T. Schaapveld[1], G. Adams[1], A. Fraser[1], D. Enoka[1], P. Sandiford[1], C. Lewis[1], D. Milne[1], R. McKree Jansen[2], K. Fong[3], H. Marshall[3], M. Tammemägi[4], N. Rankin[5], S. Crengle[6]
[1]Te Whatu Ora, Auckland/NZ ,[2]Tend Health Ltd, Auckland/NZ ,[3]The Prince Charles Hospital and University of Queensland, Queensland/AU ,[4]Brock University, St Catherines/ON/CA ,[5]University of Melbourne Melbourne School of Population and Global Health, Melbourne/AU ,[6]University of Otago, Dunedin/NZ

Introduction: We examined the views of participants, their whānau (family / support people), and primary care staff in a lung cancer screening study that compared primary care versus central hub invitations for Māori individuals aged 55-74 in the Auckland and Waitemata districts of Aotearoa, New Zealand. Our study aimed to explore the acceptability of the screening process, participant burden, and experiences at various stages of the programme.

Methods: Surveys were administered to all participants who completed a risk assessment, including those not eligible for a CT scan (n=467), those who were eligible and underwent a CT scan (n=505), and those who declined a CT scan (n=40). Interviews were conducted with a selected group of participants who underwent a CT scan (n=25). Additionally, surveys were provided to whānau members who accompanied participants to the CT scan and to staff at primary care clinics involved in the study. Data collection was carried out through a mix of online, in-person, phone, or mailed surveys, while interviews with selected participants were conducted over the phone. Quantitative data were analysed using descriptive statistics and inferential analysis (chi-square tests), while interviews and open-ended survey responses were analysed thematically.

Results: Of those who completed the risk assessment but were not eligible for a CT scan, 32% (n=149) completed a survey. Participants expressed overwhelmingly positive experiences regarding the study and the information provided. Reactions to eligibility varied, with some participants feeling relieved and pleased that their risk level was too low to require a CT scan, while others were surprised or anxious. For those who were eligible and completed a CT scan, there was a 50% response rate (n=253). These participants were largely satisfied with the process and would recommend it to others. A minor concern raised (by a small number of participants) was the waiting time for results. Sixteen whānau members completed a survey and reported feeling welcomed and valued throughout the process. For the participants who declined a CT scan, the response rate was only 10%. Reasons for decline included low perceived risk, anxiety, and concerns about transport. Fifteen clinic staff from participating practices also completed a survey, expressing overall satisfaction with being involved in the study and increased knowledge, though some noted that the study was more time-consuming than anticipated.

Conclusions: The lung cancer screening programme was generally well-received by participants, whānau, and providers, with high satisfaction regarding the information and support provided throughout the process. While most participants were satisfied with the screening process, some concerns were raised, particularly regarding waiting times for results. Overall, the programme was viewed positively, with a high level of acceptance and a willingness to recommend participation to others.

EP.04 SCREENING AND EARLY DETECTION

EP.04.08 Building Policy Recommendations Using an Implementation Framework for Low-Dose Computed Tomography Screening

S. Limaye[1], H. Loong[2], H. Horinouchi[3], G. Lai[4], D. Tan Shao Weng[4], Y.W. Kim[5], H. Wilcox[6], O. Carswell[6], E. Wheeler[6], P.K. Panda[4]
[1]Sir H. N. Reliance Foundation Hospital & Research Centre, Mumbai/IN ,[2]The Chinese University of Hong Kong Hong Kong, Hong Kong/HK ,[3]National Cancer Center Hospital, Tokyo/JP ,[4]National Cancer Centre Singapore, Singapore/SG ,[5]Seoul National University Bundang Hospital, Seoul/KR ,[6]The Health Policy Partnership, London/GB

Introduction: Lung cancer screening can reduce mortality by up to 25%, and it shifts diagnosis to an earlier stage, where lung cancer is more treatable and thus more survivable. However, many countries face challenges to implementation. In 2023, the Lung Cancer Policy Network developed a framework to support the implementation of low-dose computed tomography screening. An online toolkit was also created to assist in applying the framework. Using this framework, the Network and the Asia Pacific Coalition Against Lung Cancer held a collaborative workshop in October 2024. The workshop, part of the Asia Conference on Lung Cancer, brought together stakeholders including clinicians, screening leads and implementation researchers to develop a set of tailored policy recommendations for implementing screening in the Asia-Pacific region.

Methods: The workshop followed a webinar that showcased screening activities in the region and featured case studies from Australia, India, Singapore and South Korea. Registrants for the webinar indicated the key challenges they faced in implementing lung cancer screening, and the four most popular responses were selected for discussion at the workshop. Throughout the workshop, the Network's framework was used as a tool to discuss how to facilitate and optimise the implementation of lung cancer screening.

Results: The workshop brought together more than 40 delegates from over 10 countries. The discussion topics were: • Building awareness of screening and its benefits • Making lung cancer a policy priority • Gaining financial investment for lung cancer screening • Optimising workforce capacity for screening. In each group, delegates discussed challenges and actionable solutions, leading to the development of overarching policy recommendations.

Conclusions: The use of the implementation framework in a workshop format led to the development of tailored policy recommendations. The framework is a globally applicable tool, so this approach can be replicated to highlight the key challenges to implementation and develop tailored local and regional recommendations to meet these challenges.

EP.04 SCREENING AND EARLY DETECTION

EP.04.10 Evaluating Primary Care Practice's LCS Smoking History Accuracy for Maori Patients - Implications for a Future Lung Cancer Screening Programme

T. Schaapveld[1], S. Stevenson[2], K. Parker[1], K. Bartholomew[1], P. Sandiford[1], M. McLeod[3], S. Crengle[4]
[1]Te Whatu Ora, Auckland/NZ ,[2]Nil currently, Christchurch/NZ ,[3]University of Otago, Wellington/NZ ,[4]University of Otago, Dunedin/NZ

Introduction: Lung cancer is a common cause of cancer death for Māori (Indigenous) and non-Māori, with significant ethnic inequities in incidence and mortality in Aotearoa New Zealand. Lung cancer is the single largest contributor to the difference in life expectancy between Māori and non-Māori, hence, a key issue is developing a screening strategy that will ensure benefit for Māori. Accurate smoking history is essential for identifying individuals eligible for lung cancer screening. We evaluated records in primary care settings to determine the extent of misclassification of smokers and former smokers as 'never smoker'. This work was conducted as part of a broader lung cancer screening research programme in the Waitematā and Auckland districts of Aotearoa, New Zealand.

Methods: 1033 Māori participants from participating clinics with a recorded status of 'never smoker' were identified. Of these, 79 were excluded as they were ineligible to take part in lung cancer screening, 122 declined to participate, and 261 were uncontactable after three attempts. The remaining 571 participants agreed to complete a verification audit via a phone call. Those who reported a history of smoking were invited to participate in the lung cancer screening study.

Results: Of the 571 verification participants, 476 (83.4%) were confirmed as never smokers, 90 (15.8%) were ex-smokers, and 5 (0.9%) were current smokers. A total of 49 participants (60% of current smokers and 51% of ex-smokers) agreed to participate in the lung cancer screening study and proceeded to a lung cancer screening risk assessment. Twelve (12.6%) of these participants (11 ex-smokers and 1 current smoker) were eligible for a CT scan, with 11 completing the scan. Of those that completed the scan, ten had no significant nodules (PC1) and one participant had a low-risk nodule (PC2) (Figure 1).

Conclusions: This study continues our work as part of the first organised programme for Lung Cancer Screening. Our findings highlight inaccuracies in primary care smoking records, with 16.7% of individuals recorded as never smokers self-reporting a history of smoking. Misclassification led to missed screening opportunities for some of the misclassified in this group. Addressing this misclassification is important as a future screening programme will rely on primary care smoking records to ascertain eligibility for screening.

EP.04 SCREENING AND EARLY DETECTION

EP.04.11 Feasibility of AI-Assisted Mobile Low-Dose CT Screening in Underserved Communities in China

W. Chen
Fujian Medical University Cancer Hospital, Fuzhou/CN

Introduction: Low-dose computed tomography (LDCT) has been shown to enhance early lung cancer detection rate and reduce associated mortality by 20%. Despite the recommendations of lung cancer screening (LCS) guidelines and the evidence supporting the effectiveness of population-based LDCT screening, many significant screening barriers remain. There are limited data from clinical practice regarding whether community-based mobile LDCT screening is associated with reduced lung-cancer mortality in China. This study aims to evaluate whether community-based mobile LDCT screening program is associated with improved prognosis among adults with lung cancer in mainland China and examines the operational challenges encountered during implementation.

Methods: This study was carried out in rural area in Fujian Province, China, between July 2022 and December 2024. This study included participants comprised socioeconomically disadvantaged individuals aged ≥40 years without prior LDCT exposure. Participants underwent LDCT screening conducted by a multidisciplinary research team. With the aid of the AI-based "InferRead CT Lung Research" system, physicians conducted radiological interpretations and finalized standardized diagnostic reports. The primary efficacy endpoints were lung cancer detection and diagnosis rates. The operational challenges encountered during implementation were collected by think-aloud method.

Results: A total of 13,018 individuals (mean [SD] baseline age, 59.3 [3.8] years; 6768 [51.99%] female) participated in this study. The detection rates of suspected lung cancer cases and confirmed cases were 1.35% (n = 176) and 0.7% (n = 86), respectively. Despite the effectiveness of the lung cancer screening program, several operational challenges were identified, including securing independent and stable funding, insufficient human resources, insufficient of the project's publicity, unstandardized resident health records and unability to providing logistics and sourcing services.

Conclusions: This AI-assisted LDCT model for lung cancer screening demonstrates significant potential to reduce healthcare disparities in underserved regions and could be extended to broader populations in similar low-resource settings.

Introduction: Lung cancer remains a major challenge in oncology, characterized by its increasing incidence and high mortality rate. Despite diagnostic advances and novel therapeutic strategies, the importance of early detection and prediction of lung cancer is still decisive. To evaluate significance and the role of screening chest CT, Lung RADs category 4 group was analyzed and matching with follow ups.

Methods: For recent 13 months, we reviewed the medical record and chest CT scans of whom received lung cancer screening low dose CT scans, Total 2,175 (male 1,798, female 377) were included, The distribution of category was 1(785) 2(1,191) 3(65) 4A(89), 4B(50), 4X(5).

Results: Total 145 patients were included. Age was ranging from 55 to 79 years old, the radio of M;F was 134:11. The evaluation by follow up CT scan result was 76(stable) 37(resolved) 11(benign(inflammation), 9(malignancy), 12(loss of follow up). The character of nodule is solid(129), part solid (15) and GGN(1). The location of nodules was RUL(48), LUL(35) RLL(28), RML(17), LLL(15), endobronchial(2). Histopathology were adeno(5) squamous(2), small cell(1), adenosqamous(1). The associated significant findings were ILA(47), emphysema(24), coronary calcification (67 mild-41, moderate-18, severe-9) were shown. Previous tuberculosis infection was shown in 89/145 and active pulmonary tuberculosis was shown in 7. Among C3 lesions, lung cancer diagnosis for two more follow up was 9/155(5.8%).

Conclusions: In conclusion, the rate of lung cancer in C4 was 9/145, (6.2%), 4A(3), 4B(5), 4X(1) each. The fuzzy margin with banishing perilesional GGO has the transient lesion especially 4A nodule. The density and size determinant require additional variable such as the shape of nodule.

Tab. 1 The Distribution of Category

	No		%
1	785		36.1
2	1091	(2b 36)	50.2
3	155		7.1
4A	89		4.1
4B	50		2.3
4x	5		0.2
	2175		100

EP.04 SCREENING AND EARLY DETECTION

EP.04.13 Emphysema on Baseline CT Predicts Copd and Cardiovascular Death After 25 Years in Lung Cancer Screening

J. González[1,2], R. Yip[3], J.J. Zulueta[4], S.M. Aguayo[5], D.M. Libby[6], M.W. Pasmantier[6], D.F. Yankelevitz[3], C.I. Henschke[3,5]
[1]Translational Research in Respiratory Medicine, IRBLleida, Arnau de Vilanova and Santa Maria University Hospital, Lleida/ES ,[2]CIBER for Respiratory Diseases (CIBERES), Carlos III Health Institute, Madrid/ES ,[3]Department of diagnostic, molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York [10029]/NY/USA ,[4]Division of Pulmonary Medicine, Department of Medicine, Morningside Hospital, Mount Sinai, New York/NY/USA ,[5]Departments of Medicine, Radiology, and Research, Phoenix Veterans Affairs Health Care System, Phoenix [85012]/AZ/USA ,[6]Department of Medicine, Weill Medical College of Cornell University, New York [10021]/NY/USA

Introduction: The usefulness of assessing baseline visual emphysema in lung cancer screening (LCS) cohorts is unknown. Purpose: To determine whether assessment of emphysema on low-dose chest CT (LDCT) is a predictor of death up to 25 years later from all-causes, chronic obstructive pulmonary disease (COPD), and cardiovascular (CVD).

Methods: Prospective cohort of smokers aged 40-85 years underwent baseline LDCT screening for LC between June 2000 and December 2008 and were followed until December 31, 2024.Visual emphysema was classified as none(0), mild(1), moderate(2), or severe(3). Self-reported smoking history and comorbidities were documented at baseline. Date and cause of death (ICD-10) were obtained from the National Death Index, physicians, and family. Adjusted Cox proportional hazards regression models and Fine-Gray subdistribution hazard model analyzed emphysema and mortality outcomes.

Results: Among 9047 participants (51.2%women, 48.8%men; median age:65 years[IQR:61-69]; median pack-years: 43[IQR:28-64]), 2637(29.1%) had emphysema. It was mild(1908;21.1%), moderate(512;5.7%), and severe(217;2.4%). After adjusting for sex, age, pack-years, and years since quitting, emphysema remained a significant predictor of all-cause mortality (HR1.29;95%CI,1.21-1.38), COPD mortality (HR3.28;95%CI,2.58-4.17), and CVD mortality(HR1.14;95%CI,1.01-1.30). A dose-response relationship was observed between emphysema severity and both all-cause and COPD mortality, but not CVD mortality, with greater emphysema severity associated with higher risk. Adjusted Fine-Gray subdistribution hazard model, which accounts for competing risks, the association between emphysema and COPD mortality remained significant but was attenuated(HR3.01; 95%CI,2.36-3.84), while the association with CVD mortality was no longer significant (HR1.02;95%CI,0.89-1.16).

Conclusions: Baseline emphysema on LDCT in asymptomatic participants of a LCS cohort predicts all-cause, COPD, and CVD mortality up to 25 years later, underscoring the importance of emphysema diagnosis in comprehensive LCS programs.

Introduction: Lung cancer (LC) screening facilitates early detection, and leads to the diagnosis of other smoking-related conditions.

Methods: Descriptive study of the lung LC screening program initiated in May 2023 in Lleida, following the protocol of the International Early Lung Cancer Action Program (I-ELCAP). Includes smokers or former smokers of ≤15 years, with an exposure of ≥20 pack-years and aged 50-80. Participants undergo low-dose chest CT scans, pulmonary function tests, alpha-1 antitrypsin deficiency (AATD) screening and blood tests.

Results: A total of 276 subjects were evaluated, primarily men (63%) and former smokers (53.1%) with COPD (41.3%). Spirometry values were generally preserved (FEV1: 85% and FVC: 91% on average), however, 100(36.6%) exhibited an FEV1/FVC ratio <70%, 121(45%) had abnormalities in DLCO, and 202(76.2%)exhibited higher RV. Radiological emphysema was diagnosed in 128(46.4%) and AATD-related mutations were detected in 60 participants (23%). Eleven cases of LC (4%) were identified; ten (90.9%) were in stage I and one (9.1%) in stage IV. Six patients underwent surgery, three received radiotherapy, one chemotherapy and immunotherapy, and one refused treatment. Cases eligible for anatomopathological confirmation showed six adenocarcinomas and three squamous cell carcinomas.

Conclusions: Our LC screening pilot has proven effective in early LC detection and in potentially identifying other smoking-related diseases.

EP.04 SCREENING AND EARLY DETECTION

EP.04.15 Determinants of Lung Cancer Screening Intention Among Adults Eligible for Lung Cancer Screening

H. Poghosyan[1], S. Sarkar[1], M. Zaidi[2]
[1]Yale University, Orange/CT/USA ,[2]University of Massachusetts Lowell, Lowell/MA/USA

Introduction: Lung cancer screening (LCS) with low-dose computed tomography is a proven effective approach to reducing lung cancer mortality. Yet, this life-saving screening is underutilized. To participate in LCS, an individual must first have the intention and then take appropriate actions. Yet, little is known about the LCS intention among high-risk individuals. This study investigated LCS awareness and intention and identified individual-level determinants associated with LCS intention among screening-eligible adults who never had LCS.

Methods: From December 2023 to February 2024, we conducted a cross-sectional online survey using the Qualtrics Research Panel to recruit individuals eligible for LCS—those aged 50-80 years old without a history of lung cancer who currently use cigarettes or had quit within the past 15 years with ≥20 pack-years tobacco exposure history. This study included LCS-eligible adults who never had LCS (n=521). The self-reported survey assessed participant socio-demographics, health-risk behaviors, cancer beliefs, chronic health conditions, and awareness, use, and intention of LCS guided by the LCS participation conceptual model. The outcome variable was the self-reported intention to undergo LCS within the next 3 months if recommended by healthcare providers. We conducted descriptive statistics and multivariable logistic regression.

Results: Most participants were female (63.3%), White (83.7%), insured (91.0%) with a mean age of 60.5 (SD 7.3) years, and the majority had an annual household income of ≤$34,000 (52.6%). Most participants reported current cigarette use (83.4%). The mean cigarette-pack years of use was 38.2 (SD 15.9) and ranged from 20-120 smoking-pack years. Approximately 9.0% had a history of skin and other than lung cancer history, 19.4% reported having first-degree and 23.8% second-degree family history of lung cancer. Close to half of the participants, 43.7%, had heard about LCS, yet 93.5% reported that their healthcare provider had not discussed having LCS in the past year. About one-third (33.4%) reported intention to undergo LCS within the next 3 months if recommended by healthcare providers. In terms of cancer beliefs, 76.0% believe everything causes cancer, 27.2% believe there is little that can be done to reduce cancer risk, 75.0% agree that multiple cancer prevention recommendations are confusing, and 67.4% automatically associate cancer with death. In the regression model, participants who attended some college, retired, self-identify as Black, have a healthcare provider whom they usually visit, have a second-degree family history of lung cancer, and believe that there are too many recommendations about preventing cancer were more likely to report an intention to undergo LCS within the next 3 months if recommended compared to their counterparts.

Conclusions: Our study results showed that many LCS-eligible adults are unaware of LCS, but they are willing to undergo LCS if recommended by providers. However, most participants have not discussed LCS with their providers in the past year, indicating critical gaps in shared decision-making between the patient and the provider to discuss the benefits and risks of LCS. Effective interventions are needed to improve LCS awareness and shared decision-making in clinical settings, which will lead to patient-centered, informed decision-making in LCS and, ultimately, increase LCS uptake.

EP.04.16 Piloting Lung Cancer Screening: Tumor Detection Rate, Psychological Distress and Incidental Findings

K. Chiffi, R. Werner, E. Sostero, S. Erne, V. Englmaier, L. Jungblut, T. Frauenfelder, I. Opitz, S. Hillinger
University Hospital Zurich, Zurich/CH

Introduction: Lung cancer constitutes the leading cause of cancer-related deaths in Switzerland. Since 2019, a pilot study evaluating the feasibility and efficacy of low-dose CT lung cancer screening (LCS) program in Switzerland is ongoing. This analysis summarizes the findings and obstacles of a screening program.

Methods: 307 participants (178 males, median age: 62 years) smokers (200 active) or ex-smokers were included in the lung cancer screening consisting of an interview and a low-dose CT. In a subset of 140 participants (62 females) psychological distress was assessed using a visual analog scale (Range: 0-10). Furthermore, to assess coronary artery calcification (CAC) as incidental finding, the SHEMESH score was utilized. Imaging was scored by two experienced radiologists using a score ranging from 0 to 12.

Results: 11 cancers have been detected (3.58%), 9 lung cancers (2.93%) in stage AIS (1), stage I (3), stage IIIA (3, all incidental N2), stage IV (2), 1 thymoma, 1 thyroid cancer. Most of the participants experienced only minor psychological distress, however some instances of significant stress were reported (Figure 1A). There was a trend for higher reports of psychological distress in females compared to males ($p = 0.053$). 22.8% participants had a SHEMESH score between 4 and 12 (Figure 1B), of which 28.6% (20 participants) described symptoms potentially indicating CAC. Participants with a SHEMESH scores above 4 were advised to consult a specialist.

Conclusions: Employing low-dose CT scans as a screening modality led not only to detection of multiple malignancies; it was also seen that careful consideration of incidental finding and their implication is important within screening programs. Overall, only minimal psychological distress was reported.

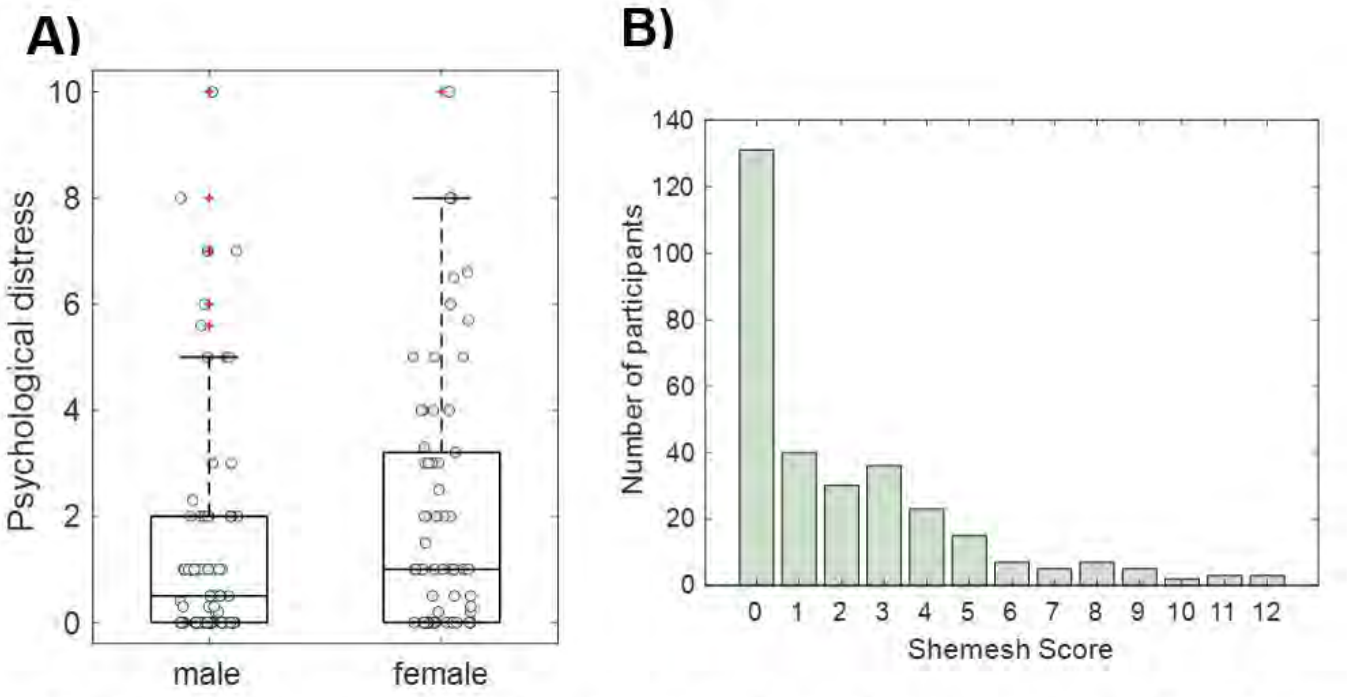

Figure 1: A: Psychological distress reports using a visual analogue scale in males and females, **B**: Number of participants per SHEMESH score

EP.04 SCREENING AND EARLY DETECTION

EP.04.17 Radiomics Predicts IASLC Grades of Invasive Pulmonary Adenocarcinoma by Distinguishing High-Grade Patterns and Predominant Subtypes

S. Zheng[1], J. Liu[1], J. Xie[1], W. Zhang[2], K. Bian[1], J. Liang[1], J. Wang[3], Z. Ye[1], D. Yue[1], X. Cui[1]
[1]Tianjin Medical University Cancer Institute and Hospital, Tianjin/CN ,[2]The Second Hospital of Shanxi Medical University, Taiyuan/CN ,[3]Tianjin University of Traditional Chinese Medicine, Tianjin/CN

Introduction: Accurate grading of invasive adenocarcinoma (ADC) according to the IASLC system is crucial for prognosis assessment and treatment planning. In the IASLC grading system, it incorporates both high-grade patterns and predominant ADC subtypes for grade classification. This study aimed to construct a radiomics model for IASLC grading by differentiating high-grade patterns and predominant subtypes.

Methods: We retrospectively collected 529 ADC cases from patients who underwent radical surgical resection. The dataset was randomly split into training and validation cohorts at a 7:3 ratio, and radiomics features were extracted from annotated CT images. A radiomics model was developed, comprising two submodels tailored for IASLC grading. One submodel identified whether high-grade patterns exceeded 20% within an ADC, while the other distinguished between lepidic and acinar/papillary predominant subtypes. The final IASLC grade was determined by integrating predictions from both submodels. Feature selection was performed using the minimum redundancy maximum relevance method and the least absolute shrinkage and selection operator. Logistic regression was applied for submodel construction, and model performance was evaluated using the area under the curve (AUC). Decision curve analysis was performed to assess clinical applicability.

Results: The radiomics submodel predicting high-grade patterns achieved AUCs of 0.95 and 0.96 in the training and validation sets, respectively, while the submodel distinguishing predominant subtypes attained AUCs of 0.83 and 0.78. By combining results of both submodels, the overall radiomics model achieved AUCs of 0.95, 0.85, and 0.96 for IASLC grades 1, 2, and 3 in the validation dataset. Decision curves showed the potential of the mdoel for clinical implementation.

Conclusions: Radiomics enables accurate IASLC grading of ADCs by differentiating high-grade patterns and predominant subtypes. The proposed radiomics model may provide precise preoperative diagnosis, potentially enhancing treatment planning.

EP.04 SCREENING AND EARLY DETECTION

EP.04.18 Preoperative Prediction of Grade 3 Invasive Non-Mucinous Adenocarcinoma Using Semiconductor 18F-FDG-PET/CT: A Diagnostic Accuracy Study

H. Notsuda[1], Y. Suzuki[2], S. Kumata[2], K. Onodera[2], C. Inoue[3], J. Tominaga[4], K. Takanami[4], Y. Okada[2]
[1]Institute of Development, Aging, and Cancer, Tohoku University, Sendai/JP ,[2]Institute of Development, Aging and Cancer, Tohoku University, Sendai/JP ,[3]Tohoku University Graduate School of Medicine, Sendai/JP ,[4]Tohoku University Hospital, Sendai/J

Introduction: Invasive non-mucinous adenocarcinoma (INMA) is a major subtype of non-small cell lung cancer (NSCLC). A three-tier pathological grading system of INMA has been introduced by the 2021 WHO classification and patients with Grade 3 INMA are known to have a poor prognosis after resection. Accurate preoperative prediction of grade 3 INMA may offer optimal treatment strategies. Conventional imaging methods, such as CT and conventional ^{18}F-FDG-PET/CT (cPET/CT), may be useful for this but the diagnostic ability seems limited. Semiconductor ^{18}F-FDG-PET/CT (sPET/CT) recently emerged as a tool to offer a higher spatial resolution and may improve diagnostic accuracy to predict grade 3 INMA.

Methods: We retrospectively reviewed 550 INMA patients who underwent surgical resection at Tohoku University Hospital between 2010 and 2022. Patients were divided into two cohorts based on the PET which they preoperatively underwent: cPET/CT (n=328) and sPET/CT (n=222). The resected INMA was pathologically classified according to WHO 2021 criteria. Diagnostic performance for predicting grade 3 INMA was assessed via receiver operating characteristic (ROC) curve analysis. Survival analyses were performed using Kaplan-Meier methods.

Results: n the cPET/CT cohort, the sensitivity and specificity for predicting grade 3 tumors were 84% and 59%, respectively, with an area under the curve (AUC) of 0.769. In contrast, sPET/CT showed improved diagnostic performance with a sensitivity of 74.5%, a specificity of 78.4%, and an AUC of 0.811, using a SUVmax cutoff of 6.8. The superiority of sPET/CT was especially notable in clinical stage II or higher, or smaller tumors (≤2 cm).

Conclusions: sPET/CT is a valuable non-invasive modality for the preoperative identification of grade 3 INMAs, offering superior diagnostic accuracy compared to cPET/CT. Its use may enhance treatment planning, including decisions regarding neoadjuvant therapy or the types of lung resection procedures, thereby contributing to improved personalized care in NSCLC.

This abstract was prepared with the assistance of ChatGPT, a language model developed by OpenAI, used for language refinement and formatting.

EP.04 SCREENING AND EARLY DETECTION

EP.04.19 Radiologic Characteristicsof Solitary Pulmonary Capillary Hemangioma

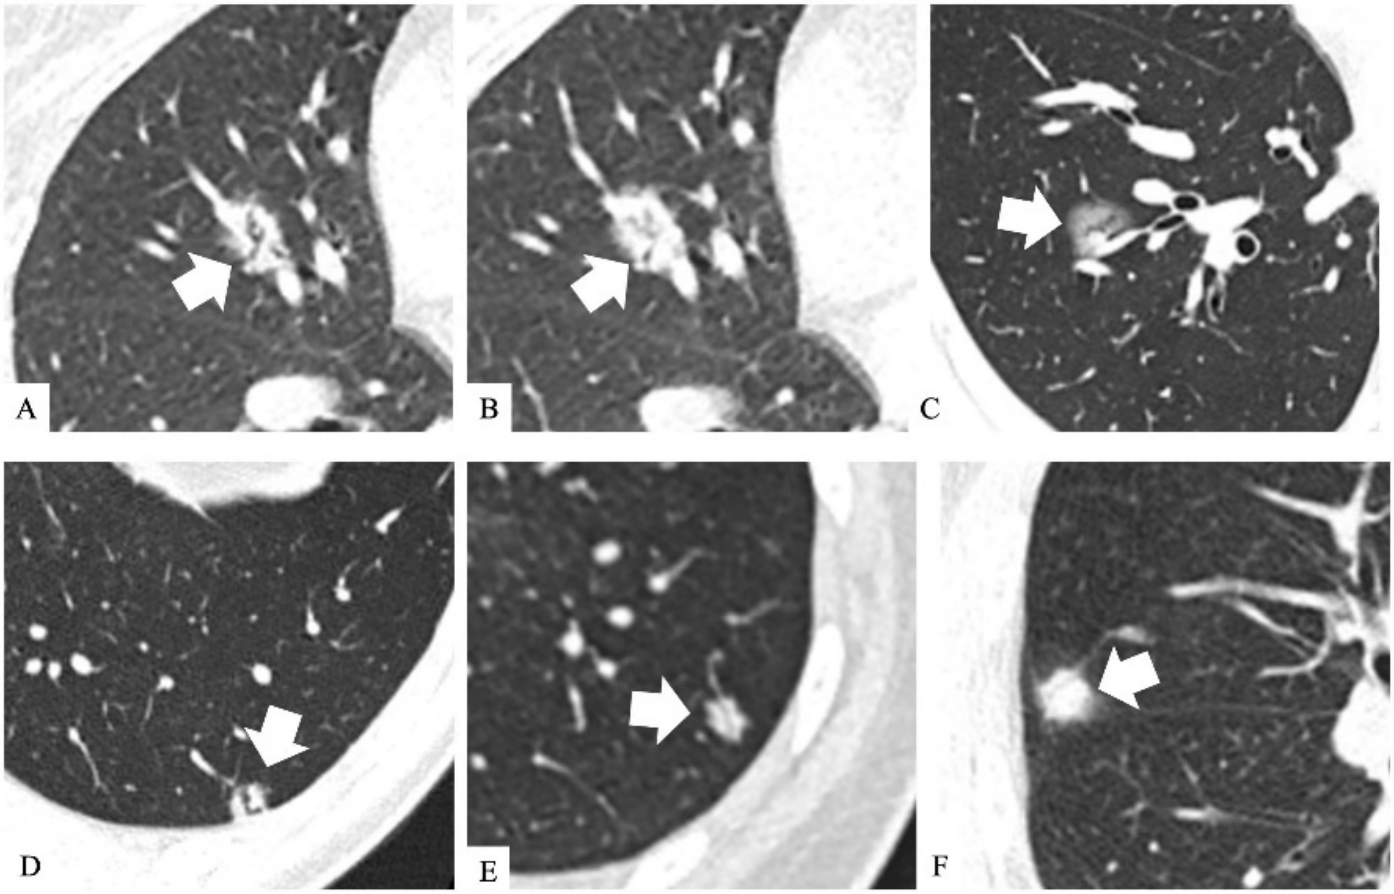
Y. Zhu, Q. Wan, X. Li, Z. Sun
The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Solitary pulmonary capillary hemangioma (SPCH) is a rare benign disease that is often radiologically underrecognized and may mimic malignant nodules such as lung adenocarcinoma. The purpose of this study is to demonstrate radiologic features of SPCH and compare characteristics between SPCH and adenocarcinoma.

Methods: This retrospective study included all histologically confirmed SPCH cases at our institution between July 2015 and December 2024. For comparison, propensity score matching lung adenocarcinoma cases in our hospital in the same period were selected. Each nodule's consistency, size, location, spiculation, pleural retraction, air bronchogram and perivascular lucency were evaluated by two chest radiologists independently, blinded to clinical and pathology information. The chi-square or Fisher's exact tests were used for categorical data and Mann-Whitney U tests for continuous data.

Results: The study comprised 44 SPCH patients (28 females [63.6%], 16 males [36.4%]; median age, 46 years [range, 27-70 years]). SPCH were predominantly located in both lower lobes (77.3%) and peripheral lung zone (79.5%), shown as solid nodules (54.5%). On CT, 54.5% were solid nodules, 27.3% nonsolid, and 18.2% part-solid. Most SPCH lacked spiculation (95.5%, 42/44) and pleural retraction (81.4%, 35/44). Air bronchograms were present in 56.8% (25/44) of SPCH, in which most of case had patent bronchiole with or without dilation passing through the nodule (N=12). There were 7 cases had dilated bronchiole obstructed abruptly by the nodule or with disruption in the peripheral area of the nodule, while the rest of the 5 cases had area of branching or tubular lucency within the central of the nodule. Perivascular lucency was observed in 9.1% (4/44) of SPCH. Comparing with the 344 matched adenocarcinomas, SPCH were more likely in both lower lobes (33/44, 75%), while adenocarcinomas were more in upper lobes (209/233, 60.8%). SPCH more liekly have air bronchogram and less likely present with lobulation, spiculation and pleural retraction (all $P<0.05$).

Conclusions: SPCH were more likely to be located in both lower lobes and peripheral lung zone, typically lacking spiculation, lobulation and pleural retraction but often exhibiting air bronchograms. Central branching and tubular lucency and perivascular lucency are more specifically seen in SPCH.



Example chest CT images showing air bronchogram in solitary pulmonary capillary hemangioma.

EP.04 SCREENING AND EARLY DETECTION

EP.04.20 Exploring Diffusion-Weighted Magnetic Resonance Imaging in Lung Cancer Screening

K. Dollar[1], W. Chua[2], C. Wu[1], C. Gregorio[1], D. Gregory[1], E. Gholian[1], C. Lee[1], D. Lee[1], Y. Xie[1], S. Ghandehari[1]
[1]Cedars Sinai Medical Center, Los Angeles/CA/USA ,[2]Stanford Medical Center, Palo Alto/CA/USA

Introduction: There is evidence that magnetic resonance imaging (MRI) offers sensitivity comparable to computed tomography (CT) in evaluating pulmonary nodules.[1] Specifically, diffusion-weighted imaging (DWI) sequences generate images based on water molecule diffusion through tissue, quantified as the apparent diffusion coefficient (ADC). ADC is typically lower in malignant tumors than in benign nodules[2],[3] and has been used in other tissues, such as thyroid nodules, as a noninvasive risk stratification tool.[4] This study examines the role of DWI in lung nodules found in lung cancer screening (LCS).

Methods: This ongoing prospective study includes participants eligible for LCS with at least one lung nodule ≥6 mm on LDCT, who then underwent MRI. Diffusion-weighted imaging (DWI) was performed using a 3T MRI scanner, and ADC maps were reconstructed. ADC values of pulmonary nodules were analyzed and compared to background lung parenchyma. Statistical analysis was conducted using a paired t-test.

Results: A total of 21 nodules were evaluated, 18 (86%) of which were solid. All solid nodules appeared on at least one MRI sequence, with 16/18 (89%) visualized on DWI, allowing for ADC calculation. The mean ADC of lung nodules was 1.094 × 10^{-3} mm^2/s, significantly higher than background lung parenchyma (0.116 × 10^{-3} mm^2/s, p<.001). All nodules remain under serial imaging, with no diagnostic procedures performed to confirm malignancy.

Conclusions: Most solid nodules larger than 6 mm were visible on MRI, particularly DWI, where ADC may aid in future risk stratification. As our study is ongoing, none of the nodules have yet undergone diagnostic confirmation of malignancy, with findings to be reported later.

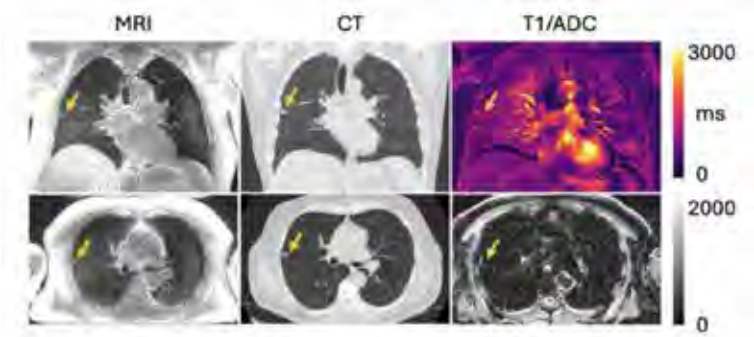


Figure 1: MR images and CT images (top: coronal cut, bottom: axial cut) showing 11x5 mm solid nodule (yellow arrow) in the peripheral right upper lobe. Last column showing T1 mapping in the top row and ADC mapping from the DWI sequence in the bottom row with signal intensity scale located on the right side.

EP.04 SCREENING AND EARLY DETECTION

EP.04.21 Imaging Manifestations in 4 Cases of Invasive Pulmonary Adenocarcinoma With Indolent Growth

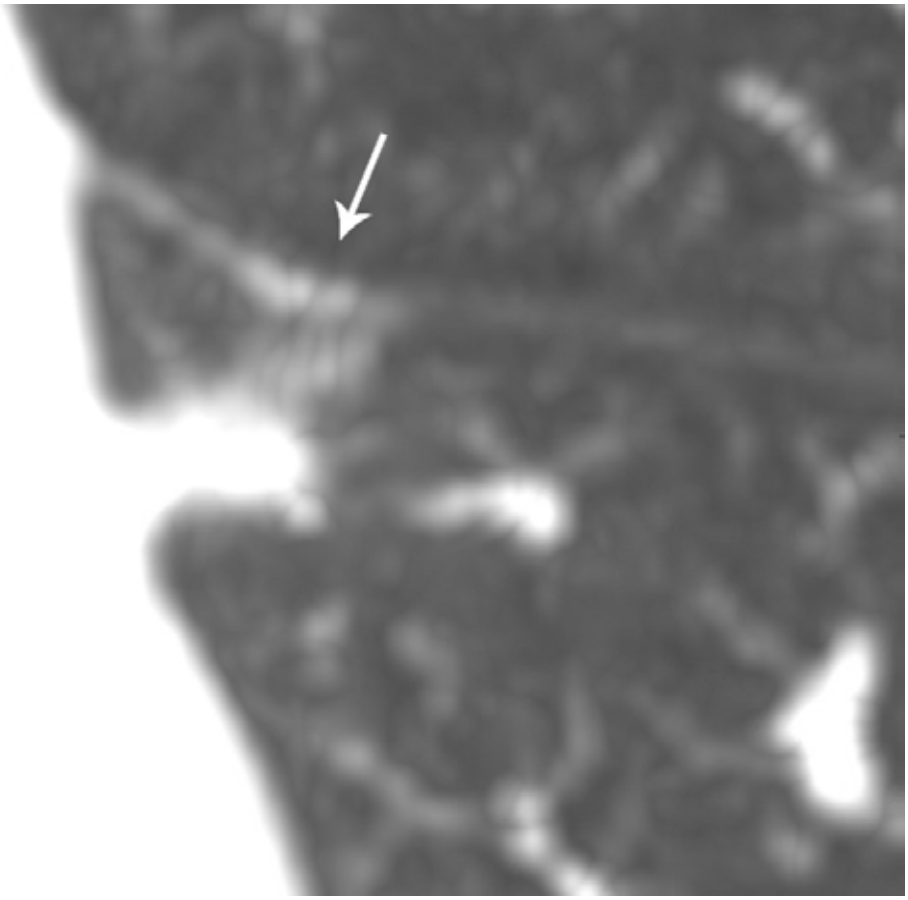
A. Yu, C. Hong, Q. Li, Y. Shi, X. Li
The First Affiliated Hospital of Hainan Medical University, Haikou/CN

Introduction: Pathologically, the invasive component within the pulmonary tumor, particular adenocarcinoma, appears as a solid opacity on thoracic CT image [1,2]. The average doubling time of solid lung cancer is 207 days (range 39-400 days) [3-7], and key factors of growth rate include histological type, size, solidity, thick coarse spiculation, smoking history [7-9]. Slow growing solid adenocarcinoma on imaging shows signs of vacuoles, air-bronchogram in tumor [10, 11]. The authors encountered 4 cases of slow growing lung invasive adenocarcinoma, and their clinical, imaging manifestations are reported as follows.

Methods: All four patients were diagnosed with peripheral lung carcinoma, comprising 3 females and 1 male, with a mean age of 57 years (range: 49-61 years). The long diameter was measured on image showing the maximal nodule section, the wide diameter was the longest perpendicular to the length. Tumor volume doubling time (VDT) at two intervals in days between the first and last imaging was calculated using the modified Schwartz equation. A standard reconstruction algorithm was used, lung window, window width, 1000 HU; window level, −700 HU. Reconstruction thicknesses were 1.25 or 1.0 mm, and the intervals were equal to each corresponding thickness. Maximum intensity projection (MIP) slab thickness was five times the original slice thickness resulting in 5 line opacities of interlobar fissure or pleural tail-sign on lung window of unsharpened image, which was known as 5-line sign. 5-line sign clear defined as smooth contour lines and clear line intervals, otherwise, it is unclear.

Results: The pathological diagnosis of pulmonary nodules in all 4 cases was invasive adenocarcinoma, including 2 cases of solid nodules and 2 cases of solid-dominant nodules with a solid component greater than 90%. All 4 cases on CT images showed pleural tail sign, and MIP reconstruction image revealed a clear 5-line sign (Figure). The average VDT of tumor is 1994 days, ranging from 1593 to 2485 days. One case showed air-bronchogram within the tumor. Follow up for 4-10 years after surgery showed no recurrence or metastasis. Figure legend: MIP reconstruction shows a clear 5-line sign (arrow). A left lung nodule with a tail sign was discovered in 2010 and surgically removed in 2018 due to accelerated growth.

Conclusions: A clear 5-line sign displayed on MIP reconstruction of a nodule with a pleural tail sign may be a meaningful sign of indolent growth in invasive adenocarcinoma of the lung in addition to the vacuole and air-bronchogram in tumor.



Keywords: lung adenocarcinoma, growth, tomography, x-ray computed

EP.04.22 Internal Validation of the IASTO-PDPI Lung Cancer Risk Level at Indonesia's National Respiratory Center, Persahabatan Hospital

R.S. Aritonang, E. Syahruddin, I.P. Pratomo, M. Rasmin, T. Damayanti, J. Zaini, E. Samoedro, F. Nurwidya, R. Sutarto
Faculty of Medicine Universitas Indonesia, Jakarta/ID

Introduction: Lung cancer is the leading cause of cancer-related mortality worldwide, often diagnosed at an advanced stage when curative surgical intervention is no longer an option, limiting treatment and prognosis. Assessing lung cancer risk is essential for guiding treatment decisions, as early detection improves survival. The IASTO-PDPI form (Indonesian Association for the Study of Thoracic Oncology-Indonesian Society of Respirology) was developed as a screening tool for high-risk individuals. Lung cancer risk factors vary across populations due to demographic and environmental differences. In Indonesia, it develops at a younger age due to earlier tobacco exposure. This study evaluates the internal validity and reliability of the IASTO-PDPI form to determine its clinical applicability for nationwide implementation.

Methods: A cross-sectional study was conducted at the outpatient clinic of Persahabatan Hospital from May 2024 to January 2025, involving 200 participants: lung cancer patients (n=150) and chronic obstructive pulmonary disease (COPD) patients (n=50). Validity was assessed using Pearson's correlation test, while reliability was evaluated using Cronbach's alpha coefficient. A p-value of <0.05 was considered statistically significant.

Results: The lung cancer group had a younger median diagnosis age of 59 years, with 61.4% of cases occurring in the 45-65 age group. In contrast, the COPD group had a median age of 65 years. COPD patients were included as a comparison group due to shared pathophysiological pathways with lung cancer, enabling a more precise risk evaluation. Validity analysis showed that 8 of 9 form items significantly correlated with the total score. Seven items demonstrated strong statistical significance (p<0.001), while family history of lung cancer (r=0.163, p=0.021) remained valid. The strongest correlations were observed for cigarette smoke exposure (r=0.664) and occupational carcinogen exposure (r=0.625), highlighting their substantial impact on lung cancer risk. Conversely, the prior cancer history item had a negative correlation (-0.113) and was not statistically significant (p=0.111), indicating invalidity. Reliability testing yielded a Cronbach's alpha of 0.420, suggesting suboptimal internal consistency.

Conclusions: The IASTO-PDPI form demonstrated good validity in identifying lung cancer risk factors but requires refinement to improve reliability. Personal history of cancer remains a recognized risk factor and may be considered in future screening eligibility criteria. In Indonesia, the likelihood of diagnosing lung cancer in individuals with prior malignancies is low, primarily due to lower life expectancy, high cancer mortality, and late-stage detection. Refining the invalid form item and enhancing reliability are essential before the clinical implementation of lung cancer screening across Indonesia.

Form Item	Correlation Coefficient (r)	p-value	Validity
Gender	0.572	<0.001	Valid
Age	0.284	<0.001	Valid
History of Cancer	-0.113	0.111	Invalid
Family History of Lung Cancer	0.163	0.021	Valid
Cigarette Smoke Exposure	0.664	<0.001	Valid

EP.04 SCREENING AND EARLY DETECTION

EP.04.23 Prediction of STAS Positivity in Non-Small Cell Lung Cancer

B. Kilic[1], M. Agkoc[1,2], O.F. Saglam[1,3], L. Chikvaidze[1], H.V. Kara[1], K. Kaynak[1], A. Turna[1], E. Ersen[1]
[1]Istanbul University - Cerrahpasa, Cerrahpasa School of Medicine, Istanbul/TR ,[2]Erzurum City Hospital, Erzurum/TR ,[3]Tokat State Hospital, Tokat/TR

Introduction: Spread through air spaces (STAS), a histopathological hallmark of tumor cell dissemination into lung air spaces beyond the primary lesion, is increasingly being recognized as a critical prognostic factor in non-small cell lung cancer (NSCLC). Its presence is correlated with aggressive tumor behavior, higher recurrence rates, and diminished survival, particularly in adenocarcinoma subtypes. Accurate preoperative prediction of STAS is essential to optimize surgical strategies, adjuvant therapies, and patient outcomes. This study aimed to identify robust clinical, pathological, and imaging predictors of STAS positivity to refine the risk stratification and inform personalized therapeutic approaches.

Methods: A retrospective cohort analysis was conducted on 380 patients with resected primary NSCLC (selected from an initial cohort of 1,166 individuals treated between September 2001 and November 2024). The inclusion criteria required comprehensive STAS data from histopathological reports. Demographic variables (age, sex, and smoking history), clinical parameters (preoperative blood cell counts and comorbidities), pathological features (tumor stage and histopathology), and imaging biomarkers (lymph node SUVmax from PET/CT) were analyzed. Statistical methods included univariate analyses (chi-square test, t-test, and Mann-Whitney U test) and multivariate logistic regression to identify independent predictors. Receiver operating characteristic (ROC) curves assessed the discriminative power of significant variables.

Results: STAS positivity was identified in 188 patients (49.5%), with a significantly higher prevalence of adenocarcinoma (62.2% vs. 34.5% in non-adenocarcinoma subtypes; p<0.0001). Elevated preoperative monocyte counts (>0.73 × 10^3/mL) emerged as a strong independent predictor (OR 15.12, 95% CI 3.14-72.76, p=0.001), alongside adenocarcinoma histopathology (OR 2.71, 95% CI 1.34-5.46, p=0.005). Pathological nodal involvement (N1/N2 stages) and higher lymph node SUVmax were associated with STAS in univariate analysis (p<0.05), but were not significant in multivariate models. ROC analysis demonstrated a moderate predictive accuracy for SUVmax (AUC=0.592), suggesting limited standalone utility. Notably, STAS-positive patients reported lower rates of excessive phlegm (6.9% vs. 16.7%, p=0.003), a novel finding that warrants further exploration.

Conclusions: This study highlights adenocarcinoma histopathology and elevated preoperative monocyte counts as robust independent predictors of STAS in NSCLC. The association between systemic inflammation (reflected by monocytosis) and STAS underscores the interplay between tumor biology and host immune responses. Although PET/CT-derived SUVmax showed univariate correlations, its limited discriminative power in multivariate analysis emphasizes the need for complementary biomarkers. These findings support the integration of inflammatory markers and histopathological data into preoperative risk models to guide surgical planning (e.g., favoring lobectomy over sublobar resection in high-risk cases) and adjuvant therapy decisions. The limitations include the retrospective design and potential interobserver variability in the STAS assessment. Future multicenter studies should validate these predictors in larger cohorts, explore the molecular mechanisms linking monocytes to STAS, and investigate advanced imaging modalities (e.g., AI-enhanced radiomics) to improve predictive accuracy.

EP.04.24 Initial Experience With Cancer Screening Center: Model to Improve Lung Cancer Screening Uptake

S. Yalamanchili[1], S. Castro[1], B. Zollinger[1], P. Cespedes[2], A. Mahajan[1], M. Subramanian[1], M.J. Weyant[1], B.J. Bassig[2], R.J. Kaltman[1], K. Suzuki[1]
[1]Inova Health System, Falls Church/VA/USA ,[2]Inova Fairfax Medical Campus, Falls Church/VA/USA

Introduction: Lung cancer screening (LCS) is an essential step for early detection and improving survival rates for patients with lung cancer. In 2022, LCS uptake in the United States remained low at 16.0%, highlighting an important area of improvement. In 2022, our hospital established an all-encompassing screening center to provide integrated, multi-cancer screening services. We sought to describe our initial experience and determine whether a cancer screening center is associated with improved LCS uptake.

Methods: A retrospective review of 1,085 medical records was conducted. Patients aged 18 and older who visited the screening center between January 1, 2022, and December 31, 2022, were included. Eligibility for lung, breast, cervical, and colorectal cancer screening was determined using the United States Preventive Services Task Force criteria at the time of the office visit. Electronic medical records were reviewed through December 31, 2023, to assess screening completion. We collected demographics, primary diagnosis, procedures ordered, insurance status, personal and family cancer history, and smoking history. LCS uptake was calculated by determining the proportion of eligible patients who completed screening with low-dose CT scans out of the total due for screening.

Results: 1,085 patients were included in the study, with a mean age of 54.8 years (Table). Among them, 65 (6.0%) were current smokers, 284 (26.2%) were former smokers, and 734 (67.6%) had never smoked. The most common cancer screening for which patients were eligible included colorectal (n=368, 33.9%), breast (n=299, 27.6%), cervical (n=241, 22.2%), and lung cancer (n=76, 7.0%). Within the 76 patients eligible for LCS, 38 qualified for both colorectal and lung (50.0%), 19 for lung alone (25.0%), 7 for breast and lung (9.2%), 3 for all four cancers (3.9%), 2 for colorectal, cervical, and lung (2.6%), 4 for breast, colorectal, and lung (5.3%), and 3 for cervical, lung, and breast (3.9%). The mean age of those eligible for LCS was 62.5 years. Of the LCS-eligible cohort, 29 (38.2%) were female, 28 (36.8%) had a personal history of cancer, 44 (57.9%) had a family history of cancer, 23 (30.3%) were current smokers, and 53 (69.7%) were former smokers. Within this LCS-eligible cohort of 76 patients due for lung screening, 67 underwent the screening test, yielding an LCS uptake rate of 88.2% (67/76).

Conclusions: Our all-encompassing cancer screening center yielded a remarkable LCS uptake and provides a possible model to improve screening uptake. We will continue to investigate our experience and explore areas of improvement.

Table: Patient Characteristics

	All Patients (n=1085)	Lung Cancer Screening Eligible Patients (n=76)
Age, mean (standard deviation)	54.8 (15.0)	62.5 (7.3)

EP.04 SCREENING AND EARLY DETECTION

EP.04.25 Integrated Biological and Imaging Assessment for Pulmonary Nodule Malignancy: A Real-World Study With Large Cohort Modeling and Validationes

Z. Li, L. Wang, N. Li, J. Cheng, P. Xia, J. Ye, Y. Ma, W. Lv, Z. Liu, J. Hu
The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou/CN

Introduction: Accurate early diagnosis of lung cancer is critical for prognosis improvement. Current imaging-based differentiation of pulmonary nodules faces limitations in specificity and sensitivity. Tumor-associated autoantibodies (e.g., 7-AABs) have emerged as promising biomarkers for early detection. Leveraging a large real-world cohort, this study innovatively integrates CT imaging features with seven lung cancer-related serum autoantibodies (7-AABs) to develop a multidimensional prediction model, aiming to optimize diagnostic accuracy and support clinical decision-making for pulmonary nodule management.

Methods: A retrospective cohort of 1,017 pathologically confirmed pulmonary nodule patients (training set: 712; validation set: 305) from the First Affiliated Hospital of Zhejiang University (January 2020-April 2024) was analyzed. Independent predictors were identified via univariate and multivariate logistic regression, followed by nomogram construction. Model performance was assessed using ROC curves, calibration plots, and decision curve analysis (DCA).

Results: Univariate analysis revealed that the combination of CT and 7-AABs achieved a higher AUC (0.794) compared to CT alone (0.667) or 7-AABs alone (0.514) (Fig1.A). Multivariate analysis identified nodule diameter (OR=1.075), nodule nature (solid vs. mixed ground-glass nodule, OR=0.134), and CT combined with 7-AABs (OR=6.581) as independent predictors. The nomogram model demonstrated excellent discrimination (Fig1.B), with AUCs of 0.826 (training set) and 0.862 (validation set) (Fig1.C). DCA confirmed its superior net clinical benefit over single-modality approaches (Fig1.D, E).

Conclusions: The integration of 7-AABs and CT significantly enhances the accuracy of distinguishing benign and malignant pulmonary nodules. The validated prediction model provides a robust tool for clinical decision-making, facilitating personalized diagnostic and therapeutic strategies.

EP.04 SCREENING AND EARLY DETECTION

EP.04.26 A Case Series on Video Fiber Optic Bronchoscopy in the Diagnosis of Non Small Cell Lung Cancer (NSCLC) Subtype: Squamous Cell

S. SAXENA
GEETANJALI MEDICAL COLLEGE AND HOSPITAL UDAIPUR, UDAIPUR/IN

Introduction: Squamous cell lung cancer is a frequently occurring carcinoma in frequent smokers1. Around 80% of lung cancers can be accounted to Non small cell lung cancer (NSCLC) out of which 20 to 30% are squamous subtype2. The symptoms include chest pains, cough, shortness of breath, loss of weight an appetite, fatigue etc. Other factors such as second hand smoke, pollution, exposure to metals or asbestos can also lead to development of carcinoma3. The diagnosis can be done using a combination of imaging, biopsy or molecular characterization

Methods: In the present study, patients with symptoms of NSCLC were diagnosed using endobronchial biopsy assisted through fiber optic bronchoscopy. Absence of pleural effusion necessitated the need for a biopsy. All the patients had a history of smoking. Washing and brushing of bronchoscope was carried out after each procedure. The biopsied samples were sent for BAL -cytology, HPE, GeneXpert NTEP (NS) and AFB culture.Case series: Patient 1: A 50 year old patient presented with the symptoms of trouble in breathing, wheezing and weight loss. With video bronchoscopy a mass lesion protruding from right upper lobe, occluding >50% of Lumen of RMB, highly vascular was observed while the left lung and trachea were normal. Two Grey white/ dark brown soft tissues measuring 0.5 x 0.2 x 0.1 cm was biopsied and sent for analysis. Non small cell carcinoma, favoring squamous cell carcinoma was diagnosed with clinical correlation. Patient 2: A 53 year old patient presented with the symptoms of coughing up blood, hoarseness, fatigue and weight loss. With fiber optic bronchoscope an endobronchial mass was seen in right main bronchus (RMB) obstructing the opening while the left bronchial tree and trachea were normal. Multiple Grey white/ dark brown soft tissues measuring 2 x 1 x 0.5 cm was biopsied and sent for analysis. Non small cell carcinoma, favoring squamous cell carcinoma was diagnosed with clinical correlation. Patient 3: A 61 year old patient presented with the symptoms of shortness of breath, weight loss, recurring lung infections such as pneumonia and bronchitis. With video bronchoscopy an endobronchial mass was seen in right main bronchus (RMB) obstructing the opening while the left bronchial tree was normal. Multiple Grey white soft tissues, completely embedded measuring 1x 0.7x 0.4 cm was biopsied and sent for analysis. Keratinizing squamous cell carcinoma, moderately differentiated was diagnosed with clinical correlation.

Results: It was observed that malignant epithelial cells arranged in sheets and clusters with high N:C round to oval nuclei with vesicular chromatin and moderate amount of pink eosinophilia. Through the biopsy the diagnosis of Non small cell lung cancer, squamous sub type was concluded.

Conclusions: In the absence of pleural effusion, biopsy using a bronchoscopy can be very effective in diagnosis. This case series demonstrates the effectiveness of Fiber optic bronchoscopy and endobronchial biopsy in diagnosing squamous cell lung carcinoma in patients presenting with various respiratory symptoms. The procedure allowed for direct visualization of endobronchial masses and provided tissue samples for pathological and microbiological analysis, leading to accurate diagnoses.

Introduction: Lung cancer screening is becoming increasingly widespread, resulting in more incidental detections of pulmonary lesions. Consequently, accurate malignancy classification is crucial. The Brock and Mayo models are well-established risk tools. This study evaluates the predictive accuracy of these models in comparison to the new LIONS PREY (Lung lesION Score PREdicts malignancY). Unlike the established models, LIONS PREY includes lesion progression as an optional parameter and assigns greater weight to smoking as a risk factor.

Methods: We retrospectively included all patients who underwent resection of a pulmonary lesion (≤30mm) at our lung cancer center between 08/2022 and 08/2024, excluding those with incomplete clinical parameters for model calculation. Two study groups were formed based on histopathological results (group M: malignant, group B: benign). The threshold for benign versus malignant nodules was defined at a predicted malignancy probability of ≥80%. We evaluated the predictive accuracy of the Brock, Mayo, and LIONS PREY models based on calibration (observed/expected ratio), discrimination (AUC), and the total number of correctly classified patients (OCC).

Results: During the treatment period, 776 patients underwent resection at our center. LIONS PREY showed a significantly higher precision according to OCC (95.4%, p=0.008) compared to the Brock (64.1%) and Mayo (69.8%) models. The calibration of LIONS PREY (O/E-ratio: 1.1) was significantly superior (p=0.036) to the Brock (1.4) and Mayo (1.3) models, indicating that both established models underestimated malignancy in pulmonary lesions. In terms of discriminatory power, LIONS PREY (AUC: 0.94; 95%-CI: 0.92-0.96) outperformed both the Brock (AUC: 0.62; 95%-CI: 0.56-0.68) and Mayo (AUC: 0.64; 95%-CI: 0.58-0.69) models (p=0.003, DeLong analysis).

Conclusions: The success of a lung cancer screening program depends on an effective model for assessing malignancy. The newly developed LIONS PREY demonstrates superior accuracy compared to the established Brock and Mayo models and should be prioritized in lung cancer screening initiatives.

EP.04 SCREENING AND EARLY DETECTION

EP.04.28 TD-GC-MS-Based Breath Analysis for Early Diagnosis of Lung Cancer

M. Asiltürk[1], D. Yonar[2], D. Köksal[3], C. Taşaltın[4], K.S. Emri[5], B. Salih[1]
[1]Hacettepe University, Faculty of Science, Ankara/TR ,[2]Yuksek Ihtisas University Faculty of Medicine, Ankara/TR ,[3]Hacettepe University, Faculty of Medicine, Ankara/TR ,[4]TUBITAK Marmara Research Center, Kocaeli/TR ,[5]Memorial Bodrum Hospital, Department of Pulmonary Diseases, Muğla/TR

Introduction: Lung cancer (LC) is the most common type of cancer worldwide and the leading cause of cancer-related deaths. Most LC patients are diagnosed at an advanced stage, as the disease is often asymptomatic in its early phases. The poor prognosis associated with advanced stages underscores the urgent need for screening and early diagnosis, when patients may benefit from potentially curative treatments. An ideal screening test should detect the disease at an early stage, have a low false-positive rate, minimize unnecessary invasive procedures, cause no harm to healthy individuals, be cost-effective, and ultimately reduce mortality. In recent years, breath analysis has emerged as a promising non-invasive diagnostic method for early LC detection.

Methods: The study analyzed breath samples from 73 (63 males/ 10 females; mean age: 62.7 years) LC patients (Stage I: 13, Stage II: 16, Stage III: 35, Stage IV: 30) and 68 healthy controls (38 males/ 30 females; mean age: 39.6 years). All LC patients were newly diagnosed, treatment-naïve individuals with an Eastern Cooperative Oncology Group (ECOG) performance status (PS) ≤ 2. The samples were analyzed using thermal desorption-gas chromatography-mass spectrometry (TD-GC-MS) to identify volatile organic compounds (VOCs). Peak area related to amount of each compound was calculated by automated integration using a software which was available onto the GC-MS system, otherwise targeted low intensity signals were integrated manually for the correlation of increasing or decreasing compound concentrations in breath. Additionally, demographic and pathological data were analyzed.

Results: 23 of 105 VOCs detected in breath were identified as potential biomarkers for LC. Compared to the control group, n-butane (p=0.039), isobutane (p=0.048), and 2,4-dimethylhexane (p=0.025) were significantly higher in LC patients, while dodecane (p=0.046) was significantly lower. Biochemical parameters did not show significant differences between age groups or genders. Smokers had elevated levels of 2-methylpentane and benzene compared to non-smokers and former smokers. Stage III and IV patients had higher median n-butane levels than earlier stages. Stage I and III patients had higher isobutane, isoprene, ethanol, 2-methylpentane, 4-methylheptane, 4-methyloctane, and ethylbenzene levels than stage II and IV patients. Stage I patients had the highest levels of acetone, benzene, toluene, isoprene, and 1,2-pentadiene, whereas stage IV patients had the lowest 1,4-dichlorobenzene levels. Other biochemical markers did not show significant differences across stages.

Conclusions: TD-GC-MS data demonstrated significant differences in VOCs between LC patients and healthy controls. Establishing a standardized protocol for breath sample collection and analysis may enable the use of these compounds as biomarkers for early LC detection in clinical settings. Such an approach may substantially improve diagnostic accuracy and promote timely interventions for patients at risk.

[1]AP-HM, Marseille/FR ,[2]Computational Pharmacology and Clinical Oncology, CRCM, Inserm, Inria, Marseille/FR ,[3]Epidemiology and health economy department - APHM, Marseille/FR ,[4]Hopital Marie Lannelongue, Le Plessis Robinson/FR ,[5]Gustave Roussy Cancer Campus, Villejuif/FR

Introduction: Criteria for lung cancer screening (LCS) eligibility are usually based on age, amount of tobacco consumption in pack-years or number of cigarettes smoked per day and duration, and delay from smoking cessation. We hypothesized that age (>45 years old), daily cigarette smoking for 10 years and history of tobacco related atheromatous diseases were relevant criteria for LCS eligibility.The primary objective was to report lung cancer prevalence after a first round of LCS among patients with history of cardiovascular atheromatous related diseases in two prospective cohorts (PREVALUNG, NCT 03976804 and PREVALUNG ETOILE, NCT 05649046). We also compared eligibility to NLST (NCT 00047385) and NELSON (NL580) trials as well as lung cancer prevalence at first LCS round and rate stage I and II LC. We finally reported outcomes after lung cancer diagnosis.

Methods: We analyzed the results of 502 patients who were prospectively enrolled in PREVALUNG and PREVALUNG ETOILE cohorts and underwent a first LCS round in two academic centers from November 2019 to May 2024. Inclusion criteria were 45-75 years old, history of a tobacco related atheromatous disease and history of tobacco consumption for 10 years. Main exclusion criteria were symptoms of LC, existing follow-up for pulmonary nodule, pulmonary fibrosis or hypertension, dyspnea at rest, active pulmonary infectious disease.Lung cancer prevalence was reported as % and 95% confidence interval. Comparison between proportions were performed using Chi squared test of Fischer's exact test when appropriate. Analyses were performed using STATA 18.

Results: Among the 502 patients, lung cancer prevalence was 2.99% [1.81 - 4.90]. 58.8% met the NELSON eligibility criteria and 50.4% met the NLST criteria. Among diagnosed lung cancer (n=15), 11 (73.3%) were detected at stage I, one (6.7%) at stage II (i.e 80% at stage I or II), one (6.7%) at stage III, and two (3.3%) at stage IV. Lung cancer prevalence at first round of LCS was significantly higher among patients with atheromatous cardiovascular diseases compared with participants of NLST and NELSON trials (risk ratio 2.91 [1.74 - 4.86] and 3.37 [1.92 - 51], respectively). Among patients with lung cancer, proportion with stage I or II lung cancer at diagnostic (80.0%) were not significantly different compared with NLST at first round (61.3%), p=NS. All patients diagnosed with lung cancer underwent lung cancer specific treatment according to the recommandations including 12 patients who underwent anatomic resection with lymph node dissection, 1 radio-chemotherapy and 2 systemic treatments. After surgery, in-hospital mortality was null and there was no serious adverse event (i.e. Clavien-Dindo > 3).

Conclusions: Among patients with history of tobacco-related atheromatous diseases, lung cancer prevalence is higher compared with NLST and NELSON populations. Lung cancer were diagnosed at a curative early stage in 80% and outcomes after curative surgical resection proved feasibility and safety. We conclude that history of tobacco-related atheromatous diseases is a relevant criteria for lung cancer eligibility.

EP.04 SCREENING AND EARLY DETECTION

EP.04.30 Second Primary Lung Cancer in Surgically Treated Breast Cancer Patients: Association or Incidental Finding?

S. Ricciardi[1], N. Ciampelli[2], v. rossi[3], E. Melis[3], F. Di Cesare[3], S. Treggiari[3], M.o. Jaus[3], G. Cardillo[3]
[1]Unit of Thoracic Surgery, Roma/IT ,[2]Saint Camillus University, Rome/IT ,[3]san camillo forlanini, Rome/IT

Introduction: Breast cancer survivors face a 40% higher likelihood of developing a second cancer, with lung cancer being the most common. Related to this risk, follow-up chest CT scans in breast cancer patients, especially those with lymph node involvement, lead to a higher detection rate of lung nodules.

Methods: Prospective study on breast cancer patients (BCPs) surgically treated in a single center between 01.2019-01.2024 was conducted. BCPs who developed pulmonary nodules after surgery were analysed. The primary aim was to estimate the frequency of lung cancer in a population of patients undergoing oncologic surgery for primary breast cancer. Secondary aim was comparing the diagnostic and therapeutic recommendations between the oncologist and the thoracic surgeon during CT evaluation of pulmonary nodule

Results: Out of 598 BCPs, 16 second primary NSCLC were identified (2.7%). A total of 136 patients showed a pulmonary nodule on CT scan, 35 of them (25.7%) were surgically resected or biopsied while 101 (74.3%) were kept in radiological follow-up. Among NSCLC, 14 (87.5%) were early stages. Retrospectively analysing all CT scan of patients with lung nodules, a different evaluation between oncologist and thoracic surgeon was noticed: the oncologist identified a suspicious lung cancer in a small percentage of patients (table 1)

Conclusions: Our analysis reported a 2.7% of secondary primary NSCLC among 598 BCPs. Due to the high risk to develop a second primary NSCLC, CT-scan during follow-up of high-risk BC patients should be considered. Moreover, a combined evaluation of CT scan between oncologist and thoracic surgeon is recommended to promptly identify second primary NSCLC

Table1. differences in evaluation of pulmonary nodules (second primary NSCLC) between surgeon and oncologist

[1]The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[2]UT Southwestern Medical Center, Dallas/TX/USA

Introduction: Early detection of lung cancer is essential for improving prognosis. This study aimed to identify key predictors of lung cancer-free survival (LCFS) in patients with persistent pulmonary nodules and to develop a predictive nomogram model.

Methods: We retrospectively analyzed data from patients with persistent pulmonary nodules evaluated at MD Anderson Cancer Center between November 2003 and December 2022. Persistent pulmonary nodules were defined as nodules visible on at least two CT scans, three months apart without evidence of shrinkage. Thoracic radiologists reviewed radiologic features. LCFS was calculated from the detection of persistent pulmonary nodules to lung cancer diagnosis or last follow-up. Multivariable Cox regression was used to identify independent predictors of LCFS, and a nomogram was constructed to estimate 6-, 12-, and 24-month cancer-free survival probabilities. Discriminative ability was evaluated using the concordance index (C-index) and time-dependent receiver operating characteristic (ROC) curves. Calibration plots assessed model agreement, and Kaplan-Meier (KM) curves compared survival across risk groups. Decision curve analysis (DCA) evaluated clinical utility against nodule size alone.

Results: A total of 392 persistent pulmonary nodules were included. The median follow-up from the second CT scan (used to define persistence) was 592 days. Nodules were randomly divided into training (n = 274) and validation (n = 118) cohorts. Multivariate analysis identified smaller nodule size, ground-glass opacity (GGO) type, and absence of spiculation as independent predictors of prolonged lung cancer-free survival (LCFS). The final nomogram, incorporating age, gender, smoking history, family history of lung cancer, emphysema, nodule size, type, location, count, and spiculation, demonstrated strong discriminatory performance, with a C-index of 0.771 in the training cohort and 0.727 in the validation cohort. The area under the ROC curve (AUC) at 6, 12, and 24 months was 0.874, 0.827, and 0.787 in the training cohort, and 0.893, 0.866, and 0.681 in the validation cohort, respectively. Calibration plots showed excellent agreement between predicted and observed outcomes. Risk stratification based on the nomogram effectively separated patients into high- and low-risk groups ($p < 0.001$). DCA demonstrated that the nomogram offered greater clinical benefit than using nodule size alone.

Conclusions: We developed and validated a nomogram for predicting cancer-free survival in patients with persistent pulmonary nodules. This tool may support clinicians in making personalized decisions regarding early detection of lung cancer.

EP.04 SCREENING AND EARLY DETECTION

EP.04.32 The Impact of Symptom Monitoring on Survival Among Patients With Lung Cancer. a 4-Year Follow-Up of the SYMPRO-Lung Study

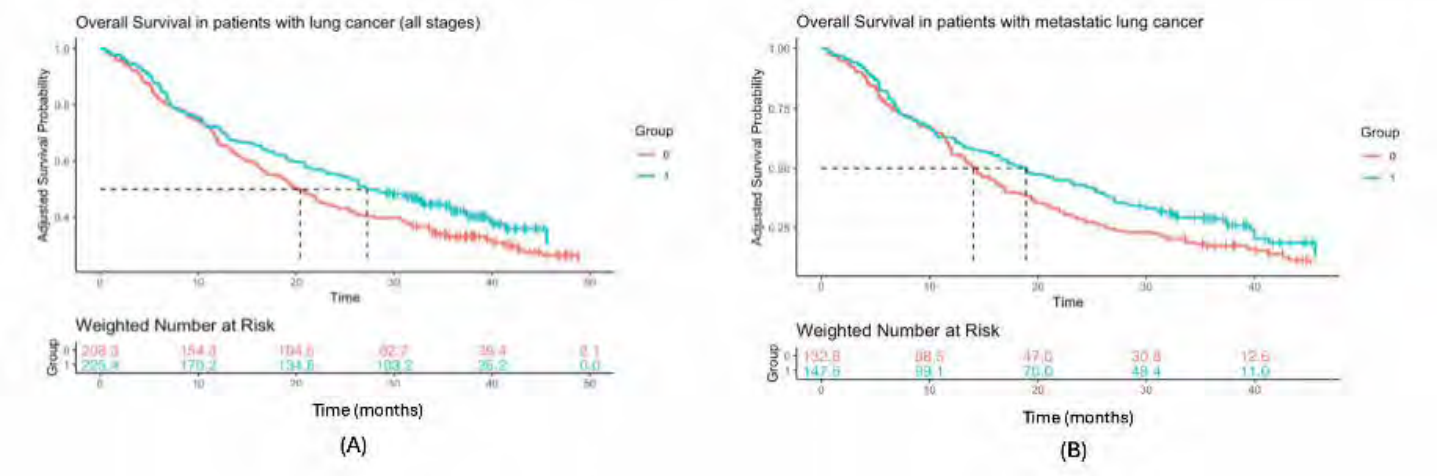
M. Hassing[1], N. Billingy[1], C. Verberkt[1], M. van den Heuvel[1], L. van de Poll[2], C. van den Hurk[3], A. Becker-Commissaris[4], I. Walraven[1]
[1]Radboudumc, Nijmegen/NL ,[2]Netherlands Cancer Institute, Amsterdam/NL ,[3]Catharina Ziekenhuis, Eindhoven/NL ,[4]Amsterdam UMC, Amsterdam/NL

Introduction: The SYMPRO-Lung study assessed the effect of patient-reported outcome (PRO) symptom monitoring on health-related quality of life (HRQoL) and Overall Survival (OS) in lung cancer patients. Within this study, a significant improvement in 1-year HRQoL and even a trend towards a survival benefit following PRO symptom monitoring was observed1. A study in metastatic cancer patients found no survival benefit within 2 years of follow-up2. Nonetheless, this effect may be more pronounced in earlier stages of the disease or with prolonged follow-up. Therefore, this study aims to assess the long-term effect of PRO symptom monitoring on OS in early- and advanced-stage lung cancer up to 4 years follow-up.

Methods: The SYMPRO-Lung study included patients with stage I to IV lung cancer. Patients in the intervention group completed weekly PRO symptom assessments. The control group received usual care. Data collection started between 2019 and 2021 and was extended with information from the national cancer registry up to 2024. Cox proportional hazards analysis was used to assess the association between PRO symptom monitoring and OS in patients with stage I to IV lung cancer, while adjusting for potential confounders (months since initial diagnosis to development of first metastasis, months since initial diagnosis to first systemic treatment, line of systemic treatment, and a random effect for site clustering). A sensitivity analysis was conducted including only patients with metastatic (M1) lung cancer.

Results: A total of 446 patients were included in the analysis. Baseline characteristics were similar across the intervention (n=235) and control group (n=211). In the total study population, PRO symptom monitoring was significantly associated with improved OS (HR 0.73, 95% CI 0.57-0.92, Figure 1A). In patients with M1 lung cancer, a tendency but non-significant association towards an OS benefit was observed in the PRO symptom monitoring group (HR 0.79, 95% CI 0.61: 1.04) (Figure 1B).

Conclusions: PRO symptom monitoring was significantly associated with improved OS over a 4-year follow-up period in patients with lung cancer. Although non-significant, a similar tendency towards a survival benefit of PRO symptom monitoring in patients with M1 disease was observed. Although the impact of PRO symptom monitoring on OS might be more pronounced in patients with early-stage lung cancer, the clearly demonstrated benefits of PRO symptom monitoring on both HRQoL as well as survival in the total lung cancer population could pave the path towards successful implementation.



Keywords: Lung cancer, Symptom monitoring

EP.04.33 Exhaled Breath Analysis Using Infrared Spectroscopy Combined With Machine Learning Algorithms for Lung Cancer Diagnosis

D. Yonar[1], M. Oztekin Artuc[2], C. Taşaltın[3], F. Temurtaş[4], D. Köksal[5], Ü. Yılmaz[6], K.S. Emri[7], F. Severcan[8,9]
[1]Yuksek Ihtisas University Faculty of Medicine, Ankara/TR ,[2]Gazi University, Faculty of Sciences, Ankara/TR ,[3]TUBITAK Marmara Research Center, Ankara/TR ,[4]Bandırma Onyedi Eylul University, Faculty of Engineering, Balıkesir/TR ,[5]Hacettepe University, Faculty of Medicine, Ankara/TR ,[6]Atatürk Chest Diseases and Chest Surgery Training and Research Hospital, Ankara/TR ,[7]Memorial Bodrum Hospital, Department of Pulmonary Diseases, Muğla/TR ,[8]Altinbas University, Faculty of Medicine, Istanbul/TR ,[9]Middle East Technical University, Ankara/TR

Introduction: Lung cancer (LC) is the leading cause of cancer-related mortality worldwide, with an overall 5-year survival rate of 19% and a median survival of 12-months. Early diagnosis is crucial, and breath analysis using Fourier transform infrared (FTIR) spectroscopy is a promising non-invasive method for the early detection of LC. This study utilized FTIR spectroscopy combined with machine learning algorithms to develop a unique breath analysis method, enabling the identification of lung cancer and its discrimination from healthy individuals.

Methods: The study analyzed breath samples from 64 LC patients and 47 healthy controls. All LC patients were newly diagnosed, treatment-naïve individuals with an Eastern Cooperative Oncology Group (ECOG) performance status (PS) ≤ 2. Spectra of breath samples were obtained using a PerkinElmer Frontier FTIR spectrometer equipped with a gas cell featuring a 16-meter optical path length and a 2.3-liter internal volume. The breath samples were categorized and classified using unsupervised multivariate analysis (principal component analysis (PCA)) and machine learning techniques. The identification of LC from infrared spectra of breath samples was examined using probabilistic neural network (PNN), support vector machine (SVM), and linear discriminant analysis (LDA) classifiers.

Results: The IR gas-phase spectra from the breath samples of both LC patients and healthy controls revealed distinct spectral bands, particularly in the 1300-800 cm-1 region. Two peaks at 879 and 882 cm-1, which belongs to out-of-plane C-H bending bands of aromatic compounds, were found to be more intense in the breath samples of healthy controls compared to those of LC patients. PCA results demonstrated the most distinct separation between the breath spectra of LC patients and healthy controls in the 915-850 cm-1 region, where out-of-plane C-H bending vibrations of substituted aromatic compounds were observed. SVM and PNN techniques were effectively applied to diagnose LC from breath IR data, achieving an accuracy of slightly over 70%. The breath diagnostic approach could potentially be used as a decision support system, as 5-fold test performances for both classifiers exceed 70%. However, the 885-870 cm-1 spectral region yielded the best results in LDA classification, with an accuracy of 83.8%, while the 915-850 cm-1 region also provided comparable predictions, with an accuracy of 81.1%.

Conclusions: FTIR spectroscopy combined with machine learning techniques, emerges a potential non-invasive tool for the diagnosis of LC through exhaled breath analysis.

Keywords: exhaled breath, FTIR spectroscopy, machine learning

EP.04.34 Preliminary Results of Added Benefit of Blood-Based Biomarkers in a Lung Cancer Screening Program

K. Chiffi, M. Ronner, F. Schläpfer, M.B. Kirschner, T. Frauenfelder, S. Hillinger, I. Opitz
University Hospital Zurich, Zurich/CH

Introduction: Screening for lung cancer using low-dose computed tomography (LDCT) has been proven effective in detecting early-stage lung cancers. However indetermined results are frequent, making the best follow-up strategy difficult to determine. Researchers have identified a signature consisting of 24 microRNAs with high prognostic value [1]. Here we combine microRNAs measurements with the results obtained from LDCT, to determine and confirm the added value of circulating microRNA biomarker measurements in an independent cohort.

Methods: Blood samples from four participants of our ongoing lung cancer screening were analyzed. All participants were later on diagnosed with a malignancy. Three were diagnosed with a lung cancer, while one participant had a thyroid cancer. Two negative controls of patients with a negative biopsy were used. microRNAs were analyzed by blinded personnel. The ratios for the presence of disease (PD) and presence of an aggressive (PAD) disease were then assessed.

Results: All four malignancies showed a positive profile for PD, and a negative profile for PAD. In the controls the thresholds for PD and PAD were not crossed. The results per each participant with the correlating details of the malignancy can be found in Figure 1.

Conclusions: In our pilot, all malignancies were labeled as presences of disease, while in the negative control samples no presence was observed. In our sample, a delineation between different lung cancer stages was not yet observed, a different picture might emerge with additional samples. As the blood collection was well tolerated and the analysis of the biomarkers is well defined, there is an added benefit to guide a risk-based approach consisting of CTs and blood-based biomarker monitoring in lung cancer screenings.

EP.04.35 Innovative Intraoperative Technique for Rapid Tumor Identification in Lung Cancer Through Spectral Characterization: A Promising Exploration

M. Li[1], S. Li[2], H. Yin[1], M. Feng[1], L. Tan[1], Q. Wang[1]
[1]Zhongshan Hospital Fudan University, Shanghai/CN ,[2]Tianjin Jinhang Technical Physics Institute, Tianjin/CN

Introduction: To investigate a novel approach for the rapid identification of lung cancer tumor location and type using distinct spectral characteristics, aiming to improve intraoperative decision-making and reduce dependence on time-consuming frozen section pathology.

Methods: This study builds upon our previous findings, which characterized the mechanical rigidity of lung cancer tumor cells using spectral features and simulated mechanical signals. The optical properties of tumor tissues were evaluated using a CMOS-based spectrophotometric camera with a resolution of less than 10 nanometers. The camera is integrated with an on-chip operating system, and we developed a corresponding interface and software platform to enable portable, handheld spectral imaging analysis.

Results: During the progression of lung adenocarcinoma from adenocarcinoma in situ (AIS) to minimally invasive adenocarcinoma (MIA) and ultimately to invasive adenocarcinoma (IAC), significant spectral differences were observed between the wavelengths of 420 nm and 650 nm. These differences reflect substantial alterations in the average cellular mechanical stiffness, which are associated with changes in cytoskeletal protein characteristics per unit area of tumor tissue. We investigated the spectral characteristics of various pathological types of lung cancer tissues. Notably, distinct spectral features were observed for normal alveolar epithelial cells, lung squamous cell carcinoma, and lung adenocarcinoma across different wavelengths. Leveraging the spectrophotometric camera, we further explored the feasibility of rapid intraoperative identification of different pathological lung cancer subtypes. In a study of 30 samples (10 normal controls, 10 lung adenocarcinomas, and 10 lung squamous cell carcinomas), spectral analysis results were in complete agreement with intraoperative frozen sections and postoperative paraffin pathology findings.

Conclusions: The distinct spectral characteristics of lung cancer, resulting from differences in membrane tension compared to normal alveolar epithelial cells, suggest a viable approach for intraoperative rapid identification. Various pathological types and developmental stages of lung cancer, such as ranging from AIS to MIA and IAC, correspond to specific spectral ranges. Further research and validation are essential to confirm the effectiveness of this technique in clinical practice.

EP.04 SCREENING AND EARLY DETECTION

EP.04.36 Evaluation of the Utility of msignal® for Lung Cancer Screening in a Rural Region of Northern Japan (Hokkaido Region)

M. Aragaki[1], A. Fujiwara-Kuroda[1], K. Ohtaka[1], H. Shiiya[1], A. Sasaki[1], H. Yamasaki[1], S. Otsuka[1], S. Narita[1], Y. Takakuwa[1], K. Yokoyama[2], H. Yamaguchi[3], Y. Ando[3], M. Mikami[3], M. Mizunuma[3], Y. Ichikawa[3], T. Kato[1]
[1]Hokkaido University Hospital, Sapporo/JP ,[2]Iwanai Hospital, Hokkaido Social Welfare Association, Iwanai/JP ,[3]Craif Inc., Tokyo/JP

Introduction: Advances in minimally invasive surgery, immunotherapy, and molecular targeted therapies have significantly improved the prognosis of patients with advanced lung cancer. However, further reducing lung cancer mortality requires early diagnosis, making widespread screening essential. In particular, Hokkaido, the northernmost and second-largest island of Japan, has one of the highest cancer mortality rates nationwide. Due to its geographically vast area and limited medical access, the cancer screening participation rate in Hokkaido remains among the lowest in Japan. Recent advances in liquid biopsy technologies have made non-invasive, repeatable cancer diagnostics increasingly feasible. Among these, microRNAs (miRNAs) are gaining attention as key biomarkers involved in tumor growth, metastasis, and the tumor microenvironment, making them useful tools for early diagnosis and understanding cancer biology. Craif Inc. has developed miSignal® Scan, a testing service that analyzes urinary miRNA profiles obtained through next-generation sequencing and applies a machine learning model to distinguish between healthy individuals and those at risk of various cancer types. This service provides a risk assessment for seven types of cancer, including lung cancer, based on a predictive model. A predictive model was developed using 278 lung cancer patients and 125 healthy controls. The data were split into training and validation cohorts in a 3:1 ratio. In the study, 37 miRNAs were upregulated and 2 miRNAs were downregulated in lung cancer. A predictive model utilizing 40 selected miRNAs achieved an area under the ROC curve (AUC) of 0.951 in a validation cohort, indicating a high potential for early lung cancer detection. In this study, this service was offered to 100 elderly residents of Iwanai Town, Hokkaido, as part of a prospective observational study. High-risk individuals were referred for further diagnostic examinations at Iwanai Kyokai Hospital or affiliated institutions.This study aims to evaluate the utility of miSignal® Scan as a lung cancer screening method in a rural region with low screening participation rates.

Methods: A model case study was conducted in a rural region of Hokkaido, Northern Japan. A total of 100 individuals (male-to-female ratio of 46:54, mean age 67.2 years) aged 60 or older who had not undergone lung cancer screening in five years were screened using the miSignal® Scan technology provided by Craif Inc. Participants classified as moderate or high risk were referred for further examination with chest CT scans.

Results: Out of 100 participants, five were classified as moderate risk. Among the three individuals who underwent CT scans, one case of suspected lung cancer was identified and subsequently diagnosed as adenocarcinoma in situ (AIS) through pathological examination.

Conclusions: Urinary miRNA-based screening is a non-invasive and convenient method that can be performed at home, making it a potentially effective screening tool for regions with geographical constraints and limited medical resources. This study highlights the potential of such methods to address existing barriers to cancer screening in underserved areas. Further large-scale prospective studies are warranted to validate its utility as a novel lung cancer screening method and to explore its role in encouraging cancer screening participation in regions with low screening rates.

Keywords: Minimally invasive screening, Liquid biopsy, Cancer screening in underserved areas

EP.04.37 An Observational Study Evaluating the Benefits of AI-Assisted Lung Cancer Screening Using Chest X-Rays in Bangkok, Thailand

C. SOUDORN[1], P. Kumjornkijakarn[1], P. Chalongviriyalert[1], P. Darnpornprasert[1], P. Ubonviroj[1], W. Chainamnan[1], I. Massayavanich[1], A. Tansawet[1], P. Srirattanakarn[1], P. Euraree[1], T. Sangsawang[1], C. Alisanant[2], M. Tippornwong[1], C. Noinark[1], T. Kittikundecha[1], P. Eksamutchai[1]
[1]Medical Service Department Bangkok Metropolitant Administration, Bangkok/TH ,[2]Medical Service Department Bangkok Metropolitant Administration, Bangkok/TH

Introduction: Lung Cancer (LC) is the most common cancer and the leading cause of cancer deaths in Thailand. Low Dose CT has been shown to improve survival; however, reimbursement is not currently available. The aim of this observational study is to evaluate the performance of Artificial Intelligence (AI) to assess LC risk in Chest X-Rays (CXRs) in the Bangkok area.

Methods: qXR-Lung Nodule (LN) and qXR-Lung Nodule Malignancy Score (LNMS) algorithm was deployed across six hospitals in Bangkok. Patients with prior LC were excluded. Images flagged for nodules by AI were read by radiologists who categorized them as having nodules/normal/inconclusive and rated the risk of malignancy for those categorized as nodules into high/low/inconclusive. Images rated as inconclusive were read by a pulmonologist who suggested follow-up investigations- CT/no action/follow-up required. The Positive Predictive Value (PPV) of LN, the PPV and Negative Predictive Value (NPV) of LNMS algorithms are reported with radiologist and pulmonologist as reference standard. Patients who were referred to CT were considered as having high-risk nodules. The predictive values of LNMS were calculated using only those patients confirmed as having nodule by either radiologist or pulmonologist. The 95% CI of the predictive values were constructed using the modified Wilson's score method.

Results: Overall, 7,784 patients were screened and the AI flagged nodule in 988 (946 low-risk and 42 high-risk) patients (12.7%). Mean age was 51.7 and 62.6% were females. 79 patients were excluded from analysis due incomplete radiologist assessment. The PPV of LN was 66.4% (63.3-69.4). The PPV of LN was higher when the nodules malignancy risk was high 96.77% (83.81 - 99.43) when compared to low risk 64.92% (61.70 - 68.01). The PPV of high-LNMS was 50.0% (33.2-66.8), and the NPV of low-LNMS was 92.8% (90.4-94.7). The incidence of suspected and confirmed lung cancer was 7.79 and 1.30 per 1000 person years respectively. Increasing age and active smoking was associated with LC in this cohort.

Conclusions: AI achieved a reasonable PPV of 66.4% in flagging nodule. This could be considered clinically useful as predictive values depends on prevalence and the reference standard for this study was radiologists and a high inter-reader variability is known among radiologists. The PPV was higher when the nodule was flagged as high-risk by LNMS. A limitation of this study is there was no comparator arm to test whether AI assisted workflow had a higher incidence compared to standard workflow.

EP.04 SCREENING AND EARLY DETECTION

EP.04.38 A Computational Framework for Estimating Transportability in Cancer Screening Trials

A. Conti[1], M. Leipzig[2], A. Brown[2], J. Jopling[3], R. Dale[2]
[1]Stanford, Stanford/CA/USA ,[2]Stanford University, Stanford/CA/USA ,[3]Johns Hopkins University, Baltimore/MD/USA

Introduction: Lung cancer screening has been shown in trials such as NLST and NELSON to reduce mortality, while trials such as PLCO and ITALUNG have reported null results. Although researchers have speculated that this variation may stem from differences in baseline demographics or trial implementation, such explanations remain largely qualitative and speculative. Despite extensive critiques of screening trials and their inconsistent results, no prior work has explicitly modeled the full probabilistic pathway from screening to mortality. In particular, the pathway from screening to subsequent treatment is typically left implicit, limiting our ability to generalize trial findings to new populations. We formalize this pathway to provide a framework for policymakers to assess whether trial results are likely to transport to novel target populations.

Methods: We started with a simple model and expanded the full expression from screening S to mortality Y by incorporating disease severity D, symptom level X, and treatment T.

Results: Under randomization of screening, the naive mortality difference of the screened groups,

$E[Y=1 |S=1] - E[Y=1 | S=0]$,

identifies the average treatment effect of a screening protocol in a target population. We demonstrate an alternate decomposition of the average treatment effect that includes nontrivial terms for the difference in treatment probability

$P(T=i|(S,X,D) = (1,x,d)) - P(T=i|(S,X,D) = (0,x,d))$,

the prevalence $P(D=d)$ of disease severity, and combinations of terms of the expected outcome difference conditioned on choice of treatment and screening

$E[Y|(T,S,X,D) = (t,s,x,d)]$.

The presence of these terms even after randomization of screening indicate how the average treatment effect of screening is sensitive to both demographic factors as well as the post-screening treatment regime, both of which may vary across populations and medical contexts. Transporting trial results may therefore fail, as differences in any of these terms in a novel demographic or medical context can result in discrepant estimates of the average treatment effect of screening.

Conclusions: Randomization of screening alone does not guarantee transportable estimates of outcome differences across medical contexts. Our framework provides an avenue to explain why some trials show significant benefits while others do not: differences in post-screening treatment regimes, symptom presentations, and disease severity distributions all influence the observed mortality effects. The original publications for NLST, NELSON, PLCO, and ITALUNG did not report the joint distributions of screening, treatment, cancer staging, and outcome needed to estimate transportability to new contexts. Modeling these components allows researchers to predict whether a screening protocol will succeed in a new setting.

To improve transportability, screening trials must move beyond reporting average effects. Instead, they should publish outcomes stratified by all causal factors linking screening to mortality, especially treatment, which is often unreported or inconsistently applied across trials. These details enable decomposition of the screening effect and estimation of how well it transfers to new populations.

Ultimately, current screening trials designs are insufficient for transportable insights. By modeling the full causal pathway and requiring detailed outcome reporting, we can move from speculative interpretation to evidence-based prediction of screening efficacy across new populations.

EP.04 SCREENING AND EARLY DETECTION

EP.04.39 Lung Cancer Early Screening via cfDNA Fragmentome Profiling

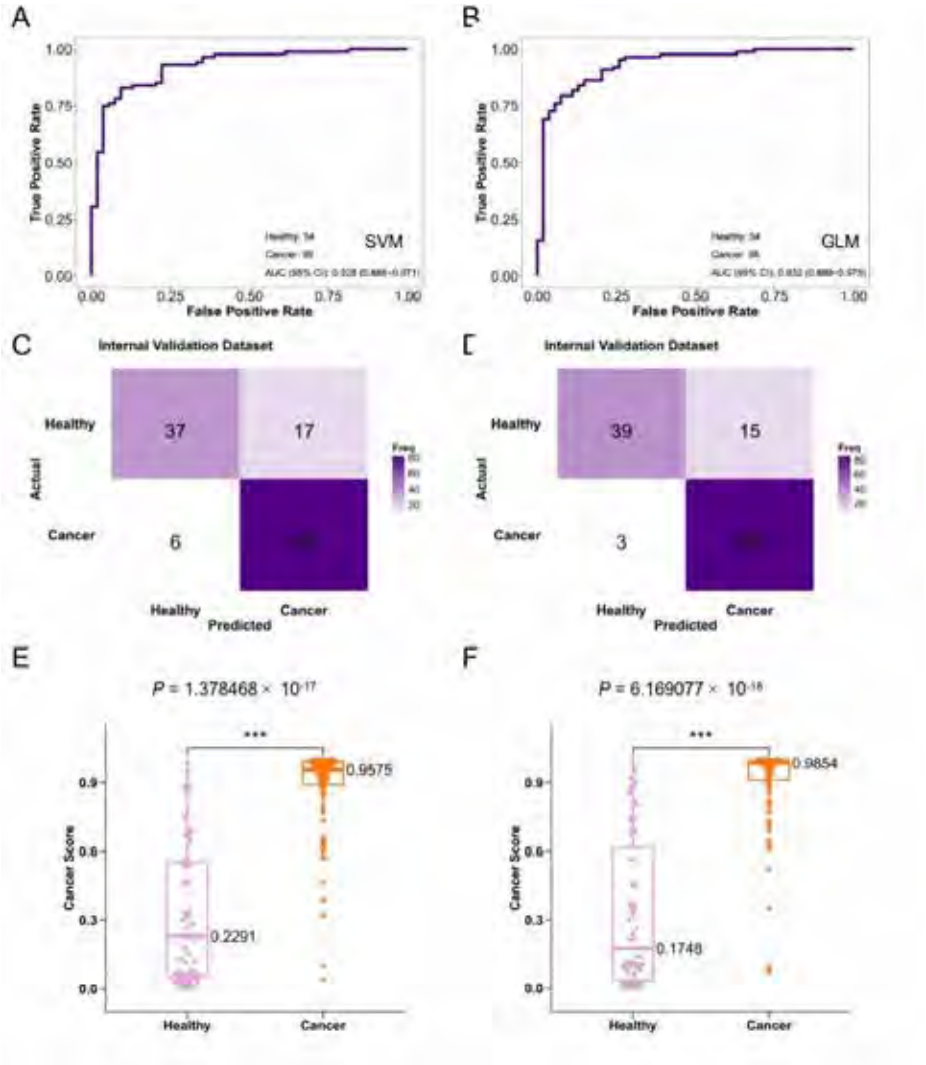
Y. Wang[1], K. Zhou[1], T. Wang[1], L. Miao[1], Z. Lin[2]
[1]Nanjing Drum Tower Hospital, Nanjing/CN ,[2]Zhejiang University, Hangzhou/CN

Introduction: Lung cancer is a leading cause of cancer-related deaths worldwide, and early screening is crucial for improving patient survival rates. cfDNA has demonstrated superior sensitivity and specificity in early screening for lung cancer. This study combines cfDNA sequencing technology with various machine learning models to explore the differentiation of benign and malignant lung nodules.

Methods: We enrolled 175 lung cancer patients and 107 healthy controls, and analyzed their plasma cfDNA samples using whole-genome sequencing (WGS). In the training cohort, multiple features were extracted, including fragment length, 3' end motif, methylation motif, N-index, E-index, and CNV, which were used as input features for analysis. We performed lung cancer malignancy prediction using generalized linear models (GLM) and support vector machines (SVM). We conducted extensive evaluation on the validation dataset. By comparing the predictions of different models, we were able to validate the accuracy, sensitivity, specificity, and generalizability of these models in lung cancer screening.

Results: This study employs deep learning algorithms to conduct multimodal integrated analysis of cfDNA molecular omics, copy number variations, and epigenetic characteristics, aiming to simultaneously achieve the differentiation of benign and malignant lung nodules. Based on the training dataset (n = 140), we constructed a multimodal deep learning classification model. The 10-fold cross-validation results showed its performance in distinguishing benign from malignant as 71.7% specificity and 92.0% sensitivity (AUC: 0.925). The model performed stably in the independent validation cohort (n = 142), with specificity and sensitivity of 72.2% and 96.6% (AUC: 0.932), respectively.

Conclusions: This study developed a deep learning model based on cfDNA multi-dimensional omics features, focusing on the precise analysis of lung cancer malignancy prediction. This approach provides a highly sensitive, non-invasive solution for lung cancer screening. Future research will involve large-scale validation and further explore the clinical potential of staging prediction and therapeutic monitoring.



Keywords: blood omics, lung cancer screening

EP.04 SCREENING AND EARLY DETECTION

EP.04.40 Preoperative Prediction of Occult Lymph Node Metastasis in Clinical Stage I NSCLC Using CT Radiomics, PET, and ctDNA

Y.J. Oh[1], G. Lee[2], J. Kim[1], H.Y. Lee[3]
[1]SAIHST, Sungkyunkwan University, Seoul/KR ,[2]Pusan National University Hospital, Pusan National University School of Medicine, Pusan/KR ,[3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR

Introduction: Accurate preoperative prediction of occult lymph node metastasis (OLNM) is essential for optimizing treatment strategy in early-stage non-small cell lung cancer (NSCLC). This study aimed to develop a multimodal predictive model combining CT radiomics, PET quantification, and ctDNA.

Methods: Patients with clinical stage I NSCLC were selected from a thoracic surgery database. Clinical data, circulating tumor DNA (ctDNA), and PET-CT quantification data were accessible for all patients. Using the preoperative contrast-enhanced CT scans, 20 radiomics features were derived from the whole tumor region of interest. All patients were divided into groups according to the pathological status of their lymph nodes, either positive (pN+) or negative (pN-) for cancer.

Results: We evaluated CT radiomics, PET, and ctDNA for OLNM prediction in 554 patients. Two predictive models were developed: Model 1 (clinical variables, CT radiomics, and ctDNA, n=554) and Model 2 (clinical variables, CT radiomics, ctDNA, and PET, n=372). LASSO regression identified key features. In Model 1, body mass index (BMI), tumor solidity, ctDNA positivity, and CT radiomics features such as kurtosis and density were selected. In Model 2, features included tumor solidity, SUVmax at the tumor edge (SUVmax_edge), and CT radiomics features, including small area low gray level emphasis, density, and mass. Model 1 achieved an AUC of 0.80 (accuracy: 0.85), and Model 2 achieved an AUC of 0.81 (accuracy: 0.87). Both models had high specificity (>0.99) but lower sensitivity. The combination of clinical, imaging, and ctDNA data enabled effective OLNM prediction across both models, supporting better risk stratification and treatment decisions.

Conclusions: Integration of CT radiomics, PET quantification, and ctDNA testing along with routine clinical variables improves OLNM prediction.

EP.04 SCREENING AND EARLY DETECTION

EP.04.41 Detecting Minimal Residual Disease (MRD) in Lung Cancer Using an Epigenetic-Based Liquid Biopsy Approach

A. Raphael[1,2], Y. Michaeli[3], s. Zirkin[3], N. Gilat[3], L. Itelson[3], Y. Ebenstein[2]
[1]Davidoff Cancer Center, Rabin Medical Center, Petah-Tikva/IL ,[2]Tel-Aviv University, Tel-Aviv/IL ,[3]JaxBio Technologies LTD., Netanya/IL

Introduction: Detecting minimal residual disease (MRD) in lung cancer is critical, as many patients relapse after curative surgery. Despite therapeutic advancements, a widely accessible, precise MRD detection method remains unavailable. Liquid biopsy, particularly analysis of cell-free DNA (cfDNA) and its epigenetic signatures, offers a promising non-invasive solution.

Methods: We developed a novel, ultra-sensitive, and cost-effective blood-based assay for lung cancer detection and monitoring.

- Sample Collection: Blood samples were collected from 47 early-stage NSCLC patients and 64 healthy individuals.
- cfDNA Isolation & Epigenetic Profiling: cfDNA was extracted, fluorescently labeled, and hybridized to a custom microarray targeting lung cancer-specific methylation regions.
- Data Analysis: An AI-based pipeline was used for biomarker selection. Epigenetic patterns were evaluated using heatmap clustering, principal component analysis (PCA), and ROC curves. Sensitivity and specificity were optimized using the Youden Index.

Results:

· Early Detection: The assay distinguished NSCLC patients from healthy controls with 91% sensitivity and 94% specificity.

· MRD Detection: In five NSCLC patients tested pre-operatively, one day post-op, and one month post-op, four showed a marked shift in their epigenetic profile post-surgery, clustering with healthy controls in PCA, suggesting significant tumor DNA clearance.

· Limitations: Small sample size, tumor heterogeneity, and potential confounding from benign lung conditions.

Conclusions: This novel epigenetic-based liquid biopsy shows strong potential for detecting MRD and monitoring recurrence in early-stage NSCLC. The observed epigenetic shifts post-surgery support its utility in real-time tumor monitoring and early intervention. Ongoing studies aim to validate these findings in larger cohorts and assess integration into personalized lung cancer management.

EP.04 SCREENING AND EARLY DETECTION

EP.04.42 Alunghive: Autonomous Registry and Analytics System to Transform Clinical Workflow and Enable Multicenter Lung Cancer Screening Research

M.N. Kammer[1], P-F. D'Haese[2], F. Maldonado[3]
[1]Centre de Recherches en Cancérologie de Toulouse, Toulouse/FR ,[2]West Virginia University, Morgantown/WV/USA ,[3]Vanderbilt University Medical Center, Nashville/TN/USA

Introduction: The expansion of low-dose CT (LDCT) lung cancer screening programs has introduced significant operational complexity across health systems, particularly in managing longitudinal workflows, follow-up adherence, and multicenter research participation. Despite growing adoption of AI tools for nodule detection and Lung-RADS classification, integration into real-world workflows remains disjointed, often reliant on manual data abstraction, unscalable registries, and fragmented communication between clinical and research teams. There is a critical need for a system-level solution that unifies imaging, clinical data, and research workflows into a single autonomous platform.

Methods: We developed LungHive, an autonomous clincial patient registry, a digital health infrastructure designed to autonomously ingest imaging and clinical data, apply validated AI pipelines, and output structured insights for both care delivery and research purposes. Within AURA, the LungHive vertical provides a turnkey solution for lung cancer screening and trial support. The system integrates with PACS, EHR, and research databases, enabling real-time AI analysis (Lung-RADS scoring, temporal nodule tracking), patient-specific registry building, and dynamic eligibility screening. We deployed AURA-LungHive at Vanderbilt University Medical Center, embedding it into the clinical screening flow and configuring it to support prospective research trials across multiple sites.

Results: AURA-LungHive processed LDCT imaging and clinical context from over 2,000 patients, producing structured outputs including Lung-RADS scores, growth metrics, risk of developing lung cancer, probability of malignancy of pulmonary nodules based upon several radiomic models, and care recommendations. Integration with Vanderbilt's workflows enabled: (1) Autonomous registry generation and real-time tracking of follow-up compliance (2) Pre-filled radiology reports and dashboards for care teams, reducing time-to-read and improving standardization (3) AI-driven eligibility algorithms that combined structured imaging and unstructured clinical data (e.g., smoking history, comorbidities) to support real-time cohort discovery for research protocols. (4) A single unified data pipeline serving both clinical care and research data capture, reducing duplication and manual effort. The system also supports federated deployments across multiple centers, allowing external institutions to join shared trials while maintaining local workflows. AURA was configured to be compliant with HIPAA, 21 CFR Part 11, and institutional IRB requirements, ensuring interoperability and auditability.

Conclusions: LungHive demonstrates a scalable, autonomous framework to support both clinical lung cancer screening and multicenter research trial infrastructure. By bridging imaging, clinical, and research systems through an AI-powered registry, the platform enables a new model of screening that is intelligent, efficient, and trial-ready. Unlike point AI tools, AURA represents a full-stack transformation of lung cancer workflow—from detection to intervention to discovery. Integration within the Vanderbilt and ongoing expansion to additional sites highlights its potential as a foundational layer for learning health systems in thoracic oncology.

EP.04 SCREENING AND EARLY DETECTION

EP.04.43 Chest X-Ray Analysis With Artificial Intelligence Software Aids in the Early Diagnosis of Lung Cancer- a Case Series

D. Koksal[1], A. BAYKAN[1], G. Durhan[1], S. Sarinc[1], M.G. Akpinar[1], F. Demirkazik[1]
[1]Hacettepe University, Ankara/TR

Introduction: Lung cancer is the leading cause of cancer-related mortality worldwide. Though screening with low dose computed tomography (LDCT) is effective in reducing mortality, widespread adoption is limited. Chest X-ray is a frequently used imaging modality. Pulmonary nodules are often missed or underreported on routine chest X-rays, contributing to missed lung cancer diagnosis. Artificial intelligence (AI)-based software has shown potential in identifying high-risk nodules. But prospective reports on the real-world impact of these tools on patient outcomes are limited.

Methods: qXR software (Qure.ai, Mumbai India) is a deep learning based algorithm that can detect lung nodules on posteroanterior (PA) chest X-rays. qXR also categorizes the nodules as low or high risk. qXR automated interpretation tool was routinely used on all chest X-rays obtained in our center from February 2024 till November 2024. Patients flagged with a high-risk nodule by qXR were reviewed by radiologists and chest physicians, and in case of suspicion were evaluated further with a thoracic CT scan.

Results: We present case series of three patients in whom AI software (qXR, Qure.ai) flagged suspicious pulmonary nodules on chest X-rays obtained for non-respiratory conditions (Table 1: case 1- screening prior to anti-TNF therapy, case 2- fever evaluation, case 3- smoking cessation counseling). Subsequent imaging and biopsy confirmed early-stage lung cancer in all cases. Each patient underwent curative surgical intervention with favourable outcomes.

Conclusions: AI-powered chest X-ray analysis can act as a safety net, particularly in settings with limited radiologist availability or high workloads. It also offers a screening opportunity independent of specific criteria such as age, smoking history, or family history of cancer diagnoses. In countries without lung cancer screening programs or where radiologists do not evaluate all chest X-rays, the use of AI software for chest X-ray analysis can enable early detection of high-risk nodules.

Table 1: Summary of patients diagnosed with early stage lung cancer through nodules detected by AI chest X-ray

Age/ Gender	Primary presentation	Admission clinic	Nodule diameter on chest X ray	Nodule diameter on CT	Diagnosis	pTNM stage
57/ Male	Evaluation for anti-TNF treatment in a patient with ulcerative colitis	Gastroenterology	9 mm	9 mm	Adenocarcinoma	T2a (vpi) N0 M0
64/ Male	Hyperglicemia and fever, diagnosed as urinary tract infection	Emergency	23 mm	19 mm	Adenocarcinoma	T1b N0 M0
65/ Female	Cessation of smoking therapy	Family medicine	18 mm	24x37 mm	Squamous cell carcinoma	T3 (satellite nodule) N0 M0

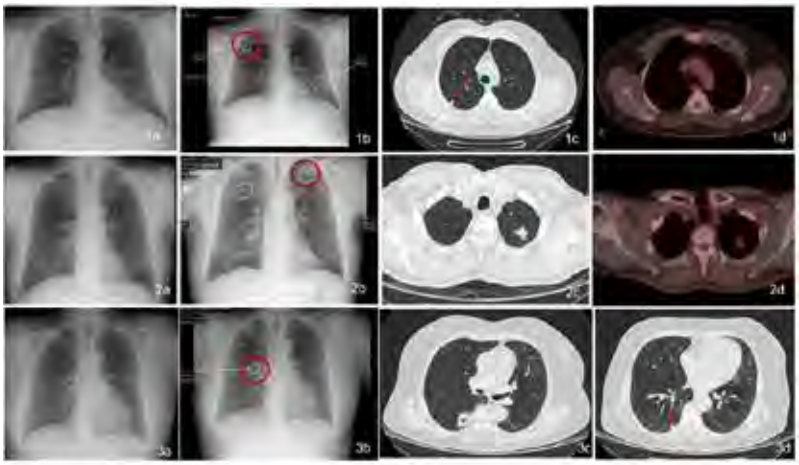

Figure. 1,2,3a: Chest X-ray image of the patients without AI, 1,2,3b: AI interpretation of chest X-ray. Suspicious nodules are marked by red circles, 1,2,3c and 3d: Computed tomography (CT) sections (Arrows show nodules), 1,2d: PET/CT sections

EP.05 PULMONOLOGY AND STAGING

EP.05.01 Use of Endobronchial Ultrasound-Guided Transbronchial Needle Aspiration in the Molecular Characterization of Non-Small Cell Lung Cancer

E. Caballeria Lamelas, M. Albert Ribera, A. Riudor Guri, C. Teixidó Febrero, D. Martínez Hernández, N. Reguart, C. Agustí García-Navarro, C.M. Lucena Pozo
Hospital Clínic de Barcelona, Barcelona/ES

Introduction: Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) represents the gold-standard technique for the assessment of hilar and mediastinal lesions. The molecular characterization of non-small cell lung cancer (NSCLC) aims to identify genetic and molecular alterations that drive tumorigenesis, disease progression and therapeutic resistance. This approach has elucidated key oncogenic mutations in genes such as EGFR and KRAS, as well as the expression of predictive biomarkers such as PD-L1 (Programmed Death-Ligand 1), which play a crucial role in guiding targeted therapies. Advances in high-throughput sequencing technologies, including Next-Generation Sequencing (NGS), have revolutionized molecular profiling, enabling the refinement of personalized treatment strategies

Methods: A retrospective cohort study was conducted, analysing 836 patients who underwent linear EBUS between 2021 and 2024 at Hospital Clínic de Barcelona.

Results: A total of 147 NSCLC patients who underwent EBUS-TBNA for molecular testing were included in the study. The cohort predominantly comprised male patients (61%) with a mean age of 66.57 years. Active smokers accounted for 39% of cases, while 51% were former smokers. Pulmonary adenocarcinoma was the most common histological subtype (56%), with the primary tumour localized in the right upper lobe in 40.1% of cases. NGS analysis was unfeasible due to insufficient sample material in 2% (3/147) of cases. The subcarinal lymph node was the most frequently sampled site (41.5%). The mean tumour cell count was 55.25. In 83% (119/144) of cases, molecular analysis was positive, with TP53, KRAS, and EGFR mutations detected in 16.6%, 26.9%, and 13.1% of cases, respectively. Regarding PD-L1, in 82% of cases (120/147), the sample was adequate for analysis, with a positivity rate of 39%.

Conclusions: EBUS-TBNA-derived cytological specimens serve as a critical resource for the comprehensive molecular characterization of NSCLC, reinforcing their pivotal role in precision oncology and the implementation of targeted therapeutic strategies.

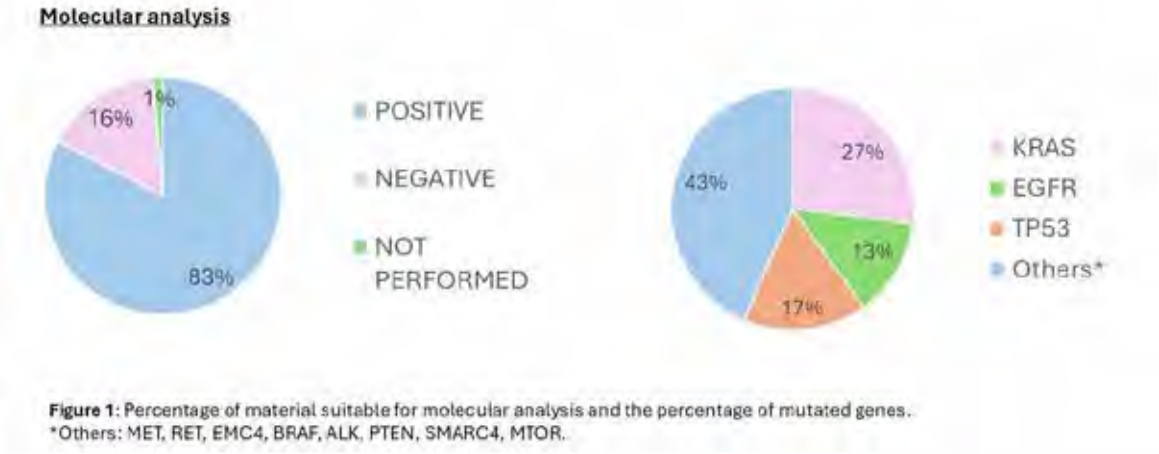

Figure 1: Percentage of material suitable for molecular analysis and the percentage of mutated genes. *Others: MET, RET, EMC4, BRAF, ALK, PTEN, SMARC4, MTOR.

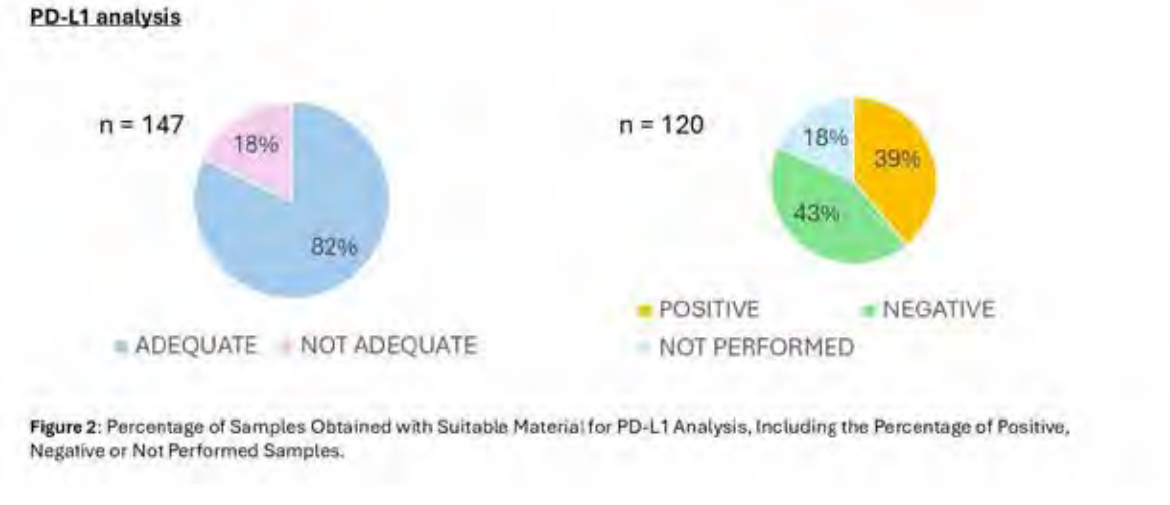

Figure 2: Percentage of Samples Obtained with Suitable Material for PD-L1 Analysis, Including the Percentage of Positive, Negative or Not Performed Samples.

EP.05.02 Evaluation of ROSE Utility in Multiplex Gene-Panel Testing Using Samples From EBUS-GS for Lung Cancer

Y. Nakamura[1], K. Murakami[2], Y. Taguchi[1], S. Yamamoto[1], S. Ariyasu[3], S. Matsumoto[4], N. Nogami[1], O. Yamaguchi[1]
[1]Ehime University Graduation School of Medicine, Toon, Ehime/JP ,[2]Saiseikai Imabari Hospital, Imabari, Ehime/JP ,[3]Kawasaki University of Medical Welfare, Kurashiki, Okayama/JP ,[4]National Cancer Center Hospital East, Kashiwa, Chiba/JP

Introduction: The genomic diagnostic yield remains a significant challenge in the era of targeted therapy. Endobronchial ultrasound-guided sheath (EBUS-GS) transbronchial lung biopsy is a widely utilized procedure for the evaluation of peripheral pulmonary lesions (PPLs). Additionally, Rapid On-Site Evaluation (ROSE) serves as a supplementary method for real-time decision-making. While both EBUS-GS and ROSE are well-established techniques for PPLs biopsy, the utility of ROSE in assessing EBUS-GS obtained samples for multiplex gene-panel testing (MGPT), including next-generation sequencing, has yet to be fully elucidated.

Methods: We retrospectively analyzed consecutive cases of patients who underwent MGPT using specimens obtained via EBUS-GS at Ehime University Hospital and Saiseikai Imabari Hospital between Spring 2020 and Spring 2024. Patients were categorized into two groups: the ROSE group (undergoing ROSE during bronchoscopy) and the non-ROSE group (without ROSE). The primary objective of this study was to determine the MGPT success rate. Statistical analysis was performed using logistic regression with inverse probability weighting (IPW) to adjust for multiple covariates.

Results: A total of 89 patients were included, of whom 60 (67.4%) were male. The median age was 72.0 years (interquartile range: 67.0-77.0 years). ROSE was performed in 33 patients (37.1%). Successful MGPT results were obtained in 31 of 33 patients (93.9%) in the ROSE group and in 42 of 56 patients (75.0%) in the non-ROSE group, demonstrating statistical significance (p = 0.043). After IPW adjustment, the ROSE group exhibited a significantly higher MGPT success rate, with an odds ratio of 5.37 (95% confidence interval: 1.09-26.4; p = 0.042).

Conclusions: Although this study could not directly assess whether ROSE improves the adequacy of gene products, it demonstrated for the first time a significant improvement in MGPT success rates when ROSE was utilized during EBUS-GS. We consider that ROSE enhances the precision of biopsies, thereby increasing MGPT success.

Table 1. Logistic regression analysis of MGPT success before and after IPW

Before IPW adjusted (mono-variate)	OR (95%CI)	p-value
Age > 70	0.51 (0.15-1.72)	0.275
Male	0.93 (0.29-2.97)	0.900
Smoking history	0.95 (0.270-3.30)	0.932
Solid tumor	0 (0-infinite)	0.994
Upper lobe	0.82 (0.28-2.44)	0.728
Outer location	1.13 (0.35-3.63)	0.843
Target legion size > 20mm	3.14 (0.67-14.78)	0.148
Distance from pleura > 10mm	0.74 (0.25-2.18)	0.583
CT-BS positive	0.74 (0.08-6.65)	0.792
Interstitial lung disease	0.32 (0.07-1.50)	0.148
"within" image of EBUS	9.14 (2.73-30.64)	0.0003
ROSE	5.17 (1.09-24.41)	0.038
After IPW adjusted	**OR (95% CI)**	**p-value**

EP.05 PULMONOLOGY AND STAGING

EP.05.03 Analysis of Left Upper Pulmonary Arterial Bronchial Concomitant Consistency Based on Three-Dimensional Reconstructio

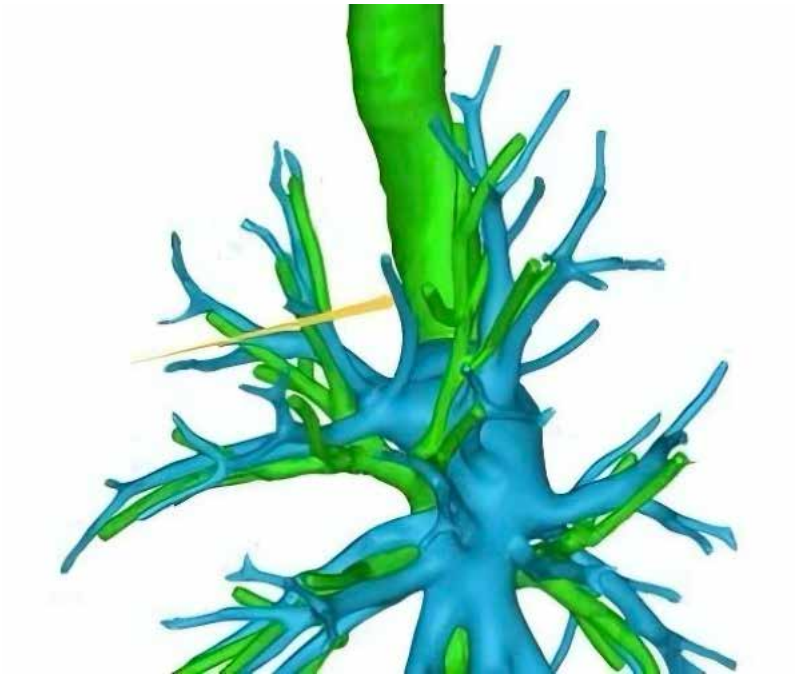
Y. Deng[1], B. Zhang[1], Z. Yu[1], X. Guo[1], J. He[2]
[1]Shenzhen Cancer Hospital, Shenzhen/CN ,[2]National Cancer Center, China, Beijing/CN

Introduction: Variations in blood vessels and bronchi in the upper lobe of the left lung are very common. The aim of this study is to summarize the accompanying conditions of arterial and bronchial variability in the left upper under three-dimensional(3D) reconstruction.

Methods: From September 2019 to December 2023, 300 patients with early-stage non-small cell lung cancer in the upper left lung who underwent preoperative lung 3D reconstruction planning were included in this study and the the accompanying pulmonary artery bronchus was analyzed.

Results: The most common type of cross lobar distribution is the variant distribution of A8 branch to the lingular region, with a total of 67 cases: A8 branch entering S5(57/300, 19%); A8 branch enters S4(9/300, 3%); A8 branch enters S4+5 (1/300,0.3%). The proportion of A8 branches with cross lobe distribution and fused fissure was 29/67(43.2%). The incidence of A8 variant distribution and fused fissure was statistically significant (P=0.001). The incidence of bronchial and arterial concomitant variation was higher in S1+2c and S3a. There was a significant statistical difference in the correlation analysis between the distribution of A1+2 branches and the accompanying variation of S1+2c arteries and bronchi (P=0.045). There was a significant statistical difference in the correlation between the common trunk types of A3a, b, and c branches and the accompanying variation of A3a arteries and bronchi (P=0.000). The most common accompanying variations of arteries and bronchi in the lingular segment were two types of mediastinal lingual artery.

Conclusions: Preoperative 3D reconstruction is helpful for in-depth analysis of the distribution of left upper lobe arteries and accompanying variations in arterial bronchi, which may facilitate surgeon to perform segementectomy for early-stage lung cancer.



Keywords: three-dimensional, left upper lobe, accompanying variation

EP.05.04 SUVmax Predicts Pathologic Complete Response and Survival in Lung Cancer Patients Undergoing Neaodjuvant Treatment

M. Ağkoç[1], H. Melek[2], H. Turna[3], F. Öner Dinçbaş[3], K. Kaynak[3], C. Gebitekin[2], A. Turna[3]
[1]Erzurum City Hospital, Erzurum/TR ,[2]Uludağ University Medical School, Bursa/TR ,[3]Istanbul University-Cerrahpasa Cerrahpasa Medical School, Istanbul/TR

Introduction: Pathologic complete response (PCR) is linked to improved overall and recurrence-free survival in patients with non-small cell lung cancer (NSCLC) treated with neoadjuvant chemoradiotherapy. While several clinical factors have been identified as predictors of PCR, the role of positron emission tomography/computed tomography (PET/CT) in this context remains under investigation.

Methods: We retrospectively analyzed 115 consecutive patients who underwent pulmonary resection following neoadjuvant chemotherapy or chemoradiotherapy at our institution between June 2006 and October 2024. Major pathologic response (MPR) was defined as the presence of less than 10% viable tumor cells, and pathologic complete response (PCR) was defined as the complete absence of viable tumor cells in the postoperative pathological examination

Results: Demographic and clinical features of the cohort is summarized in Table 1. Lower SUVmax on PET/CT performed after neoadjuvant treatment was associated with higher likelihood of PCR (p=0.008, Odds Ratio 0.85 [95% Confidence Interval 0.75-0.95]). The area under ROC curve (AUC) was 0.77 (Figure 1), and the optimal threshold of SUVmax was found to be 6.45. PCR rate was significantly lower in the higher SUVmax group (6.4% vs. 42.1%, p<0.0001). Patients who achieved a major pathologic response and complete pathologic response had median survival times of 117.6 ± 20.6 months and 56.5 ± 9.9 months, respectively (p = 0.034)(Figure)

Conclusions: Low SUVmax on PET/CT performed after neoadjuvant chemoradiotherapy is a strong predictor of pathologic complete response (PCR) and overall survival in patients with NSCLC, with a threshold of 6.45. Further research may elucidate whether select patients in this group could benefit from close follow-up rather than surgical resection.

EP.05 PULMONOLOGY AND STAGING

EP.05.05 Invasive Mediastinal Staging of NSCLC Using Vamla: Results and Perspectives

S. Samsonik[1], Y. Esakov[2]
[1]Oncology Centre No. [1] of the Yudin City Clinical Hospital of the Moscow City Health Department, MOSCOW/RU ,[2]City clinical hospital named after S. S. Yudin, Moscow City Health Department, Moscow/RU

Introduction: Invasive mediastinal staging of resectable NSCLC is still discussible field of thoracic oncology especially in the era of novel therapeutic opportunities of combined treatment. Hereby we present immediate results and impact to the treatment decisions of video-assisted mediastinal lymphadenectomy (VAMLA) and video-mediastinoscopy in routine using.

Methods: In period from August 2020 to December 2024 we retrospectively reviewed diagnostic results of 1110 patients after VAMLA. Median age was 65 (58; 69) years with male predominance 90/20. Centrally located NSCLC was diagnosed in 33 (32,4%) cases. The indications for invasive mediastinal staging were as follows: central tumor, tumor size > 30 mm, lymph node size > 10 mm, lymph node SUV > 2,5.

Results: The clinical stage (TNM 8) after invasive staging was changed in 58 (52,7%) of 110 patients (95%CI:40.3-62.3), with an up- and downstaging rates in 12 (10.9%;95%CI:5.8-18.3) and 46 (41%;95%CI:32.5-51.6) cases respectively. Firstline therapy was surgery, chemoimmunotherapy in 63 (57,2%) and 43(39,1%) cases. Complication rate following mediastinal staging was 7,2% (n=8) including recurrent nerve palsy, azygous vein injury, seroma and hemothorax in 4 (3,6%), 2 (1,8%), 1 (0,9%) and 1 (0,9%) case respectively.

Conclusions: Invasive mediastinal staging using VAMLA is important investigation for patients with clinically locally advanced NSCLC, especially to establish patients with pathomorphological N0-N1 disease to ensure the best first step in multimodality treatment.

EP.05.06 Should We Screen Patients With Stage IV Non-Small Cell Lung Cancer for Brain Metastases at Diagnosis?r

A. Goudsmit, M. Brandão, N. Kotecki, T. Berghmans
Institut Jules Bordet, Brussels/BE

Introduction: Brain metastases (BM) significantly impact morbidity and mortality in NSCLC patients, with approximately one-third developing BM during the course of their disease. According to the 2025 NCCN guidelines, every NSCLC patient should be screened for brain metastasis except stage I. However, we did not found in the literature characteristics to better select those patients who would really benefit of brain MRI screening. Regarding the treatments of BM, indications for SBRT are increasing and systemic treatments such as brain penetrating targeted therapies and immune checkpoint inhibitors are substantially modifying frontline brain therapeutic algorithm. Although prior studies suggested that brain MRI screening is associated with longer survival, it remains unclear whether early BM detection reduces the use of WBRT and related potential neurotoxicity. These advances in oncology alter the incidence and prognosis of BM, highlighting the need for a deeper understanding of BM epidemiology to optimize management strategies.

Methods: We retrospectively analyzed clinical data from patients diagnosed with NSCLC between 2010 and 2020 at Institut Jules Bordet, Belgium. All patients underwent brain MRI at diagnosis. The objective was to assess the added value of brain MRI in patients with newly diagnosed stage IV NSCLC with extracranial metastases and without neurological symptoms.

Results: Of 381 stage IV NSCLC patients initially included, 326 met the inclusion criteria; 45 patients were excluded due to symptomatic BM at baseline, and 10 due to the absence of extracranial metastases. Asymptomatic BM was detected in 53 patients (16%). Demographic characteristics are detailed in Table 1. Patients with baseline BM had a significantly worse performance status (PS) and more lung, bone, adrenal and/or soft tissue metastases at baseline. The other demographic variables showed no significant differences. First-line treatments for patients with baseline BM included best supportive care (BSC) (N=4), local brain treatment alone followed by BSC (N=6), combined local and systemic treatment (N=13), and systemic treatment alone (N=30). Among patients receiving local brain treatment (n=19), 16 underwent upfront whole-brain radiotherapy (WBRT). In the cohort without BM at baseline, 91 patients (33%) subsequently developed BM, of whom 55 received WBRT.

Conclusions: Our study confirms the high incidence of asymptomatic BM in stage IV NSCLC (1 in 6 patients), supporting systematic brain MRI in the initial diagnostic work up. Only a worse PS and some metastatic sites showed a predictive value for baseline BM. These results should be validated in prospective studies such as BrainStorm (NCT04109131), a multicentric prospective cohort.

EP.05.07 Prognostic Impact of Double Positive in EGFR Mutation and PD-L1 Expression in Resected pN0M0 G2-3 Adenocarcinoma

M. Ito[1], Y. Miyata[2], K. Suda[1], S. Ohara[1], A. Hamada[1], M. Chiba[1], M. Shimoji[1], T. Takemoto[1], H. Ujiie[1], Y. Tsutani[1]
[1]Kindai University, Osaka/JP ,[2]Hiroshima University Hospital, Hiroshima/JP

Introduction: Actionable EGFR mutation and expression of PD-L1 guide the treatment strategy in resected lung adenocarcinoma postoperatively or after recurrence. We have reported positive EGFR mutation status is a risk of recurrence in pathological intermediate or high-grade cases, and PD-L1 expression status is known to be positive in high-malignant cases with solid component. The prognostic impact of EGFR mutation accompanied by positive PD-L1 expression is little known. We evaluate the prognostic impact of concomitant expression of EGFR mutation and PD-L1 expression in completely resected adenocarcinoma.

Methods: We retrospectively reviewed consecutive completely resected pN0M0 adenocarcinoma cases with moderate or high risk of recurrence (IASLC histological Grade 2-3). EGFR mutation status and PD-L1 expression were evaluated in all reviewed cases. We excluded cases with no or little risk of recurrence (AIS, MIA, or IASLC histological Grade 1), treated with adjuvant EGFR-TKI, lack in data, or histological variant types.To evaluate the prognostic impact, recurrence-free survival (RFS) was calculated using Kaplan-Meier method and compared using the log-rank test. Significance was defined as a two-tailed P-value < 0.05.

Results: We reviewed 190 cases. EGFR mutation was detected in 81 cases and PD-L1 expression was positive (TPS >1%) in 119 cases. Forty-four cases harbored EGFR mutation accompanied by positive PD-L1 expression, and 37 cases harbored EGFR mutation without PD-L1 expression.Five-year RFS of EGFR+/PD-L1+ and EGFR+/PD-L1- were 73.1 % and 84.5 %, respectively (HR 2.77, 95%CI 1.04-6.30, p value = 0.041). There was no significant difference between two cohort regarding sex, age, surgical procedure, tumor invasive size, histological grade, pleural invasion, and lymphovascular invasion status. Multivariate analysis revealed positive PD-L1 expression (TPS >1%), tumor invasive size, and lymphovascular invasion were significantly related to worse RFS (positive PD-L1 expression: HR 2.09, 95% CI 1.040-4.206, p value = 0.039).

Conclusions: Double positive status of EGFR mutation and PD-L1 expression is related to worse RFS in resected pN0M0 histological Grade 2-3 adenocarcinoma compared to EGFR-mutant but PD-L1 negative cases. Evaluating EGFR mutation and PD-L1 expression might be useful to classify the resected cases by risk of recurrence.

Keywords: EGFR, PD-L1, staging

EP.05.08 Endobronchial Ultrasound-Guided Transbronchial Needle Aspiration (EBUS-TBNA) for Staging cN0-N1 Non-Small Cell Lung Cancer

L.R. Cabanillas-Paredes[1], S. Call[2], J. Sanz-Santos[2], L. Esteban-Tejero[2], Á. Jaén[3], C. Obiols[2], L. Luizaga[2], A.M. Andrei[2], J.M. Ochoa-Alba[2], M. Serra-Mitjans[2], R. Rami-Porta[2]
[1]Hospital Universitari Mútua Terrassa, Terrassa/MX ,[2]Hospital Universitari Mútua Terrassa, Terrassa/ES ,[3]Fundació Docència i Recerca Mútua Terrassa, Terrassa/ES

Introduction: The diagnostic performance of EBUS-TBNA for staging clinical (c) N0-1 NSCLC is low. We aimed to assess: 1) the accuracy of EBUS-TBNA; 2) the rate and associated risk factors for unsuspected (u) N2 rates in patients with NSCLC and normal mediastinum by integrated positron emission tomography (PET) - computed tomography (CT).

Methods: Retrospective observational single-centre study of all consecutive systematic EBUS-TBNA for staging cN0-1 NSCLC from 2017 to 2024. All patients with negative EBUS-TBNA underwent VAMLA as confirmatory test. Systematic nodal dissection (SND) performed during lung resection was considered the reference standard test to validate negative VAMLAs. Pathologic findings were reviewed, and staging values were calculated (including 95% confidence interval [CI]) using the standard formulas. uN2 rates were analysed in the global series and in the subgroups of tumours according to their clinical tumour and nodal categories by PET-CT. Clinical and histological variables were analysed using univariable (Chi-square or Fisher's exact test) and multivariable logistic regression to identify predictors for uN2.

Results: 112 patients (83 men; median age 67, range 46-84) underwent EBUS-TBNA. A mean of 4.7 nodal stations and a mean of 10.4 lymph nodes were sampled. 7 EBUS were positive; 105 patients underwent VAMLA and 15 were positive; 90 patients underwent resection and SND identified 1 N2 at #9 lymph node station. Table 1 shows staging values of EBUS-TBNA according to cN category. The uN2 rate for the whole series was 20.5%. The uN2 rates according to presurgical cT and cN categories by PET-CT were: 5.71% (2/35) in cT1N0; 13.3% (4/30) in cT2N0; 26.6% (4/15) in cT3N0; 33.3% (2/6) in cT4N0; 42.3% (11/26) in cN1. Multivariate logistic regression analysis revealed that cT3-4N0 (odds ratio (OR)= 3.47 [95% confidence interval (CI) 1.21-9.96], p=0.02) and cN1 (OR 3.50, 95% [CI 1.22-10.05], p= 0.02) were independently risk factors for uN2.

Conclusions: The diagnostic performance of EBUS-TBNA alone for staging this specific setting of tumours was unsatisfactory. The rate of uN2 of this cohort of patients with cN0-1 NSCLC was high. The addition of confirmatory VAMLA adds value and could be considered the reference staging procedure for staging NSCLC and normal mediastinum especially for cT3-4N0 and cN1 tumours.

Table 1. Staging values of EBUS-TBNA according to cN category

	n	Preval. (%)	Sensitivity 95% CI	Specificity 95% CI	PPV 95% CI	NPV 95% CI	Accuracy 95% CI
cN0	86	13.9	0.36 (0.15-0.64)	1 (0.95-1)	1 (0.51-1)	0.91 (0.83-0.95)	0.91 (0.84-0.96)
cN1	26	42.3	0.27 (0.09-0.56)	1 (0.79-1)	0 (0-0.20)	0.72 (0.43-0.90)	0.69 (0.5-0.83)

EP.06.01 Tumor-Infiltrating Lymphocytes as Predictors of Chemotherapy Response in Non-Small Cell Lung Cancer: A Retrospective Cross-Sectional Stud

A. Caldart Tregnago, A. Borba Reiriz, D. Ribeiro Pinto Filho, F. Firmbach Pasqualotto, M. Michelon Menetrier
Universidade de Caxias do Sul (UCS), Caxias do Sul/BR

Introduction: Tumor-infiltrating lymphocytes (TILs) have emerged as potential biomarkers of prognosis and response to therapy in non-small cell lung cancer (NSCLC). While high TIL density has been associated with better outcomes, their predictive value for chemotherapy response remains underexplored. This study evaluates the correlation between TIL density and tumor size reduction after exclusively chemotherapy treatment in NSCLC patients.

Methods: This retrospective cross-sectional study included 51 NSCLC patients (stage III-IV) treated exclusively with chemotherapy. TIL density was assessed in hematoxylin-eosin (H&E)-stained biopsy specimens obtained post-chemotherapy and categorized as low (0-25%), moderate (25-50%), or high (>50%). Tumor size before and after treatment was measured via imaging. ANCOVA was performed to determine the association between TIL density and tumor reduction, adjusting for confounders (age, sex, and clinical stage). Interobserver agreement for TIL quantification was evaluated using Cohen's kappa, Fleiss' kappa, and Krippendorff's alpha.

Results: Higher TIL density was significantly associated with greater tumor shrinkage ($F = 83.109$, $p < 0.001$, $\eta^2 = 0.551$). Patients with high TIL levels showed a mean tumor reduction of -3.18 cm (SD = 1.52), while those with low TILs exhibited a reduction of 0.52 cm (SD = 2.28). TIL density also correlated positively with overall survival, with high-density patients demonstrating the longest survival (mean 22.75 months, SD = 21.90). Interobserver agreement for TIL categorization was substantial (mean Cohen's kappa = 0.673).

Conclusions: TILs are promising biomarkers for predicting chemotherapy response in NSCLC. Standardized TIL assessment may improve patient stratification and treatment planning, with potential implications for immunotherapy escalation or, conversely, identifying patients who may not require immunotherapy. Further prospective studies integrating immunohistochemistry and molecular profiling are needed to refine TIL-based therapeutic strategies.

EP.06.02 Clinical Significance and Preoperative Prediction of High-Grade Subtypes in Early-Stage Lung Adenocarcinoma

M. Mikubo, S. Tamagawa, Y. Kondo, S. Hayashi, M. Naito, K. Shiomi, M. Ichinoe, Y. Satoh
Kitasato University School of Medicine, Kanagawa/JP

Introduction: The indication for sublober resection for early-staged lung cancer is determined based on radiographic findings including tumor size and consolidation tumor ratio (CTR) according to the JCOG study. However, some cases exhibit discrepancies between the results of preoperative imaging and postoperative histopathological examination and poor patient outcomes. The biological backgrounds of these cases remain unclear.

Methods: We reviewed 585 patients who underwent complete resection for lung adenocarcinoma with tumor size ≤3cm and cN0 between January 2011 and December 2019. We examined the relationship between clinical outcomes and histologic characteristics, especially focusing on high-grade components: solid (SOL) or micropapillary (MIP). Furthermore, the predictive ability of radiologic or cytopathologic examinations for those subtypes was evaluated.

Results: The SOL and MIP components were identified in 98 (16.8%) and 90 (15.4%) patients, respectively. Radiology-pathology discordance was found in 148 (25.2%) patients and significantly associated with the presence of histologic high-grade components, with 71.9% and 70.4% of patients with upstaged lymph node and pleural invasion statuses having high-grade components, respectively. The overall and recurrence free survival of patients with high-grade components were significantly worse than those of patients without them. In multivariate analysis, SOL and MIP components were independent prognostic factors (hazard ratio, 2.01 and 1.96; p = .02 and .02, respectively). The distribution of high-grade components was distinctly associated with tumor size and CTR. Logistic regression analyses for preoperative prediction of high-grade component demonstrated that radiographically pure-solid appearance and higher high maximum standardized uptake value were independent predictors of SOL component whereas no independent predictor of micropapillary component was found. Among pre- or intra-operative cytopathologic examinations, intraoperative touch imprint cytology exhibited the highest detection rate of MIP component (66%), and preoperative TBLB (30%) and bronchial washing cytology (36%) had low detection rates.

Conclusions: Histologic high-grade components are associated with radiology-pathology discordance and poor prognoses in early-stage lung adenocarcinoma eligible for sublober resection. The preoperative prediction of high-grade components varied between histologic subtypes, and radiologic assessment would be beneficial for predicting the SOL subtype, but not MIP. Alternatively, intraoperative cytologic assessment would complement the detection of MIP subtype.

EP.06.03 Mucoepidermoid Carcinoma of the Lower Respiratory Tract With Few to None Intermediate/Squamoid Cells: A Challenging Tumor Series

G. Pelosi[1], R. Papa[2], C. Silanus[2], E. Balladore[2], M. Cannone[2], M. Mancini[3], A. Gurrera[4], F.R. Guddo[5], F. Zanconati[6]
[1]University of Milan, Milan/IT ,[2]IRCCS MultiMedica Group, Milan/IT ,[3]Sant'Andrea University Hospital, Rome/IT ,[4]Azienda Ospedaliero Universitaria Policlinico G. Rodolico - San Marco, Catania/IT ,[5]UOC Anatomia Patologica Ospedali Riuniti Villa Sofia - Cervello, Palermo/IT ,[6]UCO Anatomia ed Istologia Patologica Azienda Sanitaria Universitaria Giuliano Isontina, Trieste/IT

Introduction: Mucoepidermoid carcinoma (MEC) of the lower respiratory tract is a malignant salivary gland-type tumor comprising mucin-secreting cells, squamoid cells and intermediate-type cells, which usually arises in central airways (WHO classification 2021). Little is known, however, about MECs of the lower respiratory tract composed exclusively or to large extent of mucin-secreting cells, which really make up diagnostic challenges.

Methods: Five MECs of the lower respiratory tract with few to none intermediate-type/squamoid cells were retrieved from the pathology archives and consultation files of the participating Institutions. Immunoreactivity for p40, CK5, calponin and S100 protein, which highlight intermediate, squamoid and myoepithelial cells, was carried out on formalin-fixed and paraffin-embedded tumor tissue by means of standard staining methods on a Ventana BenchmarkXT autostainer (Ventana Medical Systems, Tucson, AZ, USA). Fluorescence in situ hybridization (FISH) analysis for the 11q21 rearrangement, which include the MAML2 gene, was performed by using the ZytoLight SPEC MAML2 Dual Color Break Apart Probe (ZytoVision, Bremerhaven, Germany).

Results: The tumor series included 3 females and 2 males, aged 29 to 69 years and 15 to 16 years, respectively. Tumors were endotracheal (one case) or endobronchial (four cases), the latter on either the left (3 cases) or the right (one case) side, and appeared limited to tracheal or bronchial walls in all but two instances, with minimal extraparietal extension. Histologically, just glandular aggregates of mucin-secreting cells were observed, featuring variably sized cystic structures repleted and distended by mucin, with no discernible intermediate or squamoid cells. The immunohistochemical study revealed complete absence or just sparse reactivity for CK5 or p40 in rare tumor cells, with no elements being decorated with calponin and S100 protein. As any conclusive interpretation was challenging because of the inconsistency of intermediate/squamoid cells and the differential diagnosis comprised various alternatives, such as mucous gland adenoma, hyalinizing clear cell carcinoma or even metastases of mucinous or clear cell adenocarcinomas of either pulmonary or extrapulmonary origin, a MAML2 gene FISH was conducted in three out of our five cases. This analysis documented the presence of the corresponding gene translocation in most tumor cells, whereby confirming the final interpretation of MEC. Clinical correlation ruled out metastasis from synchronous or previous head and neck salivary gland tumors.

Conclusions: MECs of the lower respiratory tract with few to none intermediate/squamoid cells are diagnostic challenges, inasmuch as immunohistochemistry may be of little help or even misleading. In these cases, MAML2 FISH analysis is the most effective tool to get the correct final interpretation, provided metastasis from a head and neck salivary gland tumor sharing the same translocation has been clinically excluded. It is important to keep in mind such an unusual presentation of MECs in the lower respiratory tract, because turns out outside its semantic definition of tumors composed of mucin-secreting, intermediate-type and squamoid cells. To the best of our knowledge, this is the largest series of such a variety of MEC thus far described in the lower respiratory tract.

EP.06.04 Extranodal Extension in Lung Adenocarcinoma: Pathological Insights and Its Role as an Independent Prognostic Factor

s. tsuchida
National Cancer Center Hospital East, chiba/JP

Introduction: Extrapulmonary nodal extension (ENE) has been increasingly recognized as an important prognostic factor in various malignancies. This study aimed to explore its pathological features of ENE in lung adenocarcinoma and to clarify its prognostic impact.

Methods: We retrospectively analyzed 105 patients with N1 or N2 lung adenocarcinoma who underwent anatomical lung resection between January 2016 and December 2020. AI-driven image analysis was used to quantify tumor-infiltrating lymphocytes (CD8+, FoxP3+), tumor-associated macrophages (CD204+), and cancer-associated fibroblasts (podoplanin+). The area of cancer cells and fibrous stroma was measured in both primary and metastatic lesions. An in vitro invasion assay using A549 cancer cells co-cultured with different numbers of CAFs was performed to assess their invasive potential of A549 cells. Moreover, we assessed ENE as a prognostic factor to elucidate its clinical significance.

Results: ENE-positive patients had higher lymph node involvement and were associated with more advanced tumor stages. In contrast, patient demographics and other baseline characteristics showed no notable differences between the two groups. No significant differences in the amount of TILs, tumor-promoting-TAMs, or -CAFs in primary tumors were observed between ENE-positive and ENE-negative groups. However, fibrous stroma in metastatic lymph node, but not of the primary tumor, was significantly more abundant in ENE-positive cases (14.2 mm^2 vs. 4.0 mm^2, $p < 0.001$). In vitro invasion assays demonstrated increased invasiveness of A549 cells when cocultured with higher numbers of CAFs. ENE was an independent poor prognostic factor and was significantly associated with distant metastasis ($p = 0.0198$).

Conclusions: ENE was a pathological prognostic factor characterized by abundant fibrous stroma. Additionally, from the high frequency of distant metastases, ENE could be considered a qualitative factor of malignancy in N classification.

EP.06.05 Extensive-Stage Small Cell Lung Cancer Compared With Metastatic Extrapulmonary Small Cell Cancers- a Retrospective Study

P. Padhi[1], Y. Xiong[1], Z. Zang[1], C. Rink[2], R. Pili[1]
[1]University at Buffalo, Buffalo/NY/USA ,[2]Arizona State University, Phoenix/AZ/USA

Introduction: Extensive-stage small cell lung cancers (ES-SCLC) carry a dismal prognosis and are treated with a combination of chemotherapy and immune checkpoint inhibitors (ICI) in the frontline setting. However small cell cancers are a systemic disease and can have an extrapulmonary (EPSCC) primary and treatment is extrapolated from ES-SCLC. Similarly to ES-SCLC, prognosis of metastatic EPSCC is poor as well. There are only a few institutional case series comparing the two entities. Given its rarity we performed a retrospective study comparing ES-SCLC with metastatic EPSCC in our institution.

Methods: We reviewed the medical records of adults > 18 years age from January 2013- December 2022 with biopsy proven de-novo extensive stage small cell lung cancer and de-novo metastatic extrapulmonary small cell cancer or poorly differentiated non-large cell neuroendocrine cancers. We analyzed these cases till December 31, 2023. Patients must have received at least one cycle of systemic treatment. We analyzed 89 patients [40 EPSCC (21 males and 19 females) and 49 ES-SCLC (24 males and 25 females)] for our final analysis. Of the 40 EPSCC patients, 17 were primary gastrointestinal (GI), 14 were hepatopancreaticobiliary (HPB), 7 were genitourinary (GU) and 2 were unknown primary (CUP). Our primary endpoint was median overall survival (mOS) and median progression-free survival (mPFS). We also assessed whether the primary site could affect survival.

Results: The median age was 62.6 years in EPSCC and 68.6 years in ES-SCLC cohorts. At the time of last data analysis 3 patients were still alive and 2 patients had not yet progressed and they were all in the ES-SCLC cohort. The mOS was [9.5 months (95% CI 2.0-17) versus 10.5 months (95%CI 7.1-13.6), p=0.34] in EPSCC and ES-SCLC respectively. The mPFS was [6.4 months (95% CI 2.1-10.7) versus 8.2 months (95% CI 5.9-10.5), p=0.04] in EPSCC and ES-SCLC respectively. Patients with HBP origin had the worst prognosis with mOS of 4.7 months when compared to all other sites. Primary GI and GU patients had similar survival data with mOS of 11.0 and 12.0 months respectively (p=0.017). Only 4 patients in EPSCC received upfront chemotherapy and ICI as compared to 35 patients in the ES-SCLC cohort.

Conclusions: In our institution the mOS of de-novo metastatic EPSCC was similar to de-novo ES-SCLC, however the mPFS was lower for EPSCC. Our data shows primary HBP EPSCC carried the worse prognosis. EPSCC can be similarly treated to ES-SCLC, however currently upfront ICI has not been approved in EPSCC unlike ES-SCLC, where with the Impower133 and CASPIAN studies revealed atezolizumab and durvalumab respectively with carboplatin and etoposide (CE) were superior to CE alone. Since only 4 patients with EPSCC received upfront ICI, this may be the reason behind the worse mPFS. It would require a large collaborative trial to study whether upfront chemotherapy and ICI in EPSCC can improve survival.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.06 Characterization of SMARCA4 and SMARCA2 Alterations in Early-Stage Pulmonary Adenocarcinomas)

J. Charron, M. Maranda-Robitaille, M. Orain, P. Desmeules, A. Gagné
Institut Universitaire de Cardiologie et de Pneumologie de Québec, Québec/QC/CA

Introduction: The SWI-SNF complex plays a pivotal role in chromatin remodeling, regulating gene transcription and essential cellular functions. Its catalytic subunit is composed of proteins encoded by either the SMARCA4 or SMARCA2 genes. In thoracic malignancies, SMARCA4 alterations have gained significant interest in recent years and have been described in two clinically aggressive and poorly differentiated tumors: SMARCA4-deficient non-small cell lung cancers (NSCLC) and SMARCA4-deficient undifferentiated tumors (SDUT). These alterations are considered early driver events in tumor pathogenesis, and the co-loss of SMARCA4 and SMARCA2 has been proposed as a key oncogenic mechanism in SDUT. However, little is known about the prevalence and characteristics of these alterations in early-stage NSCLC. In this project, we aimed to characterize SMARCA4 and SMARCA2 alterations in early-stage lung adenocarcinomas.

Methods: We retrospectively selected a cohort of 672 resected early-stage pulmonary adenocarcinomas between 2000 and 2013 for which clinical, pathological, and prognostic data were reviewed. Tissue microarrays (TMA) were built from formalin-fixed paraffin-embedded blocks using 1 mm cores. Immunohistochemistry for SMARCA4/BRG1, SMARCA2/BRM, claudin 4, and SOX2 was performed. We calculated the prevalence of SMARCA4 and SMARCA2 loss and co-loss of expression and association with clinico-pathological data.

Results: Complete loss of SMARCA4/BRG1 expression was observed in 18 cases (2.7%), while SMARCA2/BRM loss was found in 29 cases (4.3%). Co-loss of both markers occurred in 2 cases (0.3%). Patients with SMARCA4-deficient adenocarcinomas had a mean age of 62.1 ± 6.5 years and were predominantly male (61.1%). Those with SMARCA2deficiency were younger (60.2 ± 8.9 years) and mostly female (68.9%). All patients had a history of smoking. The predominant histologic pattern was solid in both groups (77.8% in SMARCA4-deficient and 48.3% in SMARCA2-deficient tumors). Pathologic stage distribution (AJCC 9th edition) was similar between groups. Disease progression occurred in 8 (44.4%) and 9 (31.0%) patients with SMARCA4- and SMARCA2-deficient tumors, respectively, with progression-free survival of 667.1 ± 704.0 days and 631.0 ± 523.4 days. The two tumors with co-loss of SMARCA4 and SMARCA2 were poorly differentiated adenocarcinomas with solid patterns, preserved claudin 4, TTF1 loss, mucin production, and SOX2 positivity in one case. One patient with a stage 1B tumor is still alive after 5444 days and the other with a 1A3 stage tumor died of an unrelated disease after 3240 days.

Conclusions: SMARCA4 and SMARCA2 deficiency is infrequent in resected early-stage lung adenocarcinomas, but can be detected in tumors with poorly differentiated histology and solid patterns. These alterations appear to occur in a subset of smokers and may not be as strongly associated with poor outcomes in early-stage disease as in advanced tumors. Further work is underway to characterize the genomic alterations of these tumors.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.07 Clinicopathologic and Genomic Landscape of Lung Cancer Arising in Interstitial Lung Disease: An Expanded Cohort Analysis

s. kim[1], J. Koh[2], W. Oh[1], D. Kim[3]
[1]Guro Hospital, Seoul/KR ,[2]Seoul National University Hospital, Seoul/KR ,[3]College of Medicine, Korea University, Seoul/KR

Introduction: Patients with interstitial lung disease (ILD) are at increased risk for developing lung cancer, which often presents with poor prognosis and limited therapeutic options. Despite its clinical significance, comprehensive studies on the clinicopathologic and molecular characteristics of lung cancer arising in ILD (LC-ILD) remain limited. Previously reported with 41 cases, this cohort has now been expanded to 99, enabling a more in depth characterization of LC-ILD.

Methods: We retrospectively analyzed 99 cases of LC-ILD diagnosed between 2018 and 2024 at Korea University Guro Hospital and Seoul National University Hospital. Clinical data, histopathologic features, and genomic profiles obtained via single gene tests, next-generation sequencing (n=13) or whole-exome sequencing (n=9) were compared with a control cohort of 1,255 lung cancer patients without ILD who underwent surgical resection at Korea University Guro Hospital during the same period.

Results: Patients with LC-ILD were older (71.0 ± 7.1 vs. 68.0 ± 9.4 years, P<0.001) and predominantly male (90.9% vs. 59.3%, P<0.001), with a universal smoking history. Usual interstitial pneumonia (UIP) was the most common ILD subtype (82.9%). Squamous cell carcinoma (SqCC) was significantly more frequent in the ILD cohort (45.5% vs. 16.9%, P<0.001), predominantly located in the peripheral lung. Genomic profiling revealed frequent TP53 mutations (66.7% in total, 81.8% in SqCC), whereas key actionable driver mutations were rare: EGFR (2.8%), KRAS (12.5%), and BRAF (2.9%) mutations, with no ALK or ROS1 alterations detected. Rare druggable EGFR mutations (E19del and E20ins) were observed. Tumor mutational burden (TMB) was significantly lower in LC-ILD (1.8 vs. 7.1 mut/Mb, P<0.001). PD-L1 expression showed no significant differences by histologic subtype.

Conclusions: Lung cancers arising in ILD exhibit unique clinicopathologic and genomic features, including a predominance of peripheral SqCC, frequent TP53 mutations, low TMB, and rare actionable driver mutations. These findings suggest limited responsiveness to targeted and immune-based therapies, underscoring the need for tailored therapeutic strategies and further biomarker development in this high-risk population.

EP.06.08 Mutation Spectrum of EGFR Mutations in South Indian Population Identified by Next Generation Sequencng and Real TIME PCR

V. Ramshankar, K. Sivakumar, V. Muthukumar, A. Fathima, A. Gopalakrishnan, S. Sairman, P. Thamaraiselvan, V. Radhakrishnan
Cancer Institute WIA, Chennai/IN

Introduction: Lung cancer (LC) predisposes significant morbidity and mortality in India. The survival rates for lung cancer in India are lower than in Western countries due to late-stage diagnosis and limited access to advanced treatments. The prognosis largely depends on the stage of lung cancer diagnosis. A wide majority of our patients present in stage IV with multiple sites of metastasis. It is very challenging to introduce high-throughput molecular diagnostics in a low-resource setting due to the cost implications. However, these are mandatory to offer targeted therapy to improve lung cancer outcomes. In the current observational study, we aim to share the mutation spectrum of the EGFR gene, the well-established driver in lung cancers, both by real-time PCR and targeted massive parallel sequencing technologies.

Methods: We performed real-time PCR for the EGFR gene mutation detection (hotspots) and detected ALK, RET, ROS, and RET fusions in lung cancer FFPE tissue-derived DNA and RNA (n=548), respectively. Real-time PCR was done using a clinically validated IVD-approved assay using the protocol as given by the manufacturer. We also performed next-generation sequencing on an Illumina sequencer for lung cancer patients (n=103). The targeted panel (Oncotarget, Onecell Dx, Pune, India) with 100 actionable genes at 1000x coverage was evaluated. The data analysis was done using iCARE, an AI-driven software to decipher the SNVs, Indels, and fusions in the panel studied.

Results: EGFR mutations were positive in 278 patients (42.7%) out of 651 lung cancer patients tested using both technologies. The EGFR positivity rate derived by qPCR was 44.3% (243/548), and that of NGS was 34% (35/103). We found significantly high EGFR mutants among Indian females with 58.8% (127/243), compared to males, with 34.9% (116/243), as tested by qPCR and NGS. Among the EGFR mutations, exon 19 deletion and L858R in exon 21 were the most common mutations found by both qPCR and NGS, as expected. Additionally, we identified some rare EGFR mutants by NGS, like EGFR p.E709_710del in exon 18 and EGFRp.G724S in exon 18, indicating resistance to Afatinib, and exon 20 insertions EGFR H773_V774insGVNPH, leading to activation of the EGFR pathway. We found 80% (28/35) EGFR mutants occurring along with nonactionable genes like p53, APC, PDGFRA, RB1, and ATM1, of which mutant EGFR along with p53 was found in 60% (21/35) of the Indian lung cancer patients. The outcome of lung cancer has not improved despite the availability of targeted TKIs. It is therefore important to understand the impact of co-mutation on prognosis and treatment resistance. Mutations in p53 are associated with poor prognosis, faster progression, and increased resistance to TKIs. Patients with p53 mutations along with EGFR mutations may benefit from checkpoint inhibitors.

Conclusions: Next-generation sequencing technology has revolutionised the diagnosis, treatment, and management of lung cancer, even in a low-resource setting, proving its feasibility. It offers a multiplexed approach to detect the combination of mutations and fusions in lung cancer, emphasizing the need to consider the combinations of non-actionable gene mutations along with actionable drivers like EGFR in lung cancer.

EP.06.09 Integrated Clinical, Radiological and Molecular Profile of Lung Cancer Patients From an Incidental Nodule Detection Program

F.A.C. Sarmento Neto, J.F.d.P. Moura, L. Pontual Lima, P.A. Sarmento, I.V. Secundo, T.N. Béder, C.F.J.d.S. Menezes, H.V.S.d. Fonseca, F.G.N.d. Silva, J.E. Freire da Fonte, L. Casali, D.V. Ferraz de Carvalho, F.M.d. Gouvêa, F.M.d.S.L. Didjurgeit
Real Hospital Português de Beneficência em Pernambuco, Recife/BR

Introduction: Comprehensive molecular and immunohistochemical profiling is critical for guiding therapeutic strategies in individuals diagnosed with lung cancer. In routine practice, however, testing is often incomplete or inconsistently applied. This study aimed to characterize clinical, radiological, histological, and biomarker features in a cohort of individuals diagnosed with lung cancer within a structured nodule management program, emphasizing associations between molecular alterations, histological subtypes, and clinical variables.

Methods: Between January 2023 and December 2024, 25,358 chest CTs were performed, identifying 2,200 nodules (689 >7 mm). Follow-up adherence occurred in 237 cases, resulting in 74 lung cancer diagnoses (44 early-stage, 59,4%). Among these, 61 individuals with molecular or immunohistochemical data were included in this retrospective analysis from a tertiary center in Brazil. Descriptive statistics and chi-square tests were applied to assess associations.

Results: The median age was 74 years, and 49.2% were female. A substantial proportion (42.6%) reported no history of tobacco exposure. Most nodules were solid (85.2%) and located in upper lobes. Adenocarcinoma was the most frequent histologic subtype (85.2%). Among 59 staged individuals, stage 4 was most common (39%), followed by stage 1 (34%), stage 2 (14%), and stage 3 (10%).Immunohistochemistry revealed high TTF-1 positivity (75.4%), consistent with adenocarcinoma predominance. P40 and P63 showed low positivity (11.5%). PD-L1 expression was assessed in 38 individuals (62.3%), with significant variation across histologic subtypes (p=0.002). Low expression (<1%) occurred in 76.9% of cases, intermediate (1-49%) in 19.2%, and high (≥50%) in 3.8%. Intermediate expression was more common in acinar (33.3%) and squamous carcinomas (66.7%), while other subtypes (non-mucinous invasive, mucinous, solid, lepidic) mostly exhibited PD-L1 <1%. The only high-expression case was an invasive mixed carcinoma.EGFR testing was performed in 41.0% of individuals, with 40% positivity. Mutations occurred exclusively in adenocarcinomas and were significantly associated with histologic subtype (p=0.004), particularly non-mucinous, acinar, and lepidic patterns. EGFR positivity was more frequent in individuals without tobacco exposure (85.7%) than in former (27.3%) or current users (14.3%) (p<0.05), and more prevalent in women.No significant associations were observed between sex or smoking status and other molecular markers. ALK was tested in 39.3% of patients, with 8.7% positivity. KRAS mutations were found in 60% of those tested (16.4%), suggesting clinical relevance despite limited testing. No positive results were observed for BRAF or MSI. ROS1 was positive in 12.5% of tested individuals, but over 80% remained untested for these markers. No correlation was found between molecular alterations or PD-L1 expression and cancer stage.

Conclusions: Strong correlations were observed between biomarker profiles and histological or clinical variables, particularly for EGFR and PD-L1. These findings underscore the importance of standardized molecular testing and multidisciplinary workflows. In Brazil, testing access remains limited, with most performed externally via pharmaceutical support programs.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.10 Hypoxia-Induced Cancer Stemness, Metastasis, Angiogenesis and Immune Modulation in Lung Adenocarcinoma

K. Wang, Q. Wang
iLab Research Institute, Mountain View/CA/USA

Introduction: Lung adenocarcinoma is the most common type of non-small cell lung cancer (NSCLC) and leading cause of cancer-related deaths in the United States and worldwide. Yet this cancer remains a major therapeutic challenge due to its adaptability and resistance to treatment. Hypoxia, a key feature of the tumor microenvironment, drives tumor aggressiveness and therapy resistance. Understanding hypoxia-driven transcriptional changes is critical for improving diagnostics and targeted therapies. This study investigated the transcriptomic and proteomic responses of Stage 1 NSCLC H1437 cells under hypoxic conditions to identify key biomarkers and pathways involved in angiogenic, inflammatory, and immunosuppressive responses.

Methods: In-depth bulk RNA-sequencing (RNA-seq) analysis was performed on Stage 1 lung adenocarcinoma H1437 cells under hypoxic (1% O2 for 24 hours) or normoxic conditions to elucidate the molecular adaptations of these cancer cells to hypoxia. RNA was isolated and sequenced to create raw RNA-seq reads, which were processed and analyzed through RStudio and edgeR. Biomarkers identified through RNA-seq data analysis were verified by the Enzyme-Linked Immunosorbent Assay (ELISA) and immunohistology studies.

Results: Hypoxia upregulated hypoxia-inducible transcription factors ARNT, EPAS1, and ARNT2, while maintaining HIF1A expression, thereby facilitating tumor survival. Metabolic shifts included a transition from mitochondrial beta-oxidation to glycolysis and increased lipid biosynthesis via upregulation of FASN, ACLY, and SREBF1, which supports tumor progression. Hypoxia downregulated the cell cycle-related genes, likely mitigating the proliferation of H1437 cells. The MTT assay was performed to demonstrate the lower cell proliferations in hypoxic H1437 cells. Hypoxia also disrupted genomic stability by downregulating ATR-CHK1 cell cycle arrest pathways and suppressing BRCA1 and MDC1, thus enabling DNA-damaged cells to persist. Additionally, hypoxic H1437 cells exhibited elevated secretion of pro-angiogenic growth factors (VEGFA-C, PDGFB, and TGFB) and upregulated M2-like macrophage markers (CSF1R, IL4R, VEGFA, and CCL22) as well as osteoclast-like markers (TNFRSF11A and ACP5), which induces an angiogenic, immunosuppressive, and inflammatory microenvironment. The elevation of CCL22 and ACP5 in the supernatant of the hypoxic H1437 cells was verified by ELISA. The ACP5-positive H1437 cells were stained by TRAP. Notably, hypoxia induced stem-like phenotypes by upregulating known NSCLC stem-like markers (CD44, ALDH3B1, and PLAUR) as well as stem-like markers for other cancer types (IL3RA, ALCAM, SOX4, CEACAM6, CD24, NOTCH2, ICAM1, and NTF3). Moreover, SOX4, TGFB, and JAK/STAT emerged as key regulators of hypoxia-driven tumor progression. Additionally, hypoxia conferred apoptotic resistance through upregulation of BCL3, BCL6, BCL9, and CFLAR. Hypoxia also promoted metastatic potential by upregulating markers such as MUC1, MUC16, CEACAM5, CEACAM6, KRT19, FUT3, PLAUR, SERPINE1, NTF3, and FSCN. FUT3, an enzyme involved in CD15 (Lewis X) biosynthesis, was highly expressed, and CD15-positive H1437 cells were detected under hypoxic conditions.

Conclusions: These findings elucidated hypoxia-induced molecular adaptations and revealed key regulators of the progression, metastasis, and therapy resistance of lung adenocarcinoma. The findings demonstrate the potential of targeting HIFs and hypoxia-responsive pathways for improved diagnostic and therapeutic strategies. The biomarkers and pathways identified herein provide promising avenues for developing novel treatments and predictive tools in lung adenocarcinoma.

Keywords: lung adenocarcinoma, hypoxia, metastasis

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.11 Comprehensive Genomic Profiling in Lung Cancer Management: Insights From North Sweden

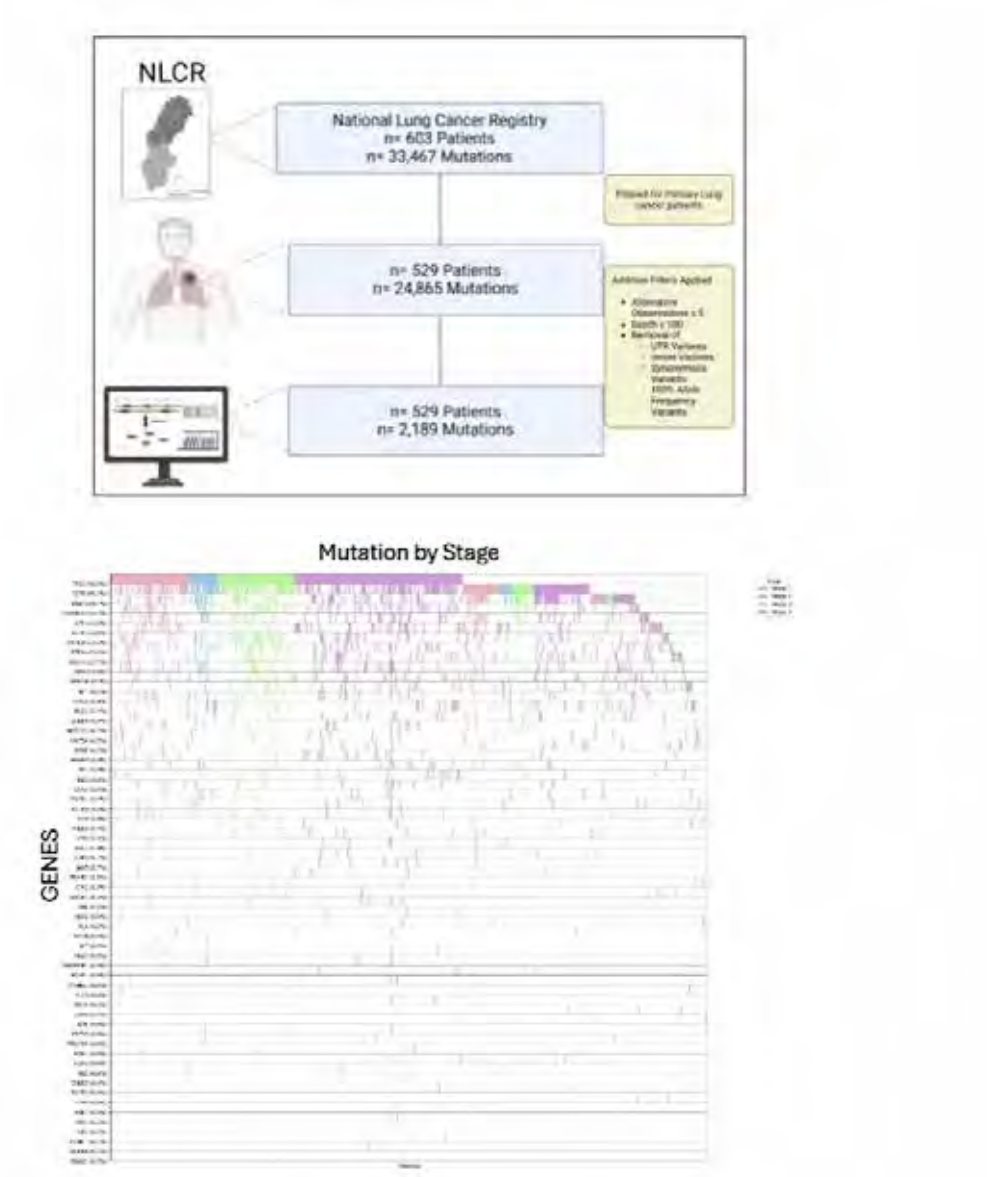
N. Karlowatz, L. Köhn, C. Patthey, J. Nilsson, B-A. Jonsson, M. Johansson
Umeå university, Umeå/SE

Introduction: The present study is a real-world in-silico study of the mutational landscape of lung cancer In the North Swedish Health Care Region. Real world data from routine genomic profiling have been used to study the mutational landscape of lung cancer. This research leverages existing genomic datasets to examine the interplay between genetic variations and a range of clinical factors, aiming to enhance our understanding of cancer genetics in a well-defined demographic setting.

Methods: This study utilized data from the Archer VariantPlex Solid Tumor 67 gene assay to analyze targeted sequencing genetic data from 529 lung cancer patients diagnosed 2011 to 2021. Individual clinical and demographic data were obtained from the Swedish National Lung Cancer Registry and matched to the genetic profiles. The relationship between clinical data, mutational patterns and patient outcomes is reported below.

Results: After quality filtration mutations in 60 unique genes were found across the cohort. The analysis revealed a mean of 2.5 mutations per tumor with a range of 0-27 mutations, indicating significant heterogeneity in mutational profiles. Geographic and demographic variations, such as lower EGFR mutation frequencies, were observed and linked to clinical factors. Mutation patterns varied significantly with age, gender, smoking status, and disease stage. Notably, early-stage lung cancer featured mutations in genes related to cellular differentiation and growth, while late-stage disease was associated with disruptions in cell cycle control and metabolic processes. Survival analysis highlighted the context-dependent prognostic value of mutations, with certain co-mutations altering the expected outcomes.

Conclusions: The findings underscore the importance of considering a broad, integrated mutational profile when evaluating prognostic markers in lung cancer. This approach could lead to more effective, personalized treatment strategies by acknowledging the complex interplay between genomic profiles and clinical characteristics



EP.06 PATHOLOGY AND BIOMARKERS

EP.06.12 Kita-Kyusyu Lung Cancer Antigen-1 Positive Is Associated With Pathological High-Grade in Lung Adenocarcinoma

Y. Kondo[1], T. Fukuyama[2], S. Mitsuhashi[1], S. Tamagawa[1], D. Sonoda[1], Y. Matsuo[1], M. Naito[1], M. Mikubo[1], K. Shiomi[1], T. Matsumoto[3], M. Ichinoe[1], S. Okada[2], Y. Satoh[1]
[1]Kitasato University School of Medicine, Kanagawa/JP ,[2]Kitasato University Medical Center, Saitama/JP ,[3]School of Allied Health Sciences, Kitasato University, Kanagawa/JP

Introduction: Kita-Kyushu Lung Cancer antigen-1 (KK-LC-1) is one of the cancer-testis antigens and is reported to be an effective treatment using T cell receptor (TCR) gene-engineered T cells. In lung cancer, KK-LC-1 expression was observed in about 30%, and the association between KK-LC-1 expression and lymph node metastasis has been reported. This study aimed to evaluate the prognostic impact of KK-LC-1 in resected lung adenocarcinomas.

Methods: We reviewed the medical records of 110 patients who underwent curative resection for lung adenocarcinoma. We evaluated an original monoclonal antibody against KK-LC-1 (Kmab34B3). The staining intensity was scored as 0 (negative), 1 (weak staining), 2 (moderate staining) or 3 (strong staining). We defined moderate staining and strong staining as positive and divided into positive and negative groups. The overall survival (OS) and recurrence-free survival (RFS) were compared according to KK-LC-1 positivity. Cox regression analyses were performed to identify prognostic factors.

Results: In total cohort, 39 patients (35%) were KK-LC-1 positive. KK-LC-1 positive was significantly associated with larger invasive size, advanced stage, presence of lymphatic invasion and vascular invasion, and lymph node metastasis. Furthermore, KK-LC-1 positivity rate was significantly higher in papillary/acinar predominant and solid/micropapillary predominant than in lepidic predominant (43.0% vs 11.1% P = 0.001, 50.0% vs 11.1%, P = 0.023) and multivariable logistic analyses revealed invasive size as independent factors with KK-LC-1 positive (Odds ratio:4.184, 95% confidential interval (CI), 1.597-10.96, P=0.003). There were no significant prognostic differences in OS (5-year OS, 79.8% vs. 94.0%, respectively, P =0.072), whereas cases with KK-LC-1 positive showed poorer RFS than those without (5-year RFS, 85.5% vs. 67.7%, respectively, P =0.020). In multivariate analysis of OS, KK-LC-1 was not found to be an independent factor (Hazard Ratio (HR) = 1.413, 95% CI, 0.444-4.499, P= 0.558). On the other hand, in multivariate analysis of RFS, pathological stage was an independent factor (HR = 5.022, 95% CI, 1.659-15.20, P = 0.004). However, KK-LC-1 was not an independent factor in RFS (HR = 1.230, 95% CI, 0.518-2.918, P= 0.638).

Conclusions: KK-LC-1 positive was significantly associated with pathological high-grade and poor RFS of lung adenocarcinoma. KK-LC-1 may be one of the prognostic factors for lung adenocarcinoma and KK-LC-1 positive cases may be candidates for TCR reconstitution therapy.

Keywords: Lung cancer, KK-LC-1, pathology

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.13 Molecular Alterations in Octogenarians With Early-Stage Lung Cancer: A Real-World Study

J. Zhu[1], L. Gros[2], W. Ma[1], J. Zhang[1], R. Yip[1], D.F. Yankelevitz[1], C.I. Henschke[1]
[1]Mount Sinai Health System, New York/NY/USA ,[2]Centre hospitalier universitaire vaudois, Lausanne/CH

Introduction: As the U.S. population ages, an increasing number of octogenarians (≥80 years) are presenting with early-stage lung cancer. However, they remain an under-studied population. We aimed to assess the frequency and types of molecular alterations in this group and examine their family history of lung cancer.

Methods: We analyzed data from the Initiative for Early Lung Cancer Research on Treatment (IELCART), a prospective multi-institutional cohort study initiated in 2016, including patients who underwent surgical resection for lung tumors ≤30 mm. Our objective was to evaluate the frequency and distribution of clinically actionable variants in octogenarians compared to younger patients and examine variations across racial groups and smoking status. We also assessed the prevalence of family history of lung cancer in this population.

Results: Among 864 patients with surgically resected lung cancer (tumors ≤30 mm), 112 (13.0%) were octogenarians. Family history of lung cancer was comparable between octogenarians (14.3%) and younger patients (19%, p=0.2). Oncogenic driver mutations were analyzed in 568 patients (65.7% of the cohort), including 97/112 octogenarians (86.6%) and 471/752 younger patients (62.6%). Clinically actionable variants were identified in 313 patients (55.1%), with similar distribution between age groups. KRAS mutations were the most frequent, identified in 193 patients (34.0%), including 27 octogenarians (27.8%) and 166 younger patients (35.2%). The G12C variant was detected in 13/27 octogenarians (48.1%) and 79/166 younger patients (47.6%), showing no age-related difference. Octogenarians exhibited a similar prevalence of EGFR mutations (32/97, 33.0%) compared to younger patients (116/471, 24.6%). Among these, classical variants included exon 19 deletions (12/32, 37.5%) and L858R substitutions (20/32, 62.5%). Other targetable alterations—including MET exon 14 skipping (9/97, 9.3% vs. 20/471, 4.2%), ROS1 fusions (2/97, 2.1% vs. 5/471, 1.1%), RET fusions (1/97, 1.0% vs. 5/471, 1.1%), ALK fusions (1/97, 1.0% vs. 9/471, 1.9%), and BRAF V600E (2/97, 2.1% vs. 19/471, 4.0%)—showed no significant differences between age groups. Clinically actionable variants varied significantly by race (p<0.001). Among 568 tested patients, 14.3% were African American, 12% Asian, 61.8% White, and 12% other races. EGFR mutations were more prevalent in Asian patients (48.5%) compared to the overall cohort (26.1%). This trend was consistent among octogenarians, with Asians representing 7.2%, African Americans 7.2%, Whites 76.3%, and other races 9.3%. Among Asian octogenarians, 71.4% harbored EGFR mutations. Smoking status significantly influenced clinically actionable variants (p<0.001). Among 568 patients, 24.0% were never smokers, 64.4% former smokers, and 12.0% current smokers. EGFR mutations were more common in never-smokers (66.2%) than former (24.6%) and current smokers (4.4%). In octogenarians, 21.6% were never smokers, 75.3% former smokers, and 3.1% current smokers. EGFR mutations were more frequent in never-smokers (66.7%) than former smokers (24.7%), mirroring the overall trend (p<0.05).

Conclusions: Among 568 patients with resected lung cancer ≤30 mm who underwent NGS analysis, 17.1% were octogenarians, with 14% reporting a family history of lung cancer. Distribution of clinically actionable variants was similar between octogenarians and younger patients but varied significantly by race and smoking status. Future studies should address outcomes and therapeutic strategies in this underrepresented population.

Keywords: octogenarians, molecular alterations, family history of lung cancer

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.14 Decreased Expression of DAAM2 Is Correlated With Poor Prognosis and Tumor Immune Microenvironment in Lung Adenocarcinoma

W. Liu[1], J. Wan[2], X. Zheng[3], S. Wang[2], X. Chen[3,4]
[1]Graduate School of Fujian Medical University, Fuzhou, Fujian Province/CN ,[2]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei Province/CN ,[3]Interdisciplinary Institute of Medical Engineering of Fuzhou University, Fuzhou, Fujian Province/CN ,[4]Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, Fujian Province/CN

Introduction: Disheveled-associated activators of morphogenesis 2 (DAAM2) has been shown to promote tumorigenesis and progression of various cancers, but its role in lung adenocarcinoma (LUAD) remains unknown. This research aimed to explore the role of DAAM2 in LUAD progression.

Methods: We used The Cancer Genome Atlas and TIMER2.0 databases to study DAAM2 expression in LUAD tissue samples, and we verified it in a tissue microarray. The correlation between DAAM2 expression and prognosis, clinicopathological characteristics, and the tumor immune microenvironment (TIME) of LUAD patients were investigated using survival, Cox regression, and correlation analyses. Functional enrichment analysis was used to investigate possible biological functions and mechanisms of DAAM2 in LUAD progression. The role of DAAM2 in the proliferation, migration, and invasion of LUAD cells were confirmed using Cell Counting Kit-8 assay, cell scratch assay, and invasion experiment.

Results: DAAM2 expression was downregulated in LUAD tissue samples and correlated with inferior survival and treatment outcome of LUAD patients. Functional enrichment analysis revealed that DAAM2 may promote LUAD progression through the cell cycle, P53, Wnt, and TGF-β signaling pathways. Furthermore, DAAM2 overexpression subdued the capacity of LUAD cells to proliferate, migrate, and invade. The number of immune cells and cellular markers infiltrated in the tumor microenvironment was significantly associated with the DAAM2 expression level.

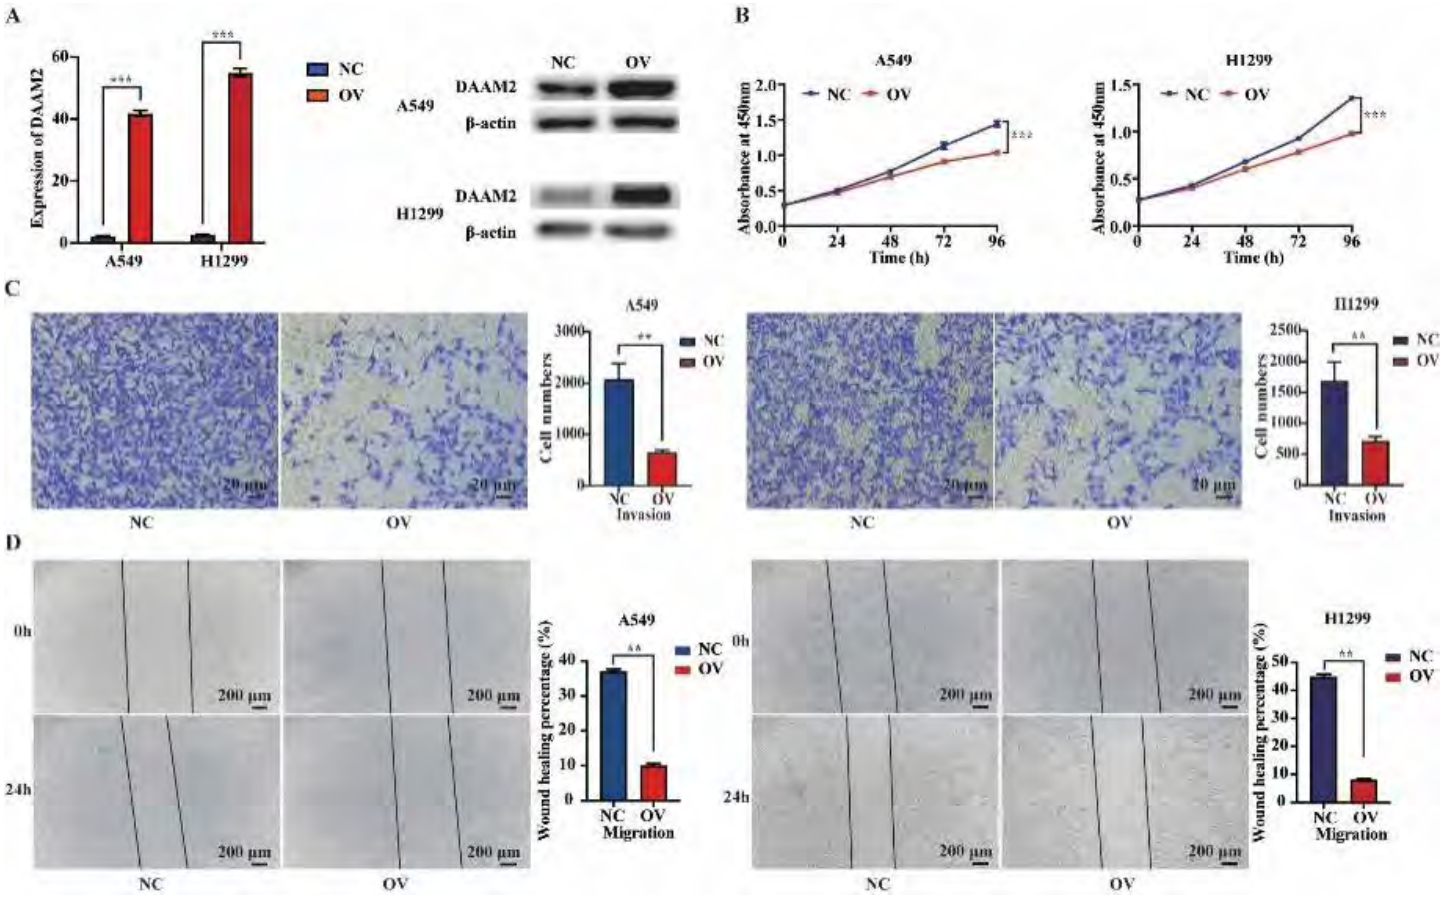


Figure1 DAAM2 overexpression inhibited the growth, migration, and invasion. (A) The cell model of DAAM2 overexpression. (B) Analysis of cell proliferation using the CCK-8 assay. (C) Analysis of cell invasion using the Transwell experiment. (D) Analysis of cell migration using the cell scratch assay.

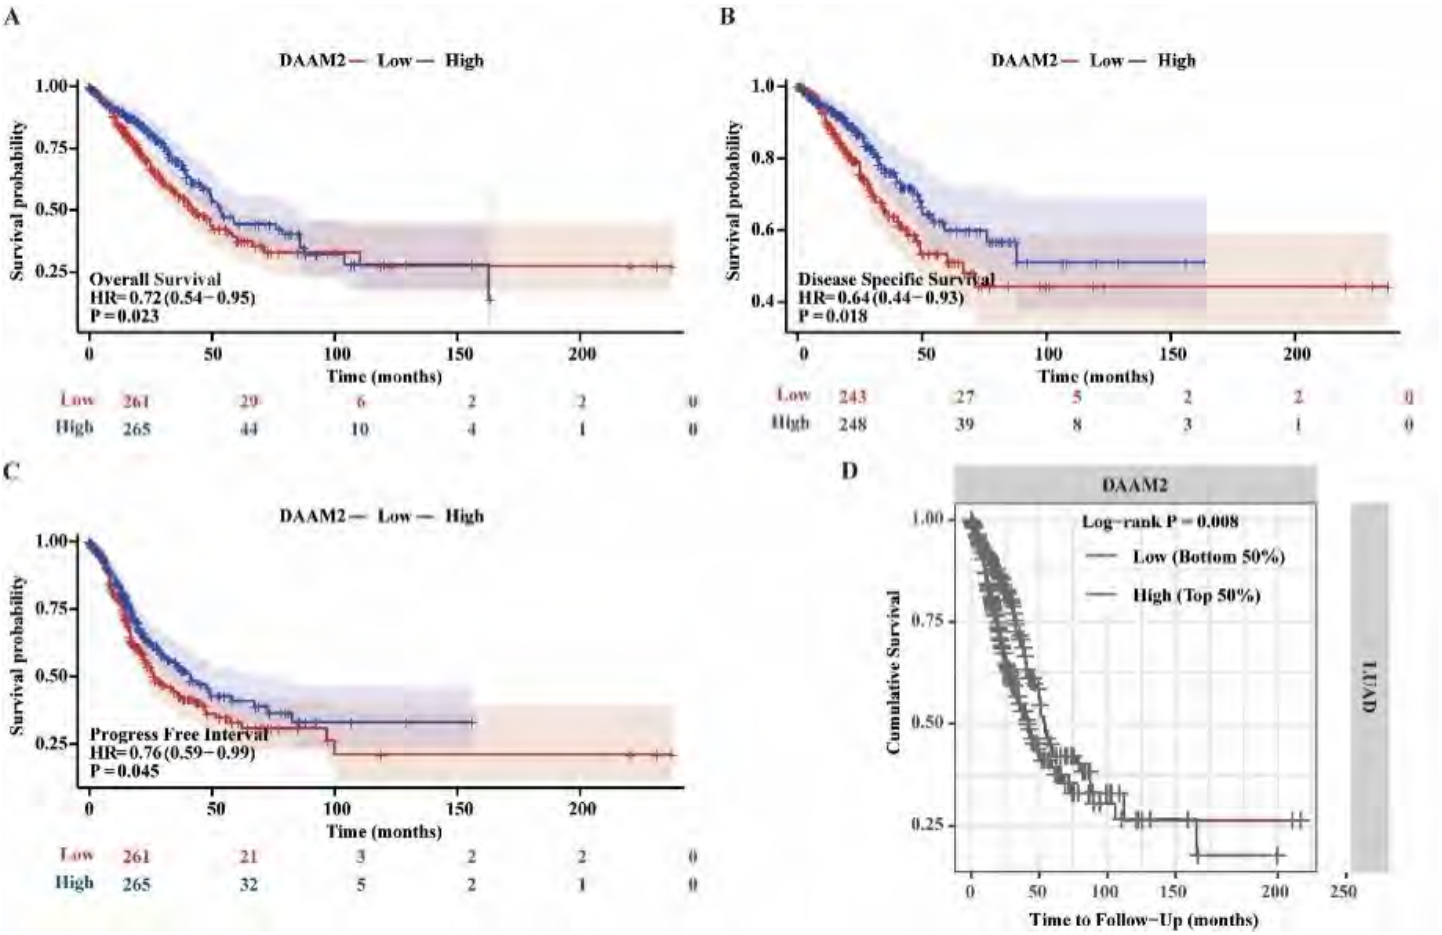

Figure2 Decreased expression of DAAM2 was correlated with poor prognosis. (A) OS; (B) DSS; (C) PFI; and (D) Cumulative survival.

Conclusions: These results indicate that DAAM2 can block tumor progression and may serve as a prognostic biomarker and therapeutic target for the treatment of patients with LUAD.

Keywords: Lung adenocarcinoma, The Cancer Genome Atlas, DAAM2

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.15 Reflex Next Generation Sequencing Testing in NSCLC: Overcoming Barriers to Equitable Molecular Profiling in an Urban Healthcare Network ?

N. Provenzano[1], B. Graham[1], C. Loya[2], D. Nick[1], M. Gottlieb[2], C. Manley[2], A. Gangemi[1], S. Lee[1], D. Flieder[2], H. Ehya[2], A. Seth[1], D.A. Baldwin[2], M. Edelman[2], J. Garfield[1], S. Padda[1]
[1]Temple University Hospital/Temple Health, Philadelphia/PA/USA ,[2]Fox Chase Cancer Center/Temple Health, Philadelphia/PA/USAI/KR

Introduction: Next-generation sequencing (NGS) enables comprehensive genomic and transcriptomic profiling. As the treatment landscape for non-small cell lung cancer (NSCLC) quickly changes, these molecular markers guide treatment selection across disease stages. However, implementation challenges, such as tissue sufficiency, provider awareness, and logistical constraints, can hinder adherence to these guidelines. Temple University Health System (TUHS) is a non-profit academic healthcare network in Pennsylvania (United States) with diverse patient populations and subspecialty services. At the start of 2023, a reflex molecular testing policy was implemented for NSCLC across multiple sites of TUHS. This study evaluates the rates of NGS DNA and RNA testing from intrathoracic samples of NSCLC obtained from pulmonary and interventional radiology (IR) procedures.

Methods: We retrospectively identified patients who underwent pulmonary or IR procedures in 2023 at three sites across TUHS that resulted in an NSCLC diagnosis. Sites included Temple University Hospital-Main Campus (TUH-MC), Fox Chase Cancer Center (FCCC), and Temple University Hospital-Jeanes Campus (TUH-JC). Reflex ordering was done by pathology and NGS testing was performed internally at FCCC and TUH-MC. We examined completion rates of NGS-DNA, NGS-RNA, and both NGS-DNA and RNA. We collected patient demographic information, comorbid diseases, tumor histology, geographic site of sampling, type of procedure performed (bronchoscopy, EBUS, CT-guided), biopsy type (transbronchial, core, fine needle aspiration) and location from which the sample was obtained (lung tissue vs. lymph node).

Results: Using search terms inclusive of pulmonary or IR procedures resulting in the diagnosis of NSCLC across sites in 2023, 306 patients were identified. Patients with histological subtypes other than NSCLC, non-lung primary malignancies, inconclusive diagnoses, or procedures that did not result in a malignancy diagnosis were excluded from further review. 277 patients remained: 232 (83.8%) received NGS DNA testing, 227 (81.9%) received NGS RNA testing, and 224 (80.9%) received both NGS DNA and RNA testing. Of the 42 (15.2%) patients that did not undergo any NGS testing, 21 (50%) did not require NGS testing for clinical management given stage IB < 4cm. Multivariate analysis is ongoing to elucidate patient and procedural factors associated with NGS-DNA and RNA testing.

Conclusions: Within a large urban healthcare network, where disparities in cancer care are prevalent, reflex DNA and RNA-based NGS testing ensures that patients diagnosed with NSCLC receive comprehensive molecular profiling, even on small samples from intrathoracic procedures. By systematically integrating NGS into routine diagnostic workflows, we hope to overcome known traditional barriers to testing, such as provider awareness and logistical constraints. Future studies should focus on providing guidance on tissue sufficiency for NGS testing and the role of circulating tumor DNA, along with identifying remaining gaps in adherence, addressing logistical and financial barriers, improving access to genetic counseling for germline risk variants, and refining strategies to further standardize biomarker testing.

Keywords: NGS, genomics, NSCLC

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.16 Immunophenotyping of the Molecular Subtypes of Small Cell Lung Cancer and Its Correlation With Prognostic and Therapeutic Implications

S. Pasricha, H. Diwan, U. Batra, R. Tripathi, M. Gupta, A. Mehta
Rajiv Gandhil Cancer Institute and Research Centre, DELHI/IN

Introduction: Molecular stratification of small cell lung carcinoma based on mRNA expression consist of four categories: achaete-scute homologue 1 (ASCL1), neurogenic differentiation factor 1 (NEUROD1), POU class 2 homeobox 3 (POU2F3) and yes-associated protein 1 (YAP1) transcriptional regulators. However, there is paucity of literature regarding the expression of these markers at protein level/ immunohistochemistry and their prognostic and therapeutic relevance including survival analysis

Methods: Formalin-fixed paraffin embedded tissue samples of 120 consecutively diagnosed unresectable SCLC patients were subjected to IHC (ASCL1, NEUROD1, POU2F3 and YAP1) and analyzed for their immunoexpression. The subtypes identified were correlated with expression of neuroendocrine marker (NE): INSM-1 and also with the response after 6-cycles of platinum-based chemotherapy: Responder (R; complete or partial response /stable disease) vs Non responder (NR; progression). Overall survival was also evaluated in correlation with these molecular IHC subtypes

Results: Majority were males (81.7%) and elicited history of smoking (70.8%). Four distinct categories were identified on the basis of relative immunoexpression of these IHC markers: ASCL1-dominant (58.5%), NEUROD1 dominant (12.1%), POU2F3+/ASCL1-/ NEUROD1- (7.8%), and ASCL1-/ NEUROD1- NOS (21.6%). All the POU2F3 positive cases were ASCL1-/NEUROD1- and were associated with absent/reduced NE (INSM-1) expression ($p < 0.0001$). Overall expression of YAP1 was very low (2.5 % cases) and not exclusive of other subtypes. NEUROD1 dominant and POU2F3+/ASCL1-/ NEUROD1- categories were significantly associated with NR ($p = 0.027$). The survival rates were 59% in responders and 50% in non-responders at 1 year (p-value= 0.928). The OS was 53% at 1year and was not significantly associated with any of the IHC subtypes (p-value 0.137). YAP1 expression although had low frequency, however, was associated with poor overall survival (p=0.013)

Conclusions: We found NEUROD1 dominant and POU2F3 dominant subtypes were associated with poor response to chemotherapy while none of the molecular subtypes were significantly associated with OS. YAP1 expression was rare and could not establish itself as a distinct molecular subtype, however, was associated with poor OS. POU2F3 can be utilized as a useful NE IHC marker, to diagnose small cell carcinoma in absence of other established NE IHC markers.

Keywords: immunoexpression, molecular stratification, small cell carcinoma

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.17 Immunological and Genetic Profile and Efficacy of Immunotherapy in NSCLC Patients With Mutations in KRAS and STK11 Genes

P. Krawczyk[1], N. Krzyżanowska[1], M. Nicoś[1], K. Wojas-Krawczyk[1], I. Chmielewska[1], M. Gil[1], T. Jankowski[1], A. Lomza-Laba[1], J. Milanowski[1]
[1]Medical University of Lublin, Lublin/PL

Introduction: Mutations in KRAS gene are among the most common genetic abnormalities in patients with non-small cell lung cancer (NSCLC) and often coexist with mutations in STK11 gene. Such co-occurrence is associated with resistance to immune checkpoint inhibitors (ICIs). This study aimed to examine the immune status and genetic profile that may affect the efficacy of ICIs.

Methods: In 20 patients with NSCLC qualified to immunotherapy or chemo-immunotherapy, we performed targeted next-generation sequencing based on the SureSelect CD Glasgow Cancer Core Panel. In addition, we assessed peripheral blood mononuclear cells' immunophenotype using flow cytometry. We performed immunological analysis before and during therapy. This study was funded by the Polish National Centre for Research and Development (LIDER/46/0237/L-12/20/NCBR/2021).

Results: Mutations in KRAS/STK11 genes co-occurred in 3 patients. The chemoimmunotherapy long-responding patient (38 months and ongoing) - NK2 - additionally had abnormalities in RAD50, PMS2, JAK1, KDR and NOTCH4, the patient with short disease stabilization (NK9) following chemoimmunotherapy (4 months) - in ATM, PMS2 and SMARCA4, while the patient with rapid progression (NK5) during pembrolizumab therapy (<2 months) - in PIK3CA, PDGFRA, H3-3A, and NOTCH4 genes. Patients NK2 and NK9, compared to the non-responder, before therapy had high percentages of CD3+ and CD4+ T cells and low percentages of CD8+/PD-1+ cells and Tregs. In NK2 and NK9 patients, in contrast to the NK5 patient, the percentages of CD8+ T cells CD8+/PD-1+ cells, CD4+/EOMES+ cells and Tregs were increasing. In the non-responding patient, an increase in the percentage of T cells with TIM-3 and LAG-3 molecules was observed.

Conclusions: Coexistence of KRAS/STK11 mutations with mutations in genes encoding DNA repair proteins: PMS2, RAD50, and ATM appears to be a favorable predictor for immunotherapy. This is probably related to DNA repair deficit in tumor cells, accumulation of somatic mutations and high number of neoantigens, and thus high immunogenicity of the tumor and activation of the immune system supported by immunotherapy. Additional mutations in oncogenes (PIK3CA, NOTCH4) may be an unfavorable predictor. Immune system analysis may be important in predicting the immunotherapy efficacy.

Keywords: NSCLC, mutations in KRAS and STK11 genes, immunotherapy

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.18 Is There Any Association Between EGFR Alterations and PD-L1 Expression in NSCLC a Single Center Experience

S. Balli, E.B. Köksoy, A. Demirkazık
Ankara University Faculty of Medicine, Ankara/TR

Introduction: Epidermal growth factor receptor (EGFR) mutation is the most common mutation in non-small cell lung cancer (NSCLC), approximately 15-45%. EGFR amplification is sometimes the only detectable molecular alteration in patients with NSCLC, also it sometimes co-occur with EGFR mutations. Previous studies reported that EGFR amplifcation occurred in about 9-64% NSCLC patients. They were distinct situations, and treatment schedules were different.

Methods: We conducted a retrospective observational study in our medical oncology department, enrolling advanced non-squamous NSCLC patients with EGFR alterations (mutation or amplification) between 2019 and 2024. Next-generation sequencing (NGS) or polymerase chain reaction (PCR) was used to detect genetic alterations in tumor tissue, and immunohistochemistry (IHC) was used to determine PD-L1 expression. The Chi-square test was used to compare these proportions in two groups. PD-L1 expression cut-off was calculated as PD-L1:1.

Results: A total of 85 advanced NSCLC patients with EGFR alterations were included in this study. EGFR amplification was found in 37 of 85 (43.5%) and EGFR mutation was found 48 of 85 (56.5%) patients with EGFR alterations. Of 48 patients with EGFR mutations, 22 patients harbored EGFR 19 del, 16 patients with 21-L858R, 8 patients harbored with rare mutations. In chi-square analysis, EGFR amplification was identified as an independent factor for the PD-L1 expression (p = 0.01).

Conclusions: We found that EGFR amplification is an independent factor for PD-L1 expression in advanced non-squamous NSCLC patients. Nevertheless, further research is needed in larger populations.

			PD L1 expressions		
			<1	>1	Total
EGFR	amplification	Count	6	31	37
		% within EGFR	16,2%	83,8%	100,0%
	mutantion	Count	25	23	48
		% within EGFR	52,1%	47,9%	100,0%

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.19 The Relationship Between PD-L1 Expression and Tumor Microenvironment in Lung Squamous Cell Carcinoma

Iwate Medical University, Yahaba-cho, Shiwa-gun/JP

Introduction: PD-L1 expression status is very important factor in order to predict therapeutic effect of immune checkpoint inhibitor (ICI). Tumor cells interact with surrounding stromal cells via complex mechanisms, and together these cells make up the tumor microenvironment (TME). Within the last decade, the TME has been shown to be important for the proliferation, invasion, metastasis, and treatment resistance of tumor cells. Stromal cells include fibroblasts, vascular cells, and immune cells. Common immune cells, including lymphocytes, neutrophils, and monocytes/macrophages, also make up the TME. Tumor infiltrate lymphocyte (TIL), tumor-associated macrophage (TAM), and cancer-associated fibroblast (CAF) are main components of TME. The aim of this study is to examine the relationship PD-L1 expression status and the density of TIL and TAM and CAF expression status in surgically resected lung squamous cell carcinomas (SQCCs).

Methods: A total of 104 SQCCs were examined. The male:female ratio was 97:7; the age range was between 51 and 87 years of age and the mean age was 71 years. Pathological stage's ratio (I:II:III) was 57:32:15. Adjuvant chemotherapy was performed in 62 patients. The mean follow-up period was 58.2 months (range, 4.9-135.3 months). Tissue microarray was built and the expression status of PD-L1, CD3 and CD8 as TILs marker, CD68 and CD163 as TAMs marker, AEBP1, α-SMA, FAP, Tenascin-C, Podoplanin, CD10, PDGFRα, PDGFRβ, FSP1 as CAFs marker was analyzed using immunohistochemistry. PD-L1 expression status of both tumor cells (TC) and immune cells (IC) were examined and classified as follows: (Negative, <1%; Positive, 1%≤). The relationship between the status of PD-L1 expression and the expression status of TME factors (TILs, TAMs, and CAFs) was investigated.

Results: The status of PD-L1 expression was as follows: Negative, 60 (58%); Positive, 44 (42%) in TCs and Negative, 63 (61%); Positive, 41 (39%) in ICs. PD-L1 expression in TCs was correlated with the density of CD3 and CD163 expression (p=0.029 and p=0.029, respectively) and PD-L1 expression in ICs was correlated with the density of CD3, CD8, CD68, CD163 expression and the status of CAFs expression (p=0.009, p=0.032, p=0.098, p=0.067 and p=0.075, respectively). The status of CAFs expression was also correlated with the density of CD8 and CD163 expression (p=0.01 and p=0.023, respectively).

Conclusions: PD-L1 expression was correlated with the status of TME, particularly in ICs. In addition, Inter-correlation among TME was found. Therefore, examining the status of TME is very important and useful because of therapeutic strategy of lung SQCC.

Keywords: PD-L1, Tumor microenvironment, squamous cell carcinoma

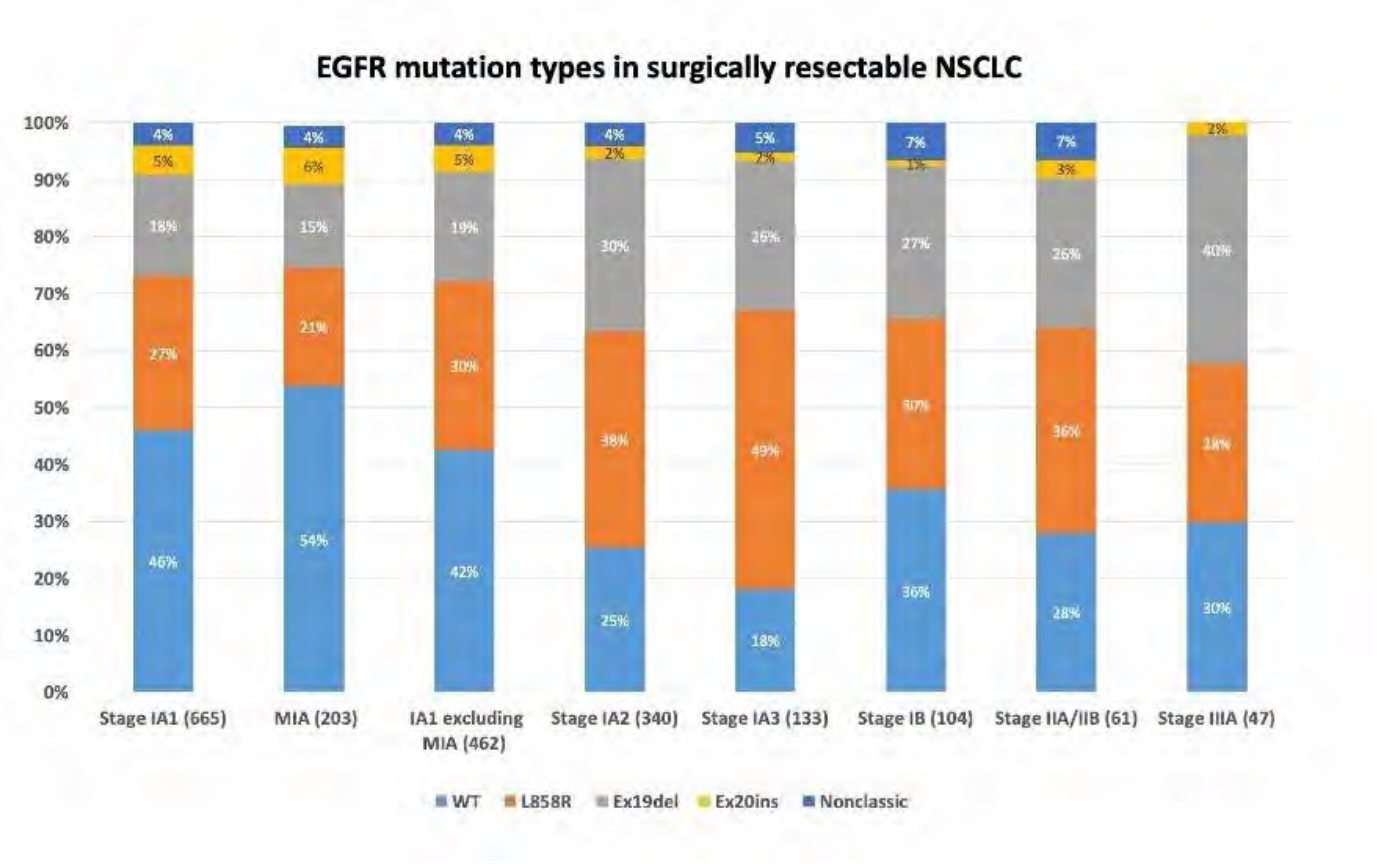
EP.06.20 Stage-Dependent Increase in EGFR Mutation Rates in Early-Stage Lung Cancer at National Taiwan University Cancer Center

T-N. Kao[1], H. Wang[2], Y-T. Chen[2], C-W. Lu[1], M-W. Lin[1], H-H. Hsu[1], M-S. Hsieh[2], J-S. Chen[1]
[1]National Taiwan University Hospital, Taipei City/TW ,[2]National Taiwan University Cancer Center, Taipei City/TW

Introduction: Epidermal growth factor receptor (EGFR) mutation is the most common driver mutation of lung cancer in Asia. This study aims to analyze the prevalence of EGFR mutations and their clinicopathological characteristics among different stages of surgically resected lung cancer at National Taiwan University Cancer Center. Specifically, we intend to examine the differential expression patterns of EGFR mutations in early-stage versus advanced-stage lung cancers, in order to elucidate their distinct roles in tumor invasiveness and early-stage oncogenesis.

Methods: This retrospective study meticulously compiled data from all surgically resected lung cancer cases, spanning stages IA1 to IIIA, who underwent EGFR mutation testing at the National Taiwan University Cancer Center between January 1, 2023, and December 31, 2024. Comprehensive clinical and pathological information for each eligible case was systematically extracted from electronic medical records. The retrieved data encompassed detailed EGFR mutation test results, precise histologic typing, histologic grading, and the complete TNM staging components.

Results: From 2023-2024, 1,351 stage I-IIIA lung cancers underwent cobas EGFR v2 testing, identifying EGFR mutations in 887 (64.2%) cases. The most frequent mutations were EGFR exon 21 L858R (32%), EGFR exon 19 deletions (Ex19del) (24%), and EGFR exon 20 insertions (Ex20ins) (4%). A striking trend emerged: the overall EGFR mutation rate and the prevalence of classic EGFR mutations (L858R/Ex19del) progressively increased with advancing tumor stage, from IA1 (53.9% and 44.8%, respectively) to IA3 (81.9% and 75.2%, respectively). Furthermore, tumor grade influenced mutation frequency, with grade 2 adenocarcinomas showing the highest EGFR mutation rate (70.0%) and grade 1 the lowest (49.0%). This finding hints at a possible link between EGFR mutation prevalence and the differentiation status or biological aggressiveness of lung adenocarcinoma.



Conclusions: Across all stages and grades, L858R was the most common mutation type. In early-stage lung cancer (stage IA1-IA3) with tumors not exceeding 3 cm, the EGFR mutation rate increased from minimally invasive adenocarcinoma (MIA) to stage IA3, suggesting that early-stage lung adenocarcinoma with EGFR mutations has a growth advantage. Regarding different EGFR mutation types, this study also showed that early-stage lung adenocarcinoma with typical EGFR mutations (L858R/Ex19del) had a growth advantage over those with atypical mutations (Ex20ins/G719X/L861Q). Consequently, the proportion of typical EGFR mutations gradually increased from MIA to stage IA3, whereas the proportion of atypical EGFR mutations decreased.

Keywords: EGFR mutation, Early-stage lung cancer

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.21 Genomic and Demographic Predictors of Survival in Patients With ALK Fusion NSCLC: Insights From a Single-Center Cohort

B. Waissengrin[1], S.Y. Choi[1], E. Vail[2], K. Sankar[1], J. Figueiredo[1], K. Reckamp[1]
[1]Cedars Sinai Medical Center, Los Angeles/CA/USA ,[2]Cedars-Sinai Medical Center, Los Angeles/CA/USA

Introduction: Patients with anaplastic lymphoma kinase (ALK) fusion non-small cell lung cancer (NSCLC) generally exhibit prolonged survival rates. In multiple phase III studies evaluating the efficacy of tyrosine kinase inhibitors (TKIs) targeting the ALK receptor, the median overall survival (OS) has not yet been reached. However, a subset of patients experiences significantly reduced OS. We aim to characterize the demographic and genomic profiles of this patient group.

Methods: We reviewed consecutive electronic medical records of patients with ALK fusion NSCLC whose next-generation sequencing (NGS) was performed and who were treated at Cedars-Sinai Cancer Center between the years 2019 to 2024. Data on demographic factors (age, sex, race, ethnicity, and smoking status), clinical information (date of initiation of ALK inhibitor TKI and date of death, if applicable), and pathological characteristics (including NGS analysis and co-mutations) were evaluated. Patient characteristics by mortality were compared using two-sample t-tests, Chi-squared tests, or Fisher's exact tests, as appropriate. Overall survival since the treatment start was compared across sex, ethnicity, race, and co-mutation status using Kaplan-Meier curves and the log-rank test.

Results: Our cohort included 68 patients with ALK fusion. At the time of analysis, 15 patients (22%) had died (median OS 43 months), while 53 patients (78%) were still alive (median OS not reached). The median age of patients who died was younger than that of the long-survival group (56 years vs. 65 years, p-0.05). Both groups were well-balanced in terms of other characteristics, including sex, ethnicity, race, smoking status and ALK Fusion variant. Genomic analysis of the cohort revealed a shorter OS for patients whose tumors harbored co mutation of TP53 mutation (median OS was not reached in both groups, p-0.014) and MTAP deletion (18.5 months versus not reached, p-0.026).

Conclusions: Our findings highlight the heterogeneity within patients with ALK fusion NSCLC, demonstrating that certain genomic alterations, specifically TP53 mutations and MTAP deletions, are associated with shorter OS despite the generally favorable prognosis seen in this population. These findings underscore the need for further research into the biological mechanisms underlying these differences, which may guide the development of more personalized treatment strategies and improve outcomes for patients with poor prognostic factors.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.22 Genomic Insights Into ALK-Rearranged NSCLC: A Comprehensive Study

W. Khatoon, K. Yadav, K. Samant, A. Nambirajan, C. Shekhara, P.S. Malik, D. Jain
All India Institute of Medical Sciences, New Delhi/IN

Introduction: The discoveries of targetable molecular alterations are leading to the advancement in precision medicine. The discovery of rearrangement in the Anaplastic lymphoma kinase (ALK) gene in Non-Small Cell Carcinoma (NSCLC), makes it another subtype of NSCLC. The ALK tyrosine kinase inhibitor (TKI) is used for treatment of such subtype, despite this treatment some patients have rapidly progressive disease, which necessitates the understanding of major risk factors.In our study, the genetic profile of different risk patients was done to identify signatures for rapid disease progression, that can be incorporated into routine molecular testing panels alongside ALK testing.

Methods: We collected ALK Immunohistochemistry and/or Fluorescence In Situ Hybridization positive 46 Formalin-Fixed, Paraffin-Embedded (FFPE) block of ALK-rearranged NSCLC patients from 2014 to 2024, from the department of pathology. On the 41 Samples, RNA fusion was detected using a custom RNA fusion panel and based on tissue availability the 32 samples were tested for 72 genes that are crucial in lung cancer using the Qiagen 72 gene panel.

Results: Out of 41 samples, 17 samples were from High-risk group (MPFS:2), 6 samples were from moderate risk group (MPFS:13.5), and 18 samples were from the low-risk group (MPFS:39), the ALK fusion partner was detected in 26 patients and 12 samples were negative, and 3 samples failed at QC level. The RNA sequencing result showed V1 as the most common variant (53.8 %, 14/26) and V5 being the least common (3.8 %, 1/26) and no direct correlation was found between ALK fusion variants and risk groups. In addition to RNA sequencing, targeted DNA sequencing was performed to identify mutations that may further define the molecular risk stratification, results are shown in figure 1. Mutations like TP53, MUC16, and CREBBP are common in all three groups and may not be genes defining the risk, whereas mutation in tumor suppressor genes including APC, ARID1A, KMT2D can be included to define the moderate risk and High-risk group. Mutation in SETD2, PIK3R1, KRAS, and EGFR along with ALK rearrangement may promote the tumor progression and contribute to poor treatment response.

Conclusions: This finding suggests that mutations in genes such as APC, ARID1A, KMT2D, SETD2, PIK3R1, KRAS, and EGFR may help in determining the aggressiveness of the tumor. Evaluating the efficacy of ALK TKIs in the context of baseline genetic alterations is essential, and combination therapies may be required for cases with co-occurring oncogenic drivers like EGFR and KRAS.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.23 Comprehensive Genomic Profiling as a Key Determinator in Clinical Staging and Treatment Planning

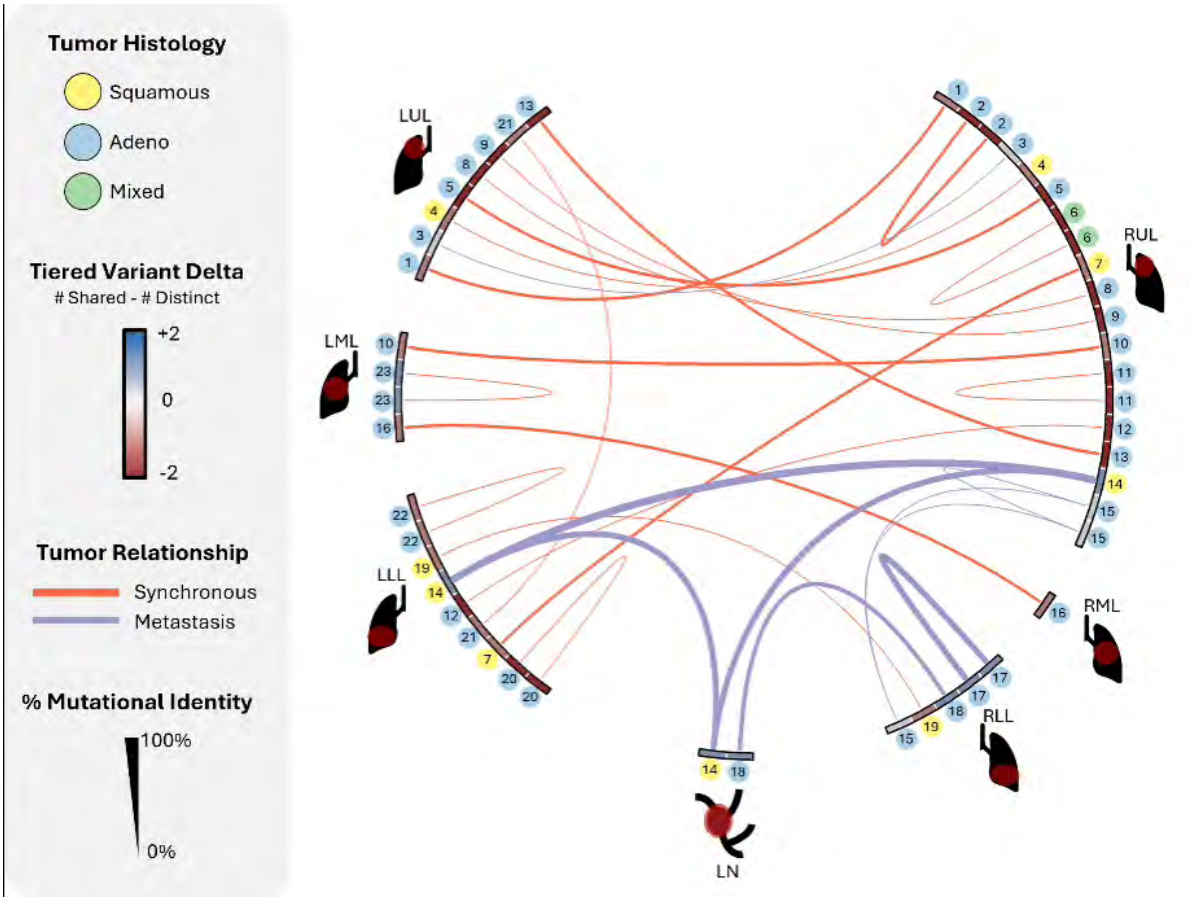
R.P. Auber[1], K. Konduri[2,3], M. Shiller[1,4]
[1]PathGroup, Nashville/TN/USA ,[2]Baylor Sammons Cancer Center, Dallas/TX/USA ,[3]Texas Oncology PA, Dallas/TX/USA ,[4]Baylor University Medical Center, Dallas/TX/USA

Introduction: NSCLC patients who present with multiple distinct lesions present a clinical conundrum. Distinguishing between synchronous primaries or metastasis can serve as a prognostic indicator, facilitate staging, and therefore influence treatment decisions. Recommended criteria for staging proximal lesions primarily relies upon histologic characterization, with one paper describing criteria to consider, yet no formal guideline has been issued. We present evidence for a valuable role of comprehensive genomic profiling (CGP) to facilitate staging in the setting of multiple lung nodules and outline guiding principles for the interpretation of composite results.

Methods: A cohort of 23 NSCLC patients encompassing 48 intrapulmonary lesions of distinct spatial localization or histologic subtype were evaluated. CGP was performed on each lesion using an FDA-cleared 505 gene NGS assay. Clinical history, morphology, and mutational profiles were cross evaluated to infer staging for each patient. Variants were tiered according to AMP/ASCO/CAP guidelines.

Results: Of the 23 patients, 22% (n=5) were designated as harboring a single primary with local or advanced metastasis, while 78% (n=18) favored the presence of synchronous primaries. Of patients with synchronous primaries, 94% harbored more unique Tier I/II variants than shared between lesions and averaged a 16% (95% CI, 11.3% to 20.7%) shared identity between mutational profiles. Comparatively, all patients with lesions denoted as being of a single primary with metastasis harbored an equal or higher ratio of shared to unique tiered variants but displayed variable levels of shared identity (average, 50%; SD, 36%). Further, we exhibit individual patients where treatment decisions were altered considering CGP results.

Conclusions: The utilization of mutational profiles to infer tumor staging has largely been unincorporated due to multiple factors including limitations in assay sensitivity, germline mutations, and known discordance between primary and metastatic sites. However, interpretation of the mutational profiles between lesions can still inform stage determination if caveats are factored into the final decision. In our experience, this approach has facilitated staging in ways that are not possible by morphology alone. The data herein often lowers staging thereby driving treatment decisions, including the possible avoidance of unnecessary treatment options. As such, we propose CGP should be recommended as a standard approach to navigate these clinical scenarios, and that payors support the use of these assays in such a way. We also hope to inspire additional discussion for the review of the use of CGP to inform staging in NSCLC patients with multiple lesions with more formal guidance.



Keywords: Staging, Genomic profiling

EP.06.24 Update of Mutation Status and PD-L1 Expression in Lung Cancer

N. Pilnik[1], V. Bengio[2], L. Alessio[3], J. Arevalo[1]
[1]CORDOBA UNIVERSITY (UNC), Cordoba/AR ,[2]Hospital Cordoba, Cordoba/AR ,[3]Hospital Frances, Cordoba/AR

Introduction: Significant progress has been made in understanding the biology of non-small cell lung cancer (NSCLC), particularly through the characterization of molecular alterations including oncogene activations (mutations, translocations, amplifications) and immune checkpoint expressions, which serve as predictive biomarkers

Methods: This study analyzed molecular alterations in EGFR, ALK gene fusion, Ros1 and PD-L1 in Caucasian and Hispanic populations from 2015 to 2025. PD-L1 expression was assessed in 146 of 260 NSCLC samples, including biopsies and surgical resections from various Cordoba institutions. Molecular testing included EGFR mutations (TheraScreen PCR kit targeting exons 18-21), ALK translocations (FISH Vysis Break-Apart and IHC clone D5F3), and PD-L1 expression (Dako Autostainer Link 48, kit PD-L1 IHC 22C3 pharmDx). Molecular profiles and PD-L1 expression were correlated with clinical variables (age, gender, smoking habits), using chi-squared or Fisher's test for qualitative variables and T-test for quantitative variables.

Results: The study included 260 NSCLC adenocarcinoma pts (165 males, mean age 63; 95 females, mean age 61). Smoking was significantly higher in males (60%) compared to females (29.62%, p=0.006). EGFR positivity was more frequent in females (11.51%) compared to males (6.35%, p=0.0001), while ALK alterations were infrequent overall (positive cases: males 1.2%, females 1.6%; p=0.4276). PD-L1 expression positivity was identified in 26% of males and 16% of females (p=0.9726), without significant gender differences. ROS-1 positivity was very rare (0.74% each gender).Of the 149 adenocarcinoma cases specifically tested for PD-L1, positivity was found in 63 cases (42.28%).PD-L1 positive and negative groups showed no significant differences regarding to age (mean 60.98 vs. 62.21 years, p=0.3736), gender (male 26% positive vs. 36% negative, female 16% positive vs. 22% negative; p=0.9726), or smoking habits (smokers: 37.58% PD-L1 positive vs. 54.36% negative; p=0.3613). EGFR and ALK status did not significantly correlate with PD-L1 expression.

Conclusions: The observed frequencies of EGFR mutations and ALK fusions are comparable to those reported in Western populations. The molecular profiling of EGFR, ALK, and PD-L1 tumor proportion scores (TPS) in NSCLC adenocarcinomas is crucial for accurate diagnosis and appropriate therapeutic decisions, underscoring the importance of personalized medicine in lung cancer management.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.25 Analysis of LAT1 Protein Expression and Clinical Characteristics of Patients With Primary Lung Cancer

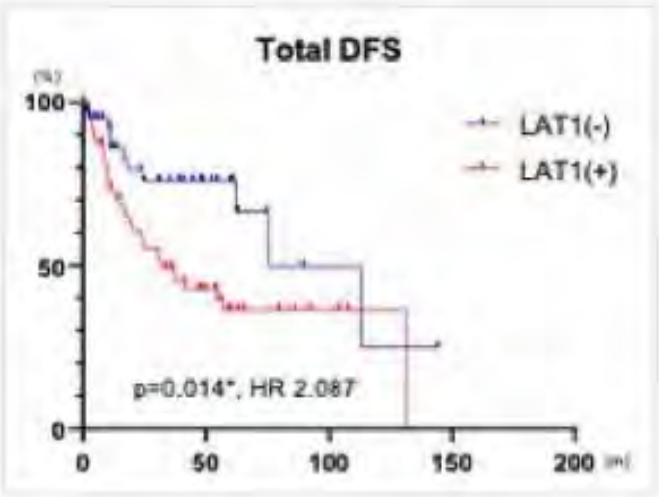
H. Koba[1], S. Yano[2], Y. Murase[1], T. Ueda[1]
[1]Kanazawa University Hospital, Kanazawa/JP ,[2]Kanazawa Univeristy Hospital, Kanazawa/JP

Introduction: The L-type amino acid transporter 1 (LAT1) is a membranous transporter that transports neutral amino acids for cells and is dysregulated in various types of cancers. One of this study aims is to investigate the correlation between prognosis or histological features of lung cancer and LAT1 expression, and the other is to clarify the heterogeneity of expression levels between primary and metastatic lesions.

Methods: We collected lung cancer specimens by surgical resection or pathological autopsy, administered from 2019 to 2021 in Kanazawa University Hospital. LAT1 protein expression of cancer cells were accessed by immunohistochemistry staining. Patient characteristics were extracted from electric record retrospectively.

Results: Totally 127 patients were corresponded for our study. The positive rate for LAT1 protein in small cell carcinoma, adenocarcinoma and squamous cell carcinoma were 58%, 50% and 94%, respectively. In the survival analysis, disease-free survival in LAT1 positive group was significantly shorter than that in LAT1 negative group (31.7m vs 76.8m, p=0.034, HR=1.99). Overall survival in LAT1 positive group was also significantly shorter than that in LAT1 negative group (84.1m vs NR, p=0.034, HR=2.35). Multiple lesions could be accessed in 27 cases in the analysis about autopsy. 22 out of 27 cases were homologous among the metastases.

Conclusions: Our study suggested LAT1 protein expression had a potency of the prognostic factor, especially in adenocarcinoma. These results were consistent with previous reports. It thinks that recruited amino acid contributes not only protein synthesis but stimulation of cancer growth. LAT1 expression heterogeneity among the metastases was low. We think further investigation as a new therapeutic target is warranted.



Keywords: LAT1, heterogeneity

EP.06.26 Resectable Lung Cancer With KRAS Mutation May Have Less Lymphatic Metastasis

C. Nakagami[1], K. Onodera[1], H. Notsuda[1], S. Kumata[1], T. Togo[1], Y. Watanabe[1], T. Watanabe[1], T. Suzuki[1], H. Oishi[1], E. Miyauchi[2], C. Inoue[3], Y. Aoyama[3], T. Koizumi[2], Y. Okada[1]
[1]Institute of Development, Aging and Cancer, Tohoku University, Sendai, Miyagi/JP ,[2]Tohoku University Hospital, Sendai, Miyagi/JP ,[3]Tohoku University Graduate School, Sendai, Miyagi/JP

Introduction: Multigene panel testing has mainly been performed in advanced lung cancer, and there is little data accumulated in resected specimens from early-stage lung cancer. At our institution, all resected specimens are tested for driver gene mutation using the the AmoyDx® Multi-Gene Mutations Detection Kit (AmoyDx). We report on the association between genetic mutations and pathological factors.

Methods: We collected pathological data from 291 patients with non-small cell lung cancer who were submitted to AmoyDx after surgical resection at Tohoku University Hospital between January 2022 and July 2024. We investigated the association between driver gene mutations and pathological factors.

Results: The median age of the patients was 72 years, and 157 were men (54%) and 134 were women (46%). The pathological stage was 0/IA/IB/II/III in 1/177/49/43/21 cases, respectively. The driver gene mutations were EGFR in 109 patients (37%), KRAS in 40 patients (14%), BRAF in 2 patients (0.7%), HER2 in 7 patients (2.4%), RET in 3 patients (1.0%), MET in 15 patients (5.1%) and ROS1, ALK and NTRK in 0 patients. The more advanced the pathological stage, the lower the rate of EGFR mutation and the higher the rate of KRAS mutation. There was no consistent trend was observed for other mutations. The proportion of KRAS mutations increased with the progression of pathological T-factors, but the proportion of positive lymph node metastases and lymphatic invasion was 5.0% (2/40) and 7.5% (3/40), respectively, in KRAS mutation-positive lung cancer, both of which were low (Table 1). On the other hand, vascular and pleural invasion were observed in a reasonable proportion of KRAS mutation-positive lung cancers, at 28% (11/40) and 35% (14/40), respectively.

Conclusions: KRAS mutation-positive lung cancers are generally considered to have a high malignant potential, but this may not be due to lymphatic metastasis but may depend on other metastatic modalities such as hematogenous metastasis or pleural dissemination.

Table 1. Association of KRAS mutation with lymphatic invasion and lymph node

		Lymphatic invasion (+)	Lymph node metastasis (+)
KRAS mutation	+	3/40 (7.5%)	2/40 (5.0%)
	-	43/251 (17%)	48/251 (19%)
Total		46/291 (16%)	50/291 (17%)

Keywords: driver gene mutation, KRAS, early-stage lung cancer

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.27 Challenges in Implementing Targeted Panel NGS for Biomarker Testing in Non-Small Cell Lung Carcinoma in Resource-Constrained Settings

A. Nambirajan, K. Yadav, S. Satapathy, S. Devgan, A. Mohan, P.S. Malik, D. Jain, S. Sahu
All India Institute Of Medical Sciences, New Delhi/IN

Introduction: The number of clinically actionable biomarkers for inoperable non-small cell lung carcinoma has increased significantly in the last decade, necessitating routine multiplex biomarker testing. In resource-constrained settings, transitioning from single-gene tests (e.g., EGFR, ALK, ROS1) to NGS-based multiplex testing requires major changes in tissue processing, biopsy reporting, and molecular testing workflows. This study aims to analyze the cost-benefit ratio of routine multiplex NGS implementation and identify potential pitfalls and challenges.

Methods: This prospective study (November 2024 to June 2025) includes baseline biopsies from patients with advanced non-small cell lung carcinoma with a pathological diagnosis of adenocarcinoma, or not-otherwise-specified, negative for EGFR mutations, ALK rearrangements, and ROS1 rearrangements. Biopsies with >30% tumor fraction were subjected to multiplex NGS using AmoyDx Handle NGS kits followed by Illumina sequencing. Post-treatment biopsies were subject to upfront NGS. Representative cases of ALK and ROS1-rearranged samples diagnosed on single gene testing were also included for validation.

Results: As of date, 75 patient samples have been included for study. Complete data is available from 40 patients including 35 treatment-naive and 5 treated patients with progression (see Figure), excluding patients whose sequencing data output lacked adequate DNA depth (DNA QC fail, n=5) and/or showed inadequate RNA controls (RNA QC fail, n=2). One or more clinically actionable predictive biomarkers were detected in 30/40 (75%) of the patients, including two post-EGFR TKI patients detected with MET exon 14 skipping mutation (n=1) and EGFR T790M mutation (n=1), undetected on single gene testing. KRAS mutations (n=6), MET exon 14 skipping mutations (n=4), ERBB2 mutations (n=6). RET fusions (n=2), ROS1 fusions (n=3), BRAF mutations (n=1) were among the ESCAT Tier 1/2 actionable drivers detected only on NGS. Further updated data will be presented in the conference.

Conclusions: Routine implementation of limited panel NGS is urgently required in any centre treating patients with lung cancer as is evident from the high numbers of clinically actionable targets that are identified only on NGS. With the availability of multiple commercial NGS kits, it is possible to standardise, validate and establish testing algorithms and workflows for cost-effective delivery of NGS results even in resource constrained settings.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.28 Circadian CLOCK Expression in Non-Small Cell Lung Cancer

M. Inoue, Y. Nabe, Y. Honda, H. Mizuuchi, J. Yoshida, M. Handa, D. Yasuda
Shimonoseki City Hospital, Shimonoseki/JP

Introduction: The circadian clock consists of multiple sets of transcription factors resulting in autoregulatory transcription-translation feedback loops. Disruption of this cellular pathway has been recently proven to be associated with cancer risk, development and progression. BMAL1 and CLOCK are the central modulators of circadian output in cells and their pathological functions in cancer. CLOCK may harbor tumor-suppressive roles that are conserved among humans and rodents. In previous reports, epigenetic or genetic inactivation of Bmal1 and/or Clock has been shown to increase tumor proliferation or growth rates in several types of cancer, such as lung cancer. On the other hand, overexpression of these circadian activators suppresses proliferative and malignant phenotypes in tumor cells. Colon cancer with higher expression levels of CLOCK were associated with lymph node metastasis and tended to be more advanced. The expression of core circadian clock genes is frequently dysregulated in human tumors; however, the specific effects and underlying mechanisms are not fully understood.

Methods: Formalin-fixed, paraffin-embedded samples were stained with CLOCK antibody by immunohistochemical (IHC) analysis. Extent of staining of CLOCK was scored as 1 (0-25%), 2 (26-50%), 3 (51-75%), 4 (76-90%), and 5 (91-100%) according to the percentages of the positive staining areas in relation to the whole cancer area. The IHC scores were analyzed for correlation to clinicopathological parameters and prognosis using Kaplan-Meier method and Cox proportional hazard regression models in patients with non-small cell lung cancers.

Results: From January 2020 to October 2022, totally 98 consecutive patients (57 males/41 females) who underwent complete resection were collected with median age 72 years (range, 54-88) at the time of operation. Extent of CLOCK protein expression in lung cancer was score 1 in 5 cases (5%), score 2 in 10 cases (10%), score 3 in13 cases (13%), score 4 in 17 (17%) and sore 5 in 53 cases (54%). The patients were divided into CLOCK normal expression group (score 4-5) and CLOCK low expression group (score 1-3). No difference in CLOCK expression were observed between sex and smoking status, and histological types. In pathological stage, normal expression rate of CLOCK for p-stage 0-IA and IB-IIIB was 87% (40/46) and 58% (30/52). CLOCK expressions were significantly decreasing in advanced disease (p=0.001). Recurrent rate (32%) of CLOCK low expression group was higher than that of high expression group (13%). However, three-year disease-free survival was 69% in normal expression group and 73% in low expression group. There was no significant difference in prognostic analysis depend on CLOCK expression, nor there any other factors.

Conclusions: Expression level of CLOCK in lung cancer were decreased in advanced disease stages. These were contrary to previous reports, which showed that the expression increased in advanced colon cancer. However, expression of CLOCK was not related to prognosis, and this result was the same as in colon cancer. In this study, we evaluated one protein level of many circadian clock factors and also the number of analyzed cases was small. Then we plan to conduct further studies by increasing the number of analyzed factors and cases.

EP.06.29 Prognostic Impact of Lepidic Growth in Intermediate and High-Grade Lung Adenocarcinoma

B. Niedermaier[1,2], E. Rolf[1], M. Allgäuer[2,3], L.V. Klotz[1,2], M.A. Schneider[2,4], M.E. Eichhorn[1,2], H. Winter[1,2]
[1]Thoraxklinik at the University Hospital Heidelberg, Heidelberg/DE ,[2]German Center for Lung Research (DZL), Heidelberg/DE ,[3]Heidelberg University Hospital, Heidelberg/DE ,[4]Translational Research Unit (STF), Thoraxklinik at the Heidelberg University Hospital/DE

Introduction: Lung adenocarcinoma is characterized by heterogeneous pathologic features and a variable growth pattern composition that can profoundly influence prognosis. Grade 1 lung adenocarcinomas, which are characterized by predominantly lepidic growth and less than 20% high-risk patterns, have a favorable survival rate compared to higher-grade tumors. However, the prognostic significance of lepidic components in intermediate and high-grade lung adenocarcinomas is still controversial. A positive prognostic impact of non-predominant lepidic growth has been observed in Asian populations, but this has not yet been validated in different populations around the world. Therefore, the aim of this study was to investigate the presence of lepidic growth in grade 2-3 non-mucinous lung adenocarcinomas and to evaluate its impact on survival in a large, European lung cancer population.

Methods: 479 consecutive patients who underwent curative resection for non-mucinous lung adenocarcinoma in pathologic grade 2-3 and stage I were enrolled in this retrospective, single-center study. The impact of lepidic components and other predictors on survival was assessed in multivariable cox regression.

Results: Of 479 patients in the total study cohort, 300 (62.6%) exhibited tumors with lepidic components. The presence of lepidic growth was significantly associated with older age (median 67 vs. 65, p=0.0149), a higher proportion of never-smokers (22.1% vs. 9.9%, p = 0.0011), predominance of acinar growth (69.0% vs. 53.1%, p = 0.0005), and a lower proportion of solid-predominant tumors (7.0% vs. 26.8%, p<0.0001). Pathologic stage according to the 8th edition of the TNM system was T1a in 37 patients (7.1%), T1b in 134 (28.0%), T1c in 72 (15.0%) and T2a in 239 patients (49.9%) without significant association to the presence of lepidic components. We observed a trend towards more lymphatic and vascular invasion in lepidic-negative patients (15.0% vs. 20.7%, p = 0.1110 and 21.0% vs. 30.7%, p = 0.0168, respectively). Median follow-up was 67 months (IQR 47 - 92 months). A cox proportional hazards analysis revealed that the presence of lepidic growth was not significantly associated with OS or RFS both in the univariable and multivariable model. Further stratification for patients with 1-10% or over 10% lepidic growth did not enhance predictive power. Significant risk factors affecting RFS were age over 70 years (HR 1.402 (1.006-1.954), p= 0.046), pathologic stage IB (HR 1.515 (1.077-2.130), p = 0.017), grade 3 (HR 1.422 (1.016-1.990), p = 0.040) and lymphatic invasion (HR 1.668 (1.123-2.477), p= 0.011).

Conclusions: The prognostic impact of lepidic components in intermediate and high-grade lung adenocarcinoma was not confirmed in this study. Our findings highlight that considerable differences between patient demographics around the world exist, and careful consideration of conflicting observations between different patient populations is warranted in order to correctly estimate the prognostic impact of lepidic growth.

EP.06.30 Single-Cell RNA Sequencing Reveals a Subset of FSIP1 Cancer Cells and Verified Its Value of Prognosis in Lung Adenocarcinoma

S. Zhang[1], W. Li[2], X. Zhang[3]
[1]Department of Molecular Diagnostic Centre, Hangzhou First People's Hospital, Hangzhou/CN ,[2]Translational Medicine Research Center, Hangzhou First People's Hospital, Hangzhou/CN ,[3]Department of Medical Oncology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN

Introduction: Lung adenocarcinoma (LUAD) is the most prevalent subtype of non-small cell lung cancer. The prognostic role of Fibrous sheath interacting protein 1 (FSIP1) in LUAD remains unclear. Thus, this study aims to identify and validate the prognostic value of FSIP1 in LUAD and explore its molecular functions.

Methods: Single-cell RNA sequencing (scRNA-seq) data of LUAD patients were collected from Gene Expression Omnibus (GEO) database, the major cell types were identified based on known markers. Additionally, the expression of FSIP1 was detected in 180 LUAD samples, Kaplan-Meier (KM) analysis of high- and low-expression patients was conducted. Univariate and multivariate Cox regression analyses were utilized to assess the prognostic ability of FSIP1. Then, FSIP1-silenced human LUAD cell lines were constructed, and the functions of FSIP1 were explored. Finally, immune infiltration analysis was also performed in LUAD patients.

Results: In this study, we identified LUAD FSIP1+ cancer cells by using scRNA-seq data from GEO database. Additionally, we investigated the protein level and prognostic value of FSIP1 in 98 LUAD patients using Tissue Microarray. Compared with the adjacent, FSIP1 was higher expressed in LUAD tissues. KM analysis revealed that the 5-year OS rate to be 30% to 59% (FSIP1High vs FSIP1Low) in Tissue Microarray. Univariate and multivariate COX regression showed that FSIP1 should be an independent factor in poor prognosis. The receiver operating characteristic curve (ROC) and time-ROC curve both indicated that FSIP1 had a good performance in prognostic model. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis showed that FSIP1 was associated with migration. Migration assay and Western blotting showed that FSIP1 influenced cell migration and PI3K/AKT pathway. FSIP1 could influence the immune cell infiltration in lung adenocarcinoma patients.

Conclusions: This study verified that FSIP1 could serve as a valuable prognostic biomarker in LUAD and analyzed its impact on the disease and its association with the immune infiltration. The findings of this research provide valuable insights into the understanding of LUAD and could potentially lead to the development of new treatment strategies.

EP.06.31 Prognostic Impact of Carcinoembryonic Antigen-Related Cell Adhesion Molecule 5 Expression in Non-Small Cell Lung Cancer

Y-H.R. Hsu[1], A. Almutrafi[2], K. Hueniken[1], A. Azaizeh[3], L. Hou[1], Q. Li[1], N-A. Pham[1], M-S. Tsao[1]
[1]Princess Margaret Cancer Centre, Toronto/ON/CA ,[2]King Abdulaziz Medical City, Riyadh/SA ,[3]Princess Iman Center for Research and Laboratory Sciences, Amman/JO

Introduction: Carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5) is overexpressed in various solid tumors including non-small cell lung cancer (NSCLC). Its expression has been associated with tumor invasion and metastasis. However, the prognostic significance of CEACAM5 expression has not been investigated in patients with NSCLC. We aim to examine the prognostic effect of CEACAM5 expression by immunohistochemistry (IHC) in a large cohort of patients with resected NSCLC.

Methods: We retrospectively evaluated CEACAM5 expression by IHC on resected NSCLC specimens from 2005 to 2012 at our institution, using the anti-CEACAM5 clone 769 antibody assay protocol developed for the tusamitamab ravtansine clinical trials. Expression levels were categorized as high (≥ 50% tumor cells at ≥ 2+ intensity), moderate (1-49% tumor cells at ≥ 2+ intensity), and low (0 or 1+ intensity), and were scored independently by three thoracic pathologists. Interrater reliability was assessed by Kendall's coefficient of concordance (KCC) and Fleiss' Kappa. Discordant classification was reviewed to achieve a consensus score. Association with categorical PD-L1 tumor proportion score (TPS <1%, 1-49% and ≥ 50%) was calculated by Fisher exact test. Association with driver mutation results was determined by Chi-squared test. Correlation with recurrence free survival (RFS) and overall survival (OS) were determined by log-rank tests.

Results: The study cohort consisted of 394 patients, including 290 with adenocarcinomas, 94 with squamous cell carcinomas, and 10 with other histologies. The cohort was composed of 210 (53%) female and 184 (47%) male patients. Two hundred twelve (54%) were stage I, 103 (26%) stage II, 69 (18%) stage III and 10 (3%) were stage IV. Eleven cases were excluded from CEACAM5 scoring due to suboptimal tumor sections for evaluation. The prevalence of high CEACAM5 expression was 16% (n = 62). Interrater reliability was moderate (KCC 0.67, Fleiss' Kappa 0.56). CEACAM5 expression was not associated with PD-L1 TPS (p=0.15), EGFR mutation (p=0.79) or KRAS mutation (p=0.19). High CEACAM5 expression was not associated with tumor stage (p=0.4), RFS (p=0.8), or OS (p=0.7).

Conclusions: In our cohort of predominantly early-stage resected NSCLC including adenocarcinoma and squamous cell carcinoma, we did not observe a significant prognostic impact of CEACAM5 expression on RFS or OS.

Keywords: CEACAM5, Biomarker

EP.06.32 Elevated SERPINA3 Expression in Bronchoalveolar Lavage Fluid Predicts Poor Prognosis in Non-Small Cell Lung Cancer

J. Kim, G. Lee, A. Woo, Y. Park, S-H. Yong, S.Y. Kim, E.Y. Kim, J.Y. Jung, Y.A. Kang, M.S. Park, S.H. Lee
Severance Hospital, Yonsei University College of Medicine, Seoul/KR

Introduction: SERPINA3 is a protease inhibitor and acute-phase protein that is elevated in inflammatory conditions and several cancers, including lung, breast and colon cancer. It is associated with tumor growth and progression. The aim of this study was to evaluate whether SERPINA3 expression in non-small cell lung cancer (NSCLC) patients could predict prognosis.

Methods: A total of 362 patients from a respiratory research registry, with bronchoalveolar lavage fluid (BALF) and blood samples collected between April 2019 and May 2021, were initially reviewed. After excluding 282 patients based on various criteria, 148 primary NSCLC patients were analyzed. Of these, 147 plasma and 135 BALF samples were used. The Institutional Review Board and Ethics Committee of Severance Hospital approved the study (IRB number: 4-2021-0228).

Results: Patients were divided into high and low SERPINA3 expression groups based on BALF levels. In the high SERPINA3 group, there were significantly fewer men (P=0.028) and the rate of progression/recurrence was significantly higher (P=0.012). Cox regression analysis showed that high BALF SERPINA3 expression was significantly associated with increased risk of death (P=0.027) and progression/recurrence (P=0.007). Other significant factors for mortality were male sex (P=0.012) and stage IV cancer (P=0.032). For progression/recurrence, stage III (P=0.001) and IV (P=0.003) were also significant. Furthermore, the high SERPINA3 group showed a significant decrease in progression-free survival (P=0.004).

Conclusions: Elevated SERPINA3 expression in BALF is associated with poor prognosis in NSCLC patients, including increased risk of mortality and progression/recurrence. It may serve as a potential biomarker for predicting outcome in these patients.

EP.06.33 Unique Features of the Tumor-Microenvironment in PL3 Non-Small Cell Lung Cancer and Their Association With Post-Operative Outcomes

E. Miyamoto[1], H. Murakami[1], H. Oda[2], C-I. Huang[2], S. Sumiyoshi[1], A. Yoshizawa[3], T. Nakagawa[1]
[1]Tenri Hospital, Tenri/JP ,[2]Medical Research Institute Kitano Hospital, Osaka/JP ,[3]Nara Medical University, Nara/JP

Introduction: Understanding the tumor microenvironment (TME) is critical for predicting the prognosis of patients with non-small cell lung cancer (NSCLC). Tumor progression to neighboring structures (i.e. PL3) is a significant factor influencing treatment decision-making and prognosis of patients with PL3-NSCLC. TME of PL3-NSCLC has intrapleural and extrapleural parts. However, the extrapleural TME of PL3-NSCLC which contains the front of tumor progression remains to be elucidated.

Methods: We retrospectively reviewed patients with pathologically proven treatment-naïve PL3-NSCLC who underwent lung resection between 2010 and 2021 at our institute. Immunohistochemical staining was performed to identify CD8a-expressing cytotoxic T lymphocytes (CD8aposCTLs) and FoxP3-expressing regulatory T cells (FoxP3posTregs) in the extrapleural and intrapleural tumor-stroma interface (ExTSI and InTSI, respectively) and podoplanin-expressing cancer-associated fibroblasts (PDPNposCAFs) in the extrapleural and intrapleural intratumoral areas (ExIT and InIT, respectively).

Results: Fifty-six patients were evaluated. CD8aposCTLs (Figure 1A-B) and FoxP3posTregs were sparsely distributed in ExTSI compared to InTSI. Conversely, PDPNposCAFs were more abundant in ExIT than in InIT. Decreased CD8aposCTLs in ExTSI were associated with significantly worse overall (Figure 1C) and recurrence-free survival post-surgery, a larger solid tumor size, a lower prevalence of tertiary lymphoid structures, and increased PDPNposCAFs in ExIT (Figure 2). Increased FoxP3posTregs in ExTSI were associated with the presence of pleural dissemination and malignant pleural effusion at surgery. PDPNposCAFs in ExIT were more abundant in tumors invading the chest wall, parietal pleura, and mediastinum than in those invading the interlobe only.

Conclusions: Our findings support the concept that the TME in PL3-NSCLC has unique features specific to the extrapulmonary components and functions as an oncological immunomodulatory niche.

Sambhajinagar/IN

Introduction: NGS-based mutational findings are increasingly utilized in oncology practice to tailor treatment strategies. This study highlights the impact of comprehensive genomic profiling compared to cost-effective short molecular panel testing and explores its potential for personalized precision medicine in a developing country setting.

Methods: This retrospective study included consecutive lung cancer patients from community oncology centers in Western India, diagnosed between March 2018 and September 2024. Clinical characteristics, including testing panels, mutational distribution, and survival outcomes, were obtained from the EMR and analyzed for progression-free survival and overall survival using Kaplan-Meier analysis

Results: A total of 2281 lung cancer patients were evaluated from a community oncology practice who underwent next generation testing (64.05%; 1461/2281) and the mean age was 65 years (IQR 56-73); with Male:Female ratio being 1:1.41 and stage distribution being 1.3%, 2.5%, 17.5% and 77.6% for Stage I, II, III and IV respectively. Comprehensive genomic panel (CGP) was performed in 52.49% (767/1461) to evaluate SNVs, CNVs, and indels spanning across over 15000 loci for 1080 tumor while short panel testing was done in 47.50% (694/1461) to assess mutation detection rates for key genes (EGFR, ALK, ROS1, MET, KRAS, BRAF, NTRK, RET, TP53, and Her2). The cohort comprised 94.9% of Non-small cell lung cancer (NSCLC) cases, with adenocarcinoma being the predominant subtype (85.2%). The mutational differences observed between the two panels were significant, with MET/RET/NTRK/BRAF alterations being more prevalent in the CGP group 7.3% (56/767) compared to the short molecular panel group 1.2% (8/694) (P<0.001). Similarly, KRAS mutations were more frequently detected in the CGP group 8.9% (68/767) vs. 2.1% (14/694) (P<0.001), as were TP53 mutations 21.4% (164/767) vs. 3.6% (25/694) (P<0.001) while HER2 alterations showed no significant difference between the two groups 2.3% (18/767) vs. 1.3% (9/694) (P=0.1362).Rare mutations were significantly more frequent in the CGP group 16.1% (87/539 mutated cases) compared to the short panel group 1.6% (6/364 mutated cases). Among the rare mutations identified in the CGP cohort, the most frequently reported alterations included PIK3CA (n=28), STK11 (n=8), RB1 (n=4), and BRCA (n=2). The median overall survival (mOS) for the entire cohort was 25.7 months (95% CI: 22.7-28.8), with a progression-free survival (PFS) of 16.0 months (95% CI: 14.4-17.6) and a median follow-up time of 29.0 months (95% CI: 26.8-31.3). Patients tested with CGP demonstrated a longer but statistically non-significant improvement in survival with mOS of 29.2 months (95% CI: 25.3-33.2) in CGP group compared to 24.3 months (95% CI: 20.7-27.8) in those tested with the short panel (P = 0.384).

Conclusions: This study from a developing country demonstrated that comprehensive genomic profiling (CGP) achieved superior detection of actionable and rare mutations compared to short molecular panel testing. Additionally, CGP was associated with improved overall survival, highlighting its potential to enhance precision oncology and the need to improve its accessibility in resource-limited settings.

EP.06 PATHOLOGY AND BIOMARKERS

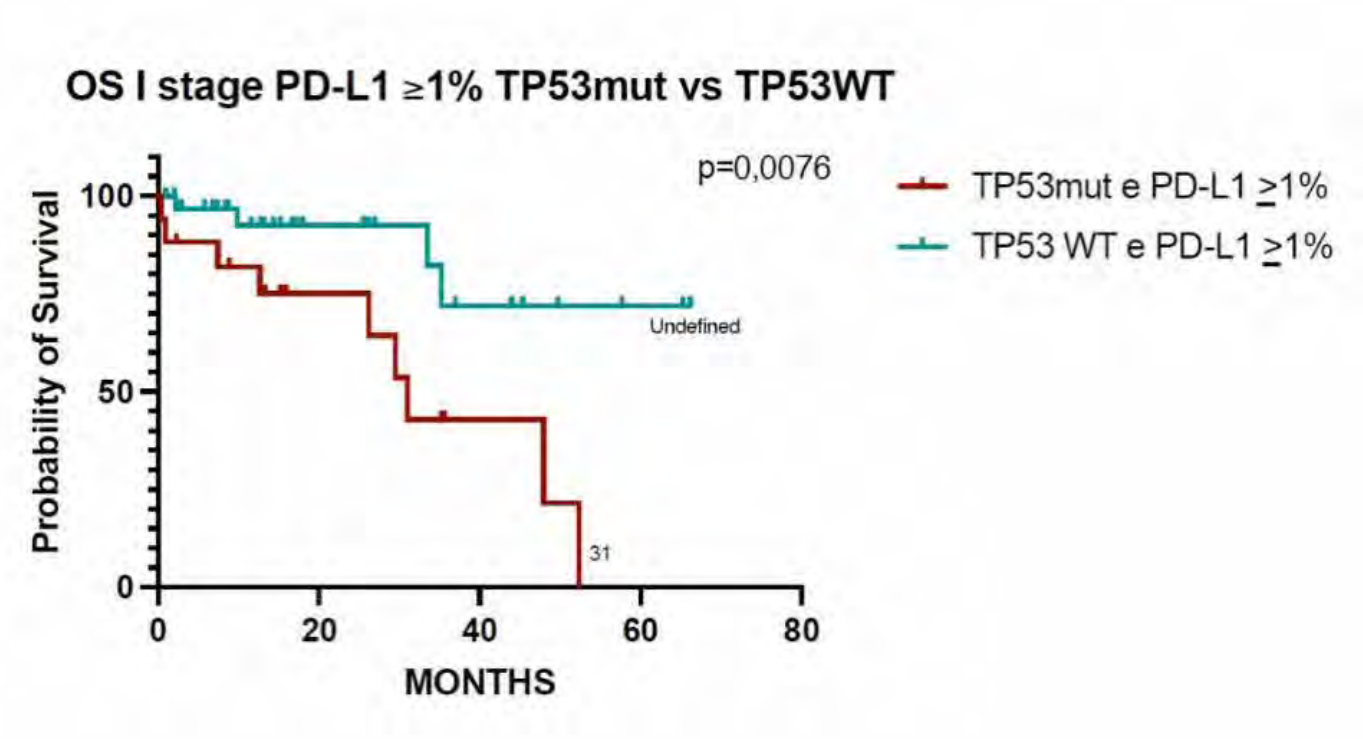
EP.06.35 Role of PD-L1 Expression and TP53Mutation as a Prognostic Factor in Early Stage NSCLC

J. Pankovics[1], L. Motta[1,2], L. Grassi Bertozzi[2], B. Pedrazzini[1], G. Schiavone[1], F. Molinari[3], A. Valera[3], S. Epistolio[3], S. Freguia[3], M. Imbimbo[1], M. Frattini[3], P. Frösch[1]
[1]EOC- Ospedale Regionale Bellinzona e Valli, Bellinzona/CH ,[2]University of Catania, Catania/IT ,[3]EOC- Ospedale Regionale Bellinzona e Valli, Locarno/CH

Introduction: Lung adenocarcinoma is a complex and heterogeneous disease. Although programmed death-ligand 1 (PD-L1) expression is an essential biomarker in treatment algorithms, its prognostic role remains unclear. While various molecular alterations have been studied for their prognostic and predictive value, their implications in early stages are less well defined. This study aimed to investigate the impact of PD-L1 expression and co-mutations on outcomes in early-stage non-small cell lung cancer (NSCLC) patients.

Methods: Single center retrospective cohort of patients diagnosed with non-squamous NSCLC between January 2018 and July 2022. A targeted NGS analysis including 22 genes (Ion TorrentTM, panel AmpliSeq Colon and Lung Cancer v2) was performed on all patients. PD-L1 expression was assessed by Immunohistochemistry (SP263 Antibody, Ventana). Statistical analyses were made using log-rank test, the two-tailed Fisher's exact test and Kaplan-Meier survival curves.

Results: Clinical data were collected for 464 patients, including 100 cases with stage I disease (21.5%), 42 with stage II (9%), 63 with stage III (13.5%), and 259 with stage IV (56%) as per the TNM 7th edition. All patients were treated according to international guidelines. High PD-L1 expression (≥50%) was predominantly observed in advanced stages (III and IV), with only 10 patients in stage I (10%). TP53 mutations were identified in 202 patients. In stage I patients (16%), TP53 mutations were mainly associated with PD-L1 expression < 50%. Analysis of overall survival (OS) in stage I revealed that patients with high PD-L1 expression had a median OS (mOS) of 26.2 months, compared to 52.3 months for those with PD-L1 expression < 50% (p=0.0016). Additionally, when comparing PD-L1 positive (≥1%) versus negative (<1%) patients, mOS was 47.9 months versus not reached, respectively, though this difference was not statistically significant. In the PD-L1 positive subgroup, patients harboring TP53 mutations had an mOS of 31 months, in contrast to a not reached mOS in those without TP53 mutations (p=0.0076).



Conclusions: These findings suggest that high PD-L1 expression is associated with worse prognosis even in early-phase lung adenocarcinoma, with TP53 mutations having an additive detrimental effect. In stage I NSCLC patients with positive PD-L1 expression, the presence of TP53 mutations significantly influenced OS. Our results underscore the importance of mutation testing in early-stage NSCLC and raise the question of whether adjuvant treatment should be considered for stage I patients with both TP53 mutations and high PD-L1 expression. Further research in this population is warranted.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.36 Non-Small Cell Lung Cancer With Diffuse Coexpression of TTF-1 and P40:A Clinicopathologic and Molecular Study of 19 Casess

J. Lin, S. Li, W. Chen, W. Wu, W. Zhang, Y. Huang, Z. Dong, C. Wu, L. Hou
Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai/CN

Introduction: The diffuse co-expression of TTF-1 and p40 in non-small cell lung carcinomas (NSCLCs) is extremely rare. Despite limited reports, comprehensive pathobiology of this NSCLC subtype—including diagnostic criteria, pathological characteristics, molecular profiles, biological behavior, and postoperative outcomes—remain largely uncharacterized.

Methods: We identified nineteen cases of NSCLCs co-expressing TTF1 clone 8G7G3/1 and p40. Their clinical, pathological, and molecular characteristics were systematically analyzed, supplemented with a review of the relevant literature.

Results: Patients with co-expression of TTF-1 and p40 were predominantly older males who smoke, with 66.7% (12/18) diagnosed at stage III-IV. All tumors were poorly differentiated NSCLCs, lacking keratinization and glandular formation and displayed either basaloid features (31.6%, 6/19) or distinct histological morphology (68.4%, 13/19) characterized by high-grade plasma-rich tumor cells with significant lymphocytic infiltration. Molecular analysis revealed recurrent mutations in TP53 (42.9%, 3/7), EGFR (26.7%, 4/15), and KRAS (13.3%, 2/15). Copy number alterations included amplifications of MCL1 (57.1%, 4/7) and MYC (42.9%, 3/7), with MCL1 amplification confirmed by FISH. Metastasis was observed in 61.1% (11/18) of cases, including 4 with distant spread and 7 involving thoracic or supraclavicular lymph nodes or the pleura. Three patients succumbed to the disease within 10-64 months following diagnosis.

Conclusions: NSCLCs with co-expression of TTF-1 and p40 display unique clinicopathological features, molecular alterations, and clinical outcomes, characterized by rapid progression and poor prognosis. The multigenic, targetable alterations in MCL1, KRAS, and EGFR underscore the critical importance of comprehensive molecular testing in these tumors.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.37 Clinical and Pathological Features of a High Altitude-Peruvian Population With Metastatic EGFR Mutated Lung Cancer

J.A. Zegarra Cárdemas
IREN Centro, Conception/PE

Introduction: Lung cancer ranks second in incidence and first in mortality (1). In Peru, lung cancer is an important cause of incidence and mortality (2,3), and the late diagnosis is the most common presentation. Motta-Guerrero et al, reported 13% of patients were diagnosed in stage III and 69.3% in stage IV (4). The Regional Institute of Neoplastic Diseases (IREN) - Center is located in a high altitude region which is a protector factor against lung cancer (5,6).

Methods: Retrospective, cross-sectional study of patients with metastatic lung cancer who underwent EGFR mutation testing from March 2020 to December 2023. Of the 112 records obtained, 18 were included. A database was created considering age, sex, origin, risk factors, symptoms, ECOG, clinical stage, histological type and grade, immunohistochemistry and EGFR gene mutation status. A descriptive analysis of the main characteristics of the patients was performed. Subsequently, a univariate analysis was performed to investigate the association with EGFR mutation. For each statistical test, significance was considered when p was less than 0.05. Statistical analysis was performed using SPSS software version 26

Results: Eighteen patients were registered. The EGFR mutation frequency was 16.07%. Among the main features, 94.4% came from high altitude regions, 44.4% were exposed to wood smoke, and the place of origin was related to the EGFR mutation (p = 0.044); the most frequent location of metastasis was bone (44.4%). The most frequent histological type in patients with exon 19 deletion was adenocarcinoma type NOS (16.7%); and in patients with point mutation in exon 21, was acinar and lepidic adenocarcinoma (11.1%). There was a higher frequency of presentation with histological grade II and III (11.1%) in patients with exon 19 deletion.

Conclusions: In a high altitude populaation, EGFR mutation was related with the place of origin, clinical stage and immunohistochemical markers.

EP.06.38 HLA-DQB1 Predicts Immunotherapy Response in NSCLC Through Augmented TCR Signaling

Y. Yang, H. Wang, Z. Pan, W. Luo, M. Huang, Y. Wang, Y. Wen, J. Huang
Guangzhou Huayin Health Medical Group Co., Ltd, Guangzhou/CN

Introduction: Complete pathological response (CPR) following immunotherapy is associated with improved survival in non-small cell lung cancer (NSCLC). However, the molecular mechanisms underlying distinct immune landscapes and their prognostic implications remained unclear. This study aimed to identify molecular signatures and clinically relevant biomarkers in immunotherapy of NSCLC.

Methods: Transcriptomic sequencing was performed on tumor, and normal lung tissues of CPR (n=6), non-CPR (n=13) patients. Differential gene expression analysis was conducted using DESeq2, with thresholds set at |log2FC| >1 and adjusted P <0.05. Enrichment of KEGG/GO pathways was evaluated via clusterProfiler. Pathway activation scores were calculated using ssGSEA, and sample heterogeneity was analyzed using correlation matrices.

Results: Compared with the non-CPR group, 1368 genes were significantly down regulated and 360 genes were upregulated in the CPR group. These genes were enriched in metabolic pathways and immunoglobulin-related biological processes. TCR-associated genes (CD3D, CD8A) and FUCA1 (a p53-regulated tumor suppressor) were upregulated in CPR, while EMT-related markers (KRT6A) were suppressed. Compared to non-CPR, the top pathways activated in the CPR group are almost all related to immune processes, including T (helper) cell differentiation, TCR related pathways. Compared to the tumor sample, the non-CPR matrix sample showed activation of interleukin-6 and vascular endothelial growth factor related pathways, downregulation of tumor characteristics and E2F transcription factor related pathways, and activation of cell cycle regulation related pathways in the tumor sample. Compared with normal tissues, tumor samples showed activation of pathways such as tumor necrosis factor, interleukin 3/6, and CD40 in normal samples, while pan cancer common characteristic pathways were activated in tumor samples. Intersection analysis identified 143 shared DEGs, including progressively downregulated HLA-DQB1(CPR>non-CPR>tumor). HLA-DQB1 linked to TCR signaling through ZAP70 activation, with sequential ZAP70 reduction across groups. HLA genotyping revealed no allelic heterogeneity among groups, excluding HLA type-driven biases and underscoring expression-level differences as prognostic determinants. HLA-DQB1 was linked to the TCR signaling pathway (Generation of second messenger molecules) in CPR samples, with its high expression driving ZAP70 activation—a kinase essential for phosphorylating substrates to initiate second messenger release. Progressive downregulation of ZAP70 from CPR to non-CPR and tumor tissues suggested that HLA-DQB1-mediated TCR engagement suppresses tumorigenesis by sustaining ZAP70 expression.

Conclusions: HLA-DQB1 is a prognostic biomarker for NSCLC immunotherapy, enhancing TCR signaling via ZAP70. Its progressive loss in non-responders suggests a mechanistic role in immune evasion. These findings support HLA-DQB1 as a predictor of therapeutic efficacy and a potential target for combination strategies.

EP.06.39 Better Prediction of Resistance to Immune Checkpoint Inhibitors in Non-Small Cell Lung Cancer : Immunoresist Project

B. Bertrand[1], T. Wolf[2], C. Tondon[2], T. Goetsch[2], L. Pabst[1,2], Q. Creusot[2], A. Bénédic[2], L. Vallois[3], M. Beau[1,2], E. Pencreach[2], V. Lindner[2], M-P. Chenard[1,2], C. Mascaux[1,2]
[1]Université de Strasbourg, Strasbourg/FR ,[2]Hôpitaux Universitaires de Strasbourg, Strasbourg/FR ,[3]Hôpitaux Civils de Colmar, Colmar/FR

Introduction: Immune checkpoints inhibitors (ICI) targeting PD1 and PDL1 have transformed the treatment of non-small cell lung cancer (NSCLC) at the metastatic stage. However, around 80% of patients do no benefit from treatment. In this work, we integrated clinical and immunohistochemical factors and set the foundation for a composite predictor of outcome with ICI.

Methods: A total of 130 patients with NSCLC who received ICI between 2015 and 2022 in Strasbourg (France) either as a monotherapy or in combination with chemotherapy, at any line of treatment, with available archival tissue samples were included. Resistance was defined by a progression-free survival (PFS) ≤ 3 months (63 patients) and sensitivity by a PFS ≥ 1 year (67 patients). Using immunohistochemistry, the expression of PDL1 and eleven other biomarkers (table 1) were assessed by two independent observers.

Results: The expression of PDL1, CD3, CD4, CD8, FOXP3 and TIM3 was statistically significant different between the two groups. Using expression thresholds determined with receiver-operating curves, we found statistically significant differences in expression status of PDL1 (1% threshold, p<0.001), CD8 (750 cells at hotspot, p=0.03), CD56 (10 cells at hotspot, p=0.02), FOXP3 (200 cells at hotspot, p= 0.03) and TIM3 (20%, p=0.01) between the two groups. The OR for sensitivity of patients who scored positive forPDL1, CD56 and FOXP3 was two times greater than negative PDL1 alone (OR 7.59[2.63, 25], p<0.001 and OR 4.27 [1.85, 10], p<0.001, respectively), andwas also greater than double negative PDL1/CD8 (OR 4.71 [1.80, 13.59],p<0.001). Using logistic regression, a multivariate explanatory model for resistance to ICI included a level of expression of PDL1 < 1% (OR 0.30 [0.12, 0.78], p=0.015) and TIM3 < 20% (OR 0.28 [0.09, 0.84], p=0.022), and low amounts of FOXP3+ cells (hotspot < 200 : OR 0.23 [0.08, 0.7], p=0.009) and CD56+ cells (hotspot < 10 : OR 0.32 [0.12, 0.87], p=0.021). This model also includes clinical factors at baseline: TNM stage IVB, corticoid treatment, platelet blood count ≥ 250,000 per microliter and the presence of bone metastases.

Conclusions: A combination of clinical and biological markers performs better at predicting resistance to ICI than PDL1 alone. We aim to expand this model with genetic data (currently being processed) before refinement and validation on independent cohorts.

Table 1 : scoring methods for immunohistochemistry slides

PDL1	Tumour proportion score
CD23	Present at the core of tertiary lymphoid structures or absent
CD3, CD4, CD8, CD56, FOXP3	Two methods were used and compared : 1. Percentage of stromal infiltration by stained cells 2. Highest count of stained cells achievable in a single microscopic frame at the 400th power (hotspot)
TIM3, VISTA	Percentage of stained non-tumour cells in the stroma
STAT3, PTEN, B2M	Histoscore method : the percentage of tumour cells stained for each of four levels of staining intensity was multiplied by the corresponding index of intensity (0 : no staining, 1 : mild, 2 : moderate, 3 : strong) ; all weighted percentages were added

PDL1 : programmed death-ligand 1 ; CD : cluster differentiation ; FOXP3 : forkhead box protein 3 ; TIM3 : T cell immunoglobulin and mucin domain-containing protein 3 ; VISTA : V-domain immunoglobulin (Ig)-containing suppressor of T-cell activation ; STAT3 : signal transducer and activator of transcription 3 ; PTEN : phosphatase and tensin homolog ; B2M : beta-2-microglobulin

Introduction: Spread through air spaces (STAS) is a recently validate prognostic factor for survival in NSCLC, but the possibility to pre-operatively individuate it remains challenging. In this study, we consider clinical, pathological and metabolic factors with the aim to individuate possible STAS predictors.

Methods: Clinical and pathological characteristics of patients who underwent anatomical lung resection from 1/01/2018 to 31/12/2023 were reviewed and retrospectively analyzed. Patients with GGO tumors, MIA, AIS, and/or distant metastases, receiving neoadjuvant treatment were excluded. Only patients underwent pre-operative 18-FDG Positron Emission Tomography(PET) were included. Operatory and pathological report were reviewed to collect data on histology, STAS, pleural invasion, lymphovascular invasion and necrosis.The PET parameters considered were SUVmax, SUVmean, SUVpeak,Total Lesion Glycoysis(TLG) and Metabolic Tumours Volume(MTV).The primary end-point was the association between clinical, metabolic and pathologic characteristics with STAS presence. Odds Ratios (ORs) with 95% confidence intervals(95% CIs) were estimated for each variables of interest. A P-value<0.05 was considered significant. A multivariable logistic regression model was developed using stepwise regression (forward selection, enter limit and remove limit, p = 0.10 and p = 0.15, respectively), to identify independent predictors of STAS.

Results: The final analysis was conducted on 224 patients that met the inclusion/exclusion criteria. Histology consisted in adenocarcinoma in 164 (72.3%) patients, while stage Ia was present in 160 (71.4%) cases.STAS was detected in 24(10.7%) cases.Metabolic parameters did not correlated with STAS presence (table), while pathological characteristics did. High grade adenocarcinoma tumors (solid, papillar and micropapillary) presented a statistically significant higher risk of STAS presence compared to low grade histology (acinar, lepidic): 20.8% vs 4.3%, p=0.003, OR 5.87 , 95%CI 1.83-18.78. Also tumour grading significantly correlated with STAS: 4.6% in G1-G2 tumors vs 23.5 % in G3 tumors (p=0.001, OR 5.79, 95%CI 2.12-15-78).Multivariable confirmed as independent prognostic factor the tumours grading: OR 5.44, 95% CI 1.75-16.84, p=0.003. Considering stage Ia tumours only, STAS occurred in 20 cases (12.5%). High grade adenocarcinoma(p<0.001), high tumour grading (p=0.001),lymphovascular invasion (p=0.034) and pT>2cm (p=0.017) resulted significantly correlated with STAS presence. Multivariable confirmed as independent risk factors the high grade adenocarcinoma histology(OR 6.10,95%CI1.17-31.74,p=0.032) and high tumour grade(OR4.73, 95%CI 1.16-19.23,p=0.030).

Conclusions: In our study, STAS presence risk is not correlated with metabolic parameters, while adenocarcinoma subtype and tumours grading seem to stratify the STAS occurrence risk. This information may be used to plan appropriate anatomical lung resection and follow-up schedules in patients with pre-operative diagnosis.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.41 CD200 as a Novel Prognostic Biomarker in Early-Stage Lung Adenocarcinoma Immune Microenvironment

L. Mao, Z. Huang, Y. Li
Fudan University Shanghai Cancer Center, Shanghai Medical College, Fudan University, Shanghai/CN

Introduction: Early-stage lung adenocarcinoma (LUAD) prognosis remains challenging, with immune microenvironment dynamics and recurrence biomarkers poorly defined. This study aimed to characterize immune infiltration patterns and identify prognostic biomarkers linked to recurrence.

Methods: Public TCGA data (421 early-stage LUAD samples) were analyzed via bioinformatics tools (DESeq2, edgeR, xCell) to evaluate immune cell infiltration and differential gene expression. A prognostic model integrating Cox regression and LASSO was developed. Clinical validation included 123 early-stage LUAD patients, with immunohistochemistry (CD3, CD8, CD20, CD68, CD200) and digital pathology (QuPath) to quantify immune cells. Survival analysis and multivariate Cox regression assessed independent prognostic factors.

Results: CD200 emerged as a key independent prognostic biomarker. High CD200 expression correlated with increased recurrence risk (HR=2.30, p=0.015) and immune infiltration (B cells, macrophages, CD8+ T cells). Tumor tissues exhibited reduced CD200 expression versus normal (p=0.036). Immune infiltration analysis revealed CD4+ naïve T cells as a risk factor and NKT cells as protective. Mature tertiary lymphoid structures (TLS) were associated with higher CD200 density (p<0.001). CD68+ macrophages independently predicted poor DFS (AHR=1.87, p=0.045).

Conclusions: CD200 and immune cell infiltration (CD68+ macrophages, CD8+ T cells) are critical prognostic indicators in early-stage LUAD. CD200's role in immune evasion highlights its potential as a therapeutic target. Validation in larger cohorts and functional studies are warranted to optimize personalized immunotherapy strategies.

EP.06.42 Clinical Characteristics and Treatments of Patients With Advanced Non-Squamous NSCLC KRAS-Mutated With or Without STK11

E.M. Urbanska[1], M.J. Stelmach[2], F. Fischer[3], J. Aarøe[4], M. Avander[5], E. Santoni-Rugiu[1,6], S. Conte[7], J.L. Hansen[3,8]
[1]Copenhagen University Hospital, Copenhagen/DK ,[2]Zealand University Hospital, Naestved/DK ,[3]Quantify Research, Stockholm/SE ,[4]AstraZeneca Nordics, Oslo/NO ,[5]Daiichi Sankyo Nordics ApS, Copenhagen/DK ,[6]University of Copenhagen, Copenhagen/DK ,[7]AstraZeneca Nordics, Stockholm/SE ,[8]University of Oslo, Oslo/NO

Introduction: KRAS is a frequently mutated oncogene in non-squamous (NSQ) Non-Small Cell Lung Cancer (NSCLC) with significant molecular and clinical heterogeneity and different prognostic and therapeutic implications. The impact of KRAS mutations on survival remains ambiguous due to co-mutations, such as STK11. Current KRAS-targeting drugs focus on the specific KRAS mutation, G12C, with varying treatment responses and intrinsic resistance, often influenced by co-mutations. Therefore, understanding the biological context of KRAS-mutated NSCLC, including the PD-L1 expression associated with KRAS mutations, may support the development of treatment strategies. We aimed to describe demographic characteristics, treatment, and survival outcomes of advanced NSQ NSCLC patients KRASm with or without STK11m (KRASm±STK11m).

Methods: Patients diagnosed with advanced NSQ NSCLC between January 1, 2017, and December 31, 2022, in Denmark were identified in the Danish National Cancer Register. Information on KRAS and STK11 mutations status [tested by polymerase-chain reaction (PCR), and since 2018 at increasing frequency next-generation sequencing (NGS)] as well as PD-L1 expression (by immunohistochemistry) from the diagnostic biopsy was collected from the National Pathology Register. Details on comorbidities and treatments were retrieved from the National Patient Register and the National Hospital Medication Register, respectively. Patient characteristics were assessed at diagnosis, and first-line (1L) treatments were defined as chemotherapy (CT), radiotherapy (RT), immunotherapy (IO), and combinations of them, administered between diagnosis and the 1st follow-up scan post-diagnosis. Overall survival (OS) was assessed by the Kaplan-Meier estimator.

Results: In total, 9822 patients were identified with advanced NSQ NSCLC between 2017 and 2022. Of these, 2024 were reported with KRASm±STK11m, 1934 with only KRASm, 68 with only STK11m, 90 with co-mutated KRAS and STK11, and 565 with KRAS wild type. The remaining 7233 patients had either an inconclusive result or were not tested. Approximately, 54% of the KRASm±STK11m patients were diagnosed in 2021 and 2022, compared to 46% between 2017 and 2020, which may reflect an increase in NGS testing practice in Denmark. Females were predominant among patients with KRASm±STK11m (63%), while males were predominant among patients with STK11m only (69%). At diagnosis, patients with KRASm±STK11m were on average 69.8 years of age, and they had a comorbidity index of 0.6. PD-L1 expression levels above ≥50% were observed in 46.2% of patients with KRASm±STK11m, 47.8% with only KRASm, 16.2% with only STK11m, and 12.2% with co-mutations. About 80% of KRASm±STK11m patients received 1L treatment, most frequently as RT (22.3%, n= 451), IO (18.5%, n=374), CT (18.2%, n=369), and CT+IO (9.9%, n=200). Notably, 20% did not receive 1L treatment. OS in patients with KRASm±STK11m at 6 and 12 months was 54.4% and 36.8%, respectively, while median OS was 7.03 months.

Conclusions: Overall, 20.6% of Danish patients diagnosed with NSQ NSCLC included in our study were reported with KRASm±STK11m during the period 2017-2022. In addition, our data show that a large proportion of patients in the study cohort had an inconclusive test or was not tested. Therefore, broader usage of molecular testing nationwide can provide more accurate epidemiological evaluation of this patient population and its unmet therapeutic needs.

EP.06.43 Using Artificial Intelligence to Leverage Phenotypic, Genomic and Proteomic Correlations in Lung Carcinoma Patients With MET Alterations

S. Hernandez[1,2], D. Curto[1,2], M. Alonso[1,2], M. Peressini[2], H. Bote de Cabo[1], M. Zurera[1], J. Zugazagoitia[1,2,3], L. Paz-Ares[1,2,3,4], F. Lopez-Rios[1,2,3,4], E. Conde[1,2,3,4]
[1]Hospital Universitario [12] de octubre, Madrid/ES ,[2]Research Institute Hospital [12] de Octubre (imas[12]), Madrid/ES ,[3]CIBERONC, Madrid/ES ,[4]Universidad Complutense de Madrid, Madrid/ES

Introduction: Oncogenic MET activation in patients with non-small cell lung carcinoma (NSCLC) can occur due to gene mutations, amplification, fusions, and protein overexpression. Accordingly, these dysregulation mechanisms have been investigated for the development of targeted therapies and antibody-drug conjugates. Although MET exon 14 skipping mutations (M14M) and high-level MET copy number gain (MCNG) are established or emerging predictive biomarkers in most guidelines, the predictive role of MET overexpression as detected by immunohistochemistry (IHC) remains unclear. Furthermore, the correlation among M14M, MCNG, and MET IHC is controversial. We hypothesize that using artificial intelligence (AI) in this setting can advance our understanding of genomically mediated MET overexpression. This strategy could serve as a first step toward the potential deployment of MET IHC as a predictive biomarker for antibody-drug conjugates.

Methods: We retrospectively identified all NSCLC patients tested with Oncomine (Thermo Fisher Scientific) next-generation sequencing (NGS) panels between 2020 and 2025 who exhibited M14M. In addition, high-level MCNG (≥10 copies) was also recognized by NGS through DNA analysis. Automated IHC for MET (Ventana SP44 clone) was performed on all cases with these MET alterations, and subsequently scanned and analyzed using off-label software (NDP). MET IHC was also evaluated by three pathologists, each providing a four-tier classification based on staining intensity (0 and 1+: negative, 2+ and 3+: positive). The consensus human score was compared with the AI result. Since the reliability of NGS for detecting gene amplifications (compared to FISH) has been questioned in specimens with low tumor content, we opted to use an additional AI algorithm (PathAI AIM-tumorCellularity) to confirm that samples with high-level MCNG contained ≥20% tumor content.

Results: In the NGS cohort of 2,170 NSCLC patients, 30 (1.4%) exhibited M14M and 12 (0.5%) had high-level MCNG, with no overlap between these groups. The majority of the samples analyzed were core-needle biopsies (42.8%), followed by surgical specimens (33.3%). Of these 42 patients, 21 were male and 21 were female, and 31 (73.8%) had adenocarcinoma. The median high-level MCNG was 13.7 (range: 10-27.1). Among patients with M14M, six (20%) also exhibited low-level MCNG (range: 4.5-7.9). Manual scoring of MET IHC was 3+ in 36.7% (11/30) of M14M cases (including all cases with low-level MCNG) and 66.7% (8/12) of MCNG cases. Interestingly, four (13.3%) M14M cases and two (16.7%) MCNG were scored as 1+. When evaluated using AI, all samples with M14M or high-level MCNG showed at least 2+ immunoreactivity. The proportion of patients with 3+ scores was higher in the AI group compared with the consensus manual scoring (66.7% versus 45.2%).

Conclusions: There was substantial agreement between MET IHC and the two currently established MET predictive biomarkers, particularly when AI algorithms were applied. AI-powered MET IHC scoring has the potential to refine the identification of MET alterations in patients with NSCLC.

EP.06.44 Tertiary Lymphoid Structures in the Tumor Micro Immune Environment of EGFR Positive Lung Cancer Are Associated Prognosis

H. Yamaguchi
Fukushima Medical Univercity, Fukushima City/JP

Introduction: We have been studying the tumor micro immune environment(TME) in lung cancer such as tertiary lymphoid structure(TLS), and there are still many unknowns about TME in EGFR mutation-positive lung cancer. We investigated TME in EGFR mutation-positive lung cancer patients.

Methods: We included 213 patients with non-small cell lung cancer who underwent surgery at our institution between January 2007 and December 2015, who were positive for EGFR mutations and were further considered for TLS; TLS was defined as a population of lymphocytes containing PNAd-positive epithelial vessels.

Results: The median age was 67 years (37-90 years), 34% were male, 66% were female, and 62 patients had a history of smoking. The histological type was adenocarcinoma in 209 cases: Stage I in 172 cases and II-IV in 41 cases; L858R in 132 cases and Exon19 del in 81 cases; TLS High in 75 (57%) of L858R-positive cases and 31 (37%) of Exon19 del-positive cases (P=0.011). DFS was significantly higher in TLS High in all cases (P=0.028). There was no clear difference in Stage I, but in Stage II and above, the TLS High group tended to do better, especially in L858R. In univariate and multivariate analysis of DFS, p-Stage and TLS were independent predictors of prognosis.

Conclusions: There are reports that TLS is associated with DFS in EGFR-positive lung cancer, although L858R-positive lung cancer is more likely to have TLS, and there are scattered reports that Exon19del has better PFS and TKI efficacy. On the other hand, the ATTLAS trial reported that ICI tended to be more effective than L858R. This study suggests that differences in EGFR mutations may be related to the tumor microenvironment, especially TLS expression, and may affect the efficacy of TKIs and ICIs.

Keywords: Lung cancer, EGFR, TLS

EP.06.45 Heterogeneity of Tumor Microenvironment and PD-L1 Expression in NSCLC and Tumor Draining Lymph Nodes After Solid Organ Transplantation

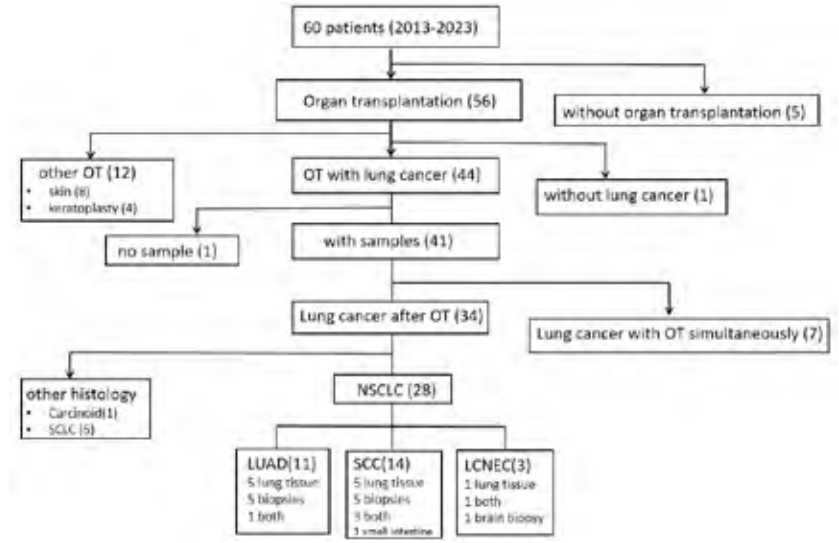
Z. Yu[1], S. Li[2], C. Schneider[1], D. Kauffmann-Guerrero[2], J.M. Fertmann[2], M. Arredondo[2], M. Freiwan[2], J. Behr[2], A. Tufman[2], R. Hatz[1], J. Kovacs[1]
[1]Department of Thoracic Surgery, University Hospital, Ludwig Maximilians University (LMU), Munich/DE ,[2]Department of Medicine V, University Hospital, Ludwig Maximilians University (LMU), Munich/DE

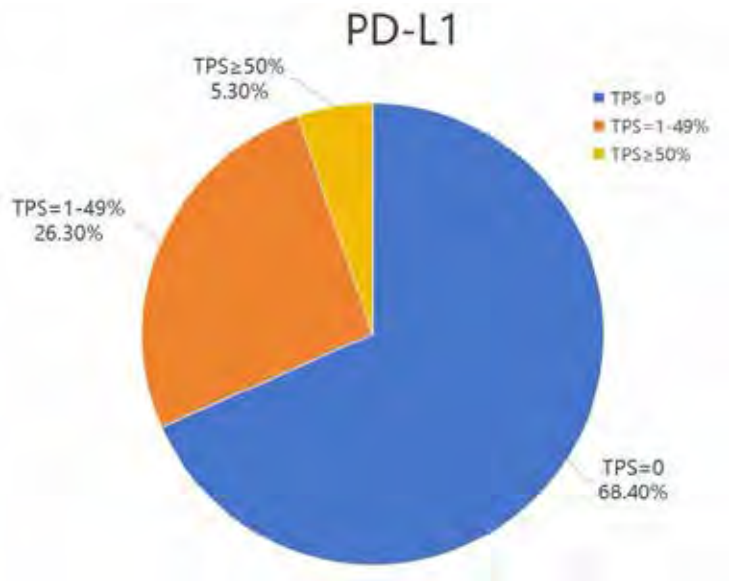
Introduction: Lung cancer is one of the most common malignant tumors after solid organ transplantation (SOT). This study aims to reveal the heterogeneity of the tumor microenvironment (TME) and PD-L1 expression in NSCLC after SOT.

Methods: We performed a retrospective study of NSCLC patients after SOT from 2013 to 2023 and the clinical characteristics were described and summarized. Immunohistochemistry was used to quantify expression of PD-L1. Statistical analyses were completed in GraphPad Prism.

Results: 28 patients who developed NSCLC after SOT were ultimately included (lung [n=10], kidney [n=6], liver [n=3], heart [n=5], other [n=4]) (Figure 1). At diagnosis, 13 patients (46.4%) were in stage I and II, while 15 patients (53.6%) were in stage III and IV. 16 patients (57.1%) underwent surgical treatment after diagnosis. The median survival time after diagnosis was 18 months, with a 1-year OS rate of 61.2% (95% CI: 40.3-76.7%) and a 2-year OS rate of 34.2% (95% CI: 16.8-52.5%). PD-L1 testing was performed on 19 samples, among which 5 cases (26.3%) showed 1-49% expression, 1 case (5.3%) showed high expression (TPS=70%), and 13 cases (68.4%) showed negative PD-L1 expression. Multiple clinical studies have shown that among the general NSCLC population, 40-60% of patients exhibit PD-L1 positivity, with 20-30% of patients having TPS ≥50% (Figure 2).

Conclusions: Our data indicate that PD-L1 expression in NSCLC after SOT is lower compared to the general NSCLC population. Our cohort describes NSCLC after SOT. Most patients were treated with surgery, which is consistent with the literature. PD-L1 expression levels in NSCLC after SOT are lower than in NSCLC in a non-immunosuppressed and may reflect differences in the TME which should be explored in further experiments. The next step is to examine the differences in immune-related genes by using microarrays.





Keywords: NSCLC, SOT, PD-L1

EP.06.46 Frequent Co-Existence of RBM10 Mutation in Patients With Non-Squamous NSCLs Harboring EGFR Point Mutationse

K. Suda[1,2], K. Sakai[1], M. Ito[1], J. Yoshimoto[1], S. Ohara[1], M. Chiba[1], M. Shimoji[1], A. Hamada[1], H. Oiki[1], S. Fukuda[1], K. Nishio[1], Y. Tsutani[1]
[1]Kindai University Faculty of Medicine, Osaka-Sayama/JP ,[2]Izumi City General Hospital, Izumi/JP

Introduction: Mutations of the RBM10 (RNA-binding motif 10) gene that encodes for a regulator of alternative splicing has been implicated in lung cancer pathogenesis as well as drug tolerance to EGFR-tyrosine kinase inhibitors (TKIs). However, there are insufficient data on which non-small cell lung cancer (NSCLC) patients are more likely to develop RBM10 mutations.

Methods: We analyzed 190 NSCLC specimens obtained from surgical resection at Division of Thoracic Surgery, Department of Surgery, Kindai University Faculty of Medicine between June 2022 through April 2024 by NGS analysis.

Results: RBM10 mutation was not detected in 38 patients with squamous cell carcinoma (0%), while 18 patients out of 152 non-squamous NSCLC patients (12%) had RBM10 inactivating mutations (nonsense or frameshift mutations). The prevalence of RBM10 mutation was significantly higher in EGFR-mutated tumors (14/68 patients, 21%, $p < 0.01$) and KRAS-mutated tumors (3/25 patients, 12%, $p < 0.01$) compared with EGFR/KRAS wild-type non-squamous NSCLC patients (1/60 patients, 2%). Among patients with non-squamous NSCLCs with EGFR mutation, the prevalence of RBM10 mutation was numerically higher in patients with point mutations (26% in L858R, 9% in exon 19 deletion, and 38% in uncommon point mutations, Figure 1). In contrast, the prevalence of TP53 co-mutation were equivalent between these EGFR mutation subtypes (31% in L858R, 32% in exon 19 deletion, and 38% in uncommon point mutations, Figure 1).

Conclusions: RBM10 mutations were enriched in EGFR- or KRAS-mutated non-squamous NSCLCs, especially in tumors with EGFR point mutations.

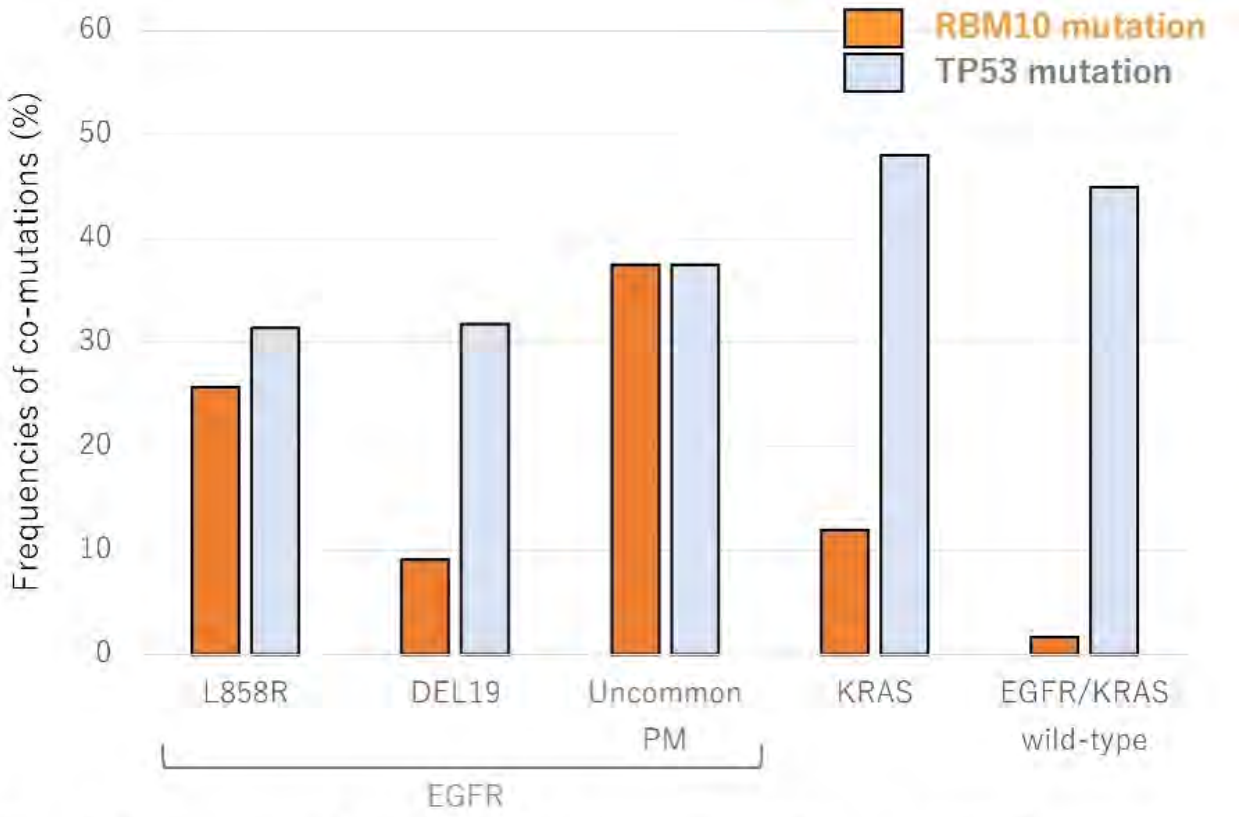

Figure 1. Frequencies of RBM10 or TP53 mutations in EGFR-mutated, KRAS-mutated, or EGFR / KRAS wild type non-squamous NSCLC patients.

Keywords: EGFR mutation, Co-mutation, non-squamous NSCLC

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.47 A Ten-Gene DNA Damage Repair-Related Signature for Predicting Prognosis and Treatment Response in Non-Small Cell Lung Cancer

H. Li, F-M. Kong
The University of Hong Kong, Hong Kong/HK

Introduction: DNA damage repair (DDR) plays a crucial role in maintaining genomic integrity and regulating cancer risk, progression, and therapeutic response. DDR alterations are frequently observed in non-small cell lung cancer (NSCLC), presenting both challenges and opportunities for treatment strategies. A deeper insight into DDR molecular characteristics in NSCLC can greatly enhance patient management by improving prognosis prediction and guiding personalized treatment strategies. This study aimed to investigate the association between DDR alterations and NSCLC prognosis and to develop a DDR-based prognostic model for risk stratification in NSCLC patients.

Methods: Biomarker discovery was conducted using the GSE68465 dataset (n = 462). We employed machine learning approaches, including LASSO and Cox regression models, to identify a DDR-associated gene signature. From an initial pool of 644 DDR-related genes, 128 were selected using univariate Cox regression, and a ten-gene DDR prognostic model was established using LASSO Cox regression. This model was validated in the TCGA cohort (n = 589) for overall survival (OS). Model performance was evaluated using the concordance index (C-index) and area under the curve (AUC) in both the training and validation cohorts. Furthermore, clinical validation was conducted, and a nomogram was developed for personalized risk assessment. Immune infiltration analysis was conducted to evaluate the impact of the DDR signature on the tumor microenvironment.

Results: We identified a ten-gene DDR signature comprising WDHD1, PIAS1, WRNIP1, DDIT4, SMARCA4, PIK3R1, ARID1A, TP53BP1, ZBTB40, and APTX, which demonstrated a strong correlation with NSCLC prognosis. This signature was significantly associated with poor OS in the training cohort (HR=1.8, 95% CI: 1.6-2.1, p<0.0001) and was robustly validated in the TCGA cohort (HR=1.96, 95% CI: 1.08-3.57, p=0.025). High-risk DDR patients demonstrated significantly poorer overall survival (OS) in clinical validation. To enhance personalized patient management and treatment planning, a nomogram was developed by integrating the DDR signature with clinical factors such as TNM stage, age, and gender. Immune infiltration analysis revealed that NSCLC samples with a high DDR signature exhibited significant alterations in immune cell infiltration, including: Increased infiltration of myeloid-derived suppressor cells (MDSCs) (z-score=3.5, p<0.001) and decreased infiltration of plasma B cells (z-score=-2.4, p<0.01), CD8+ T cells (z-score=-2.3, p=0.02), and myeloid dendritic cells (z-score=-2.19, p=0.03). These findings suggest that a high DDR signature is associated with an immunosuppressive tumor microenvironment, characterized by reduced infiltration of key immune effector cells and increased MDSC accumulation.

Conclusions: We present a novel DDR-related gene signature for risk stratification and identification of NSCLC patients with poor prognosis. This DDR-based prognostic model holds promise for guiding personalized treatment strategies. Furthermore, immune infiltration analysis highlights the impact of DDR alterations on the tumor immune microenvironment, offering insights into potential implications for NSCLC immunotherapy.

EP.06.48 Complementary Role of IHC in ALK Fusion Detection: A Validation Study of NSCLC NGS-Based Screening in Seven Laboratories

S. Clavé[1], C. Montironi[2], G. Oliveras[3], M. Varela[4], L. Catasús[5], M. Sese[6], A. Hernández-Gallego[7], C. Teixidó[2], A. Urbizu[7], A. González-Vidal[5], L. Pijuan[4], I. Sansano[6], N. Baixeras[4], C. Vásquez[3], B. Fuertes[3], I. Sánchez-Güerri[1], L. López-Vilaró[5], J-L. Mate[7], B. Bellosillo[1], J. Hernández-Losa[6], A.M. Muñoz-Mármol[7]

[1]Hospital del Mar, Barcelona/ES ,[2]Hospital Clínic, Barcelona/ES ,[3]Hospital Universitari Dr. Josep Trueta, Girona/ES ,[4]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat/ES ,[5]Hospital de la Santa Creu i Sant Pau, Barcelona/ES ,[6]Hospital Universitari Vall d'Hebron, Barcelona/ES ,[7]Hospital Universitari Germans Trias i Pujol, Badalona/ES

Introduction: Next-generation sequencing (NGS) is the recommended technology for the assessment of non-small cell lung cancer (NSCLC) biomarkers. Gene fusion detection presents methodological challenges especially when using amplicon-based technologies. Furthermore, these alterations have low incidence, making it difficult to standardize the assay validation phase. The objective of this study is to verify ALK fusion NGS results by retesting negative samples using immunohistochemistry (IHC) in seven reference centers in Catalonia.

Methods: A total of 553 negative (without alterations in EGFR, KRAS, BRAF, ALK, ROS1, NTRK, RET, or MET) from 1,910 NSCLC samples assessed in 2022, were retested using VENTANA anti-ALK (D5F3) antibody. Resulting ALK NGS-IHC discordant cases were further studied using fluorescence in situ hybridization (FISH). Information regarding the screening test, the results obtained, and the number of cases non-assessable by NGS were compiled.

Results: Among the 1,910 NSCLC samples analyzed by NGS in 2022, 35 were ALK-positive (1.8%), 990 were negative (51.8%), and 48 were non-assessable (2.5%). Of the negative cases, the NGS ALK result was verified by IHC in 553 samples (113 studied with SureSelect Agilent NGS panels, and 440 with Thermo Fisher Oncomine technology). Only 2 samples presented a discordant ALK result, both assessed with the Oncomine Comprehensive Assay (Thermo Fisher) in the same center. One of them presented a positive ALK FISH pattern but the other was negative, leading to only one misdiagnosed ALK-positive case out of 1,910 (0.05%). Regarding the screening method, only one center analyzed fusions using DNA-based NGS by hybrid-capture (SureSelect Agilent Custom panel and Illumina sequencing). The remaining centers analyzed fusions at the RNA level using amplicon panels: Oncomine Focus Assay, Oncomine Precision Assay, and Oncomine Comprehensive Assay (Thermo Fisher). This panel is the only one that does not perform alternative fusion analysis using ALK gene expression differences (imbalance score) for detecting novel or rare fusions. In all seven centers, alternative ALK techniques used are primarily IHC and FISH, and to a lesser extent, the Idylla GeneFusion Assay (Biocartis).

Conclusions: The reliability of the ALK-fusion results obtained by NGS in NSCLC patients is very high, despite the methodological differences among the NGS panels used across centers. As with any other technique, there is a possibility of false negative results, that can be minimized in this case using NGS panels that perform alternative fusion analysis for novel or rare fusions. IHC is a reasonable option to retest a negative NGS result, when clinical or histological evidence suggests an ALK fusion.

EP.06.49 Analysis of EGFR Mutations Using Highly Sensitive Digital Droplet PCR for EGFR Mutation-Positive NSCLC

S. Takemoto[1], Y. Umeyama[2], H. Gyotoku[3], H. Taniguchi[4], M. Ozasa[5], K. Mine[1], T. Fukuda[1], F. Hayashi[1], K. Akagi[4], S. Ono[1], H. Tomono[1], N. Honda[1], Y. Dotsu[1], M. Matsuo[4], M. Fukuda[6], H. Mukae[1]
[1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki City/JP ,[2]Sasebo City General Hospital, Nagasaki Sasebo City/JP ,[3]Nagasaki Harbor Medical Center, Nagasaki City/JP ,[4]Nagasaki University Hospital, Nagasaki City/JP ,[5]Saiseikai Nagasaki Hospital, Nagasaki City/JP ,[6]Japanese Red Cross Nagasaki Genbaku Isahaya Hospital, Nagasaki City/JP

Introduction: It has been reported that the T790M mutation, which cannot be detected using the usual test for EGFR mutations, can be detected using highly sensitive digital PCR (ddPCR). However, prospective studies on the relationship between the detection of the T790M mutation by ddPCR and the efficacy of EGFR-TKIs are scarce. This study aimed to explore how EGFR T790M mutation detectable only by ddPCR in tissue prior to treatment affects EGFR-TKI treatment.

Methods: This was a single-institution prospective cohort study. Patients with EGFR mutation-positive, advanced, or recurrent NSCLC were eligible. T790M was quantified using ddPCR in tumor tissues before treatment with EGFR-TKIs. The threshold to determine positivity for T790M by ddPCR was analyzed using an experimental system in which plasmids containing the EGFR T790M mutation were mixed with nucleic acids to adjust the ratio of wild-type EGFR to EGFR T790M.

Results: A total of 21 patients participated in this study between December 2019 and May 2022. The median age of the patients was 72 years (range, 42-84 years). There were 12 females (57.1%), 13 at Stage IV (61.9%), 20 patients with PS 0-1(95.2%), and 12 patients never smoked (57.1%). The most common EGFR mutation was del19 (57.1%). Twelve patients (57.1%) were treated with osimertinib. The thresholds were considered “negative” at 1.1 copies/mL or less, “positive” at 5.47 copies/mL, and “not determinable” at all other levels. Six patients (28.6%) were determined to be positive for T790M. The median T790M EGFR detected by ddPCR was 1.8 (range: 0.43-350) copies/μL. The median PFS was 12.5 months and the median OS was 31.9 months in the overall population. The patients were divided into two groups. Osimertinib (OSI) and other drugs (OTH). Median PFS was 13.5 months in the OSI group and 11.0 months in the OTH group (HR: 01.53, 95%CI: 0.55-4.24). Median OS was 31.9 months in the OSI group and 27.3 months in the OTH group (HR: 0.59, 95%CI: 0.16-2.08). In the OTH group, all patients were treated with afatinib, except for one patient who was treated with erlotinib and ramucirumab. Additionally, the patients was divided into two groups. T790M positive (T790M POSI) and T790M not positive group (T790M NON-POSI) . Median PFS was 19.6 months in the T790M POSI group and 12.5 months in the T790M NON-POSI group (HR: 0.45, 95%CI: 0.10-2.06). OSI group was further divided into two groups according to T790M status. Median PFS was 39.6 months for the T790M POSI group and 12.5 months for the T790M NON POSI group (HR: 0.34, 95%CI: 0.08-1.45). NON-OSI group was further divided into two groups according to T790M status. Median PFS was 34.9 months for the T790M POSI group and 9.9 months for the T790M NON POSI group (HR: 0.25, 95%CI: 0.06-1.15).

Conclusions: There was a trend toward better PFS in the T790M POSI group in both the OSI and NON-OSI groups. EGFR T790M positivity by ddPCR may be a predictor of the response to EGFR-TKIs.

EP.06.50 Development of a Novel AI-Augmented Small Cell Lung Cancer (SCLC) Algorithm for Accurately Classifying Cell Types From H&E

J. Reeves[1], A. Knesis[2], O. Ghasemi[2], J. Ramoth[2], L. Haeggblom[2], K. Isse[2], G. Golan[3], L. Chorev[3], L. Ilfeld[3], L. Alaluf[3], R. Sadan[3], A. Bart[3], R. Rosenstock[3], D. French[2], K. Bloom[1]
[1]Nucleai, CHICAGO/IL/USA ,[2]Amgen, Thousand Oaks/CA/USA ,[3]Nucleai, Tel Aviv/IL

Introduction: Small cell lung cancer (SCLC) is an aggressive cancer with 5-year survival rate of <10%. Recent treatment advances have primarily been from immunomodulatory agents including checkpoint inhibitors and t-cell engagers. However, understanding the tumor microenvironment with standard pathological assays like H&E remains challenging as SCLC tumor cells closely resemble the surrounding immune cells and are difficult to distinguish by pathological review. While deep learning models have predicted outcome for SCLC patients from H&E, they have focused on learning patient-level characteristics. In contrast to other tumor indication models, SCLC models have not provided cell-level classification of the tumor tissue due to challenges in appropriately annotating and learning this information. We developed a novel AI model for SCLC using slides sequentially stained with a duplex chromogenic IHC and H&E that accurately phenotypes cell-level information from H&E slides.

Methods: Commercially sourced samples from SCLC resections were sequentially stained with a duplex chromogenic IHC of CD45 (immune) and TTF1 (tumor) followed by H&E staining. The slides were scanned and the digitized images were split into training and validation sets for deep learning pathologist annotation and model assessment. H&E and duplex IHC scanned images were co-registered to allow for pathologist driven deep learning based on ground truth staining of duplex IHC. Nucleai's baseline tumor H&E model was optimized for SCLC based on annotation of tumor, immune (including lymphocyte, granulocyte, macrophages), and stromal cells. Results were compared to a SCLC model trained by pathologist annotation without access to duplex staining.

Results: Analysis of withheld validation samples against duplex staining ground truth pathological annotation found that the H&E only model faired significantly worse at distinguishing between key cell classes than the one informed by duplex stains. Tumor cells (n = 3,709) had higher specificity in the duplex trained model (89.9%) compared to the H&E only model (61.4%) and retained comparable sensitivity (92.8% duplex model, 98.8% H&E alone). Similarly, lymphocytes (n = 698) had poor detection in an H&E only model and improved significantly by deep learning to the duplex stain (sensitivity: 83.6% duplex model, 51.1% H&E alone; specificity: 93.0% duplex model, 98.9% H&E alone).

Conclusions: We propose that this novel AI algorithm that is capable of differentiating tumor cells from surrounding microenvironment within SCLC on H&E slides and provides researchers a new tool for interrogating the tumor-immune interactions critical for a mechanistic understanding of key therapeutic interventions in this indication.

EP.06.51 Development of Novel IHC Assay for PD-L1 Detection in Non-Small Cell Lung Cancer

F. Lian[1], F. Willett[2], M. Maclennan[2], S. Khelifa[1], B. Vennapusa[1], H. Gautrey[2], M. Parkin[2], K.R. Wilson[2], K. O'Toole[2], S. Dayal[1]
[1]Leica Biosystems, San Diego/CA/USA ,[2]Leica Biosystems, Newcastle/GB

Introduction: Non-small cell lung cancer (NSCLC) is globally a leading cause of cancer-related deaths. Each year, around 2 million new cases are attributed to lung cancer, and the same number of yearly deaths are reported. Due to the poor overall survival rate, this cancer type results in high mortality.

PD-L1 is one of the biomarkers associated with NSCLC progression and can be a valuable cancer immunotherapy target. Hence, accurate PD-L1 estimation in tumor cells can better inform treatment regimens and improve patient care. Leica Biosystems has developed a novel PD-L1 immunohistochemistry (IHC) assay and analyzed its initial performance by comparing it to Ventana's PD-L1 SP263 assay.

Methods: The study objective was to ascertain the concordance of the Leica Biosystems CAL10 assay with the comparator (SP263 assay) at 50% tumor proportion score (TPS). If the TPS was ≥50%, then the sample was scored positive; if the TPS was<50%, then the PD-L1 status was categorized as negative. Additionally, concordance was similarly assessed at a 1% cut off.

A total of 150 unique formalin-fixed, paraffin-embedded (FFPE) cases cut to 4µm serial sections were enrolled in the study. Each case was randomly assigned a unique ID and had triplicate glass slides stained with CAL10 antibody, BOND negative rabbit control, and H&E. Similar triplicate glass slides were generated with SP263 antibody, Ventana negative control, and H&E. Each slide set (stained with CAL10 or SP263) was read and scored independently by the 2 pathologists. Both pathologists first read SP263 stained slide set. After a washout period of 5 weeks, the CAL10 stained slide set of the same cases was read by the same study pathologists, following which the concordance between the 2 assays was estimated by the study biostatistician.

Results: The inter-assay concordance was estimated by measuring overall percent agreement (OPA), negative percent agreement (NPA), and positive percent agreement (PPA). For 50% TPS assessment, a total of 260 (133 case reads by the first pathologist plus 127 case reads by the second pathologist) paired estimates by the 2 reading pathologists were generated for the unique FFPE cases. Out of the 260 paired reads, OPA was 90.3% (235 total agreements/260 total paired reads*100), NPA 86.3% (127 negative agreements/147 negative paired reads*100), and PPA 95.5% (108 positive agreements/113 positive paired reads*100).

For analysis at the 1% cut off, OPA was 96.9% (252 total agreements/260 total paired reads*100), NPA 91.8% (45 negative agreements /49 negative paired reads*100), and PPA 98.1% (207 positive agreements/211 positive paired reads*100).

The lower bound of the estimated OPA at 50% cut off was 86.1% while for 1% TPS, it was 94.0%, which met the pre-defined target of a minimum OPA lower bound value of 85%.

Conclusions: The Leica Biosystems CAL10 assay-which is under development-has demonstrated that its preliminary performance is comparable to that of the comparator SP263 assay. Although these results look promising, further verification and validation studies are required to confirm these initial findings.

EP.06.52 TTF-1 Negativity Predicts Poor Outcomes in Advanced Non-Squamous NSCLC Also in the Immunotherapy Era: A Multicenter Cohort and Meta-Analysis

L. Brunetti[1], V. Santo[1], A. Cortellini[2], A. Gelibter[3], A. Lugini[4], G. Spinelli[5], D. Santini[6], A. Vendittelli[1], G. La Cava[1], M. Fiorenti[1], E.C. Mingo[1], L. Cristofani[4], M. Sabrina[7], S. Ricciardi[8], F. Pantano[1], B. Vincenzi[1], G. Tonini[1], M. Russano[1]
[1]Fondazione Policlinico Campus Bio-Medico, Rome/IT ,[2]Operative Research Unit of Medical Oncology, Rome/IT ,[3]Policlinico Umberto I, 'La Sapienza' University, Rome/IT ,[4]San Giovanni-Addolorata Hospital, Rome/IT ,[5]CdS Aprilia, "Sapienza" University of Rome - Polo Pontino, Aprilia/IT ,[6]Sapienza University of Rome, Rome/IT ,[7]Policlinico Tor Vergata, Rome/IT ,[8]San Camillo Forlanini Hospital, Rome/IT

Introduction: Immune checkpoint inhibitors (ICIs) significantly improved outcomes in advanced non-squamous non-small cell lung cancer (NSCLC), yet robust prognostic biomarkers beyond PD-L1 remain critically needed. We systematically evaluated the prognostic role of Thyroid Transcription Factor-1 (TTF-1), previously known as favorable in chemotherapy-treated NSCLC, in patients receiving first-line immunotherapy-based regimens.

Methods: We conducted a multicenter retrospective analysis involving 163 advanced non-squamous NSCLC patients treated with first-line immunotherapy or chemo-immunotherapy, and a historical chemotherapy-only cohort (n=37) for comparison. Patients were stratified by TTF-1 expression. Primary endpoints were progression-free survival (PFS) and overall survival (OS). To robustly validate our retrospective findings, and to weigh the role of TTF-1 in the immunotherapy era, we performed a comprehensive systematic literature review and meta-analysis following PRISMA-guidelines, integrating results from 9 studies encompassing 14 cohorts and 2,019 patients.

Results: TTF-1 negativity (25.5%) correlated with significantly poorer median PFS (6.7 vs 16.0 months; HR 2.22, 95% CI 1.59-3.13, p<0.001) and OS (11.5 vs 26.4 months; HR 2.33, 95% CI 1.64-3.45, p<0.001), independent of PD-L1 status and treatment regimen. Multivariate analysis confirmed TTF-1 negativity as an independent adverse prognostic factor for both PFS (HR 2.17; p<0.001) and OS (HR 2.08; p<0.001). A four-level composite analysis combining TTF-1 and PD-L1 expression revealed significant prognostic interplay. Patients in the TTF-1−/PD-L1low (<50%) group exhibited the worst outcomes and served as the reference. TTF-1+/PD-L1high (≥50%) patients showed the most favorable prognosis for PFS (HR 0.29, 95% CI 0.17-0.50, p<0.001) and OS (HR 0.25, 95% CI 0.14-0.44, p<0.001), followed by TTF-1+/PD-L1low (PFS: HR 0.51, 95% CI 0.32-0.80, p=0.004; OS: HR 0.53, 95% CI 0.33-0.84, p=0.008). Conversely, the TTF-1−/PD-L1high subgroup did not significantly differ from the double-negative group in either PFS (HR 0.63, p=0.23) or OS (HR 0.62, p=0.23). Stratified analyses confirmed that among TTF-1 positive patients, PD-L1 ≥50% significantly predicted better outcomes (PFS HR 0.56, p=0.01; OS HR 0.46, p=0.003), whereas among TTF-1 negative patients, PD-L1 status did not significantly influence survival (PFS HR 0.68, p=0.31; OS HR 0.67, p=0.32).The meta-analysis confirmed TTF-1 negativity as a predictor of inferior outcomes across multiple immunotherapy and immunochemotherapy regimens (PFS HR 1.75, 95% CI 1.50-2.04; OS HR 1.76, 95% CI 1.45-2.14; both p<0.0001).

Conclusions: TTF-1 negativity is a strong independent prognostic biomarker for poor outcomes in advanced non-squamous NSCLC patients treated with immunotherapy-based regimens, even among those with high PD-L1 expression. Integrating TTF-1 assessment in clinical practice could enhance patient stratification and treatment personalization, warranting prospective validation.

EP.06.53 c-MET Expression in Non-Squamous NSCLC: Molecular Correlation and Interobserver and Intersample Concordance on Scoring

M. Muto-Ishizuka[1,2], J.J. Lin[1], K. Wannasai[3], M.L. Ganci[1], R.A. Meredith[4], M.P. Smeltzer[4], J.L. Peterson[1], A. Do[1], M.K. Banwait[1], A.B. Rider[1], A.R. Shih[1], A.N. Hata[1], Y.P. Hung[1], I. Dagogo-Jack[1], R.S. Heist[1], Z. Piotrowska[1], J.F. Gainor[1], M. Mino-Kenudson[1]
[1]Massachusetts General Hospital, Boston/MA/USA ,[2]Nihon University School of Medicine, Tokyo/JP ,[3]Chiang Mai University, Chiang Mai/TH ,[4]University of Memphis, Memphis/TN/USA

Introduction: Emerging therapies targeting c-MET overexpression in non-squamous non-small cell lung cancer (NSCLC) have recently demonstrated promising results. However, evaluating c-MET expression can be challenging due to heterogenous expression within the tumor. Furthermore, little is known about the relationship between c-MET expression and driver alterations, nor the effect of treatment on c-MET expression.

Methods: c-MET expression was assessed on resected lung adenocarcinomas without neoadjuvant therapy, available pre-operative biopsies, and excision/biopsy/cytology (non-resection) specimens from patients with advanced stage non-squamous NSCLC with/without tyrosine kinase inhibitor (TKI) therapy. All specimens underwent molecular profiling using targeted next-generation sequencing. Immunohistochemistry for c-MET (clone SP44; Roche Ventana) was evaluated using H-score and 2-tiered classifications with the cut-off of 3+ in ≥25% or ≥50% of tumor cells. Resections were evaluated by 3 (2 senior and 1 junior) pathologists, and the interobserver reproducibility was assessed via interclass correlation coefficient (ICC) and Fleiss Kappa coefficient (ƙ). c-MET expression was compared between driver alterations using t-Tests and Fisher's exact tests. c-MET expression was also compared between specimens procured at different time points in a subset of patients.

Results: The study cohort consisted of 281 patients with non-squamous NSCLC (age 22-94 [mean 67] years; Female: Male = 172:109, Stage I/II/III/IV =71/41/43/126). Of those, 150 underwent lung resections (all adenocarcinomas, pathologic Stage I/II/III/IV =71/41/34/4) with pre-operative biopsies available in 31. In the analysis of interobserver concordance of 3 pathologists assessing c-MET expression on resections, global ICC for H-score was 0.772 to 0.845, and the ƙ for the 25% and 50% cut-offs were 0.4855 to 0.7324 and 0.5300 to 1.0000, respectively. The ƙ was higher between senior pathologists and for biopsy samples. In the 31 biopsy/resection pairs, the intrasample reproducibility for H-score was ICC 0.246, and the ƙ for the 25% and 50% cut-offs were -0.1932 and -0.2000, respectively. With the 25% and 50% cut-offs, 12 (38.7%) and 8 (25.8%) cases were positive in the resection and negative in the pre-operative biopsy, respectively, while 2 (6.5%) and 0 cases were negative in the resection and positive in the biopsy. In the resection cohort, c-MET expression was associated with pathologic Stage (mean H-score: I vs II-IV = 173 vs 251, p<0.0001). In TKI-naïve tumors, c-MET expression was higher in fusion positive tumors (p = 0.026 in the resection cohort) or in ALK positive tumors only (p = 0.0079 in the non-resection cohort) than the rest of the cohort. Paired pre- and post-TKI specimens were available from 28 patients with advanced non-squamous NSCLC. Of those, c-MET expression was increased (from <25% to ≥25%/≥50% or from ≥25% to ≥50%) in 6 (21.4%) cases, decreased (from ≥50% to <25%) in 3 (10.7%), and similar in 19 (67.9%) after TKI therapy.

Conclusions: Interobserver agreement for c-MET expression was moderate to excellent in both resections and biopsies. However, c-MET expression may be underestimated in biopsies due in part to significant intratumoral heterogeneity. c-MET expression correlated with tumor stage and was relatively high in fusion-positive tumors. c-MET expression was the same or higher post TKI in 90% of treated patients.

EP.06.54 The Landscape of Actionable Genomic Alterations in Non-Small Cell Lung Cancer. A Single Institution Quality Improvement Initiative

A.S. AL Lawati, A. Awan, B. Lo, J. Martin, A. Almutawa, G. Hrubesz, P. Wheatley-Price
University of Ottawa, Ottawa/ON/CA

Introduction: Identification of actionable genomic alterations (AGA) in non-small cell lung cancer (NSCLC) is crucial to guide appropriate therapy for patients. Molecular profiling (accuracy and timeliness) can be inconsistent between centers and countries. Our centre adopted a new Next Generation Sequencing (NGS) panel, Oncomine Comprehensive Assay version 3 (OCAv3) ®, in 2021. Through our QI initiative, we will try to identify whether our test detected AGAs at an anticipated rate.

Methods: This is a retrospective single center QI project of patients diagnosed with NSCLC at a Canadian tertiary academic hospital with in-house testing, from July 1, 2021, to June 30, 2023, representing the initial 24 months after adopting OCAv3. All adult patients with confirmed NSCLC, of any stage, who had NGS by OCAv3 were reviewed, including those with attempted but unsuccessful tests. Patients with other active malignancies were excluded. With an ethics board waiver for QI projects, patient charts and pathology reports were reviewed, collecting simple patient demographics, molecular testing results and treatment details. Here we report the results of the molecular testing.

Results: Overall, 1276 consecutive cases where the OCAv3 lung NGS panel was used were included. Demographics: 42% male; median age 69 years; 90% adenocarcinoma; 48% stage 4 at time of testing. Of the 1276 cases, the sample was insufficient, or the test failed in 88 (6.9%) cases. The rates of AGAs are shown in Table 1, overall and by early vs advanced stage. PDL1 was tested in 1218 cases (95.4%), of whom 437 (34.3%) were PDL1 <1%, 356 (27.9%) were PDL1 1-49%, and 425 (33.3%) were PDL1 >=50%, There were single cases with NRG1 , PTEN and NTRK.

Conclusions: In this large QI series, we broadly identified AGAs at an anticipated rate, although the rates of ALK and ROS1 fusions are slightly lower than in other published series. This data will inform clinical trial portfolio planning. Ongoing work will look at how many patients received appropriate targeted therapy, and survival outcomes.

Table

Mutation	Number of cases in entire cohort (n=1276)	% overall	Number (%) stage 1-3	Number (%) stage 4
EGFR mutations				
EGFR (all types)	181	14.1%	81 (44.8%)	100 (55.2%)
Common EGFR	134	10.5%	64 (47.7%)	70 (52.2%)
EGFR exon 19 del	74	5.8%	37 (50%)	37 (50%)
EGFR L858R	60	4.7%	27 (45%)	33 (55%)
Atypical EGFR	34	2.6%	10 (30.3%)	24 (72.7%)
EGFR exon 20	13	1.0%	7 (53.8%)	6 (46.2%)
Non-EGFR mutations				
MetEx14	33	2.6%	13 (39.4%)	20 (60.6%)
KRAS G12C	209	16.4%	113 (54.1%)	96 (45.9%)
KRAS (non-G12C)	299	23.4%	168 (56.2%)	129 (43.1%)
BRAF V600E	20	1.6%	12 (60%)	8 (40%)
BRAF (non-V600)	55	4.3%	30 (54.4%)	25 (43.6%)
Her2 mutation	18	1.4%	10 (55.6%)	8 (44.4%)
PIK3CA mutation	36	2.8%	16 (44.4%)	20 (55.6%)
Fusions				
ALK fusion	27	2.1%	7 (26%)	20 (74%)
RET fusion	16	1.3%	5 (31.2%)	11 (68.8%)
ROS1 fusion	9	0.7%	4 (44.4%)	5 (55.6%)

Note: NRG1 fusions, PTEN mutations and NTRK fusions were identified in 1 patient each in this cohort.

Keywords: NSCLC, NGS, Mutations

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.55 Racial Differences in ERBB2 Mutations in Lung Adenocarcinoma: Insights From a Multi-Cohort Study

Y-H. Chang[1], J-W. Chen[2], H-Y. Chen[3]
[1]Institute of Molecular and Genomic Medicine, National Health Research Institutes, Zhunan/TW ,[2]Graduate Institute of Biomedical Sciences, National Chung Hsing University, Taichung/TW ,[3]Institute of Statistical Science, Academia Sinica, Taipei/TW

Introduction: ERBB2 (HER2) mutations, particularly exon 20 insertions, are increasingly recognized as key oncogenic drivers in lung adenocarcinoma. However, racial variations in mutation prevalence and subtype distribution, especially between Asian and Western populations, remain poorly characterized. This study examines ERBB2 mutation profiles across racial groups in a multi-cohort dataset.

Methods: Whole-exome sequencing data from 380 lung adenocarcinoma patients (72% Asian) were analyzed. ERBB2 mutations were identified in 9 patients (detection rate: 2.3%), including 3 from Taiwan. Mutation subtypes (exon 20 insertions vs. S310F/Y), co-occurrence with EGFR and KRAS mutations, and racial background (Asian vs. non-Asian) were evaluated using descriptive statistics.

Results: Among ERBB2-mutated cases, 88.9% were EGFR/KRAS wild-type, confirming ERBB2 as an independent driver. Exon 20 insertions predominated (66.7%), with 50% occurring in Taiwanese patients, despite Taiwan comprising only 33.3% of the cohort. S310F/Y mutations (22.2%) exceeded global averages. Asians, constituting 66.7% of ERBB2-mutated cases, reflected higher mutation rates in East Asian populations.

Conclusions: Exon 20 insertions are the dominant ERBB2 mutation subtype in lung adenocarcinoma, with potential enrichment in Taiwanese patients, suggesting racial disparities. The elevated S310F/Y frequency merits further study. Larger multi-ethnic cohorts are essential to confirm these trends and guide targeted therapies.

EP.06.56 Genomic and Immune Characteristics Linked to Second-Line Combination Immunotherapy Outcome in EGFR-Mutated Advanced NSCLC

T. Tian[1,2], X. Zhang[1,2], H. Zhou[1,2], J. Li[1,2], L. Li[1,2], R. Bai[1,2], K. Xu[1,2], Y. Xu[1,2], C. He[1,2], L. Xu[1,2], F. WANG[3], J.C. Yin[3], H. Wang[1,2], H. Tang[1,2], S. Wei[1,2], J. Li[1,2], R. He[4], S. Niu[5], Z. Zhang[1,2]
[1]The First Affiliated Hospital of USTC, Hefei/CN ,[2]University of Science and Technology of China, Hefei/CN ,[3]Nanjing Geneseeq Technology Inc., Nanjing/CN ,[4]Bozhou Traditional Chinese Medicine Hospital Anhui Province, Bozhou/CN ,[5]The Pulmonary Department of Taihe County Traditional Chinese Medicine Hospital, Fuyang/CN

Introduction: Immune checkpoint inhibitors (ICIs) combined with anti-angiogenic agents and chemotherapy have demonstrated safety and tolerability as second-line treatment options for patients with EGFR-mutated advanced NSCLC resistant to EGFR tyrosine kinase inhibitors. However, reliable predictive biomarkers of treatment outcome remain to be explored.

Methods: Eleven patients with EGFR-mutated advanced NSCLC were enrolled in this study. All patients received ICIs plus anti-angiogenic agents and chemotherapy as second line therapy following progression on EGFR-TKI treatment. FFPE biopsy tissue and peripheral blood samples were collected from all patients before initiating second-line treatment. Comprehensive genomic profiling of tissue and circulating tumor DNA (ctDNA) was performed using a panel of 437 cancer-related genes. Tumor-infiltrating immune cells were characterized using multiplex immunohistochemistry (mIHC).

Results: Of the ten patients with evaluable genomic characteristics, 100% had detectable EGFR mutations, predominantly 19del (40.0%) and L858R (50.0%) mutations. The remaining patient carried EGFR S768I and V769L mutations along with EGFR amplification. The most frequent concurrent genetic event detected in tumor samples was TP53 mutation (40.0%), followed by MYC amplification (20.0%) and SMAD4 mutation (20.0%). Notably, the presence of TP53 mutations was significantly associated with shorter progression-free survival (PFS) outcome (HR=8.25, P=0.028). A higher tissue mmVAF (minVAF/maxVAF) level (>0.3) was associated with longer PFS (HR=0.10, P=0.016). In contrast, in plasma ctDNA, a higher mmVAF was associated with shorter PFS (HR=6.99, P=0.039). Moreover, a high density of tumor-infiltrating CD56bright NK cells associated with longer PFS (HR=1.71E-10, P=0.003).

Conclusions: These findings highlight the potential of TP53 status, mmVAF and immune cell infiltration as biomarkers for guiding personalized treatment strategies in patients with EGFR-mutated advanced NSCLC undergoing second-line immunotherapy combined with anti-angiogenic agents and chemotherapy. Further validation in large cohorts is warranted to confirm these results and optimize therapeutic approaches.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.57 Molecular Analysis of Driver Negative Lung Cancer for Rearrangements and Fusions Using a New HiC Sequencing Assay

W. Ricketts, K. Sikkink, B. Skrable, B. Kilburn, A. Durbin, A. Hastie, A. Schmitt
Arima Genomics, Carlsbad/CA/USA

Introduction: Molecular testing in lung cancer has led to the identification of driver mutations that can be effectively targeted by new therapeutics. In addition to single point mutations that activate signaling proteins such as EGFR and KRAS, the presence of various fusion proteins that lead to protein overexpression and activation of key pathways have become prominent drug targets. Detection of these fusion proteins by FISH or sequencing is possible but may be limited due to changes in breakpoint regions, the panel may not target the fusion partner, or RNA expression may be affected by sample fixation or processing. This study aims to improve detection rate of targetable fusions and rearrangements in non-small cell lung cancer (NSCLC) using a new method called FusionPlus sequencing.

Methods: FusionPlus sequencing is a novel whole genome DNA-sequencing assay for detection of structural variation based on Hi-C chemistry method leveraging the sequencing of linked pairs of reads which occur nearby one another in 3-dimensional and linear space, from FFPE samples. Linking reads amplifies the rearrangement signal giving it much higher sensitivity. In previous studies, FusionPlus has been shown to detect gene fusions and rearrangements in many different tumor types missed by other clinical testing modalities such as FISH and RNA sequencing.

Results: In a pilot set of NSCLC samples, FusionPlus sequencing demonstrated 100% concordance with FISH and/or RNA sequencing results (10/10, including 4 ALK, 2 MET, 2 ROS, 1 NTRK, and 1 RET fusions). In this current study, we have examined 100 NSCLC FFPE specimens (25 complete, to date), which were previously determined by DNA and RNA sequencing to be negative for drivers such as EGFR and KRAS mutations and fusions of ALK, MET, NTRK, RET, and ROS. In the first 25 samples, we have detected eleven total rearrangements in FGFR1 (7), RAD51B (2), ERBB2 (1) and FGFR4 (1). We have also detected two amplifications, one MET and one KRAS. The other 75 samples have been sequenced and are currently being analyzed.

Conclusions: Encouraging results from this study suggest that FusionPlus sequencing may be a valuable tool in the molecular classification of lung cancers and could lead to improvement in patient care. FusionPlus can detect gene fusions and rearrangements that are known to drive cancer and may be used for therapy selection, including in cases which were negative by standard genetic testing.

Keywords: fusion, rearrangements, biomarker

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.58 CEACAM5 as a Biomarker for Differentiating Ground-Glass Opacities From Other Lung Cancers

J.M. Bader[1], W. de Santis[2], E. Kane[3], A. Ahmad[4], S. Prince[1], A. Jaiswal[2], C. Cho[2], M. Kidacki[2], L. Chen[2], S. Dacic[1], G. Woodard[1]
[1]Yale New Haven Hospital, New Haven/CT/USA ,[2]Yale University, New Haven/CT/USA ,[3]New York Medical College, New York City/NY/USA ,[4]Vanderbilt University, Nashville/TN/USA

Introduction: Carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5) is a cell adhesion molecule implicated in tumor cell migration, invasion, and resistance to apoptosis. Its role as a circulating biomarker in the form of CEA is well-established in some gastrointestinal malignancies. However, CEACAM5 is also overexpressed in approximately 25% of non-small cell lung cancer (NSCLC), particularly lung adenocarcinoma, yet its role as a biomarker and therapeutic target remains unclear. Previously, we demonstrated elevated CEACAM5 RNA expression in ground-glass opacities (GGO). In this study, using a separate patient cohort, we assess CEACAM5 protein expression as a potential biomarker for GGO compared to other solid NSCLC tumors.

Methods: CEACAM5 immunohistochemistry (IHC) was performed in a CLIA setting on surgically resected GGO (n=42) and NSCLC (n=200) with known clinical demographics and radiographic growth characteristics. Expression was quantified with standardized H-score by an expert thoracic pathologist and compared between GGO and solid NSCLC. Sub-group comparisons were also performed based on gender, smoking status, tumor histology, and tumor stage. GGO specimens underwent multiplex immunofluorescence (mIF) to characterize the immune microenvironment and quantify CD8+ and CD20+ immune cell infiltration to explore immune correlations with CEACAM5 expression.

Results: GGO exhibited significantly higher mean CEACAM5 expression than the overall NSCLC cohort (H-score:53vs27, P<0.001). This increase was also observed when comparing GGO to specific NSCLC subtypes including lung adenocarcinoma (n=57, H-score:53vs35, P=0.009), squamous cell (n=20, H-score:53vs5, P=0.003), and large cell carcinoma (n=10, H-score:53vs12, P=0.024). Among the adenocarcinoma cohort, stage 1 adenocarcinoma showed lower levels of CEACAM5 compared to stage 2-4 adenocarcinoma (H-score:28vs50, P=0.089). Among the GGO cohort, specimens with H-score≥100 exhibited a tumor microenvironment with higher density of PanCK+ tumor cells (5.5%vs2.2%, P=0.017)(Figure 1). Among patients with ≥2 documented preoperative CT scans, all GGO specimens with H-score≥100 (n=6) developed a new radiographic solid component compared to GGO with H-score<100 (100%vs38%, P=0.035).

Conclusions: Our findings demonstrate that CEACAM5 is significantly overexpressed in GGO compared to other forms of solid NSCLC, suggesting its potential utility as a biomarker for identifying and monitoring these lesions. Notably, within the GGO cohort, higher CEACAM5 expression was associated with increased tumor cell density and development of a new solid component on imaging. These findings provide insight into the biological significance of CEACAM5 in lung cancer evolution and its possible role in tumor progression. Future studies should explore the clinical utility of CEACAM5-targeted strategies for early detection of invasive lung cancer and lung nodule risk stratification.

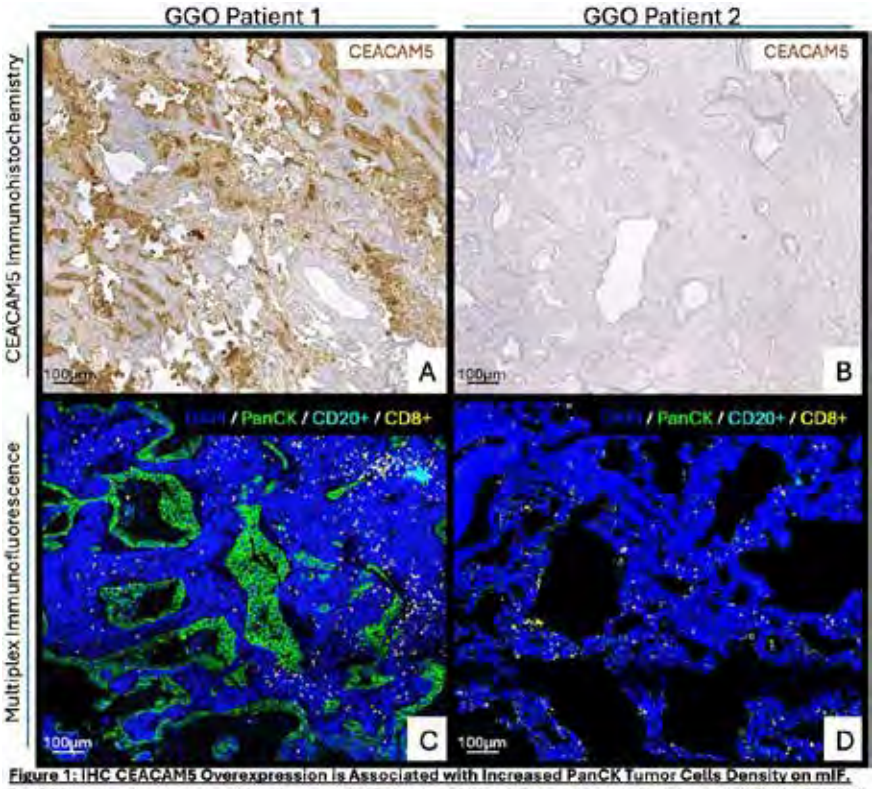

Figure 1: IHC CEACAM5 Overexpression is Associated with Increased PanCK Tumor Cells Density on mIF.
Two GGO specimens are represented by columns labeled Patient 1 and Patient 2. Top row is immunohistochemistry (IHC) with CEACAM5. The bottom row is multiplex immunofluorescence (mIF) for DAPI (all cell types), PanCK (malignant epithelial cells), CD8 (cytotoxic T cells), and CD20 (B cells). Increased CEACAM5 expression (Figure 1A) is associated with increased PanCK cell density (Figure 1C).

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.59 Dna+RNA-NGS Testing in NSCLC Patients With Primary Resistance to First-Line Non-Targeted Therapy and Negative Driver Genes (Dream Study)

B. Han[1], Y. Han[1], J. Lu[1], Y. Lou[1], W. Wang[1], Y. Kuang[1], R. Zhao[1], N. Gao[2], D. Zhang[2], M. Huang[2]
[1]Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/CN ,[23]D Medicines Inc, Shanghai/CN

Introduction: Immunotherapy is the first-line standard treatment for advanced NSCLC patients with negative driver genes. However, primary resistance is relatively common. Gene fusion mutations are a key cause of this primary resistance. Research shows RNA-NGS has a higher gene fusion detection rate than DNA-NGS, effectively preventing fusion mutation miss-detection and helping identify therapeutic targets. This study enrolls NSCLC patients with DNA-NGS confirmed negative driver genes and primary resistance to first-line non-targeted therapy. Through DNA+RNA co-testing, it aims to determine the proportion of patients with poor first-line non-targeted therapy efficacy due to missed driver gene detection, especially fusion mutations. Driver gene positive patients can get targeted treatment, highlighting the importance of DNA+RNA co-testing for better NSCLC treatment and prognosis.

Methods: Research Design: The prospective study is divided into two parts. Part A collects samples from NSCLC patients whose driver genes are negative as detected by traditional DNA-NGS and who have primary resistance to first-line non-targeted therapy. These samples will undergo simultaneous DNA+RNA-NGS co-testing to analyze relevant proportions and characteristics. Part B enrolls patients with positive driver genes identified in Part A. According to patients' wishes, they are divided into a targeted therapy group and a non-targeted therapy group. Sample Selection: It is estimated that 508 cases will be included in Part A and 64 cases in Part B. Evaluation **Methods:** The primary research endpoints are the proportion of patients with positive driver genes redetected by DNA+RNA NGS co-testing and the objective response rate (ORR) of different treatment groups. Secondary and exploratory endpoints include the first-line median progression-free survival (PFS) of drug-resistant patients, clinical characteristics, and the impact of different factors on the testing. Statistical analysis will be performed using SPSS 26.0, and appropriate testing methods will be selected based on the data type.

Results: The main endpoints of this study are the proportion of patients with positive driver genes (especially fusion mutations) detected by simultaneous DNA+RNA-NGS co-testing and the ORR comparison in driver-gene-positive patients with or without targeted therapy. The further updated data will be presented at the Conference.

Conclusions: Through simultaneous DNA+RNA-NGS co-testing, it will be elucidated that in a subset of patients, suboptimal efficacy of first-line non-targeted therapies and compromised overall prognosis will be attributable to the failure to detect driver genes, particularly fusion variants.These findings provide a scientific rationale for the implementation of simultaneous DNA+RNA-NGS co-testing in NSCLC patients at the time of initial diagnosis.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.60 Exploring the Role of the Oral Microbiome in Saliva Sputum Bronchoalveolar Fluid and Tissue Tumor in Lung Cancer a Systematic Review

J.A. Zuluaga León
Luis Carlos Sarmiento Angulo Cancer Treatment and Research Center (CTIC), Bogotá/CO

Introduction: To investigate the relationship between the oral microbiome and the development or progression of lung cancer (LC) using metagenomic sequencing techniques

Methods: Databases, including PubMed and EMBASE, were reviewed from January 2015 to July 2024. Eligible studies included investigations of oral microorganisms through genomic sequencing and the molecular mechanisms associated with lung cancer (LC) in saliva, sputum, bronchoalveolar lavage fluid (BALF), or tumor tissue from patients with LC. A quality analysis of the studies was conducted using the New Castell scale (NCS), and a qualitative synthesis was performed according to the localization and sample type

Results: Of the 1,880 scrutinized articles, 50 studies were selected, comprising 29 cross-sectional, 7 case-control, and 14 cohort studies. The quality analysis sheds light on potential biases. The findings revealed a conspicuous overgrowth of specific microbial taxa in the saliva and BALF samples of LC patients, including Veillonella and Streptococcus. However, Veillonella was associated with a better response to ICIs therapy. Conversely, samples from the Bacteroides genus, related to periodontal disease, exhibited no significant correlation with LC. Although oral microorganisms in the tumor tissue varied, their presence was associated with a poor prognosis in LC. However, Prevotella nigrescens was associated with longer PFS. Fusobacterium nucleatum had an inadequate response in ICs. Oral microorganisms are related to the biodegradation of xenobiotics, amino acid and sugar metabolism, including sucrose, as well as a proinflammatory environment that can inhibit the immune response and disrupt cellular redox homeostasis

Conclusions: The Overgrowth of certain oral microorganisms in saliva and BALF is associated with diagnosis, poor prognosis, and a low response to immunotherapy. Further, well-designed studies should evaluate the impact of the oral microbiome on the response to ICs

Keywords: Oral microbiome, Lung cancer, Metagenomic sequencing

EP.06.61 FGRF-2: A Prognostic Biomarker and Potential Therapeutic Target in NSCLC

M.P. Barr[1], C. Murtagh[2], S.G. Gray[3], A-M. Baird[4], J.J. Phelan[4], S. Nicholson[2], S. Cuffe[2], V. Young[2], R. Ryan[2], G.J. Fitzmaurice[2], S. Finn[3]
[1]St James Hospital & Trinity College Dublin, Dublin/IE ,[2]St James's Hospital, Dublin/IE ,[3]St James's Hospital & Trinity College Dublin, Dublin/IE ,[4]Trinity College Dublin, Dublin/IE

Introduction: Fibroblast growth factors (FGFs) and their receptors (FGFR1-4) regulate a number of cellular processes and are known to be involved in tumorigenesis. The overexpression, amplification, mutation and fusion of FGFR genes in lung cancer are closely linked to tumor initiation, progression and resistance, suggesting that targeting the FGF-FGFR axis is an attractive therapeutic strategy for the treatment of lung cancer. Evaluating the efficacy and safety of selective FGFR inhibitors in lung cancer patients with FGFR abnormalities are currently ongoing. The development of novel FGFR2-targeted therapies hold promise for mitigating the toxicities and resistance reported with the use of small molecular inhibitors targeting FGFR-1 and FGFR-4. In this study, a role for FGFR-2 as a biomarker in NSCLC was examined.

Methods: Expression of total FGFR-2 and its isoform, FGFR-2b, was examined in a panel of 20 NSCLC cell lines by RT-qPCR. A tissue microarray (TMA) consisting of 209 surgically resected tumor tissues from NSCLC patients resected at St James's Hospital was generated. A cell line microarray (CMA) was also prepared which consisted of lung adenocarcinoma (H3122, H2228, H1975) and large cell lung carcinoma (H460) cells. Immunohistochemical (IHC) staining for FGFR-2 (Novus Biologicals, clone 1G3) and FGFR-2b (clone Fc-FGF1) was optimized using the Benchmark Ultra (Roche Diagnostics). Tissue staining was independently assessed and graded by a Consultant Histopathologist using the H-score (staining intensity × percentage cell positivity). FGFR-2 protein expression was correlated with demographic and clinicopathological parameters such as age, gender, histology, tumor grade, stage, smoking status and overall survival. Statistical analyses were performed using SPSS v26.0 or GraphPad Prism v6.01 statistical software.

Results: Total FGFR-2 and FGFR-2b were differentially expressed across different NSCLC cell line genotypes and histology. The lung adeno-squamous cell line, NCI-H596, expressed significantly higher levels of total FGFR-2 relative to the normal bronchial epithelial cell line, BEAS-2B ($p<0.001$). Of interest, FGFR-2b gene expression was increased by 40- and 70-fold in SNU2535 (ALK+) and H358 (KRAS, CTNNB1) cells, respectively ($p<0.001$). Immunocytochemical analysis of the CMA showed intense staining for FGFR-2 (H-score=300) in H3122 (ALK+) cells. Diffuse membranous and cytoplasmic FGFR-2 staining patterns were evident in NSCLC tissues, with notable positive staining of lung alveolar macrophages. Optimization of FGFR-2b staining was unsuccessful using different antibody clones. FGFR-2 expression was significantly higher in females vs. males ($p<0.05$), between adenocarcinoma (ADC) tissue vs. squamous cell (SqCC) tissue ($p<0.001$) and in non-smokers compared to current ($p<0.01$) or former smokers ($p<0.01$). There were significantly higher levels of FGFR-2 in stage I, II and III lung tumors relative to stage IV ($p<0.05$) and in patients with N0 vs. N1 disease ($p<0.05$). NSCLC patients with ADC histology and high FGFR-2 expression had worse 5-year ($p=0.20$) and overall survival ($p=0.40$) outcomes. Similar findings were found at 5-year ($p=0.09$) and overall survival ($p=0.05$) in patients with SqCC tumors expressing high levels of FGFR-2.

Conclusions: These data provide evidence for the potential use of FGFR-2 as a prognostic biomarker for enabling better patient selection in future clinical trials for novel FGFR-2 targeted therapies.

EP.06.62 Based on Labyrinth Microfluidic Chip in Evaluating Therapeutic Efficacy for Leptomeningeal Metastasis of Lung Cancer

Y. MENG TENG[1], H. Long[2], L. Xue[3]
[1]Labyrinth Biotech, Su Zhou/CN ,[2]The Second Affiliated Hospital of Nanchang University, Nan Chang/CN ,[3]Su Zhou Labyrinth Biotech, Nan Chang/CN

Introduction: The assessment of therapeutic efficacy for leptomeningeal metastasis (LM) in lung cancer relies on the RANO criteria, yet its clinical utility remains limited. Cerebrospinal fluid (CSF) circulating tumor cells (CTCs) may serve as a real-time biomarker to overcome current limitations. This study evaluates the clinical value of the Labyrinth microfluidic chip in isolating and analyzing CTCs, aiming to explore its feasibility for efficacy assessment.

Methods: A prospective study enrolled six LM patients (cytologically confirmed) from the Second Affiliated Hospital of Nanchang University (January-December 2024). All patients received systemic therapy and intrathecal chemotherapy. The Labyrinth chip dynamically quantified CTCs in CSF samples collected pre-treatment, post-treatment cycles, and at progression. CTC dynamics were compared with RANO criteria for consistency.

Results: Among six patients (5 males, 1 female; median age 59.5 years), Patient 1 achieved partial response (PR) after three intrathecal pemetrexed cycles (CTCs decreased from 312 to 0.4 cells/mL). On February 22, CTCs rebounded to 5 cells/mL but stabilized (stable disease, SD at 0.6 cells/mL) after combined fumetinib therapy by May 28. Patient 3 exhibited initial CTCs of 1,651.8 cells/mL post-chemotherapy. Upon progression (PD on May 9, CTCs: 2,693.4 cells/mL), afatinib combined with bevacizumab reduced CTCs to 294.6 cells/mL (PR by July 11), followed by PD on July 30 (CTCs surged to 3,318.6 cells/mL). CTC dynamics provided an average 14-day earlier warning of progression compared to RANO criteria.

Conclusions: The Labyrinth microfluidic chip enables precise CTC quantification in CSF, offering a novel approach for early therapeutic efficacy assessment in lung cancer LM.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.63 New Approaches for Enhancing the Efficacy of "Liquid Biopsy" in Non-Small Cell Lung Cancer

S. Smirnou[1], A. Miadzvedz[1], S. Pivavarchyk[1], T. Vakhomchyk[1], H. Subach[1], P. Karatkevich[1], A. Portyanko[1]
[1]N.N. Alexandrov National Cancer Centre of Belarus, Lesnoy/BY

Introduction: "Liquid biopsy" is a modern technology for diagnosing various molecular-genetic abnormalities in tumors. The main drawback of currently used cfDNA analysis methods is their low diagnostic sensitivity. There are numerous approaches aimed at improving this parameter: increasing the volume of analyzed blood plasma, enhancing coverage in NGS studies, and employing technologies with high analytical sensitivity (Beaming-PCR). However, the use of expensive technologies significantly raises the overall cost of ctDNA analysis. One of the alternative approaches aimed at increasing the levels of ctDNA in the bloodstream of patients may be a single irradiation of tumor sites, leading to the massive apoptosis of malignant cells. The aim of current study is to enhance the effectiveness of ctDNA detection in patients with lung cancer.

Methods: The study will include 40 patients with III-IV st. NSCLC (adenocarcinoma and squamous cell lung cancer) who will undergo a standard radiotherapy (III st.) or single local irradiation of the tumor site at a dose of 4 Gy (IV st.), as well as 20 patients in the control group. Plasma samples (8 ml) will be collected at the following time points: before irradiation and 6, 12, 24, and 48 hours after. ctDNA analysis will be conducted using droplet digital PCR, targeting pathogenic variants in the EGFR, KRAS, BRAF genes, and methylation of the promoter region of the RASSF1A gene. If a statistically significant increase in ctDNA concentration will be detected during a specific time point, an additional 5 pts with NSCLC progressed on therapy with EGFR inhibitors (Erlotinib, Gefitinib) and negative for EGFR T790M in plasma will be included. The study protocol has been approved by the Ethics Committee of the N.N. Alexandrov National Cancer Centre of Belarus.

Results: Currently, 29 patients with NSCLC have been included in the study, and patient recruitment is ongoing. The concentration of ctDNA has been assessed in 11 patients with NSCLC. Before irradiation ctDNA was detected in 82% of cases with an observed increase in cfDNA levels in the bloodstream after irradiation in 91% of cases. CtDNA was detected in 100% of cases at the 6 and 48-hour time points.

Conclusions: We expect to obtain data that will improve ctDNA diagnostics in patients with NSCLC. The study will determine the feasibility of using single local irradiation of tumor sites in patients with NSCLC to induce cfDNA release into the bloodstream. Successful outcomes could enhance the diagnostic sensitivity of tests for detecting the T790M mutation in ctDNA from patients undergoing EGFR inhibitor therapy.

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.64 ISET CTC-DNA shows higher sensitivity then ctDNA in early stage lung cancer patients

F. Lococo[1], M. Heidary[2], Y. Liu[2], I. Desitter[2], J. Evangelista[3], A. Campanella[1], M. Giannakoulis[2], K. Vasileiou[2], K. Prevost[2], A. Decina[2], D. Brechot[2], P. Paterlini[2]
[1]Thoracic surgery Unit, Università Cattolica del Sacro Cuore, Rome/IT ,[2]Rarecells, Paris/FR ,[3]Thoracic Surgery Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome/I

Introduction: Lung cancer (LC) is a leading cause of cancer deaths in the world. Early detection of lung cancer can reduce mortality, as demonstrated by low-dose computed tomography (LDCT) screening. However, there is a need to complement LDCT screening to increase adoption, reduce patients' exposure to radiation and increase specificity/sensitivity. Several molecular approaches have been developed for non-invasive early-stage detection of LC based on the analysis of circulating tumor DNA (ctDNA), however, this marker is barely detectable and present in very small quantities in the plasma of early-stage lung cancer patients.The present work explores the combined analysis of CTC (Circulating Tumor Cells)-DNA, extracted from blood using the hypersensitive ISET® platform from Rarecells, and ctDNA, extracted from plasma according to standard procedures.

Methods: We analyzed DNA extracted from the isolated CTC, plasma, tumor tissue, and leucocytes from 50 patients undergoing surgery for early stage lung cancer. Next Generation Sequencing was performed on all the DNA samples using a panel (Agilent Technologies, Inc.) targeting 983 regions from 53 target genes. Libraries were prepared with the SureSelectXT technology (Agilent Technologies, Inc.) following the manufacturer's instructions. Pairedend (2x111 bases) sequencing was performed on a MiSeq device (Illumina, Inc.).

Results: Direct comparison of tumor-tissue related variants detected in CTC-DNA, in corresponding cfDNA and paired primary FFPE tumor tissues from 6/6 cases clearly show increased number of tumor-tissue related variants in CTC-DNA as compared to cfDNA.

Conclusions: (Preliminary): These preliminary results, if confirmed by the coming data from the whole cohort, suggest that CTC-DNA obtained with an hypersensitive approach could improve early stage lung cancer detection and early lung cancer recurrence detection by increasing the sensitivity of ctDNA-based results.

Note: Further updated data from the 50 patients included in the study will be presented at the Conference.

Keywords: Liquid Biopsy DNA Markers, Lung Cancer, Early Detection

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.65 Mosaic Chromosomal Alterations and the Risk of Incident Lung Cancer: A Systematic Review and Meta-Analysis

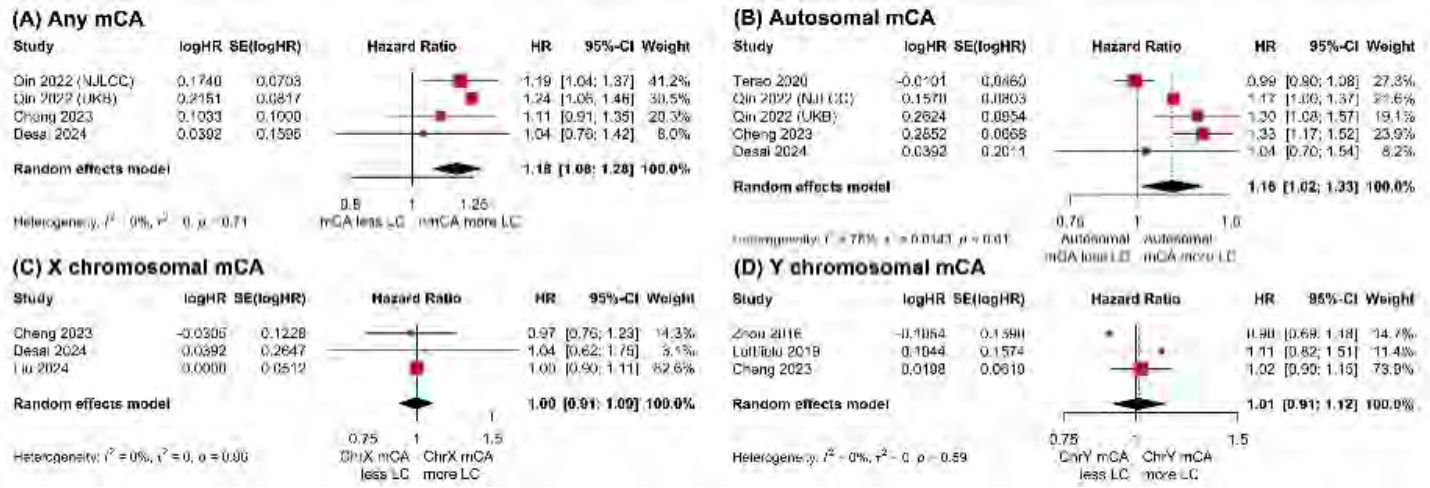
B. Ponvilawan[1], C. Kanitthaniyom[2], S. Saowapa[2], S. Subramanian[3], D. Bansal[4]
[1]Northwestern University Feinberg School of Medicine, Chicago/IL/USA ,[2]Texas Tech University Health Sciences Center, Lubbock/TX/USA ,[3]Langley High School, McLean/VA/USA ,[4]Endeavor Health, Evanston/IL/USA

Introduction: Mosaic chromosomal alterations (mCA) are somatic alterations in hematopoietic stem cells designated by large-size chromosome loss, gain, or copy-neutral loss of heterozygosity, whose prevalence increases by age. Despite the presence of mCA being associated with an elevated risk of developing hematologic cancers, the data on mCA and incident lung cancer risk are still conflicting. We aim to evaluate the risk of developing lung cancer in individuals harboring mCA.

Methods: All articles related to mCA and lung cancer were retrieved from Embase and Medline databases from inception to February 2025. Eligible studies must be cohort studies that evaluated mCA status upon study entry, then compared lung cancer incidence among individuals with mCA and those without. All participants in the study must not have prior lung cancer diagnoses. Hazard ratios (HR) or odds ratios (OR), along with their 95% confidence intervals (CI), were extracted and combined using the generic inverse variance method. We also performed subgroup analyses based on the type of chromosome alteration (autosomal vs X chromosome (ChrX) vs Y chromosome (ChrY)). All statistical analyses were performed in R version 4.3.2.

Results: In total, seven studies were included in the meta-analysis: four for autosomal mCA in both sexes, three for ChrX mCA in females, and three for ChrY mCA in males. mCA was associated with an increased incidence of lung cancer (HR 1.19, 95% CI 1.08-1.28), especially in those with autosomal mCA (HR 1.16, 95% CI 1.02-1.33; Figure 1A-B). However, sex chromosome mCA was not associated with incident lung cancer (HR 1.00, 95% CI 0.91-1.09 and 1.01, 95% CI 0.91-1.12 for ChrX and ChrY mCA, respectively; Figure 1C-D).

Conclusions: The occurrence of mCA was associated with an elevated risk of incident lung cancer and was mainly driven by autosomal mCA, but not those involving sex chromosomes mCA. This observation might result from the limited number of major oncogenes or tumor suppressor genes on the sex chromosomes that are associated with lung carcinogenesis. mCA detection may serve as a valuable tool for lung cancer risk stratification, and further studies to validate this role are sought.



Keywords: mosaic chromosomal alteration, lung cancer, risk factor

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.66 Prediction of Immune-Related Adverse Events by Human Leukocyte Antigen (HLA) and Other Biomarkers in Patients With Non-Small Cell Lung Cancer

Sánchez, A. Vargas-Aliaga, M. López-Herrero, G. Guevara, B. Manzanares-Martín, R. Gonzalez-Fernández, E. Aranda
Hospital Universitario Reina Sofía de Córdoba, Cordoba/ES

Introduction: Immune-related adverse events (AEs) in patients (pts) with non-small-cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICIs) lead to treatment interruptions and toxic deaths. The mechanisms responsible for their occurrence are unknown and biomarker research is needed to help us reduce the associated morbidity and mortality. The association between HLA-I and autoimmune diseases has been described, and recent studies seem to find a similar association between HLA-I and irAEs.

Methods: We analyzed the clinical characteristics of 233 patients with stage IV NSCLC receiving ICIs monotherapy (antiPD1/PDL1) in first or second line at our center between 2018-2024. In addition, a high-resolution HLA-I assay was performed in 75 pts. The impact of clinical and pathological variables affecting the risk of developing irAEs was assessed using a univariate and multivariate logistic regression model and Fisher's test was used to analyze the association between HLA-I zygosity and HLA-I types with irAEs.

Results: 57 pts (24.5%) presented possible irAEs (28.5% grade >= 3). 6.4% discontinued ICIs definitively due to toxicity. The most frequent irAEs were skin toxicity (26.3%), endocrinopathies (19.3%), pneumonitis (15.3%) and arthritis (10.2%). The median time to onset of irAEs was 146 days. Homozygosity at one or more HLA-I loci was not associated with a lower risk of irAEs (p= 0.7). Patients with HLA C*06:02 were associated with an increased risk of endocrinopathy (p=0.036) and HLA C*05:01 with skin toxicity (p=0.04). After multivariate analysis in the total sample, irAEs were associated with a higher % PDL1 expression (OR 1,02 95% CI (1-1,036) p=0,04) and a lower neutrophil-to-lymphocyte ratio baseline (OR 1,19 95% CI (1,03-1,39) p= 0,02). Finally, we found an association between irAEs and the clinical benefit of treatment (partial response + complete response + stable disease) (p<0,001)

Conclusions: irAEs could be related to low NLR and expression of PDL-1, in addition to some HLA-I types seem to be related to the presence of irAEs. Further studies with more patients in our setting would be necessary to corroborate our findings.

Keywords: HLA, irAEs, NSCLC

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.67 Longitudinal ctDNA Profiling in HER2-Altered NSCLC Treated With HER2 Adc: Preliminary Results From the RESOLUTION Trial

C. Su[1], J. Chen[1], X. Zhang[1], L. Liu[1], J. Zhao[1], G. Gao[1], J. Zhu[1], S. Zhao[1], H. Tang[2], C. Jia[2], S. Jia[2]
[1]Department of Medical Oncology, Shanghai Pulmonary Hospital & Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai/CN ,[2]Huidu (Shanghai) Medicine Ltd., shanghai/CN

Introduction: Circulating tumor DNA (ctDNA) testing offers a non-invasive approach to identify actionable genetic alterations and monitor treatment response in advanced non-small cell lung cancer (NSCLC). In patients with HER2-mutant NSCLC, ctDNA profiling enables dynamic assessment of tumor burden and molecular changes, supporting more precise therapeutic decision-making. RC48, a novel antibody-drug conjugate (ADC) targeting HER2, has demonstrated promising anti-tumor activity in various solid tumors. ctDNA-guided strategies may enhance the clinical utility of ADCs like RC48, particularly in the context of combination regimens with immunotherapy or anti-angiogenic agents. Further investigation is warranted to explore ctDNA-informed treatment approaches in HER2-altered NSCLC.

Methods: RESOLUTION is a single-arm, phase II clinical trial investigating the efficacy and safety of a novel combination therapy in treatment-naïve patients with locally advanced or metastatic NSCLC harboring HER2 alterations. A total of 28 eligible patients will receive disitamab vedotin (2.0 mg/kg), tislelizumab (200 mg), and bevacizumab (7.5 mg/kg), all administered intravenously every 3 weeks, until disease progression or unacceptable toxicity. To enable non-invasive, real-time monitoring of tumor dynamics, longitudinal circulating tumor DNA (ctDNA) testing is incorporated as a key exploratory component of the trial. Peripheral blood samples are collected at baseline (C1D1), on-treatment (C3D1, C5D1, C7D1, and C10D1), and at the time of disease progression (PD). ctDNA profiling is performed using PredicineCARE, a targeted next-generation sequencing (NGS) assay covering 152 cancer-related genes, and PredicineEPIC, a genome-wide methylation assay. These assays are employed to characterize mutation and methylation patterns in ctDNA, enabling the evaluation of molecular response and potential mechanisms of resistance throughout the course of treatment.

Results: From April 2024 to January 2025, 11 patients were enrolled in the study, and 9 patients were evaluable for efficacy. Among these patients, 3(33.3%) achieved a partial response and 6(66.6%) had stable disease. The confirmed ORR was 33.3%, and the median duration of response was 5.1 months.A total of 29 blood samples from 9 patients were analyzed using the PredicineCARE assay. Across all samples, the assay detected 167 mutations and 148 copy number variations (CNVs). At baseline, 56 mutations and 79 CNVs were identified. The most frequently altered genes at baseline (>50% of patients) were ERBB2 (7/9), TP53 (7/9), and AKT3 (5/9). Tumor fractions were estimated based on the allele frequencies of detected mutations in each sample. A reduction in tumor fraction was observed at C3D1 in 5 of 9 patients, while the remaining patients maintained stable levels. Notably, an increase in tumor fraction was detected as early as C5D1 in 6 patients, which was concordant with and preceded clinical progression. Methylation analyses are currently ongoing.

Conclusions: Our result suggested the combination therapy is a promising treatment strategy for NSCLC with HER2 alteration. The first-stage interim analysis revealed acceptable efficacy to support proceeding to the further stage. Longitudinal ctDNA analysis enabled dynamic monitoring of tumor burden and early detection of disease progression, underscoring its potential as a non-invasive tool for real-time treatment response assessment.

EP.06.68 Clonal Hematopoiesis (CH)-Derived Mutations Detected in Non-Small Cell Lung Cancer (NSCLC) Liquid Biopsies (LBx)

D. Kozono[1], D.R. Gandara[2], A.D. Fine[3], D.W. Brown[3], R. Hodges[3], J.D. Hughes[3], C. Xu[3], B. Yilmazel[3], K. Johnson[3], M. McDevitt[3], R.W. Madison[3], A.B. Schrock[3], A. Gasco[3], H. Tukachinsky[3]

[1]Brigham and Women's Hospital/Dana-Farber Cancer Institute, Boston/MA/USA ,[2]University of California, Davis Comprehensive Cancer Center, Sacramento/CA/USA ,[3]Foundation Medicine Inc, Boston/MA/USA

Introduction: CH results from fitness-enhancing mutations in hematopoietic stem cells. Although many CH mutations are in hematological driver genes, some occur in genes with solid tumor relevance (e.g. TP53, ATM, CHEK2). We report the prevalence of CH mutations in genes relevant to NSCLC.

Methods: For LBx from 762 patients with NSCLC, plasma cell-free DNA and white blood cell (WBC) DNA were sequenced in parallel at equal depth on the FoundationOne®Liquid CDx platform. A variant origin prediction (VOP) algorithm leveraging fragmentomics and other features, trained and validated using WBC, was used to classify mutation origins in 21,456 additional NSCLC LBx.

Results: In the WBC-sequenced cohort (N=762), CH mutations in EGFR were detected in 2 (0.3%) samples (T415K and V843I), in BRAF in 3 (0.4%) (T244P, K499Q, D594N), and in KRAS in 4 (0.5%) samples (G12D, V14I, I24N, A59G). Established driver mutations were detected as tumor-somatic [EGFR in 86 (11.2%) (L858R, exon19 deletions, exon20 insertions, G719X, S768I, L861Q), ERBB2 in 9 (1.2%), BRAF V600E in 8 (1.0%), and MET exon14 skipping in 8 (1.0%)]; none of these were CH. CH mutations in genes with emerging clinical implications in NSCLC were detected at low frequencies: 16 (2.0%) NF1, 4 (0.5%) TP53 Y220C and RB1, and 1 (0.1%) KEAP1 and SMARCA4. For the VOP cohort (N = 21,456), Figure 1 shows the prevalence of predicted CH origin mutations in relevant genes. Figure 2 shows the predicted tumor-somatic versus CH origin distribution of specific variants in KRAS, EGFR, and BRAF.

Conclusions: CH does not appreciably confound detection of established targets in NSCLC LBx. However, emerging targets such as TP53 Y220C, BRAF nonV600E, and SMARCA4 mutations may be CH-derived in some LBx and ruling out CH origin via tissue testing, equal depth WBC sequencing, or algorithmic prediction of origin may be advisable.

Figure 1 Prevalence of predicted CH origin of NSCLC targetable variants and emerging targets in 21,456 LBx

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.69 Real-World Utilization of Tissue-Free ctDNA Monitoring in Patients With Lung Cancer on Targeted Therapies +/- Chemotherapy

H. Husain[1], W. Li[2], L. Pasquina[2], R. Madison[2], A. Gasco[2], M. Childress[2]
[1]University of California San Diego, San Diego/CA/USA ,[2]Foundation Medicine Inc, Boston/MA/USA

Introduction: Evidence increasingly supports utilizing circulating tumor DNA (ctDNA) monitoring for early treatment response and emerging resistance in patients with advanced or metastatic disease receiving targeted therapy (TT). However, little is known about the real-world utilization of ctDNA monitoring in this setting. Here we describe the use of a tissue-free ctDNA monitoring assay in patients with lung cancer receiving TT.

Methods: The clinical laboratory developed test, FoundationOne®Monitor, was available on a limited pilot to 90 physicians familiar with liquid biopsy to use in their practice. The schedule and number of tests were at the physician's discretion. Enrollment was on a rolling basis. Current/planned therapy abstraction was requested but not required. ctDNA was detected and quantified by ctDNA tumor fraction (TF), and variants were tracked with variant allele frequency (VAF).

Results: Across multiple US oncology practices, 34 physicians ordered FoundationOne®Monitor for lung cancer patients between 09/30/2024-02/17/2025. A total of 535 tests for 349 patients were ordered, with 526 tests (98.3%) yielding results and a median turnaround time of 8 days. Therapies were abstracted for 193 patients and included 59 (31%) TT and 11 (6%) chemotherapy+TT (chemo+TT). 3 patients switched to or added TT, and 8 switched away from TT or removed TT from chemo+TT during testing. At data cutoff, the median time on the pilot was 46.5 days (interquartile range [IQR]: 29.3-65). Restricting to patients enrolled ≥65 days to allow for serial monitoring (n=179), the median number of tests per patient was 2. The median interval between first and second tests was 51 days (IQR: 35-72) and was similar among patients receiving TT or chemo+TT. The median cadence of serial testing (3+ tests, n=42 patients) was 33.3 days (IQR: 27.8-42). Patients receiving TT (n=13) or chemo+TT (n=2) had similar cadence. Among patients receiving TT or chemo+TT, the range of ctDNA TF across all timepoints was 0-43% with 0.19% being the lowest detected value. The lowest known/likely pathogenic, targetable variant VAF detected was 0.06%. 28.6% (12/42) of patients exhibited dynamic ctDNA TF throughout testing (timepoint results: newly detected TF: 4; increase: 5; <50% decrease: 1; >=90% decrease: 3; clearance: 7). Of patients with ctDNA TF detected, 31.6% (6/19) cleared ctDNA TF in a median of 46.5 days from the first test, all but 1 receiving TT alone. A total of 298 unique known/likely pathogenic alterations were detected. Changes in ctDNA TF, copy number alterations, and VAF of target genes were complementary. New variants emerged after the first test in 23 patients. Emergence of new known/likely pathogenic variants co-occurred with increased or stable ctDNA TF in 30.4% (7/23) of patients with new emerging variants and included known resistance alterations. When new variants emerged while ctDNA TF decreased, variants were in known clonal hematopoiesis-associated genes.

Conclusions: ctDNA-based monitoring at the discretion of physicians across US-based institutions indicated a preference for monitoring every 4-6 weeks across lung cancer subtypes and therapy classes. Among patients receiving TT or chemo+TT, dynamic changes in ctDNA TF and detected variants were observed that informed response and interpretation of imaging.

EP.06.70 Development and Clinical Application of Ultra-Sensitive Digital EV Assay Targeting GLUT1 for Early Diagnosis of Non-Small Cell Lung Cancer

T. Kato, H. Huang, T. Ryo, Y. Imamura, Y. Nomata, H. Takenaka, H. Watanabe, Y. Kawasumi, K. Nakanishi, Y. Kadomatsu, H. Ueno, S. Nakamura, T. Mizuno, T.F. Chen-Yoshikawa
Nagoya University, Nagoya/JP

Introduction: Lung cancer remains the leading cause of cancer-related mortality worldwide. The five-year survival rate for lung cancer patients diagnosed at an advanced stage is dismal; however, early detection significantly improves clinical outcomes. In this study, we have developed a novel liquid biopsy method for the early diagnosis of non-small cell lung cancer using intratumoral extracellular vesicles (EVs) extraction technology and an ultrasensitive digital EV assay (UDA). UDA captures target EVs by coupling magnetic beads with capture antibodies and detection antibodies and then enhances the fluorescent signal with tyramide and detects them by flow cytometry. This is an assay that achieves ultrasensitive results that surpass those of conventional ELISA.

Methods: We extracted intratumoral EVs from four lung adenocarcinoma and squamous cell carcinoma specimens from surgical cases at our hospital, and four normal lung specimens from the same patient, and performed proteomic analysis using 10 plex TMT labeling together with two lung cancer cell line EVs. We also integrated lung cancer gene expression data from The Cancer Genome Atlas (TCGA) and predicted location data from the Human Protein Atlas (HPA) to identify candidates for lung cancer-specific EV surface proteins. We also performed UDA targeting candidate proteins using patient plasma.

Results: Proteomic analysis of intratumoral EVs detected 1653 proteins. Using these, PCA analysis made it possible to distinguish between lung cancer and normal lung. By calculating the fold change between lung cancer and normal lung from tissue EVs and TCGA data and comparing the two data, 50 common proteins were detected, and further integrating HPA data, GLUT1 was identified as a lung cancer-derived EV surface protein. UDA targeting GLUT1 was performed using 38 lung cancer plasma samples and 9 non-cancer plasma samples from our department, and ROC analysis was performed, resulting in an AUC of 0.776. When this was analyzed in combination with CEA and CYFRA, the AUC was 0.860. In the study of stage I lung cancer, UDA alone showed an AUC of 0.833, and when combined with CEA and CYFRA, the AUC was 0.883.

Conclusions: By combining tissue EV analysis and UDA, we have developed an innovative liquid biopsy method that targets previously unknown extremely low-abundance EV surface proteins. We will continue to utilize this liquid biopsy method to develop biomarkers that contribute to early diagnosis and precision medicine for lung cancer.

EP.06.71 Clinical Application of Expert Software Based on Tumor Biomarkers to Stratify Lc-Risk in a Hospital Thoracic Tumor Committee

A. Barco Sánchez[1], E. Luque Crespo[2], A. Wals Zurita[2], T. Garcia Manrique[2], L. De Cabo Lopez[3], J. Trape Pujol[4], J. Moreno Conde[2]
[1]Hospital Universitario Virgen Macarena, Seville/ES ,[2]Hospital Universitario Virgen Macarena, Sevilla/ES ,[3]External consultant, Barcelona/ES ,[4]Althaia Xarxa Assistencial Universitària de Manresa, Manresa/ES

Introduction: Lung cancer (LC) is responsible for 1.8 million deaths annually. While low-dose computed tomography (LDCT) aids early detection, its availability is limited. Tumor biomarkers (TBs) provide a complementary diagnostic tool, though their optimal combination remains uncertain. We collaborated with Dr. Molina's group to develop an expert software to interpret TB panels. This study evaluates the effectiveness of the expert software "CLAUDIA", enhancing clinical decision-making in the Thoracic Tumor Committee.

Methods: A prospective study was conducted at Macarena University Hospital, including all patients evaluated by the Thoracic Tumor Committee for suspected LC in 2023. Patients were assessed following international guidelines. TB levels were measured and analyzed using CLAUDIA, an expert software trained on over 5,000 cases. The software classified the LC risk as high, moderate, or low. With moderate-risk cases, we recommend reanalyzing after 3-4 weeks. The software's reports were compared with final histopathological diagnoses, classified per WHO 2015 guidelines. Serum TB concentrations were measured using electrochemiluminescent assays.

Results: Among 138 cases assessed, 16 patients with renal failure were excluded as it may interfere with TB levels. Of the remaining 122 patients, 89 (73%) were diagnosed with cancer: 32 (36%) adenocarcinomas, 22 (25%) squamous cell carcinomas, 17 (20%) nonspecific NSCLC cases, and 12 (13%) small cell carcinomas (SCLC) (6 other histologies). Radiographic nodules were the primary diagnostic trigger. The CLAUDIA software correctly identified 89.57% of cases, showing a Sensitivity: 91%, Specificity: 84.6%, positive predictive value: 95.3% and negative predictive value: 73.3%. 12 patients were classified as moderate risk, of which 4 were finally no cancer and 8 LC. In addition to the risk of LC, the software suggests the most likely histological subtype taking into account the different TB expression patterns. The percentage of success in discriminating between SCLC and NSCLC was 99%.

Conclusions: This study confirms the effectiveness of a six-TB panel (CEA, CA 15-3, SCC-Ag, CYFRA 21-1, NSE, and ProGRP) combined with CLAUDIA software in diagnosing LC. The software enhances diagnostic accuracy (89,5%) and facilitates rapid decision-making, improving patient care. CLAUDIA provides a valuable tool for risk stratification and clinical decision support, particularly in Rapid Diagnostic Units.

EP.06.72 Lung Cancer EGFR Mutation Prediction via cfDNA Fragmentome Profiling

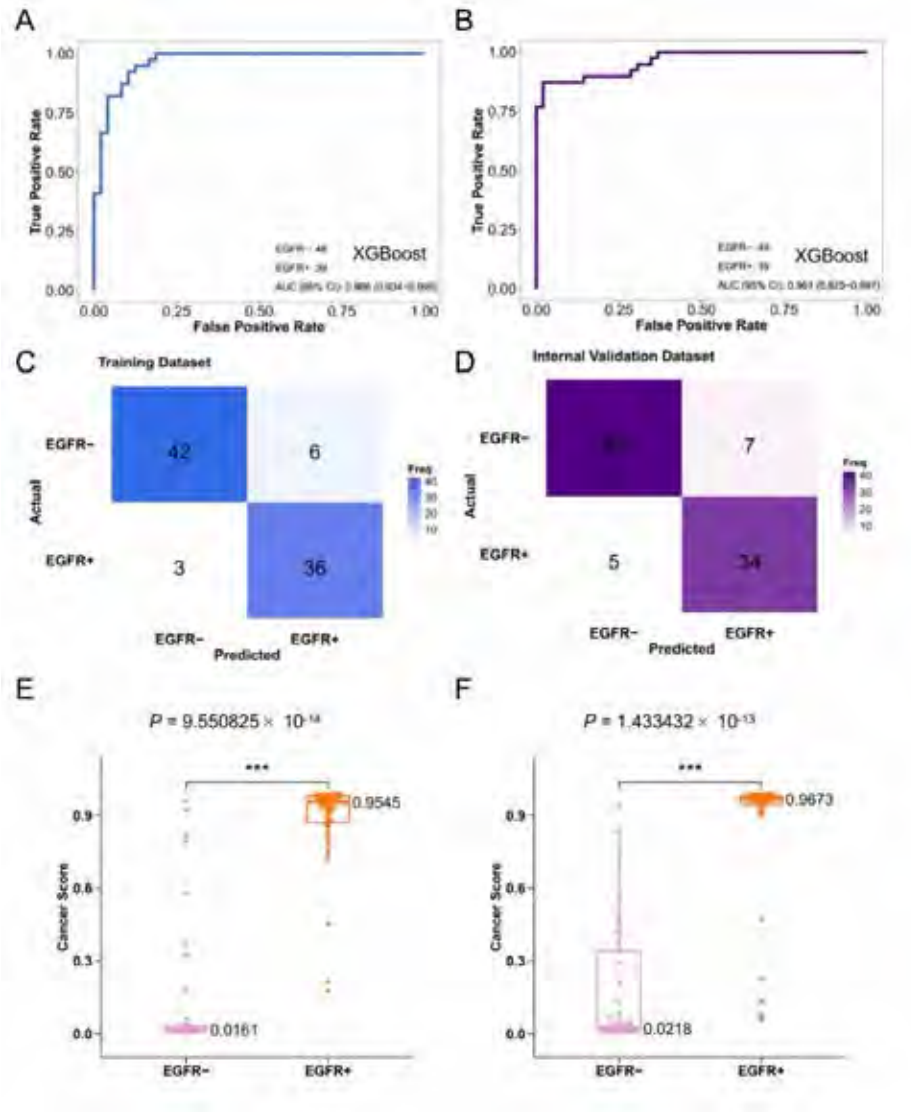
Y. Wang[1], K. Zhou[1], T. Wang[1], L. Miao[1], Z. Lin[2]
[1]Nanjing Drum Tower Hospital, Nanjing/CN ,[2]Zhejiang University, Hangzhou/CN

Introduction: Lung cancer is a leading cause of cancer-related deaths worldwide, and early detection of EGFR mutations has become one of the key indicators in lung cancer gene alterations. cfDNA (Circulating free DNA) is a novel biomarker that enables non-invasive detection of tumor-related mutations through blood samples. This study combines cfDNA sequencing technology with various machine learning models to explore the EGFR mutation prediction.

Methods: We enrolled 175 early lung cancer patients and analyzed their plasma cfDNA samples using whole-genome sequencing (WGS). In the training cohort, multiple features were extracted, including fragment length, 3' end motif, methylation motif, N-index, E-index, and CNV, which were used as input features for analysis. We predict EGFR mutation-positive population using generalized linear models (GLM) and support vector machines (SVM), while also combining XGBoost models. We conducted extensive evaluation on the validation dataset. By comparing the predictions of different models, we were able to validate the accuracy, sensitivity, specificity, and generalizability of these models in EGFR mutation prediction, thus providing strong data support for clinical application.

Results: This study employs deep learning algorithms to conduct multimodal integrated analysis of cfDNA molecular omics, copy number variations, and epigenetic characteristics, aiming to achieve the precise prediction of EGFR mutation. Through the analysis of relevant features, differences were revealed in various features, including terminal motifs and breakpoint features. The EGFR mutation prediction model built based on these features showed excellent performance in the training set (n = 87, specificity 87.5%, sensitivity 92.3%, AUC: 0.966) and maintained consistency in the validation cohort (n = 88, specificity 65.3%, sensitivity 97.4%, AUC: 0.953).

Conclusions: This study developed a deep learning model based on cfDNA multi-dimensional omics features, focusing on the precise analysis of EGFR mutation prediction. This approach provides a highly sensitive, non-invasive solution for early detection of EGFR mutation.



Keywords: blood omics, machine learning, EGFR mutation

EP.06.73 Co-Driver Mutations in Fusion-Positive NSCLC: Liquid Biopsy Insights From 2,369 Patients

L.C. Roisman[1,2], W. Kian[3], A. Anoze[4], R. Gillis[4], D. Kahala[4], D. Levitas[3], R. Grinberg[4], N. Asna[4], S. Jain[5], L. Soussan-Gutman[6], S. Olsen[5], N. Peled[4]
[1]Assuta Ashdod Hospital, Ashdod/IL, Jerusalem/IL ,[2]Ben Gurion University, Beer Sheva/IL ,[3]Assuta Ashdod Hospital, Ashdod/IL ,[4]Shaare Zedek Medical Center, Jerusalem/IL ,[5]Guardant Health Asia Middle East and Africa, Singapore/SG ,[6]Rhenium Oncotest Ltd., Modi'in-Maccabim-Re'ut/IL

Introduction: While kinase fusions represent established therapeutic targets in non-small cell lung cancer (NSCLC), the co-occurrence of additional driver mutations may influence treatment response and resistance mechanisms. This study characterizes the landscape of co-driver mutations across different fusion architectures in ALK, RET, and ROS1 fusion-positive NSCLC from liquid biopsy.

Methods: Comprehensive genomic profiling of 2,369 lung cancer patients with fusion genes was performed using liquid biopsy (Guardant360) from October 2016 to September 2022. Patients were stratified by primary driver (ALK: n=1,506; RET: n=594; ROS1: n=269) and fusion architecture: nonreciprocal fusions (NRF: 5 -partner-3 -kinase), reciprocal fusions (RF: 5 -kinase-3 -partner), or bidirectional reciprocal and nonreciprocal fusions (BRNRF: concurrent RF and NRF). Co-occurring genomic alterations were analyzed for frequency, distribution, and association with fusion partners and breakpoints.

Results: Notable differences in co-mutation profiles were observed across kinase fusions. EGFR alterations demonstrated fusion-specific distributions: amplifications were more prevalent in RET fusions (9.2% overall; 16.4% in BRNRF) compared to ALK (7.8%) and ROS1 (3.0%), while Exon 19del mutations were enriched in RET fusions (10.6% overall; 14.1% in NRF). Partner-specific analysis revealed EGFR Exon 19del was predominantly detected in CCDC6-RET NRF (11.1%), and EGFR amplifications in EML4-ALK NRF (6.1%) and KIF5B-RET BRNRF (16.7%). KRAS G12* mutations were more frequent in RET (4.0%) than ALK (2.0%) or ROS1 (0.7%) fusions, with the highest prevalence in RET-NRF (4.7%) and were primarily observed in EML4-ALK NRF (1.9%), CCDC6-RET NRF (3.3%), and CD74-ROS1 BRNRF (2.0%). MET amplifications showed distinct patterns: ALK (5.6% overall), RET (6.2% overall with enrichment in BRNRF at 9.4%), and rare in ROS1 (1.0%), with highest frequencies in EML4-ALK NRF (4.7%) and KIF5B-RET BRNRF (5.1%). These co-mutations followed specific patterns across fusion architectures, with EGFR and MET alterations enriched in BRNRF and RF architectures, particularly in RET fusions, compared to NRF variants.

Conclusions: This large-scale genomic analysis reveals distinct co-driver mutation landscapes across kinase fusion architectures in NSCLC, with RET fusions showing the highest frequency of actionable co-alterations. The partner-specific and architecture-dependent distribution of co-driver mutations suggests potential functional implications in disease biology and therapeutic response. These findings provide molecular rationale for incorporating comprehensive genomic profiling into diagnostic protocols and considering co-driver mutation status in therapeutic decision-making for kinase fusion-positive NSCLC patients.

EP.06.74 Clinical Validity of Repeated CTCs and CAM-L Enumeration in Treatment Monitoring of Metastatic Non-Small Cell Lung Cancer

M. Siringo[1,2], M. De Meo[1], C. Nicolazzo[3], A.J. Gelibter[4], P. Gazzaniga[1]
[1]Sapienza university of Rome, Rome/IT ,[2]Sant'Andrea Hospital, Rome/IT ,[3]Link Campus University, Rome/IT ,[4]Policlinico Umberto [1], Rome/IT

Introduction: The introduction of targeted therapies and immune checkpoint inhibitors (ICIs) has improved survival in metastatic non-small cell lung cancer (mNSCLC). However, reliable biomarkers to predict patient prognosis are needed. Circulating tumor cells (CTCs) have been identified as a prognostic factor associated with poor overall survival (OS). Moreover, cancer-associated macrophage-like cells (CAM-Ls), circulating macrophages that have internalized dying tumor cells before re-entering circulation, are emerging as a promising biomarker. Nevertheless, the role of their combined enumeration for mNSCLC is unexplored.

Methods: Serial CTC/ CAM-L levels were analyzed in 77 patients with mNSCLC treated with first-line regimens, specifically ICIs (39%), targeted therapies (22%), or chemotherapy (39%). Blood samples were analyzed for CTC and CAM-L levels at baseline (T0) and after three months (T1) using the CellSearch platform. The association of these biomarkers with progression-free survival (PFS) and OS was evaluated. Multivariate analysis adjusted for tissue PD-L1, treatment type, number of metastasis, and age was performed.

Results: Using a ≥1 CTC cut-off for positivity, 21 patients had 0 CTCs at both T0 and T1 (neg/neg), 10 and 17 patients converted between CTC negative and positive (neg/pos, pos/neg), and 29 patients had ≥1 CTC at both time points (pos/pos). MedianOS for the groups was 26, 33, 10, and 10 months, respectively (p<0.0001), and medianPFS was 13, 18, 5, and 6 months, respectively (p<0.0001). CTC non-responders (pos/pos) showed shorter PFS and OS compared to CTC responders (pos/neg). T1-CTC negativity and T1-CAM-L positivity were associated with better PFS and OS, independent of clinical factors. CAM-L positivity was more frequent in the ICIs-treated population (OddsRatio 3.53, 95% CI 1.34-9.25; p=0.009).

Conclusions: Serial assessments of CTCs and CAM-Ls are strong independent predictors of PFS and OS. These findings suggest their potential as prognostic biomarkers in mNSCLC and highlight the need for further clinical trials to validate their utility.

	PFS			OS		
	HR	CI 95%	p	HR	CI 95%	p
Overall population (77 patients)						
T1 CTC pos vs T1 CTC neg	5.91	2.58-13.54	<0.0001	6.68	2.72-16.44	<0.0001
CTC resp vs CTC non-resp	15.47	3.63-65.95	<0.0001	8.94	2.35-33.92	0.001

Introduction: Targeted therapies have revolutionized treatment and outcomes for patients with advanced non-small cell lung cancer (NSCLC). Despite these advances, treatment resistance eventually occurs. To better understand mechanisms of resistance to targeted therapy, patients require a repeat tissue biopsy and genomic testing which is often challenging for patients. Liquid biopsy with circulating tumor (ct)DNA analysis may yield a less invasive, faster approach for molecular diagnosis of resistance.

Methods: Targeted therapies have revolutionized treatment and outcomes for patients with advanced non-small cell lung cancer (NSCLC). Despite these advances, treatment resistance eventually occurs. To better understand mechanisms of resistance to targeted therapy, patients require a repeat tissue biopsy and genomic testing which is often challenging for patients. Liquid biopsy with circulating tumor (ct) DNA analysis may yield a less invasive, faster approach for molecular diagnosis of resistance.

Results: As of January 2025, 75 eligible patients were enrolled, with a median age of 66 years; 56% were female, 99% had adenocarcinoma and 72% were never-smokers. The most common baseline actionable genomic alterations (AGAs) at enrollment were EGFR mutations (53/75, 71%) and ALK rearrangements (13/75, 17%). At the time of analysis, plasma ctDNA testing was completed for 67 patients (1 insufficient ctDNA, 7 pending). Compared to pre-treatment NGS results, 14% (9/66) gained AGAs and 36% (24/66) had loss of AGAs (Table 1). Gains included EGFR C797S, BRAF V600E, KRAS G12C, ERBB2 ex20ins and EGFR amplification. In addition, 36% (24/66) had variants reported consistent with clonal hematopoiesis (variant allele frequency =>2%).

Conclusions: Preliminary data demonstrate that plasma-based ctDNA NGS with the TSO500™ can detect emergent alterations in 14% of patients in a real-world setting. This has the potential to inform targeted therapeutic strategies and avoid costly and invasive repeat tissue biopsies. The observed loss of AGAs could be explained by post-therapy driver mutation clearance or insufficient ctDNA levels, although further exploration is needed.

EP.06.76 Real-World Use of Tissue-Free ctDNA Monitoring in Patients With Lung Cancer Receiving Immunotherapy And/Or Chemotherapy

H. Husain[1], W. Li[2], L. Pasquina[2], R. Madison[2], A. Gasco[2], M. Childress[2]
[1]University of California San Diego, San Diego/CA/USA ,[2]Foundation Medicine Inc, Boston/MA/USA

Introduction: Circulating tumor DNA (ctDNA) is an emerging biomarker for monitoring early treatment response in patients with advanced lung cancer receiving immunotherapy (IO) and/or chemotherapy (chemo). However, optimal monitoring timing and cadence in this setting is unknown. Here we describe the real-world use of a tissue-free ctDNA monitoring assay in patients with lung cancer receiving IO and/or chemo.

Methods: The clinical laboratory developed test, FoundationOne®Monitor, was available in a limited pilot to 90 physicians familiar with liquid biopsy. The schedule and number of tests were determined by each local medical team as appropriate for their practice. Enrollment was rolling. Therapy abstraction was requested but not required. ctDNA was detected and quantified by ctDNA tumor fraction (TF), and variants were tracked with variant allele frequency (VAF).

Results: The range of ctDNA TF was 0 - 83%. The lowest ctDNA TF and pathogenic variant VAF values detected were 0.15% and 0.09% respectively. Changes in ctDNA TF were observed in 56% (27/50) of patients during their course of testing (timepoint results: newly detected: 8; increase: 17; <50% decrease: 5; 50-89% decrease: 7; 90-99% decrease: 1; clearance: 7). Of patients with ctDNA TF detected, those receiving IO monotherapy were less likely to have clearance of ctDNA TF in the observed time (chemo: 30.8%, 4/13; chemo+IO: 20.0%, 2/10; IO: 12.5%, 1/8,), and only 25.0% (2/8) had 50-90% reduction in ctDNA TF, occurring 47 days after the first test for one patient and after a switch in therapy for the other patient. A total of 458 unique known/likely pathogenic alterations were detected. In patients with multiple tests, 68% (34/50) had new variants emerge after the first test. Emergence of new known/likely pathogenic variants co-occurred with increased or stable ctDNA TF in 28% (14/50) of patients with new emerging variants. For patients in which emerging new variants occurred with ctDNA TF reduction, variants were in known clonal hematopoiesis genes: TP53, DNMT3A, CHEK2.

Conclusions: In real-world ctDNA-based monitoring across lung cancer subtypes, physicians monitored plasma approximately every 1-2 cycles, with a preference for every cycle for patients on chemo+/-IO. A broad range of ctDNA dynamics and emerging variants were observed that informed therapy response and reinforced changes on imaging.

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment, yet their efficacy in non-small cell lung cancer (NSCLC) remains limited. Peripheral immunity plays a key role in antitumor responses, emphasizing the need to look beyond the tumor microenvironment. This study aims to assess changes in peripheral blood cell subsets and their potential correlation with therapeutic efficacy and clinical prognosis in NSCLC patients undergoing ICI treatment, providing insights into the interplay between systemic immunity and treatment outcomes.

Methods: 11 patients with NSCLC and receiving first-line ICI treatment from Consorcio Hospital General Universitario de Valencia were included. Peripheral blood samples were collected in EDTA K2 tubes before treatment initiation. PBMCs were isolated using Ficoll-Paque Plus, and RNA was extracted and analyzed with the nCounter® SPRINT Profiler using the PanCancer Immune panel. Normalized counts were obtained using the nSolver platform. Bioinformatic analysis was performed in R Studio, including heatmaps and principal component analysis (PCA) to explore gene expression patterns. The association between gene expression and survival was assessed using Kaplan-Meier analysis and Cox regression.

Results: PCA analysis did not show a clear distinction between sample groups, preventing the definition of clusters using ellipses. However, the top 20 genes contributing most to sample variability were identified. Unsupervised clustering of these genes stratified patients based on clinical benefit and survival (Figure attached). Gene Ontology (GO) analysis showed that the most highly expressed genes in surviving patients were related to B cell differentiation and activation, while the least expressed genes were associated with Th17 lymphocyte differentiation. Kaplan-Meier analysis revealed that 9 of these 20 genes were significantly associated with patient survival.

Conclusions: Our findings highlight the critical role of peripheral immune dynamics in shaping immunotherapy outcomes in patients with NSCLC. While global gene expression did not clearly differentiate patient groups, a subset of 20 genes was identified as key contributors to sample variability and was associated with clinical benefit and survival. These results underscore the potential of peripheral immune markers in predicting response to ICIs and warrant further investigation in larger cohorts.

EP.06.78 T Lymphocyte Subpopulations as Predictive Biomarkers in Non-Small Cell Lung Cancer Patients Treated With Anti-Pd(L)1 Inhibitors

T. Moran-Bueno[1], A. Hernández González[1], F. Grau Leal[2], M. Domenech Viñolas[1], A. Notario Rincón[1], C. Mariño Siancas[1], E. Martinez-Caceres[3], C. Zurera[3], L. Herrera Martinez[1], M. Batllori Casanovas[1], S. Sánchez Martin[1], A. Esteve Gomez[1], A. Gonzalez Valencia[1], M. Cucurull Salamero[1], M. Saigi Morgui[1], E. Carcereny Costa[1], J. Climent Marti[3]
[1]Catalan Institute of Oncology, Badalona/ES ,[2]Institut Germans Trias i Pujol, Badalona/ES ,[3]Hospital Universitari Germans Trias i Pujol, Badalona/ES

Introduction: Immune Checkpoint Inhibitors (ICIs) have revolutionized NSCLC treatment. However, patient response varies significantly, highlighting the need for reliable predictive biomarkers. This study investigated peripheral blood T lymphocyte subpopulations in lung cancer patients receiving anti-PD(L)1 therapy, analyzing their relationship with tumor characteristics, treatment response, and tumor progression.

Methods: Peripheral blood T lymphocyte subpopulations were analyzed in 50 NSCLC patients receiving anti-PD1/PDL1 in monotherapy as first and second line or consolidation after chemoradiotherapy. Immunophenotyping was performed using multiparametric flow cytometry with a comprehensive panel of memory/differentiation markers and expression of co-stimulatory/activation molecules. Cytometry data analysis was conducted using conventional gating strategies and multiparametric high-dimensional approach. Clinical stratification was based on tumor stage (III vs IV) according to TNM classification, and treatment response using RECIST criteria. Statistical analyses for conventional cytometry data were performed using R software and high-dimensional cytometry data underwent unsupervised multiparametric analysis using the R-edge algorithm. Currently, single-cell RNA sequencing analysis and TCR clonotype profiling are being completed in a subset of patients (N= 14).

Results: Significant differences in peripheral T lymphocyte subpopulations correlated with tumor stage, with stage IV patients exhibiting higher proportions of naive-like T cells compared to stage III patients. Effector memory (EM) T cells with mixed Th1/17 phenotype showed significant reduction in non-responders and at tumor progression. Double-positive (CD27+CD28+) EM T cells correlated with improved treatment outcomes

Conclusions: The study identified distinct T-cell immunological signatures that serve as potential biomarkers for advanced tumor stage characterization, therapeutic response and tumor progression monitoring. These findings could provide a more precise immune status assessment for patient stratification and treatment response evaluation in patients with PD(L)1 blockade therapy

Keywords: peripheral blood T lymphocyte subpopulations, anti-PD(L)1 therapy, Non-small cell lung cancer

EP.06.79 Liquid Biopsy Shortens Time to Diagnosis and Treatment Selection: Primary Results From the International L1St Study

F. Barlesi[1], V. Muthu[2], L. Sánchez Lorenzo[3], A-M. Baird[4], S. Peters[5], F. Touri[6], M. Hazar Rethinam[6], N. Chalabi[6], F. Ciardiello[7]
[1]Gustave Roussy, Villejuif/FR ,[2]Marivek Healthcare Consulting, Epsom/GB ,[3]Clínica Universidad de Navarra, Madrid/ES ,[4]Lung Cancer Europe, Dublin/IE ,[5]Lausanne University Hospital, Lausanne/CH ,[6]F. Hoffmann-La Roche Ltd, Basel/CH ,[7]Università degli Studi della Campania Luigi Vanvitelli, Naples/IT

Introduction: Timely, comprehensive (tissue/liquid) molecular testing is required to identify effective molecularly guided treatment for advanced cancer. Standard sequential assessments often delay decisions by weeks; minimising this is critical to improving patient outcomes. L1st (NCT05846594) assesses the potential of liquid-based comprehensive genomic profiling (by FoundationOne®Liquid CDx; F1LCDx®) to streamline standard of care (SoC) diagnostic workup and expedite clinical decision-making and treatment start in people with clinical suspicion of advanced lung (presented here)/gastrointestinal cancers.

Methods: F1LCDx was performed in participants who did not/did have tissue biopsy prior to enrolment (basic/extended workup, respectively). The report was provided to the treating physician as soon as results were available. Primary endpoint: time from diagnostic pathway initiation (date of first request for biopsy/tissue/blood by a healthcare professional) to complete pathological and molecular workup (time to diagnosis; TTD), per ESMO/national guidelines, in the basic workup group. Secondary endpoints: time from diagnostic pathway initiation to anticancer treatment recommendation after complete pathological diagnosis (TTR); concordance between F1LCDx and SoC treatment recommendation (TR).

Results: By clinical cutoff (23 Oct 2024), 159 participants had basic workup; 98, extended. Median F1LCDx vs SoC TTD: 15.0 vs 34.0 days (median difference -14.0; Wilcoxon signed rank P < 0.0001) with basic workup (primary endpoint); 14.0 vs 35.0 days (median difference -17.0; P < 0.0001), with any workup (Figure) (also significant with extended workup). Median F1LCDx vs SoC TTR with any workup: 20.0 vs 43.0 days (median difference -16.0; P < 0.0001). F1LCDx and SoC TR concordance with any workup was 78% (57/73 participants with F1LCDx- and SoC-based TR). 199/242 participants (82%) had genomic alterations. Key alterations, filtered for ESCAT, included BRCA2 (42/242; 17%), EGFR (34/242; 14%), BRCA1 (32/242; 13%), KRAS (28/242; 12%), ALK (25/242; 10%), MET (24/242; 10%), PIK3CA (18/242; 7%), ERBB2 (17/242; 7%) and RET (6/242; 2%). Non-ESCAT-filtered key genomic alterations included RB1 and TP53 (151/242; 62%). 125/187 participants (67%) had a tumour fraction >1%. 41/257 participants (16%) were assigned a first-line targeted therapy based on F1LCDx (vs 31/257 [12%] with SoC).

Conclusions: In advanced lung cancer, high-quality liquid biopsy should become best practice: it allows for significantly improved diagnostic workup and the potential to improve TTR vs SoC by several weeks, as molecular diagnostics can be initiated before tumour specimen collection and reveals complex genomic alterations (e.g., MET Exon 14) that can inform TRs in the first-line (and in subsequent lines) of therapy.

EP.06.80 Immunological Markers of Prognosis in Lung Cancer: T-Cell Subpopulations and Their Correlation With Clinical Outcomes

L. Negrini[1], F. Vezzoli[1], V. Martini[2], G. Cognolato[1], S. Gobbato[1], R. Alsati[1], E. Turki[1], M. Bitrus[1], G. Borra[2], S. Genestroni[2], A. Gennari[1], F. Biello[2]
[1]University of Eastern Piedmont, Novara/IT ,[2]AOU Maggiore della Carità, Novara/IT

Introduction: Immune checkpoint inhibitors (ICIs) have improved outcomes for patients affected by lung cancer (LC), but reliable predictors of treatment efficacy are lacking. T-cell subpopulations have shown promise as biomarkers, since their presence at tumor sites and in peripheral blood seems to correlate with immune responses and clinical outcomes in patients undergoing immunotherapy. Identifying specific circulating T-cell phenotypes could help tailor immunotherapy strategies and optimize patient selection.

Methods: Peripheral blood samples were collected at baseline from patients affected by advanced LC treated with ICIs at the 'Maggiore della Carità' Hospital in Novara, Italy. Analyses were conducted on a subgroup of patients participating in the Immuno-EGA study (n = 32). Flow cytometry was used to assess circulating CD3+, CD4+ (Th), CD8+ (Tc), exhausted (CD28+LAG3+PD1+TIGIT+, Exh), exhausted-like (CD28+PD1+TIGIT+, ExhL), and senescent (CD28-CD57+KLRG1+, Sen) lymphocytes. Associations with overall survival (OS) and progression-free survival (PFS) were evaluated using the Log-rank test and Cox regression. Potential confounders, including age, sex, BMI, and smoking status, were considered in multivariable analyses. The correlation between the percentage of T-cell subpopulations and plasma metabolic biomarkers was assessed using the Spearman test.

Results: Patients with a higher proportion of circulating CD4+ Sen lymphocytes had improved OS (HR 1.02E-06 [1.62E-12 - 0.64], p = 0.043) and PFS (HR 1.17E-11 [1.61E-21 - 0.086], p = 0.030). These associations remained significant after adjusting for age, sex, BMI, and smoking status (table below). Conversely, a higher percentage of peripheral CD4+ Exh cells showed a trend toward worse PFS (HR 63.96 [0.53 - 7729.67], p = 0.089). This subpopulation also positively correlated with plasmatic carboxyhemoglobin (CoHb) percentage (r = 0.55, p = 0.011).

Conclusions: Our preliminary data suggest that characterizing T-cell subpopulations may provide valuable insights into the clinical outcomes of patients with advanced LC treated with ICIs. Further studies on larger patient cohorts are necessary to confirm these observations and explore their potential in guiding personalized immunotherapy.

		Multivariate Cox model adjusted for: age (<65 vs ≥65), BMI (<25 vs ≥25), sex (M vs F) and smoking status (smokers vs non-smokers)			
	T-cell population	HR	Lower HR	Upper HR	Pvalue
OS	CD4+CD28-CD57+KLRG1+	7.83E-13	1.02E-24	0.60	0.0459
PFS	CD4+CD28-CD57+KLRG1+	1.20E-12	2.04E-23	0.07	0.0301

EP.06.81 Observational Study of Concordance Between Tissue-Based ODxTT CDx and In-House Plasma OPA Gene Analysis in NSCLC Patients

K. Nakanishi, K. Ito, S. Matsuura, R. Inoue, M. Esumi, S. Esumi, Y. Fujiura, Y. Suzuki, T. Sakaguchi, Y. Nishii, O. Taguchi, O. Hataji
Matsusaka Municipal Hospital, Matsusaka City/JP

Introduction: Genomic profiling is important in the treatment of non-small cell lung cancer, and the Oncomine Dx Target Test multi CDx system® (ODxTT CDx) is widely used in Japan. However, it is less likely to use in cases where the treatment is rushed because the test requires many slices, and the turnaround time (TAT) takes about 10 days. The Oncomine Precision Assay® (OPA) can be examined on plasma or pleural fluid, and since the test can be performed in our hospital, the TAT takes about one day, so it is expected to be used in cases that require early intervention. The purpose of this study was to investigate the reliability of plasma-based gene profiling using OPA and to examine its consistency with the results of tissue-based ODxTT CDx.

Methods: We retrospectively reviewed the concordance rate and the clinical course of 51 patients who had plasma based OPA and FFPE based ODxTT CDx retrieved at the same time from May 2022 to February 2025 at our hospital.

Results: The sex was 27 males and 24 females, the median ages were 73 years old (40-89years old), and the histology was Ad 39/Sq 10/NOS 2. The median difference between OPA and ODxTT CDx was 5 days (0 - 53 days), and none of the patients received systemic chemotherapy between the examinations. The concordance rate of detectable genetic variants in both OPA and ODxTT CDx was calculated. 36 of 51 cases were matched, with a concordance rate of 70.6% (95% Confidence Interval [CI], 56.2 - 82.5). Next the concordance rate of detectable genetic variants in both OPA and ODxTT CDx was calculated, limited to the driver oncogene. 43 of 51 cases were matched, with a concordance rate of 84.3% (95% CI, 71.4 - 93.0). The positive predictive value of OPA for ODxTT CDx was 95.7% (22/23 cases, 95% CI, 78.1 - 99.9). Three of the four OPA-positive and ODxTT CDx-negative cases were non-driver oncogenes such as PIK3CA, and ERBB2 S310F was detected in one case.

Conclusions: Plasma OPA can detect gene mutations that are useful as first-line therapy, and the concordance rate was high when limited to the Driver oncogene. We suggest that treatment can be initiated without waiting for ODxTT CDx results once a gene mutation is detected in OPA.

Keywords: Genomic profiling, Plasma-based testing, Driver oncogene concordance

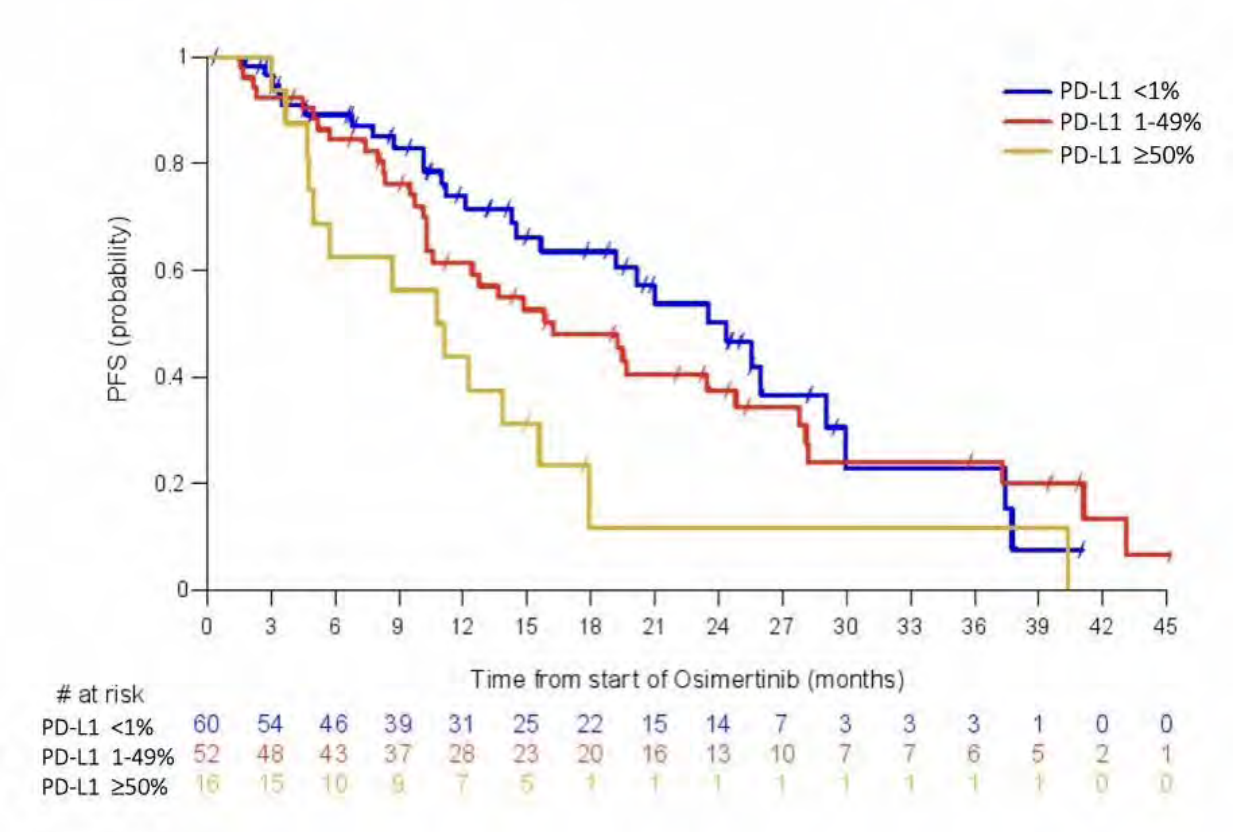
Svizzera Italiana, Bellinzona/CH ,[9]Cantonal Hospital Graubünden, Chur/CH ,[10]University Hospital Basel, Basel/CH ,[11]University Hospital Geneva, Geneva/CH ,[12]Cantonal Hospital Aarau, Aarau/CH ,[13]Seeland Cancer Center, Bern-Biel/CH ,[14]Comprehensive Cancer Center Zurich, Zurich/CH

Introduction: Osimertinib monotherapy is a first-line treatment option for patients (pts) with metastatic non-small cell lung cancer (NSCLC) with a common epidermal growth factor (EGFR) mutation. Recently, osimertinib in combination with chemotherapy and lazertinib in combination with amivantamab have shown improvement in progression free survival (PFS) and overall survival (OS) compared to osimertinib alone. However, increased efficacy comes at the price of more toxicity and patient selection for treatment intensification remains uncertain. Therefore, it's important to identify predictive biomarkers for efficacy of osimertinib. Previous studies suggested a prognostic role of PD-L1 in this setting. We investigated the association of PD-L1 expression with osimertinib outcomes.

Methods: 128 EGFR-mutated pts from 13 Swiss centres with osimertinib first-line treatment and available PD-L1 tumour proportion score (TPS) were retrospectively analysed. Three PD-L1 groups were defined: No expression (<1%), PD-L1 low (1-49%) and PD-L1 high (≥50%). Survival outcomes were compared using the log-rank test. Primary resistance was defined as progressive disease as best response or progression free survival (PFS) < 6 months.

Results: Out of 128 patients 60, 52 and 16 pts had PD-L1 <1%, low and high. Median age was 68 years (range 38-93), 61% were females, 84% had PS ≤ 1, 57% were never smokers, 59% had an exon 19 deletion and 38% L858R exon 21. Patients and tumour characteristics among PD-L1 groups were well balanced except for more pts with exon 21 L858R mutations in the PD-L1 high vs. low vs. PD-L1 <1% group (63% vs. 29% vs. 38%, p=0.009). There was a significant difference in median PFS with 24.4 months (95% CI, 15.6-29.0) for PD-L1 <1% vs. 16.2 months (95% CI, 10.3-24.8) for PD-L1 low vs. 10.9 months (95% CI, 4.7 - 15.6) for the PD-L1 high group (p=0.023). Primary resistance occurred more frequently in PD-L1 high vs. low vs. <1% pts (38% vs. 15% vs. 10%, p=0.027). Median OS was similar among the groups: 65.3 months (95% CI, 38.4-NR) for PD-L1 <1%, 58.1 months (95% CI, 26.7 - 65.0) for PDL-1 low and not reached (95% CI, 18.2-NR) for PD-L1 high pts (p=0.365).

Conclusions: In our real-world data analysis of a Western population with EGFR mutated NSCLC high PD-L1 expression was associated with significantly shorter PFS and a higher proportion of primary resistance to first-line osimertinib. These results indicate that osimertinib may suffice in PD-L1 negative pts, and treatment intensification should be evaluated in PD-L1 positive, particularly PD-L1 high pts.



Keywords: osimertinib, PD-L1, prognostic marker

EP.06 PATHOLOGY AND BIOMARKERS

EP.06.84 Impact of Preoperative Brain Natriuretic Peptide Levels on Postoperative Outcomes in Lung Cancer Patients

S. Otsuka, H. Shiiya, R. Takagi, K. Okada, A. Sasaki, K. Ohtaka, A. Fujiwara-Kuroda, H. Ujiie, M. Aragaki, T. Kato
Hokkaido University Hospital, Sapporo/JP

Introduction: Recent advancements in lung cancer treatment, including surgical intervention and drug therapy have dramatically improved patient prognosis. However, both treatments carry risks of cardiac complications, and cardiovascular hormones like brain natriuretic peptide (BNP) have been known to be associated with the occurrence of these complications. These days, several studies have reported that serum levels of cardiovascular markers could serve as markers for early diagnosis and assessment of disease progression for certain cancers. However, most studies included patients with advanced cancer, without surgical indication, and no reports have focused on lung cancer. This study examines the relationship between preoperative BNP levels, tumor characteristics, and long-term prognosis in lung cancer patients undergoing curative resection.

Methods: Patients who underwent radical resection for lung cancer at our institution from January 2012 to June 2019 were divided into high (≥18.5 pg/ml) and low (<18.5 pg/ml) BNP groups. The cutoff value was determined according to the guideline on heart failure in Japan. Continuous variables were analyzed through the Mann-Whitney U test, while categorical data were examined using Fisher's exact test. Kaplan-Meier curves were used to analyze postoperative overall survival (OS) and relapse-free survival (RFS). To adjust for baseline characteristic imbalances between two groups, an analysis with propensity score matching focusing on the cohort excluding cases in which limited resection was performed due to the risks of lobectomy was conducted. Cumulative incidence function was analyzed using the Gray's test. Multivariate Cox proportional hazards models were used to identify the independent predictors of postoperative OS.

Results: The final cohort includes 430 patients, composed of 222 higher BNP patients and 208 lower BNP cases. In the group with higher BNP, patients tended to be older ($p<0.01$) and had a higher prevalence of underlying comorbidities such as ischemic heart disease ($p<0.01$) and interstitial pneumonia ($p<0.01$). To evaluate the association among tumor size, maximum standardized uptake value (SUVmax) on positron emission tomography, and BNP levels, we calculated the Spearman's rank correlation coefficients. No significant correlation was found between BNP levels and tumor size (Spearman's rho=0.021, p=0.66) or SUVmax (Spearman's rho=0.075, p=0.12) . The patients with elevated BNP levels had lower OS (p=0.03) but no significant difference was observed in the RFS (p=0.09). In a subgroup limited to patients who can tolerate lobectomy, blood BNP levels were associated with OS before (p=0.03) and after propensity score marching (p=0.03) as well. Competing risk event analysis revealed higher mortality due to diseases other than lung cancer in the high BNP group ($p<0.05$), but there was no association between blood BNP levels and postoperative recurrence (p=0.86). Multivariate analysis showed male sex (HR: 2.10, 95% CI: 1.37-3.23) and pathological stage ≥II (HR: 2.32, 95% CI: 1.56-3.45) were independently associated with the OS. The HR for preoperative BNP levels was 1.49 (95% CI: 0.96-2.30).

Conclusions: Preoperative BNP levels in patients with lung cancer may reflect potentially compromised patient condition and show an association with postoperative OS. Nevertheless, no significant association was observed between tumor progression and BNP levels.

EP06.85 Real-World Performance of NGS Panels in Detecting Actionable Genomic Alterations in NSCLC

M. Querol Vilà[1], E. Marin[2], A. Arcocha[1,2], D. Martínez[1], C. Montironi[1,2], P. Alonso[1], E. Hernández[1], A. Carrasco[1], J.C. Laguna[1,2], A. Navarro[2,3], C. Lucena[1], M. Sanchez[1], C. Agustí[1], R. Marrades[1], L. Mezquita[1,2,3], N. Reguart[1,2,3], C. Teixido[1,2,3]
[1]Hospital Clinic of Barcelona, Barcelona/ES ,[2]Laboratory of Translational genomics and Targeted therapies in Solid Tumors, IDIBAPS, Barcelona/ES ,[3]University of Barcelona, Barcelona/ES

Introduction: NGS testing is now routine in non-small cell lung cancer (NSCLC), with multiple panels used in clinical practice to identify clinically relevant actionable genomic alterations (AGAs). This study aimed to assess the performance of different NGS panels, including RNA-based events, in a large single-institution population evaluated since 2016.

Methods: Patients (pts) diagnosed with advanced NSCLC between 2016 and 2024 underwent molecular characterization using a range of NGS panels: Oncomine Solid Tumor DNA (OST) with customized nCounter RNA, Oncomine Focus Assay DNA/RNA (OFA), Oncomine Comprehensive Assay DNA/RNA (OCA), and Oncomine Precision Assay DNA/RNA (OPA).

Results: A total of 1,465 pts were included, the majority with stage IV (54%) and adenocarcinoma histology (63%). The overall NGS success rate was 91.6%, with 122 samples deemed non-evaluable. Panel-specific success rates were: OST + nCounter (91.3%, 367/402), OFA (85.6%, 430/502), OCA (91.7%, 132/144), and OPA (95.2%, 401/421). The overall AGA detection rates were: OST + nCounter (50.7%), OFA (44.0%), OCA (39.6%), and OPA (47.5%). Statistically significant differences in AGA detection were observed between OST + nCounter and both OFA and OCA ($p < 0.05$), with a trend toward significance for OPA vs. OCA ($p = 0.09$). Detection of non-AGA alterations also varied across panels ($p < 0.05$), with OCA reporting the highest incidence (48.6%) compared to OFA (22.1%), OST + nCounter (29.4%), and OPA (36.6%). Both METex14 skipping and ALK fusion showed a declining detection trend over time. Although no statistically significant, detection rates were numerically lower with newer panels: METex14, 3.0% (12/402) with OST + nCounter vs. 1.9%, (8/421) with OPA; ALK fusion, 2.5% (10/402) vs 0.7% (1/144) with OCA.

Conclusions: These results reinforce the value of NGS in routine clinical practice and suggest that panel selection may influence detection sensitivity for certain AGAs. This is particularly relevant for low-prevalence alterations such as METex14 and ALK fusions, where even modest reductions in detection rates may significantly impact the identification of patients eligible for targeted therapies.

EP.06 PATHOLOGY AND BIOMARKERS

EP06.86 Evaluating Sustainment of Results in Quality Improvement Focused on Molecular Testing in Non-Small Cell Lung Cancer Patients

R. Choksi, MD[1], D.P. Petro, MD[1], M. Gart, MBA[2], E. Alwon, MS[2], P. Dave, MHA[2], B. Wang, MBA[2], P. Varughese, PharmD, MBA[2], R. Geller, MD[2], J. Scott, MD[2]
[1]University of Pittsburgh Medical Center (UPMC), Pittsburgh/PA/USA ,[2]Integra Connect, West Palm Beach/FL/USA

Introduction: In June 2022, Integra Connect (IC) published positive results of a quality improvement project (QI) focused on stage IV NSCLC patients (pts) conducted in partnership with the University of Pittsburg Medical Center (UPMC) aimed at improving EGFR testing rates, molecular testing rates across all NCCN recommended markers, and rates of pts who received EGFR test results prior to first-line treatment1. IC and UPMC sought to reassess those same measures two years later to see if UPMC sustained the improvement.

Methods: Pts included were treated at UPMC and identified via manual chart abstraction as newly diagnosed with stage IV NSCLC that received first-line therapy. The initial baseline of the QI was 1/1/2017-8/31/2020, followed by a first-post-baseline period 9/1/2020-12/31/2020, and second-post-baseline period of 1/1/2021-9/30/2021. To assess whether results were sustained two additional evaluation periods were observed in the calendar years 2022 and 2024.

Results: Median age in the initial QI was 68 (range 36 - 89) and 49% male. In the additional observation periods 2022 and 2024 the median age was 70 (range 45 - 89) and 54% male. The EGFR testing rate for pts at baseline was 94% and increased to 96% by the second post-baseline period and in 2022 reached 98%, but in 2024 reduced to 93%. Testing across all NCCN recommended markers increased from 52% at baseline to 76% by the second post-baseline and in 2022 reached 89% followed by 92% in 2024. The rate of pts receiving their EGFR test results prior to initiating first-line treatment was 72% at baseline and increased to 88% by the second post-baseline and in 2022 remained at 88%, but in 2024 dropped to 77%.

Conclusions: The QI implemented at UPMC for stage IV NSCLC led to continuous improvement in full panel biomarker testing climbing to 92% of pts tested for all actionable mutations. However, the rate of pts with EGFR test results in hand prior to initiating first-line treatment dropped after the completion of the QI, yet the rate remained above the baseline. This demonstrates the importance of continuous monitoring to ensure quality improvement efforts are sustained.

Introduction: Despite the recent trend toward sublobar resection, lobectomy with lymph node dissection (LND) remains the standard treatment for radiologically invasive (solid-dominant) clinical stage IA non-small cell lung cancer (NSCLC) measuring >2-3 cm. We aimed to develop a predictive model for pathologic low-grade malignant lung adenocarcinoma (LLA) to identify potential candidates for limited surgery, such as sublobar resection or simple lobectomy without LND, depending on tumor location. This study was conducted as an early supplementary analysis of JCOG1413, a randomized phase III study evaluating the clinical benefits of the extent of LND in patients with c-stage I-II NSCLC. This primary analysis results will be released in 2026 or later.

Methods: Among 1,711 patients enrolled in JCOG1413 from January 2017 to August 2021, we analyzed 633 patients with radiologically invasive (solid-dominant on thin-section computed tomography [TSCT], consolidation-to-tumor ratio [CTR] >0.5-1.0) c-stage IA tumors measuring >2-3 cm. All patients underwent lobectomy with either systematic or lobe-specific LND. In this study, LLA was defined as adenocarcinoma with a lepidic-predominant pattern, without pleural and lymphovascular invasion, and without pulmonary and nodal metastases. A multivariable logistic regression analysis with stepwise selection method was performed to develop a predictive model based on clinical and radiological factors. Leave-one-out cross-validation was conducted, and sensitivity, specificity and concordance statistics were calculated to evaluate diagnostic performance.

Results: LLA was detected in 71 patients (11%), and the developed prediction model for LLA included the following four variables: (1) tumor size in the mediastinal window setting on TSCT (x1), (2) presence or absence of ground-glass opacity (x2), (3) tumor location (central or peripheral) (x3), and (4) maximum standardized uptake value on positron emission tomography (x4). The predictive formula was p = (exp [-0.9615 - 0.0657x1 + 1.4390x2 + 0.8017x3 - 0.3118x4]) / (1 + exp [-0.9615 - 0.0657x1 + 1.4390x2 + 0.8017x3 - 0.3118x4]). Continuous variables (x1, x4) and categorical variables (x2, x3) were used to predict the probability. The concordance statistics was 0.8439. The risk of incorrectly predicting LLA was low, at only 4.7%, when Youden's index was maximized with a specificity of 95%. When the cut-off value was set to 34.5, sensitivity and specificity were 37.1% (95% confidence interval [CI]: 25.9-49.5%) and 95.3% (95% CI: 93.2-96.9%), respectively.

Conclusions: The proposed model is a clinically accessible and non-invasive tool for predicting pathologic low-grade malignant adenocarcinoma in patients with radiologically invasive (solid-dominant) clinical stage IA NSCLC measuring >2-3 cm.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.02 Development and Validation of a High-Speed and High-Throughput 3D Reconstruction Algorithm in Pulmonary Vasculature and Nodules Localization

Z. Chen, W-z. Zhong
Guangdong lung cancer institute, Guangzhou/CN

Introduction: Efficient vascular systems are vital for organ function, yet existing anatomical models often overlook vascular structures, limiting their effectiveness in precision medicine. Enhanced understanding of vascular anatomy could improve patient-specific treatment strategies, particularly for early-stage lung cancer.

Methods: We developed an AI algorithm named watershed topographical segmentation (WTS) using a 3D U-Net architecture, augmented by InceptionV3 units and a graph neural network (GNN). The model was trained on a retrospective cohort of 15,433 patients with ground-glass pulmonary nodules (GGNs) from multiple hospitals in China. We utilized an internal prospective validation cohort (1,161 patients) and an external validation cohort (1,460 patients) to evaluate localization accuracy and guide wedge resections.

Results: The WTS model achieved an area under the curve (AUC) of 0.939 in internal ten-fold cross-validation, significantly outperforming traditional segmentation methods (AUC 0.695). In prospective cohorts, the model demonstrated localization accuracy of 92.25% for peripheral nodules and 94.45% for intrapulmonary nodules, with external validation showing similar results (90.90% and 83.00%, respectively).

Conclusions: Our findings indicate that the WTS model can accurately simulate vascular watershed boundaries, enhancing surgical planning and intraoperative navigation. Improved precision in pulmonary nodule localization may reduce surgical trauma and complications, ultimately benefiting lung cancer treatment outcomes. The watershed topographic map is a valuable resource for clinicians and educators, especially in settings with limited access to experienced surgeons.

EP.07.03 Lung Cancer: Artificial Intelligence, Biometrics and Modeling of Alive Supersystems for Best Management

O. Kshivets
Bagrationovsk Hospital, Bagrationovsk/RU

Introduction: Non-small cell lung cancer (LC) is an extremely complex global problem. 5-survival (5YS) and life span after radical surgery for patients wih LC (LCP) (T1-4N0-2M0) - alive supersysems was analyzed. The importance must be stressed of using complex system analysis, artificial intelligence (neural networks computing), synergetics, simulation modeling and biometrics in combination, because the different approaches yield complementary pieces of prognostic information.

Methods: We analyzed data of 786 consecutive LCP (age=57.7±8.3 years; tumor size=4.1±2.4 cm) radically operated and monitored in 1985-2025 (m=674, f=112; upper lobectomies=284, lower lobectomies=180, middle lobectomies=18, bilobectomies=46, pneumonectomies=258, mediastinal lymph node dissection=786; combined procedures with resection of trachea, carina, atrium, aorta, VCS, vena azygos, pericardium, liver, diaphragm, ribs, esophagus=199; only surgery-S=629, adjuvant chemoimmunoradiotherapy-AT=157: CAV/gemzar + cisplatin + thymalin/taktivin + radiotherapy 45-50Gy; T1=328, T2=260, T3=137, T4=61; N0=528, N1=133, N2=125, M0=786; G1=199, G2=248, G3=339; squamous=423, adenocarcinoma=313, large cell=50; early LC=221, invasive LC=565; right LC=422, left LC=364; central=298; peripheral=488. Variables selected for study were input levels of 45 blood parameters, sex, age, TNMG, cell type, tumor size. Regression modeling, clustering, SEPATH, Monte Carlo, bootstrap and neural networks computing were used to determine significant dependence.

Results: Overall life span (LS) was 2245.9±1741.5 days and cumulative 5-year survival (5YS) reached 73.4%, 10 years - 65.2%, 20 years - 42.5%. 516 LCP lived more than 5 years (LS=3118.2±1527.7 days), 148 LCP - more than 10 years (LS=5054.4±1504.1 days).199 LCP died because of LC (LS=562.7±374.5 days). 5YS of LCP after bi/lobectomies was significantly superior in comparison with LCP after pneumonectomies (78.2% vs.63.5%, P=0.00001 by log-rank test). AT significantly improved 5YS (65.6% vs. 34.8%) (P=0.00001 by log-rank test) only for LCP with N1-2. Cox modeling displayed that 5YS of LCP significantly depended on: phase transition (PT) early-invasive LC in terms of synergetics, PT N0—N12, cell ratio factors (ratio between cancer cells- CC and blood cells subpopulations), G1-3, AT, blood cell circuit, prothrombin index, age, bilirubin, procedure type (P=0.000-0.044). Neural networks, genetic algorithm selection and bootstrap simulation revealed relationships between 5YS and PT early-invasive LC (rank=1), PT N0—N12 (rank=2), thrombocytes/CC (3), healthy cells/CC (4), eosinophils/CC (5), erythrocytes/CC (6), segmented neutrophils/CC (7), lymphocytes/CC (8), monocytes/CC (9); stick neutrophils (10); leucocytes/CC (11). Correct prediction of 5YS was 100% by neural networks computing (area under ROC curve=1.0; error=0.0).

Conclusions: 5YS of LCP after radical procedures significantly depended on: 1) PT early-invasive cancer; 2) PT N0--N12; 3) cell ratio factors; 4) blood cell circuit; 5) biochemical factors; 6) hemostasis system; 7) AT; 8) LC characteristics; 9) LC cell dynamics; 10) surgery type: lobectomy/pneumonectomy; 11) anthropometric data. Optimal diagnosis and treatment strategies for LC are: 1) screening and early detection of LC; 2) availability of experienced thoracic surgeons because of complexity of radical procedures; 3) aggressive en block surgery and adequate lymph node dissection for completeness; 4) precise prediction; 5) adjuvant chemoimmunoradiotherapy for LCP with unfavorable prognosis.

Keywords: lung cancer, surgery, survival

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.04 Pathological Investigation of Bronchial Stump and Bronchopleural Fistula After Anatomical Pulmonary Resection for Lung Cance

H. Arai, M. Toyoda, Y. Mishina, S. Nakamura, M. Matsumura, T. Sawazumi, K. Okudela, T. Iwasawa
Kanagawa Cardiovasclar and Respiratory Center, Yokohama/JP

Introduction: Bronchopleural fistula (BPF) after anatomical pulmonary resection for lung cancer is a severe complication that continues to be of concern despite advances in medical devices. However, little is known about the physiological mechanism that leads to BPF formation, and there has been no detailed pathological study of natural bronchial stump formation after anatomical pulmonary resection.

Methods: The aim of this study was to examine features of BPF from a clinco-pathological perspective. A total of 1002 cases that underwent anatomical pulmonary resection for lung cancer at Kanagawa Cardiovascular and Respiratory Center from April 2011 to April 2021 were reviewed retrospectively. BPF was diagnosed based on bronchoscopic findings such as fistula or fluid bubbling. Clinical-pathological data were collected from medical records and correlations of BPF with clinical features were evaluated. In addition, natural microscopic bronchial stump formation after anatomical pulmonary resection was examined in autopsy cases without lung cancer recurrence. After careful removal of staplers from the bronchial stump in autopsy cases, histological specimens were investigated microscopically.

Results: The subjects underwent lobectomy (n=784), segmentectomy (n=185), bilobectomy (n=18) and pneumonectomy (n=2). BPF developed in 6 cases (0.6%), and was significantly associated with right lower lobectomy ($p<0.001$) and presence of interstitial pneumonia (IP) ($p<0.001$). The median period from the procedure to onset of BPF was 25 (20-260) days. Autopsy cases that underwent radical lobectomy and had no recurrence included a 79-year-old female with squamous cell carcinoma (SCC): pStage IA; an 85-year-old male with SCC: pStage IB; a 71-year-old male with SCC: pStage IIB; and an 81-year-old male with large cell neuroendocrine carcinoma: pStage IB. Microscopic investigation revealed fibrosis in the crimped portion of the remaining bronchial wall structure and fibrous tissue surrounding staple holes in concentric circles. The bronchial epithelium had turned around and covered the bronchial lumen at the blind end.

Conclusions: Previously reported risk factors for BPF include right lower lobectomy, diabetes mellitus and poor nutrition. IP was also identified as a risk factor for BPF in this study. Microscopic findings from autopsy cases revealed that after anatomical pulmonary resection the bronchial stump had epithelial damage due to adhesion of the bronchial wall caused by staples, and fibrosis due to the repair reaction. Concentric fibrosis was observed around the hole, suggesting a repetitive repair response to staple movement due to breathing. Thus, under conditions of strong negative intrathoracic pressure, such as those in IP, the patient may be more likely to develop BPF. There was also a wide range of onset times for BPF, which suggests that late onset BPF might be correlated with mechanical factors.

Keywords: anatomical pulmonary resection, bronchial stump, bronchopleural fistula

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.05 Oncologic Outcomes of Segmentectomy Versus Lobectomy in Early-Stage Lung Adenocarcinoma With High-Risk Pathologic Features

Z. Li, R. Li, J. Chen, R. Yang, G. Zhang, B. Qiu
National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Several randomized controlled trials have demonstrated that segmentectomy provides acceptable oncological results for small-sized non-small-cell lung cancer. However, the high-risk pathologic features can significantly influence prognosis of early-stage lung adenocarcinoma (LUAD). The generalizability of JCOG 0802 and CALGB 140503 trial results to patients with these high-risk features remains uncertain. This study aimed to compare oncologic outcomes between lobectomy and segmentectomy in clinically early-stage LUAD patients with high-risk pathologic factors.

Methods: This single-center retrospective study involved patients with clinical stage IA LUAD and high-risk pathologic features who underwent lobectomy or segmentectomy from 2016 to 2020. Patients with occult nodal metastasis were excluded. High-risk pathologic features were defined as visceral pleura invasion, lymphovascular invasion, spread though airspaces or poorly differentiated. Cumulative incidence of recurrence (CIR) and lung cancer-specific cumulative incidence of death (LC-CID) were compared using Fine and Gray's competing risks regression. Death due to other causes was considered as a competing risk. Propensity score matching (1:1) and inverse probability of treatment weighting were employed to reduce selection bias.

Results: A total of 1137 patients were identified, including 930 (81.8%) who underwent lobectomy and 207 (18.2%) who underwent segmentectomy. In unmatched cohort, no significant difference in CIR was observed between segmentectomy (5-year CIR rate, 9.0%) and lobectomy patients (5-year CIR rate, 13.0%; hazard ratio (HR), 1.51; 95% confidence interval (CI), 0.93-2.46; P = 0.10) (Fig 1A). In the propensity score-matched cohort, there was no significant difference in CIR between segmentectomy (5-year CIR rate, 9.1%) and lobectomy patients (5-year CIR rate, 7.6%; HR, 0.82; 95% CI, 0.42-1.62; P = 0.57) (Fig 1B). In inverse probability-weighted cohort, segmentectomy was not a significant predictor of worse CIR (HR, 1.11; 95% CI, 0.59-2.10; P = 0.75) (Fig 1C). Similarly, LC-CID showed no significant differences between segmentectomy and lobectomy across unmatched cohort (HR, 1.91; 95% CI, 0.75-4.92; P = 0.18), propensity score-matched cohort (HR, 0.72; 95% CI, 0.19-2.69; P = 0.62) and inverse probability-weighted cohort (HR, 1.16; 95% CI, 0.39-3.49; P = 0.79) (Fig 1D-1F).

Conclusions: Segmentectomy demonstrates comparable oncologic outcomes to lobectomy in clinically early-stage LUAD patients with high-risk pathologic features, including visceral pleural invasion, lymphovascular invasion, spread through airspaces, and poorly differentiated. These findings support the feasibility of segmentectomy in this population.

EP.07.06 Preserved Ratio Impaired Spirometry Are Associated With Poor Postoperative Outcomes in Clinical Stage I Non-Small Lung Cancer

T. Shiotani[1], N. Shiraha[1], T. Tamura[1], M. Watanabe[1]
[1]NHO Iwakuni Clinical Center, Iwakuni-city/JP

Introduction: The preserved ratio impaired spirometry (PRISm) is an airflow limitation status that identifies a group of individuals with impaired lung function who do not meet the spirometry-assessed definition of chronic obstructive pulmonary disease (COPD). PRISm is defined as forced expiratory volume in 1 second (FEV1)/forced vital capacity (FVC) ≥ 0.7 and percent predicted FEV1 < 80%. Although PRISm is recognized as a risk factor for elevated complication rates of cardiovascular disease and mortality of respiratory disease, the association between PRISm and postoperative outcomes in lung cancer remains unclear. We investigated the association between PRISm without restrictive spirometric pattern (RSP) and postoperative outcomes in early-stage lung cancer.

Methods: Patients who underwent surgery for non-small cell lung cancer (NSCLC) with clinical stage I at Iwakuni Clinical Center between January 2015 and December 2021 were included. The patients were divided into two groups: patients with normal pulmonary function (the normal group) and those with FEV1/FVC ≥ 0.7 and percent predicted FEV1 < 80% (the PRISm group). Patients with RSP on pulmonary function test or those with COPD were excluded. We compared postoperative complications, the duration of postoperative hospital stay, recurrence-free survival within three years after surgery (3-year RFS), and survival within three years after surgery between the two groups.

Results: Of 443 patients who underwent surgery, 23 patients were conducted in the PRISm group. Although there were no significant differences between the normal group and the PRISm group regarding postoperative complications (21 (5.2%) vs. 2 (5.3%), P = 1.00) and postoperative hospital stay (6 (2-8) days vs. 6 (3-21) days, P = 0.68), 3-year RFS (Fig.1) and 3-year OS (Fig. 2) had significant differences between them (3-year RFS, 0.94 (0.91-0.96) vs. 0.77 (0.54-0.90), P < 0.001; 3-year OS, 0.94 (0.91-0.96) vs. 0.83 (0.60-0.93), P = 0.033).

Conclusions: PRISm was associated with poor 3-year RFS and 3-year OS after surgery for NSCLC in stage I. PRISm might be a risk factor of poor outcomes in early-stage NSCLC.

EP.07.07 Prognostic Analysis and Molecular Characteristics of Bubble-Like Appearance-Type Lung Adenocarcinoma

K. Murakami[1], H. Saito[1], K. Yamamoto[2], R. Kasajima[3], K. Washimi[1], N. Shigeta[1], S. Shigefuku[1], T. Isaka[1], T. Nagashima[1], S. Katakura[1], S. Murakam[1], T. Kondo[1], Y. Miyagi[3], T. Yokose[1], H. Ito[1]
[1]Kanagawa Cancer Center, Yokohama/JP ,[2]Yokohama City University School of Medicine, Yokohama/JP ,[3]Kanagawa Cancer Center Research Institute, Yokohama/JP

Introduction: Bubble-like appearance (BLA)-type lung adenocarcinoma (LUAD) is a group of LUAD that may be misdiagnosed as chronic inflammatory lesions on imaging and followed up for a long period, as we previously reported. BLA-type LUAD has four imaging features on thin-section CT: polygonal shape, slight ground-glass opacity (GGO) around the tumor, three or more dilated small bronchi (air bronchograms) within the tumor area, and clear pleural indentations. In addition, BLA-type LUAD has a slow growth rate, including a scaly growth pattern, and the main pathological feature is a collapsed tumor center. However, the prognostic significance and molecular characteristics of BLA-type LUAD remain unclear. This study aimed to compare the prognosis and molecular features of BLA-type LUAD with those of non-BLA-type LUAD.

Methods: We retrospectively analyzed the clinical records of 1166 patients who underwent complete surgical resection with lobectomy for LUAD at the Kanagawa Cancer Center between 2010 and 2019. BLA-type LUAD was defined based on the four computed tomography characteristics described earlier. Survival curves were estimated using the Kaplan-Meier method. The prognosis of BLA-type LUAD (BLA group) and non-BLA-type LUAD (non-BLA group) were compared after adjusting for confounding factors. The confounding factors were age, sex, smoking history, CEA level, and CT tumor size. Multivariable analyses were performed using a Cox proportional hazards regression model with the following variables: radiographical GGO component, adenocarcinoma subtype, pathological tumor invasive size, pathological lymph node metastasis, lymphatic permeation, vascular invasion, visceral pleural invasion, and EGFR mutation to explore factors related to RFS and OS of all the patients, including the BLA group. In addition, clinicopathological features, epidermal growth factor receptor (EGFR) mutation status, and programmed death ligand 1 (PD-L1) expression were analyzed.

Results: A total of 2145 consecutive patients with primary LUAD underwent complete surgical resection with lobectomy. Finally, 122 patients in the BLA group and 1044 patients in the non-BLA group were included in the study. The 5-year RFS rates of patients in the BLA and non-BLA groups were 79.0% and 68.6%, respectively, and after adjusting for confounding factors, the RFS was significantly better in the BLA group than in the non-BLA group (hazard ratio [HR], 0.56; 95% confidence interval [CI], 0.38-0.85; p=0.006). Similarly, the 5-year OS rates of patients in the BLA and non-BLA groups were 92.9% and 82.6%, respectively, and even after adjusting for confounding factors, the BLA group showed significantly better survival (HR, 0.43; 95% CI, 0.24-0.80; p=0.008). The BLA group had a higher EGFR mutation rate than the non-BLA group (63.1 vs. 45.6%; p<0.001), with a particularly high proportion of exon 21 L858R mutations (58.4%). In contrast, the PD-L1 expression rate (TPS ≥1%) was 9.0%.

Conclusions: The prognosis of BLA-type LUAD was better than that of non-BLA-type LUAD owing to the association of multiple factors, including pathological tumor invasive size, fewer lymph node metastases, and pathological low-grade tumors. BLA-type LUAD exhibited higher EGFR mutation rates than non-BLA-type LUAD and lower PD-L1 expression than previously reported. These results suggest that BLA-type LUAD is more oncologically distinct tumor than regular LUADs.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.08 Quantifying Resection Margins in Lung Cancer Patients Undergoing Sublobar Resection Using CT-Based 3D Reconstruction

M-W. Lin[1], L-W. Chen[2], M-S. Hsieh[2], Y-C. Chang[2], J-S. Chen[2], C-M. Chen[2]
[1]National Taiwan University Hospital, Taipei City/TW ,[2]National Taiwan University, Taipei City/TW

Introduction: Sublobar resection has emerged as a standard treatment option for early-stage peripheral non-small cell lung cancer. Achieving an adequate resection margin is crucial to prevent local tumor recurrence. However, gross measurement of the resection margin may lack accuracy due to the elasticity of lung tissue and interobserver variability. Therefore, this study aimed to develop an objective measurement method, the CT-based 3D reconstruction algorithm, to quantify the resection margin following sublobar resection in lung cancer patients through pre- and postoperative CT image comparison.

Methods: An automated subvascular matching technique was first developed to ensure accuracy and reproducibility in the matching process (Figure 1). Following the extraction of matched feature points, another key technique involves calculating the displacement field within the image. This is particularly important for mapping discontinuous deformation fields around the surgical resection area. A transformation based on thin-plate spline is used for medical image registration. Upon completing the final step of image registration, the distance at the resection margin was measured.

Results: After developing the CT-based 3D reconstruction algorithm, we included 12 cases for resection margin distance measurement, comprising four right middle lobectomies, six segmentectomies, and two wedge resections (Table 1). The outcomes obtained with our method revealed that the target registration error for all cases was less than 2.5 mm.

Conclusions: Our method demonstrated the feasibility of measuring the resection margin following sublobar resection in lung cancer patients through pre- and postoperative CT image comparison. Further validation with a multicenter, large cohort, and analysis of clinical outcome correlation is necessary in future studies.

EP.07.09 Preliminary Results of One-Stop Shop: Results From the First Twenty-One Tumor Resections Compared to a Stage-Matched Control Group

G-M. Monsch, D. Schneiter, T. Gaisl, C. Steinack, O. Lauk, K. Chiffi, S. Ulrich, I. Opitz
University Hospital Zurich, Zurich/CH

Introduction: We have implemented a one-stop shop (OSS) concept for patients with suspected malignant pulmonary nodules, consisting of: Robotic-assisted navigation-bronchoscopy with integrated cone-beam CT, biopsy, marking of the nodule (fiducial/ICG), fresh-frozen examination and direct oncological resection in one general anaesthesia.

Methods: Comparison of the first 21 patients undergoing our OSS concept to UICC-stage-matched (1:1) control group (n=21), in which patients had preoperative transbronchial biopsy/wedge-resection for diagnostic purposes. Time period was compared from first CT-scan with suspicious lesion to treatment.

Results: There was no relevant difference regarding median age (70 vs. 71 years; p=0.959) and gender (p=0.537) between the two groups. Ten patients had an UICC-Stage IA2, eight IA1, two Tcis and one IB. IN both groups, all surgeries were performed by a minimal-invasive approach (VATS/RATS). Time from first CT-scan with suspicious lesion to treatment was significant shorter in the OSS cohort (41 days vs. 61. days respectively, p=0.0032). There was no difference in overall hospitalisation between the groups (median 4 days in both groups, p=0.5).

Conclusions: With our OSS approach, potentially malignant pulmonary lesions can be diagnosed and treated efficiently, minimizing delays in patient care in patients, which are suitable for primary resection. This concept may also reduce costs by shortening overall hospital stay, as no additional hospitalisation is required for diagnostic intervention. Nevertheless, further analysis is needed to fully evaluate its potential impact.

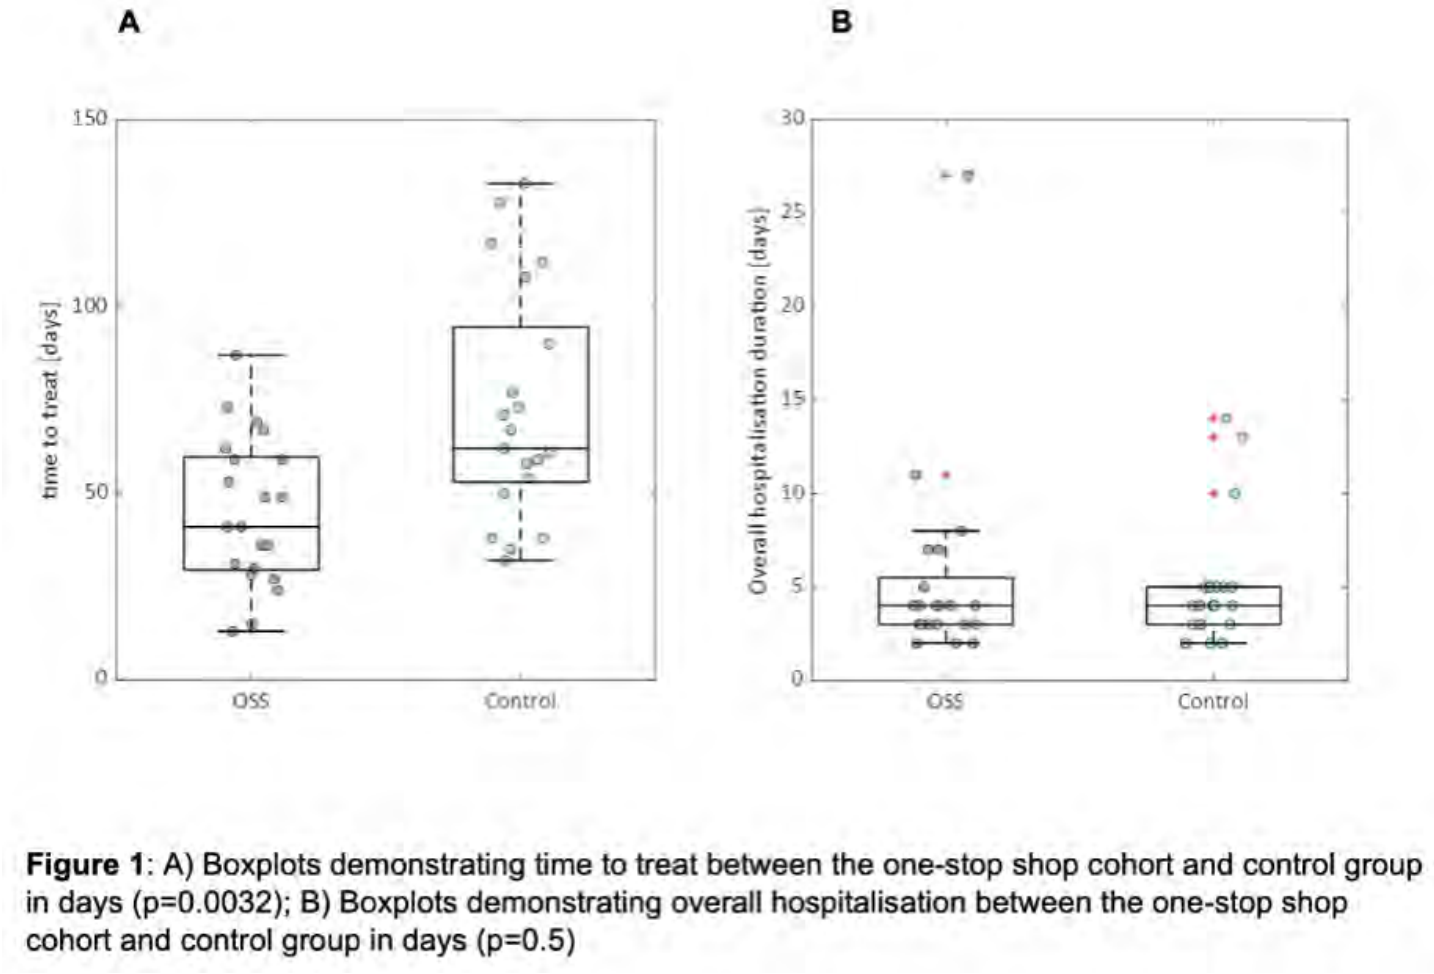

Figure 1: A) Boxplots demonstrating time to treat between the one-stop shop cohort and control group in days (p=0.0032); B) Boxplots demonstrating overall hospitalisation between the one-stop shop cohort and control group in days (p=0.5)

EP.07.10 Analysis of Residual Lung Volume After Segmentectomy Using 3DCT and Risk Factors for Decline in Postoperative Pulmonary Function

S. Ohtani, T. Miyoshi, K. Nomura, Y. Matsumura, Y. Ohtaki, K. Tane, K. Aokage, M. Tsuboi
National Cancer Center Hospital East, Chiba/JP

Introduction: Lung segmentectomy is increasingly performed as a less invasive alternative to lobectomy, especially in patients with early-stage lung cancer or limited pulmonary reserve. However, some patients experience a decline in pulmonary function equivalent to that after a lobectomy. In particular, the relationship between lung volume loss after segmentectomy and the pulmonary function decline remains unclear. This study aims to investigate the residual lung volume after segmentectomy using detailed 3DCT and to identify the risk factors for pulmonary function decline.

Methods: We retrospectively analyzed 169 patients who underwent lung segmentectomy at our institution between January 2017 and December 2023. All patients had pulmonary function test data between 6 and 18 months postoperatively. The postoperative pulmonary function decline ratios were calculated as the ratios of post- to pre-operative forced expiratory volume in 1 second (FEV1.0) and forced vital capacity (FVC). Patients with both ratios below 0.9 were classified as the pulmonary function decline group, while the remaining were classified as the normal group. Lung volumes were reconstructed and measured using REVORAS™ (Ziosoft) based on pre- and post-operative HRCT images. The predicted residual lung volume was defined as the volume of both lungs excluding the segment to be resected on the preoperative CT. The predicted postoperative lung volume proportion was defined as the proportion of the predicted residual lung volume to the whole lung volume. The predicted postoperative respiratory function was calculated based on this value.

Results: The median age was 73 years, and 85 were male. Lung cancer was diagnosed in 158 patients, and the median tumor diameter was 1.8 cm. Of 169 cases, 139 were classified as the normal group, and 30 as the pulmonary function decline group. The decline group showed a tendency for a larger tumor maximum diameter ($p=0.05$), but there was no significant difference in the predicted postoperative lung volume proportion ($p=0.863$). The ratios of measured postoperative FEV1 and FVC to their predicted postoperative values were significantly higher in the normal group than in the decline group (FEV1: 1.11 vs. 0.92, $p < 0.001$; FVC: 1.14 vs. 0.94, $p < 0.001$). In addition, the ratio of measured postoperative residual lung volume to its predicted value was also significantly higher in the normal group than in the decline group (1.07 vs. 1.00, $p < 0.001$).

Conclusions: Our results suggest that the predicted postoperative lung volume alone was not sufficient to predict decline in postoperative respiratory function. Although the residual lung expansion plays an important role in compensating for lost volume, it can be influenced by factors such as lung compliance and postoperative thoracic adhesions. Future investigations should also consider additional variables, including postoperative pain management, perioperative performance status, and comorbidities.

EP.07.11 Comparison of Robotic Assisted Thoracoscopic Lobectomy and Video-Assisted Thoracoscopic Lobectomy for Early Stage Non-Small Cell Lung Cancer

T. Takenaka, N. Iwamoto, F. Kinoshita, T. Matsubara, K. Takada
Kyushu University Hospital, Fukuoka city/JP

Introduction: Robotic-assisted thoracoscopic (RATS) pulmonary resection for early-stage non-small lung cancer (NSCLC) is being increasingly performed in world wide. To evaluate its safety and oncologic efficacy, we compared the outcomes of both RATS and video-assisted thoracoscopic (VATS) lobectomy in patients with stage 0 or IA NSCLC.

Methods: From August 2014 to December 2024, a total of 330 patients with resected stage 0 or IA NSCLC who underwent RATS (n=133) and VATS (n=174) pulmonary lobectomy were included. A da Vinci Si surgical robot (Intuitive Surgical, Inc, Santa Clara, CA) was used to perform RATS lobectomy. A VATS lobectomy was performed using the 4-port technique. Perioperative and clinicopathologic outcomes were evaluated.

Results: The baseline characteristics were similar between RATS and VATS groups. There were more right upper lobectomies and fewer left upper lobectomies in the RATS group compared to VATS group. Intraoperative blood loss was statistically lower in the RATS group than in the VATS group. No significant differences were found in operative time, duration of chest tube drainage, Frequency of postoperative complications and postoperative hospital stay. In lymph node (LN) dissection, the RATS group had significantly a higher number of LN and total number of LN harvested.

Conclusions: Both RATS and VATS lobectomies are safe and feasible for the treatment of early-stage NSCLC. RATS achieved similar perioperative outcomes and higher LN dissection. The minimally invasive nature of RATS surgery and its significance in dissection may contribute to improved long-term outcomes.

Table 1

Factors	VATS (n=186)	RATS (n=144)	p-value

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.12 The Impact of Quantification Parameters and Clinicopathologic Characteristics on the Prognosis of Stage Ia Invasive Lung Adenocarcinoma

Z. Liu, J. Mei
West China Hospital, Sichuan University, Chengdu/CN

Introduction: The risk factors for postoperative recurrence of stage IA invasive lung adenocarcinoma (LUAD) are still unclear. Studies have shown that consolidation-to-tumor ratio can predict prognosis, but the solid size is difficult to measure accurately. This study aims to identify high-risk factors for postoperative recurrence of stage IA invasive LUAD using deep learning (DL)-based quantitative parameters combined with clinical and pathological characteristics of tumors.

Methods: The maximum total size on axial images (MTSA) and the maximum solid size on axial images (MSSA) were evaluated by two chest radiologists, and the solid component ratio (CTR) was calculated. Maximal total size on multiplanar reconstructed images (MTSMPR), total volume (TV), solid component volume (SV), and solid component volume percentage (SV%) were evaluated by DL, with 0HU, -50HU, -100HU, -150HU, -200HU, -250HU, -300HU, -350HU, and -400HU as the thresholds of solid components, respectively. The DL-based quantification was compared with manual measurements to find the optimal predictor. Combined with clinical and pathological characteristics, competing risk model was used to identify independent risk factors for recurrence.

Results: A total of 2,117 patients with pathological stage IA invasive LUAD were included, and 50 patients experienced recurrence and 26 patients died. The recurrence prediction performance of manual measurements was inferior to that of DL-based quantification. In DL-based quantification, SV0HU% (with 0HU as the solid component threshold) was most closely associated with recurrence, which was superior to other measurements. Univariate and multivariate analysis showed that pathological stage, SV0HU% (HR = 8.95, 95% CI: 4.32-18.57, P < 0.001), pathological stage (HR = 12.14, 95% CI: 1.58-93.13, P = 0.016), pathological subtype (HR = 3.04, 95% CI: 1.46-6.34, P = 0.003), vascular or neural invasion (HR = 3.83, 95% CI: 1.56-9.42, P = 0.003), and spread through air space (HR = 2.34, 95% CI: 1.23-4.44, P = 0.009) were independent risk factors for recurrence of stage IA invasive LUAD.

Conclusions: Among the quantitative parameters of tumors, DL-based SV0HU% was most closely related to postoperative recurrence of stage IA invasive LUAD. In addition, common clinical and pathological characteristics can be used to identify patients at high risk of recurrence and should be considered when assessing the prognosis of patients with stage IA disease.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.13 Thoracoscopic Combined Anatomicalsublobarresection for Deep Intersegmental Small-Sized Non-Small Cell Lung Cancer

y. sun, f. shao
Nanjing Chest Hospital, Nanjing,China/CN

Introduction: The optimal approach for sublobar resection of small-sized nodules in deep-seated, intersegmental locations, as opposed to peripheral lung regions, remains undetermined. This retrospective study compares the surgical and oncological outcomes of deep intersegmental lung cancer (DILC) treated with combined anatomical sublobar resection (CASR) versus combined non-anatomical extended resection (CNER).

Methods: Data were collected from 95 consecutive patients with small (≤2 cm) cN0 DILC who underwent CASR or CNER between March 2019 and November 2024. DILC was defined as a lesion located within the inner two-thirds of the lung parenchyma, involving the junction of adjacent lung segments, as determined by thin-slice (1 mm) and three-dimensional computed tomography. Patients were categorized into two groups: the CNER group, which underwent (sub)segmentectomy with an extended wedge resection of an adjacent segment, and the CASR group, which underwent (sub)segmentectomy combined with (sub)segmentectomy of an adjacent segment.

Results: All patients successfully underwent surgical resection: 38 received CNER and 57 received CASR, with no severe morbidity or perioperative mortality. The CASR group exhibited a significantly lower rate of intraoperative complications (0% vs. 10.5%, P = 0.012), while postoperative complication rates did not differ significantly (7.01% vs. 10.5%, P = 0.546). CASR was associated with a wider surgical margin compared to CNER (2.5 cm vs. 1.6 cm, P < 0.001), while tumor size (1.2 cm vs. 1.2 cm, P = 0.92) and the number of lymph nodes resected (6.3 vs. 6.1, P = 0.71) were comparable between the groups. Local recurrence occurred in six patients (15.8%) in the CNER group at the surgical margin, whereas one patient (1.8%) in the CASR group experienced recurrence in the lymph node basin of the original tumor (P = 0.01). Over a median follow-up of 31 months, the CASR group demonstrated higher local recurrence-free survival (98.2% vs. 84.2%), five-year disease-free survival (96.6% vs. 81.6%), and overall survival (94.7% vs. 89.5%), though the differences were not statistically significant (P = 0.196, 0.403, and 0.724, respectively).

Conclusions: CASR is a safe and effective surgical approach that provides adequate surgical margins, potentially reducing the risk of margin failure—an essential factor in preventing local recurrence. CASR may be a preferable alternative to CNER for patients with DILC.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.14 Contemporary Stereotactic Body Radiation Therapy Utilization Trends for Stage I Non Small Cell Lung Cancer

S. Sakowitz, H. Tupper, L. Benjamin, S. Oh, T. He, R. Ronaghi, C. Channick, B. Rosenberg, R. Salehi-rad, M.I. Smith, J. Bando, T. Young, I. Barjaktarevic, M. Velez, A. Gower, A. Cummings, J. Goldman, A. Lisberg, E. Garon, J. Yanagawa, E. Cameron, B. Burt, S. Revels, P. Toste, J. Lee, A. Lee, J. Deng, H. Lee, P. Benharash, D. Moghanaki
David Geffen School of Medicine at UCLA, Los Angeles/CA/USA

Introduction: The utilization of SBRT for stage I non-small cell lung cancer (NSCLC) has been increasing since its introduction in the early 2000s. However, recent trends and reasons for declining preferences for surgery have not been reported.

Methods: A retrospective cohort study was conducted using the National Cancer Database (NCDB) to analyze patients ≥18 years diagnosed with histopathologically confirmed clinical stage I NSCLC diagnosed between 2004 and 2021. Patients were categorized by receipt of Surgery, SBRT, non-SBRT Radiation, or No-Treatment. Exclusion criteria included prior chemotherapy or radiation before surgery and unknown surgical status. Temporal trends were assessed using Cuzick's test, and statistical analyses were performed using Stata 18.0.

Results: Among 343,557 patients with clinical stage I NSCLC, 59% (n=202,517) received surgery, 19% (n=64,159) received SBRT, 12% (n=41,991) underwent non-SBRT Radiation, and 10% (n=34,890) received no treatment. SBRT patients were older, more frequently insured by Medicare, and had greater comorbidity burden. Tumor sizes were smaller, with a predominance of stage IA disease in the SBRT cohort. From 2004 to 2021, SBRT utilization increased from ~1% to 35% (P<0.001), while surgery rates declined from 68% to 41% (P<0.001). The proportion of untreated patients decreased from 16% to 10% (P<0.001). Reasons for patients not undergoing surgery included "not planned for surgery" (74%), "not surgical candidate" (21%), and "refused surgery" (5%). The proportion of patients with surgical contraindications receiving SBRT declined from 22% in 2004 to 18% in 2021 (P<0.001), whereas those for whom surgery was not planned as first-line therapy increased from 74% to 77% (P<0.001).

Conclusions: Utilization of SBRT for stage I NSCLC continues to increase, independent of a rise in surgical contraindications or patient refusal of surgery. This shift may reflect the perceived advantages of SBRT. Until results from ongoing phase III trials become available, patients preferring SBRT should continue to be counseled about surgery, given the potential benefits it can offer patients.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.15 Model Navigated Anchor Based Responsive CT Hybrid Surgery for Intraoperative Localization and Resection for Small Pulmonary Nodules

X. Zhang
Peking University First Hospital, Beijing/CN

Introduction: With the widespread application of computed tomography (CT) screening and the ever-increasing evidence suggesting the efficacy of sub-lobar resection for early lung malignancies, the precise localization and resection of small pulmonary nodules, especially those that are hard to locate or multiple nodules, calls for attention.

Methods: We collected the consecutive records of patients receiving model-navigated anchor-based responsive CT hybrid (MONARCH) surgery or preoperative CT-guided puncture localization and resection for small pulmonary nodules in our center between 1 January and 31 December 2024. Localization-specific and perioperative parameters were analyzed and compared between the two methods.

Results: All patients underwent localization and resection without significant complications, and the median time for MONARCH localization was 39 minutes. There was no statistical difference in localization outcomes between the two groups (MONARCH: precise 50%, helpful 43.33%, missed 6.67% vs. conventional: precise 49.49%, helpful 42.42%, missed 8.08%, p=1.000). The MONARCH approach displayed superiority in rates of intraparenchymal hemorrhage (0% vs. 16.16%, p=0.022), pneumothorax (0% vs. 29.30%, p<0.001). As for the time of chest tube placement, drainage volume, and postoperative complications, no significant inferiority was found. All the MONARCH surgeries achieved complete resection, and no statistical difference was discovered compared to the conventional approach.

Conclusions: The MONARCH surgery for small pulmonary nodule localization and resection is feasible and effective. Without transthoracic puncture, the technique suits settings like multiple pulmonary nodules or those unfit for puncture or direct tactile localization.

EP.07.16 Minor Ground-Glass Opacity Differences Were Associated With Prognostic Variation in Solid-Predominant Clinical Stage IA Lung Adenocarcinoma

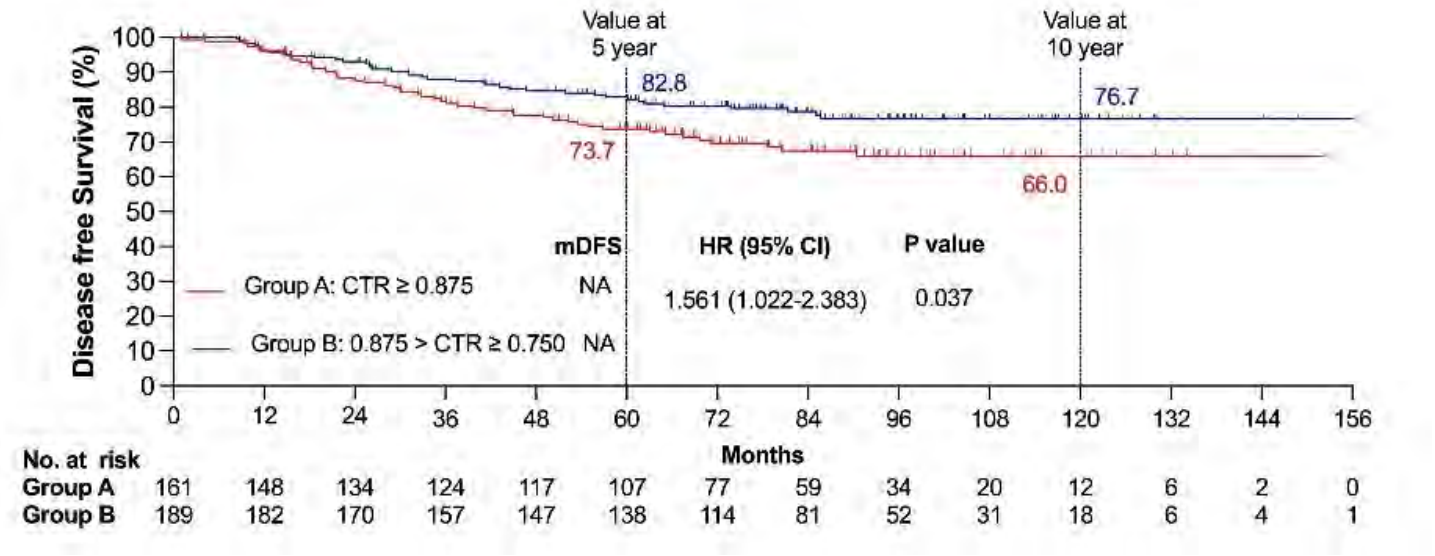
P-H. Chen[1,2], T-H. Young[2], H-H. Lu[1], H-H. Hsu[1,3], J-S. Chen[1]
[1]National Taiwan University Hospital, Taipei City/TW ,[2]Institute of Biomedical Engineering, College of Medicine and College of Engineering, National Taiwan University, Taipei/TW ,[3]National Taiwan University Cancer Centor, Taipei/TW

Introduction: Advances in low-dose and multi-slice CT have improved early detection of NSCLC, increasing the diagnosis of small tumors with ground-glass opacity (GGO) components. GGO presence is associated with better prognosis and lower invasiveness, even in tumors with similar solid diameters. The consolidation-to-tumor ratio (CTR) is commonly used to quantify GGO and is considered a potential independent prognostic marker. However, its prognostic significance in solid-predominant tumors (CTR > 0.75), particularly in stage IA adenocarcinoma, remains unclear.This study aims to evaluate whether small differences in GGO influence prognosis in clinical stage IA solid-predominant adenocarcinoma and to clarify the prognostic role of CTR in solid-predominant adenocarcinoma.

Methods: We retrospectively reviewed 3575 NSCLC patients who underwent lung resection from 2011 to 2018 at National Taiwan University Hospital. After applying strict inclusion criteria, 350 patients with clinical stage IA solid-predominant adenocarcinoma (CTR ≥ 0.75, solid component <3 cm) were analyzed. Patients were stratified by average CTR (cutoff: 0.875) into group A (CTR ≥ 0.875, n=161) and group B (0.75 ≤ CTR < 0.875, n=189). Preoperative imaging, clinicopathologic features, and postoperative outcomes were evaluated. Survival analyses were performed using Kaplan-Meier and Cox regression models.

Results: Group B showed significantly better 5-year disease-free survival (DFS) than Group A (82.8% vs 73.7%, HR=1.561, p=0.042), despite only minor differences in GGO components. Overall survival (OS) was comparable between groups (97.3% vs 98.6%, p=0.266). Multivariate analysis identified gender and solid component size on CT as independent preoperative predictors of DFS. The CTR-DFS association remained significant in patients undergoing lobectomy, while DFS did not differ between lobectomy and sublobar resection within either group. Analysis using finer CTR cutoffs (0.75-0.95) also demonstrated significant DFS differences (p=0.0117) in a linear Cox regression model.

Conclusions: CTR demonstrated a significant impact on disease-free survival, even with minor differences, in stage IA solid-predominant adenocarcinoma. Both linear and multivariate Cox regression analyses identified CTR as an independent prognostic factor. Surgical approach (lobectomy vs. sublobar resection) did not significantly affect survival outcomes. Further studies are needed to confirm these findings in non-solid-predominant adenocarcinoma.



Keywords: ground-glass opacity, sublobar resection

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.17 Patient Characteristics, Surgical Outcomes, and Treatment Decisions in Early-Stage Resected NSCLC in Canada

A.L. McGuire[1], B. Melosky[2], N. Ahmadi[3], R. Meza[4], A. Wallace[5], G. Vaseghi[1], K. Xu[4], J. Spicer[6], A.J. Seely[7]
[1]Vancouver Coastal Health, Vancouver/BC/CA ,[2]University of British Columbia, Vancouver/BC/CA ,[3]University of Toronto, Toronto/ON/CA ,[4]BC Cancer Research Institute, Vancouver/BC/CA ,[5]Dalhousie University, Halifax/NS/CA ,[6]McGill University Health Centre, Montreal/QC/CA ,[7]Ottawa Hospital Research Institute, Ottawa/ON/CA

Introduction: Non-small cell lung cancer (NSCLC) is the most commonly diagnosed type of lung cancer. Of these patients, approximately 50% are diagnosed during the early stages of their disease (I-III), and amongst these, less than 30% are diagnosed with resectable NSCLC. Currently, in Canada, there is limited data characterizing this heterogenous early-stage resectable patient population, treatment pathways, and the molecular testing landscape. The primary aim was to describe the patient characteristics, treatment, and referral patterns of early-stage resected NSCLC patients, estimate the prevalence/frequency of biomarker testing and biomarkers of interest (i.e. EGFRm, PDL1). Secondary objectives included describing the surgical treatment outcomes, short-term follow-up, and testing methods for biomarkers and immunotherapy markers.

Methods: This observational cohort study utilized data from the Canadian Association of Thoracic Surgeons (CATS) national database and prospectively enrolled patients across Canada for 12 months (End date March 2025). The CATS national database includes data from nine thoracic surgery centers across Canada, with another ten centers that have either expressed interest or in the process of being onboarded. Study measures, including patient demographics, clinical characteristics, treatment patterns, and surgical outcomes, were collected. Continuous study measures were reported descriptively with mean and median. Frequencies and percentages were used to document categorical measures of interest. Time to event analysis was conducted for post-surgical timelines and time to testing. These results were presented as median time and IQR time to event.

Results: The study population included 162 patients with a mean age of 70.03 ±7.30 years, 56% females. Stage I was the most common one (39.5%), followed by Stage III (30.9%) with 24.7 % of stage IIIA, and stage II (29.6%). The most frequent histological subtype was acinar adenocarcinoma (24.7%), followed by solid adenocarcinoma (15.5%). The median time from preoperative biopsy to thoracic surgery was 21 days (IQR=33-1), and surgery consultation to operation was 48 days (IQR= 92-28). The median length of stay was 3 days (IQR=6-2) from surgery to discharge. The consultation with thoracic surgeons to medical oncologists was 71 days (IQR=99.8-29.5), and for 8 patients who needed neoadjuvant therapy, consultation with a medical oncologist to the starting of first neoadjuvant treatment was 23 days (IQR=29.5-19). There was variation in biomarker testing across centers: Halifax, McGill, Ottawa, and UBC. Key biomarkers analyzed were EGFR status, ALK rearrangement, ROS1 mutation, BRAF mutation, KRAS mutation, and PD-L1 expression. Pre-operative testing was performed more at the McGill and Ottawa centers. More molecular tests were performed post-operatively than pre-operatively. EGFR testing was performed in 50.7% of post-operative cases, compared to 25.3% pre-operatively. ALK rearrangement testing was conducted in 48.8% of post-operative cases, compared to 24.7% pre-operatively. For PD-L1 expression, testing was more frequently performed post-operatively than pre-operatively.

Conclusions: This study provides important insights about testing patterns, treatment decisions, and surgical outcomes for NSCLC surgical candidates across Canada. Variation in different regions' biomarker testing highlights the need for a national standard. This study is still ongoing, aiming to include a total of 200 persons with lung cancer.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.18 Optimizing Intraoperative Lymph Node Dissection in Stage I NSCLC: A Risk-Stratified Approach Based on CNN Model Predictions

Y. Fu, R. Hou
Shanghai Chest Hospital, Shanghai/CN

Introduction: Surgery is now the mainstay of curative local treatment for stage I non-small cell lung cancer (NSCLC) in clinical settings. As an important component, lymph node (LN) resection is a well-established prognostic factor, closely related with recurrence and survival in resectable NSCLC. Therefore, more precise surgical scope involving the resection of LNs is one of the clinical problems that need to be solved urgently. So we aimed to use our conducted model for predicting occult lymphatic metastasis (OLM) to appropriately stratify the risk of OLM and explore the effect of intraoperative lymph node dissection on the prognosis of patients with clinical stage I NSCLC with different OLM risks.

Methods: According to the OLM risk prediction score based on the CNN model conducted in the prospective surgical cohort comprised of 2489 stage I NSCLC patients, 85th percentile in the training set was used as the cut-off value of OLM high- and low-risk groups. Both groups were divided into two groups (1-5 LNs and ≥6 LNs) according to the number of LN dissection, and two groups (less than 3 N2 and 3 N1 and no less than 3 N2 and 3 N1) according to the number of LN stations cleared, respectively. Then, the high-risk group patients were further divided into clinical stage T1 and T2a, which were divided into two groups according to the above number of discharged LNs, respectively. With DFS and CSS as the research endpoints, the survival curve was plotted by Kaplan-Meier analysis, and the Cox proportional risk regression model was used to evaluate the impact of the number and station of intraoperative LN dissection on the prognosis of patients.

Results: Stratified with 85th percentile of risk score of patients in the training set (n=1991) as the cut-off value (0.399), patients in the testing set (n=250) were divided into high- and low-risk group. The results of Kaplan-Meier curve and survival analysis showed that DFS was better in low-risk people with less than 6 LNs or 3 N2 and 3 N1 cleared (P=0.00035 and P<0.0001, respectively), while removal of more than 6 LNs benefit DFS and CSS of clinical T2a high-risk populations (P=0.016 and P=0.00046, respectively). However, no statistical difference in survival due to lymph node dissection factors was observed in other groups.

Conclusions: The results of this study based on the previous OLM prediction CNN model suggested that intraoperative resection of less than 6 LNs and less than systemic LN dissection could bring survival benefit to low-risk people with OLM, while such resection range was insufficient for clinical T2a high-risk patients. Accordingly, it provided a reference for the scope of intraoperation LN dissection of clinical phase I NSCLC, guiding individualized treatment.

EP.07.19 Temporal Advances of Surgical Outcomes in Posterior Segment ectomy for Primary Lung Cancer

R. Kiriyama, Y. Yoshida, M. Yotsukura, T. Haruki, H. Watanabe, Y. Yatabe, S-i. Watanabe
National Cancer Center Hospital, Tokyo/JP

Introduction: The JCOG0802 trial demonstrated that segmentectomy was superior to lobectomy in overall survival for small-sized peripheral non-small cell lung cancer. However, segmentectomy was associated with longer operation time, greater blood loss, and prolonged air leakage. Among complex segmentectomies, posterior segmentectomy is considered technically difficult and challenging because segmental structures are deep in the lung parenchyma from the interlobar fissure. This single-institution retrospective study examined periodical changes in surgical outcomes of posterior segmentectomy.

Methods: The study included 95 patients who underwent S10 or S9+10 segmentectomy for primary lung cancer at our institution between January 2012 and December 2023. The interlobar and posterior approaches were defined as surgical procedures where segmental structures were dissected from the interlobar fissure and the inferior pulmonary ligament.

Results: The interlobar approach and posterior approach included 32 and 63 patients, respectively. The number of posterior segmentectomies increased yearly, and the posterior approach became standardized in 2019. The median age was 70 years; 36 were male, and 47 had never smoked. 49 cases were right-sided surgeries. The median operation time, blood loss, and postoperative hospital stay was 116 (interquartile range (IQR), 106-126) minutes, 17.5 (IQR, 4.5-30.5) ml, and 3.5 (IQR, 3.2-3.8) days in the interlobar approaches, and 106 (IQR, 101-111) minutes, 8.0 (IQR, 1.3-14.7) ml, and 3 (IQR, 2.3-3.7) days in the posterior approach. The major (> Grade IIIa) complications occurred in one (2.4%) and five (7.9%) cases, and there were no mortality cases. The median surgical margin was 21.5 (IQR, 17.5-25.5) mm and 20 (IQR, 18-22) mm (P = 0.25).

Conclusions: With the accumulation of surgical cases, the posterior approach that minimizes the unnecessary division of lung parenchyma replaced the interlobar approach for posterior segmentectomy. The operation time became shorter, and perioperative outcomes were encouraging.

EP.07.20 Evolution of Overall Survival (OS) After Good Quality Curative-Intent Lung Cancer Surgery in a Population-Based Cohort

O.A. Akinbobola[1], M. Smeltzer[2], M. Ray[2], C. Fehnel[1], A. Saulsberry[1], K. Dortch[1], R.U. Osarogiagbon[1]
[1]Baptist Cancer Center, Memphis/TN/USA ,[2]University of Memphis School of Public Health, Memphis/TN/USA

Introduction: Surgical resection is the most effective treatment for non-small cell lung cancer (NSCLC), with OS influenced by both surgical quality, tumor biology, and adjuvant therapy. Having previously demonstrated sequential improvements in surgical quality and OS, we now evaluate survival outcomes specifically among patients who received high-quality surgery.

Methods: The ongoing population-based Mid-South Quality of Surgical Resection (MS-QSR) project involved a pre-intervention era (Era 1: 2004-2008); introduction of a lymph node (LN) collection kit (Era 2: 2009-2013); its widespread adoption (Era 3: 2014-2018), and introduction of a standardized pathology gross dissection protocol (Era 4: 2019-2023). We compared recipients of good quality surgery (defined by IASLC R0 resection and American College of Surgeons' Operative Standard-5.8), evaluated OS with Kaplan-Meier analysis and Cox proportional hazards models with adjusted hazard ratios (aHR) controlling for age, race, sex, insurance status, rurality, comorbidities, pre-radiologic tumor size, histology, IASLC margin classification, receipt of PET/CT, invasive staging, neoadjuvant therapy, final surgical technique, extent of resection, teaching status, and surgeon specialization (with Era 1 for reference).

Results: 7,162 patients underwent curative-intent resection: 987 (14%) in Era 1, 2,219 (31%) in Era 2, 2,057 (29%) in Era 3, and 1,899 (26%) in Era 4. From Era 1 to 4, IASLC R0 resection rates increased from 0% to 32% (p<0.0001), attainment of OS-5.8 increased from 4% to 67% (p<0.0001), 120-day mortality decreased from 10% to 4% (p<0.0001), and five-year OS improved from 48% to 70% (p<0.0001). Among patients with IASLC R0 resections, 5-year OS for Stage I was 67%, 63%, and 72% in Eras 2 to 4 (p=0.0056). Among patients meeting OS-5.8, 5-year OS for Stage I was 63%, 62%, and 73% in Eras 2 to 4 respectively (p<0.0001). OS was stable across eras for Stage II-IV patients in both groups.

Conclusions: Surgical quality improved across all eras, and OS gains were primarily observed in Era 4 Stage I patients. Controlling for high quality surgery eliminated OS differences in stages II-IV patients across eras. However, Stage I patients in Era 4 had improved survival even among those who received high surgical quality, suggesting additional contributing factors beyond surgical improvements. Ongoing research is evaluating potential biologic explanations for these findings.

Era	Era 1 (2004-2008)	Era 2 (2009-2013)	Era 3 (2014-2018)	Era 4 (2019-2023)

EP.07.21 The Efficacy of the 'Lung Partial Resection Prior to Lobectomy Method' as a No-Touch Isolation Technique in Lung Cancer Surge

H. Adachi[1], H. Ito[2], K. Shiomi[3], K. Suzuki[4], N. Takahashi[5], T. Ueno[6], T. Okazaki[7], M. Endo[8], S. Shiono[9], K. Sekihara[10], Y. Saito[11], A. Saito[1], N. Sawabata[12]

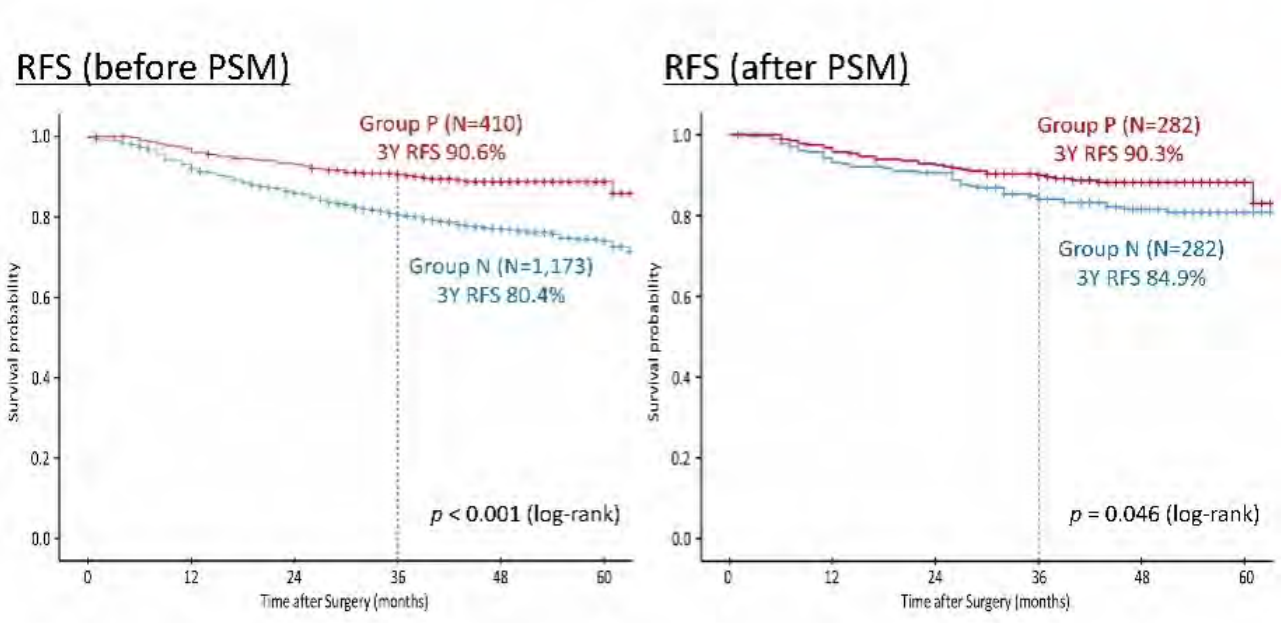
[1]Yokohama City University, Yokohama/JP ,[2]Kanagawa Cancer Center, Yokohama/JP ,[3]Kitasato University, Sagamihara/JP ,[4]SHOWA Medical University Northern Yokohama Hospital, Yokohama/JP ,[5]Saitama Cardiovascular and Respiratory Center, Kumagaya/JP ,[6]Shikoku Cancer Center, Matsuyama/JP ,[7]Osaki Citizen Hospital, Osaki/JP ,[8]Yamagata Prefectural Central Hospital, Yamagata/JP ,[9]Yamagata University, Yamagata/JP ,[10]Hamamatsu University School of Medicine, Hamamatsu/JP ,[11]Teikyo University School of Medicine, Itabashi/JP ,[12]Nara Medical University School of Medicine, Kashihara/JP

Introduction: Although "no-touch isolation technique (NTIT)", which will theoretically prevent intraoperative release of circulating tumor cells (CTCs) from primary tumor, has been reported, its efficacy for the treatment for non-small cell lung cancer (NSCLC) is uncertain. We evaluated the efficacy of the 'lung partial resection prior to lobectomy method' as a NTIT in surgery for patients with c-stage IA-IB NSCLC.

Methods: We retrospectively reviewed the data of 1,825 patients with c-stage IA-IB (8th) NSCLC who underwent lobectomy + mediastinal lymph node (LN) dissection at 25 Japanese institutes in 2017-2018. Among them, we excluded patients who received neoadjuvant therapy or whose pathological diagnosis was adenocarcinoma in situ or minimally invasive adenocarcinoma, we enrolled and analyzed 1,583 patients in this study. We classified patients into 2 group according to the presence of undergoing lung partial resection (e.g. for intraoperative pathological diagnosis) prior to lobectomy (Group P; who underwent, and Group N; who did not) and compared the postoperative relapse-free survival (RFS) of both groups.

Results: The 410 and 1,173 patients were classified into Group P and Group N. The median follow-up periods were 48 months in both groups. Patients in Group P showed significantly better RFS than those in Group N (3-year RFS 90.6% vs. 80.4%, respectively, p <0.001). However, much confounding factors existed between groups, we performed propensity-score (PS) matching method with use of 17 confounding factors (type of institute, age, sex, smoking history, laterality, tumor location, primary lobe, cT factor, maximum tumor diameter, consolidation-to-tumor ratio, tumor appearance on CT, presence of conducting preoperative PET, SUVmax value, presence of pathological diagnosis before surgery, presence of conducting preoperative TBLB, presence of conducting preoperative percutaneous CT-guided biopsy, and surgical approach) and re-evaluated among 282 matched pairs. Even after PS matching, significantly better RFS was found in Group P than in Group N (3-year RFS 90.3% vs. 84.9%, respectively, p =0.046). Subset analyses among PS matched cohort revealed that the RFS in Group P showed tendency to be better than in Group N among patients without pathologically proven LN metastasis (3-year RFS 92.1% vs. 87.3%, p =0.081), whereas no intergroup difference was shown among patients with pathologically proven LN metastases (3-year RFS 65.6% vs. 52.4%, p =0.418).

Conclusions: For the patients with NSCLC without LN metastases, lung partial resection prior to lobectomy method can be the NTIT that prevents the intraoperative release of CTCs and improves postoperative RFS.



RFS, relapse-free survival; PSM, propensity score matching

EP.07.22 Major Lung Resections for Non-Small Cell Lung Cancer: Does Postoperative Pneumonia Remain a Life-Threatening Complication?

K. Grapatsas[1], F. Doerr[2], N. Baldes[2], M. Metzenmacher[3], M. Wiesweg[3], C. Taube[4], F. Oezkan[4], M. Stuschke[5], N. Guberina[5], S. Bertram[6], D. Theegarten[6], M. Schuler[3], S. Bölükbas[7]
[1]University Medical Center Essen-Ruhrlandklinik, Essen/DE ,[2]University Medical Center Essen, Ruhrlandklinik, Essen/DE ,[3]University Medical Center Essen, Department of Medical Oncology, Essen/DE ,[4]University Medical Center Essen, Ruhrlandklinik, Department of Pulmonary Medicine, Essen/DE ,[5]University Medical Center Essen, Department of Radiation Therapy, Essen/DE ,[6]University Medical Center Essen, Institute for Pathology, Essen/DE ,[7]University Medical Center Essen, Ruhrlandklinik, Department of Thoracic Surgery, Essen/DE

Introduction: Despite advancements in medical technology and surgical techniques, pneumonia remains the most common postoperative complication. This study aimed to evaluate the incidence and outcome of postoperative pneumonia in non-small cell lung cancer (NSCLC) patients undergoing major lung resections, and identify key risk factors.

Methods: A retrospective analysis was performed on prospectively collected data of patients undergoing major pulmonary resections for NSCLC at an university medical center from 2016 to 2023. Postoperative pneumonia was diagnosed based on the European Perioperative Clinical Outcome (EPCO) criteria, which include new pulmonary infiltrates, leukocytosis, fever, purulent sputum, antibiotic therapy, and increased oxygen demand. Empiric antibiotic therapy was initiated in all cases and adjusted according to antibiogram findings. Major resections included anatomical lobe resections (lobectomies) and pneumonectomies. The study was approved by the institutional ethics comittee (23-11306-BO).

Results: Data from 1,802 patients were analyzed. Lobectomy was the most common procedure (89.2%), followed by bilobectomy (4%) and pneumonectomy (6.8%). Stage I disease was present in 44.3% of patients, and stage II in 22.1%. Postoperative pneumonia occurred in 4.5% of cases. Patients with pneumonia had higher rates of unplanned ICU admission (0.9% vs. 16.1%, p=0.01) and 30-day mortality (0.7% vs. 20.5%, p=0.01). The extent of resection did not significantly influence pneumonia rates (p=0.14). Risk factors included advanced age (age >70 years: 0.8% vs. 1.9%, p=0.05), reduced preoperative diffusing capacity of the lungs for carbon monoxide (DLCO <60%: 0.7% vs. 1.9%, p=0.02), and revision surgery (1.1% vs. 4.4%, p=0.03). Multivariate analysis identified delirium (HR: 13.659, 95% CI: 2.214-84.275, p=0.01), postoperative renal failure (HR: 7.308, 95% CI: 1.334-40.047, p=0.02), and ECOG PS 3 (HR: 2.111, 95% CI: 0.812-5.487, p=0.03) as significant predictors of pneumonia.

Conclusions: Pneumonia after major lung resections remains a significant cause of mortality. Efforts to mitigate modifiable risk factors and to identify and manage postoperative complications hold promise to improve patient outcomes.

EP.07.23 Single Port Robot and Navigational Bronchoscopy During Single Episode of Anesthesia: Less Is More

P. Ross, P. Skabla, L. Ross, T. Meyer
Main Line Health System, Wynnewood/PA/USA

Introduction: Robotic lung resection with the multiport robot has been reported to improve perioperative metrics and may influence long term oncologic outcomes. Navigational bronchoscopy has emerged as an excellent platform to diagnose pulmonary nodules in any region of the lung. In our four-year experience, combining robotic bronchoscopy with multiport robotic surgery under single episode of anesthesia enhances the patient experience; diagnosis and definitive therapy are completed on the same day. We are evaluating the value of the Single Port (SP) robot on our Minimally Invasive Diagnosis and Surgery (MIDAS) program.

Methods: We reviewed the records of all patients having MIDASP (single port robot) operations between November 2024 and March 2025. Perioperative outcomes as well as short term follow up were collected. Robotic bronchoscopy was performed with Ion navigational bronchoscope and indocyanine green (ICG - 0.2cc) was used to mark nodules for sub lobar resections. We used the DaVinci Single Port (SP) robot; operations were performed through a 3 - 4 cm subcostal incision docking the robot through an access port. Double lumen endotracheal tube and CO2 insufflation were used in all procedures. Stapling was performed at the bedside for SP patients. Node dissection was completed on all patients. We used our MIDAS postoperative pathway for pain medications, chest drain management, and discharge criteria.

Results: Thirteen patients had MIDASP. Demographics include: Gender - Female 8, Male 5; Age - Mean 70 years, Range 56 - 81 years. All Single Port cases were completed without conversion to another surgical approach. Resections included lobectomy (3) and sub lobar (11). All patients were extubated in the operating room and there were no reintubations or ICU admissions. Chest drains were removed before discharge. Length of stay was 1.1 days; 12 of 13 patients were discharged on post op day 1. Final pathology confirmed: NSCLC (7), Carcinoid (2), Metastatic Urothelial Carcinoma (1), Benign Metastasizing Leiomyoma (1), Solitary Fibrous Tumor of the Pleura (2). NSCLC stages were: 1a (4), 1b (2), 4 (1). There were no mortalities or complications.

Conclusions: The Single Port (SP) robot has added a new dimension to minimally invasive thoracic surgery. Our initial experience with the single port robot has documented safety, decreased length of stay, equivalent node dissection, and similar perioperative morbidity/mortality. Subjectively the patients experience less pain, and we are evaluating this quantitatively. A single episode of anesthesia approach to managing lung nodules adds value to the patient's journey. Since a single subcostal incision may have less impact on the patient's physiology, incorporating the single port robot into this surgical pathway may enhance short- and long-term outcomes.

Keywords: robotic surgery, early lung cancer, navigational bronchoscopy

EP.07.24 Study on Complex Segmentectomy Cases at Our Institution

T. Nagashima, Y. Kaburaki, N. Shigeta, I. Takada, R. Matsuyama, C. Kanno, T. Isaka, H. Ito
Kanagawa Cancer Center, Yokohama/JP

Introduction: The effectiveness of segmentectomy for early-stage lung cancer has been demonstrated, and the number of segmentectomy cases is increasing. However, segmentectomy often involves more complex procedures compared to lobectomy. Among these, complex segmentectomy (other than simple segmentectomy), which involves multiple segmental border resections, tends to be even more complex than simple segmentectomy (such as left upper segmentectomy, left lingular segmentectomy, bilateral S6 segmentectomy, and bilateral basal segmentectomy). On the other hand, from the perspective of tumor localization and margin control, there are many cases where complex segmentectomy, including subsegments, should be selected. This study examined the perioperative outcomes of complex segmentectomy cases at our hospital and compared the prognosis of early-stage lung cancer cases.

Methods: From January 2017 to December 2024, 777 cases of lung cancer or metastatic lung tumors that underwent video-assisted thoracoscopic surgery (VATS) segmentectomy at our institution were included. The cases were divided into a simple segmentectomy group and a complex segmentectomy group, and perioperative outcomes were compared. For early-stage lung cancer cases, recurrence rates were also compared.

Results: There were 309 cases (40%) of simple segmentectomy and 468 cases (60%) of complex segmentectomy. Complex segmentectomy was performed in 60.9% of lung cancer cases and 57.6% of metastatic lung tumor cases. The proportion of complex segmentectomies showed an increasing trend over the years. The complex segmentectomy group had smaller tumors compared to the simple segmentectomy group (1.8 cm vs. 2.0 cm, p=0.033), but there were no significant differences in age, smoking index, or respiratory function. The operation time was approximately 10 minutes longer (160 minutes vs. 150 minutes, p=0.001), and the duration of drain placement was shorter (2.4 days vs. 2.6 days, p=0.030) in the complex segmentectomy group. There were no significant differences in the incidence of postoperative complications (≧GIII), persistent pneumothorax (≧7 days), or the need for pleurodesis. In lung cancer cases (cT1N0, R0: n=569), there was no significant difference in the cumulative recurrence-free survival rate (p=0.885).

Conclusions: Although complex segmentectomy was associated with a slight increase in operation time, no significant differences were observed in postoperative complications. Furthermore, there was no difference in the prognosis of lung cancer cases. It seems acceptable to select complex segmentectomy when necessary.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.25 Real-World Treatment Patterns and Outcomes of Stage I-III Resectable Non-Small Cell Lung Cancer (NSCLC) in Portugal

A. Barroso[1], M. Soares[2], F. Ferro[3], C. Freitas[4], S. Simões[5], F. Estevinho[6], T. Sequeira[7,8], L. Barradas[9], U. Brito[10], F.M. de Sousa[11], C.M. Bastardo[12]
[1]Unidade Local de Saúde de Gaia e Espinho, Porto/PT ,[2]IPO Porto, Porto/PT ,[3]Unidade Local de Saúde de Santa Maria, Lisboa/PT ,[4]Unidade Local de Saúde de São João, Porto/PT ,[5]Fundação Champalimaud, Lisboa/PT ,[6]Unidade Local de Saúde de Matosinhos,, Matosinhos/PT ,[7]IPO Lisboa, Lisboa/PT ,[8]Universidade de Lisboa, Lisboa/PT ,[9]IPO Coimbra, Coimbra/PT ,[10]Unidade de Saúde do Algarve,, Faro/PT ,[11]MSD, Paço Arcos/PT ,[12]MSD, Paço de Arcos/PT

Introduction: Lung cancer remains the leading cause of cancer-related deaths, with non-small cell lung cancer (NSCLC) accounting for over 80% of cases. The five-year survival rate of resectable NSCLC is highly dependent on the stage and resectability status, ranging from 92% for stage IA to 26% for stage IIIB. Understanding real-world data on Portuguese patients is crucial to measuring the impact of the disease and identifying potential gaps in care. Therefore, this study aimed to describe the characteristics, treatment patterns, and overall survival (OS) of patients diagnosed with resectable stage I-III NSCLC in Portugal by stage at diagnosis.

Methods: Retrospective, multicenter, observational study that included patients diagnosed with potentially resectable stage I-III NSCLC between July 2016 and December 2017, with follow-up until June 2022.

Results: Of the 401 patients included, 237 (59%) had stage I, 83 (21%) stage II, and 81 (20%) stage III NSCLC. Most patients were males (61%), aged 60 years or older (78%), and were mainly past or current smokers (71%). Additionally, 82% had at least one comorbidity at diagnosis. Most cases were adenocarcinomas (54%). PD-L1 testing was performed in 40% of cases, with 56% expressing less than 1% of PD-L1 positive cells. Genomic testing was conducted on 41% of tumors, of which 39% underwent NGS analysis. Specific alterations were reported in 48% of samples, particularly EGFR mutations (30%). Symptomatic patients had a mean time of 16 weeks from symptoms onset to referral. The mean time from diagnosis to treatment initiation was significantly longer for stage I and II patients than those in stage III (11, 10, and 7 weeks, respectively, p<0.001). Among stage I patients, 84% underwent surgery, either alone (56%) or combined with neoadjuvant systemic therapy (NAT) (1%), adjuvant systemic therapy (AT) (26%), or both (1%). Most stage II patients underwent surgery (83%), 58% received AT, and only 8% received NAT. In stage III patients, 80% underwent surgery, 22% of which in combination with NAT, 38% with AT, and 7% with both NAT and AT. Most patients who received NAT or AT were treated with a two-drug combination including cisplatin. A total of 17 patients underwent both surgery and radiotherapy (RT), including 2 with stage I, 4 with stage II, and 11 with stage III disease. Among non-surgical patients, 74% received only RT (97% stage I, 79% stage II, and 13% stage III patients) and 22% received RT and systemic therapy (0% stage I, 21% stage II, and 75% stage III patients), with stereotactic body radiation therapy (SBRT) being the preferred approach. Median OS was significantly higher for stage I (73 months) than for stage II patients (68 months, p<0.001). The median OS for stage III patients was not reached.

Conclusions: This study provided a comprehensive characterization of clinical and demographic characteristics of patients and treatment patterns for potentially resectable stage I-III NSCLC in Portugal from July 2016 to December 2017. Results highlight stage-specific differences in management and OS. However, ongoing evaluation of real-world treatment patterns is essential to further optimize patient outcomes in NSCLC.

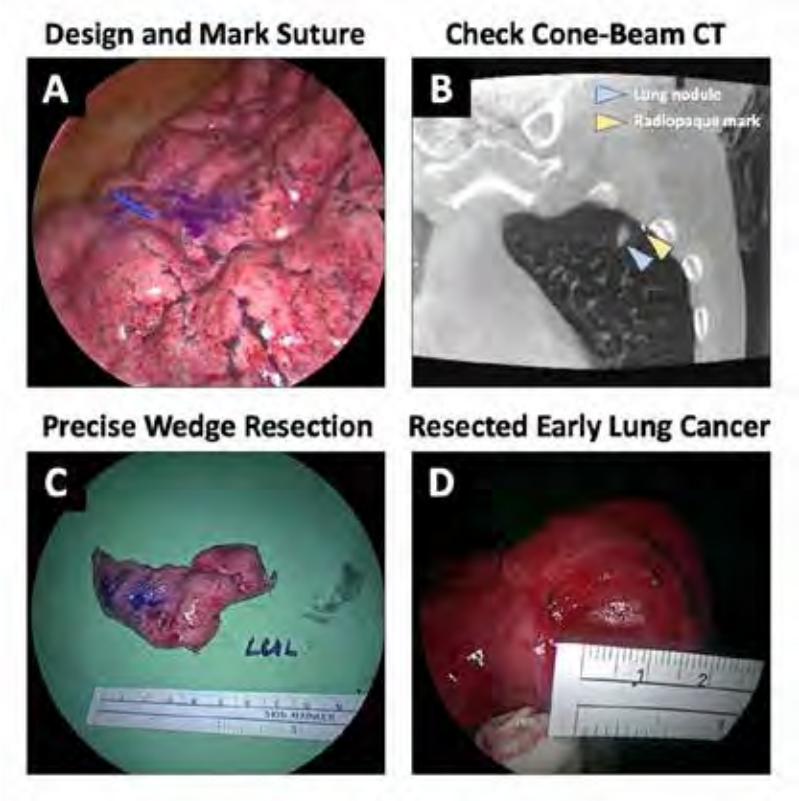
EP.07.26 A Novel Thoracic Localization Technique: Combining Intracorporeal Radiopaque Marker Suturing and Intraoperative Cone-Beam CT

T-N. Kao[1], J-H. Chung[2], H-C. Liao[1], S-W. Kuo[1]
[1]National Taiwan University Hospital, Taipei City/TW ,[2]National Taiwan University Cancer Center, Taipei City/TW

Introduction: Lung cancer remains a major cause of mortality, and early detection of small lung nodules via low-dose CT screening is increasing. Video-assisted thoracoscopic surgery (VATS) is a primary treatment, but the non-palpable nature of these nodules necessitates precise localization. Current CT-guided percutaneous methods using dye, wires, or coils, while accurate, suffer from drawbacks including patient discomfort, psychological distress, and risks of pneumothorax, hemothorax, and air embolism. To address these limitations, we introduce a novel localization technique combining intracorporeal radiopaque marker suturing and intraoperative cone-beam CT in the hybrid operating room.

Methods: We retrospectively reviewed patients undergoing VATS single wedge resection for lung nodules requiring localization. An intracorporeal radiopaque marker suturing technique, guided by intraoperative cone-beam CT, was employed. No preoperative invasive procedures were performed. Following general anesthesia and standard thoracic access, the lung nodule's approximate surface location was marked. A radiopaque marker thread was then intracorporeally sutured to the visceral pleura at this site. Intraoperative cone-beam CT scanning precisely determined the distance between the marker and the nodule, enabling accurate nodule identification and wedge resection.



Results: From May 2022 to March 2025, a total of 241 patients underwent VATS single wedge resection for lung nodules requiring localization using the described intracorporeal radiopaque marker suturing technique with intraoperative cone-beam CT guidance. Notably, this technique proved particularly beneficial for localizing lung nodules deemed difficult for traditional percutaneous methods due to their proximity to the diaphragm or mediastinal structures (including the aorta, heart, and other vital structures), their location beneath bony structures (ribs, scapula, spine, sternum), or their presence within lung fissures. The average localization time per patient was 12 minutes, and the average number of total CT scans during the entire surgery was 2. Importantly, no instances of hemothorax, pneumothorax, air embolism, or procedure-related postoperative pain were observed.

Conclusions: This novel intracorporeal suturing localization technique effectively avoids the pain associated with preoperative percutaneous puncture and eliminates major risks such as hemothorax, pneumothorax, and air embolism. Its utility is particularly pronounced for challenging-to-access lung nodules. Furthermore, the total number of CT scans was lower than reported with traditional localization methods, potentially reducing radiation exposure to medical staff. This approach demonstrates a safe and feasible technique for early lung cancer localization, achieving rapid, precise, and non-percutaneous localization while mitigating risks and patient discomfort.

EP.07.27 Unravelling Sublobar Resections: Real-World Outcomes after Wedge vs Segmentectomy and Recurrence Risk Factors

S. Fra[1,2], A. Cabañero Sánchez[1], G.M. Muñoz Molina[1], U. Caballero Silva[1], L. Gorospe[1], A. Benito Berlinches[1], R. Mirambeaux[1], E. Vílchez Pernias[1], J.D. Lozano Ayala[1], F. Puig Sánchez[3], S. Carrasco Oliva[4], L. Lomanto Navarro[1], N. Moreno Mata[1,2]
[1]Ramon y Cajal University Hospital, Madrid/ES ,[2]University of Alcalá, Madrid/ES ,[3]Hospital Nuestra Señora del Prado, Talavera de la Reina/ES ,[4]Toledo University Hospital, Toledo

Introduction: Although post-hoc analysis of the CALGB study found no differences in oncological outcomes between anatomic segmentectomy (S) and wedge (W), doubts remain about whether they are truly equivalent in real world settings. In addition, most of the current literature haven't analyzed the association of genetic mutations and detailed pathologic features with recurrence after sublobar resections. The aim of our study is to compare long-term outcomes of S and W and investigate risk factors of recurrence.

Methods: We retrospectively analyzed patients diagnosed with c0-IA non-small cell lung cancer (NSCLC) that underwent S or W with curative intent between 01/01/2018 and 31/12/2022 (follow-up until 01/12/2024). Carcinoid tumors and large cell carcinomas were excluded. Survival was estimated using Kaplan-Meier and compared using log-rank test. Cumulative incidence of recurrence was modeled with death as a competing risk for recurrence. Competing risk analysis with a Fine-Gray's test was used to analyze recurrence. Multivariable analysis using backwards strategy was performed.

Results: The study included 87 patients in the S group and 40 in the W group. Median follow-up was 34 months. Regarding clinical and pathologic features, younger age (p=0.018), higher DLCO (p=0.001), higher nodule-pleura distance on CT (p=0.001), greater proportion of vascular (p=0.004) and lymphatic invasion (p=0.049), and greater number of resected nodes (p=0.000) and biopsied N2 stations (p=0.000) were observed in S compared to W. All procedures were performed by VATS, with only one conversion to thoracotomy in the S group (1.14%).No significant differences were observed in OS (p= 0.507)(Figure1A). Although the difference was not statistically significant, the segmentectomy group showed a trend towards lower recurrence risk (SDHR=0.77; 95% CI: 0.21-2.89; p=0.709)(Figure1B), after adjusting for age and vascular/lymphatic invasion. Recurrence was observed in 21 patients (16.53%): 14 (11.02%) locoregional and 7 (5.51%) distal. In multivariable analysis, lymphatic invasion (SDHR=10.56;CI95%:3.81-29.26;p=0.000), positive PDL-1 expression (SDHR=5.94;CI95%:1.78-19.75;p=0.004) and ALK translocation (SDHR=10.96;CI95%:4.21-28.49;p=0.000) were associated with increased risk of recurrence (locoregional or distal). Age (SDHR=1.07;CI95%:1.02-1.14;p=0.014), micropapillary (SDHR=4.32;CI95%:1.29-14.41;p=0.017) and solid (SDHR=5.85;CI95%:1.57-21.77;p=0.008) adenocarcinoma patterns, and KRAS mutation (SDHR=5.12;CI95%:1.65-15.87;p=0.005) were associated with increased risk of locoregional recurrence.

Conclusions: Although not statistically significant, in our study segmentectomy was associated with lower risk of recurrence. After sublobar resections, special attention should be paid to lymphatic invasion, PD-L1 positive expression, micropapillary and solid adenocarcinoma patterns, and ALK and KRAS mutations in order to guide follow-up and future studies regarding potential adjuvant therapies in early-stage NSCLC patients.

EP.07.28 Real-Time Image-Guided Indocyanine Green Fluorescencedual-Visualization Technique Forthoracoscopic Segmentectomy

Y. sun, F. shao
Nanjing Chest Hospital, Nanjing,China/CN

Introduction: The primary goal of thoracoscopic segmentectomy is the complete resection of early pulmonary carcinoma while sparing as much of the normal pulmonary parenchyma as possible, but an obvious trade-off exists between the pulmonary parenchymal preservation and an adequate resection margin. In this clinical trial, we developed and evaluated a real-time image-guided indocyanine green (ICG) fluorescence dual-visualization technique to confirm the resection margin by improving the intraoperative localization of the pulmonary nodule and identification of the intersegmental boundary line (IBL).

Methods: This study was utilized in 35 patients with a screening-detected lung nodule <2 cm to complete thoracoscopic segmentectomy from December 2020 to June 2021. Computed tomography-guided localization of the pulmonary nodule with ICG solution was performed on the day of surgery. During the surgery, after dissecting the targeted pulmonary segmental arteries, ICG at 5mg/body was injected into the systemic vein.

Results: We observed no toxicity. The dual-visualization technique was successfullyimplemented in all 35 patients to achieve a negative resection margin, which was more than 2 (mean 2.71 ± 0.59) cm, or the size of the tumor based on the final pathological examinations. No intraoperative complications occurred and only one patient had postoperative prolonged air leaks, which was ceased 8 days later after conservative management without reoperation.

Conclusions: This technique demonstrated safety and efficacy in achievingoncologically adequate resection margins while preserving pulmonary parenchyma during thoracoscopic anatomical segmentectomy. Comparative studies are warranted to evaluate long-term outcomes against conventional techniques.

EP.07.29 Single-Port Robotic Anatomical Lung Resection Using the Novel Chinese SP1000 Robotic System: Initial Experience

S. Lin[1], X. Guo[1], G. Cheng[2], X. Yu[1], H. Xiao[1], L. Fan[1], J. Feng[1], Z. Yu[1]
[1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital and Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, Shenzhen city/CN ,[2]Shenzhen Edge Medical Co., Ltd., Beijing/CN

Introduction: RATS, first introduced in 2002 by Melfi et al., has rapidly become the preferred technique in many thoracic centers worldwide due to its enhanced visualization, precision, maneuverability, and tremor filtration advantages. While multi-port robotic-assisted thoracic surgery (mRATS), involving 3 to 4 ports, remains the standard, the drive towards further minimizing invasiveness has paved the way for the exploration of single-port robotic surgery (uRATS). The evolution of robotic-assisted thoracoscopic surgery (RATS) has been revolutionized by single-port platforms (uRATS), offering superior triangulation flexibility and reduced intercostal nerve compression. However, evidence comparing these access strategies remains absent in the uRATS literature. This study aims to compare the clinical outcomes of subcostal and intercostal access routes using the single-port robotic surgery platform SP1000.

Methods: From January to July 2024, a total of 15 patients were enrolled, undergoing either subcostal uRATS (6 cases) or intercostal uRATS (9 cases) anatomical lung resection surgeries. The anatomic sequence of the robotic Edge SP1000 (Figure 1A-B) subcostal and intercostal lobectomy/segmentectomy is similar to the conventional intercostal robotic technique. For the subcostal uRATS group, a 4-cm utility incision is made in the subcostal margin at the mid-clavicular line during the operation (Figure 1C-D) and a 12-mm assistant port was initially created in the fifth intercostal space (ICS) along the midaxillary line (MAL) (Figure 1C-D).for intercostal uRATS group, A 4 cm utility incision was made in the fifth ICS along the posterior axillary line (PAL) during the operation (Figure 1E, F). The study involved a detailed comparison of operative times, blood loss, number of lymph nodes dissected, and postoperative complications.

Results: All surgeries were completed successfully. The intercostal group had shorter surgery times (156.0±33.4 minutes vs. 209.2±33.6 minutes, P=0.010), more lymph nodes dissected (21.3±5.7 vs. 13.5±4.5, P=0.014), and less intraoperative blood loss (17.2±13.7 mL vs. 70.0±34.6 mL, P=0.001). There were no significant differences between the two groups in terms of postoperative complication rates, hospital stay duration, drainage volume, and there were no infections or deaths within 30 days post-surgery in either group.

Conclusions: The study demonstrates that both subcostal and intercostal uRATS approaches are feasible and effective for anatomical lung resection. Despite the subcostal approach's longer operative times and greater blood loss, it remains a viable option under specific surgical conditions. Future research should focus on optimizing these techniques to enhance their clinical efficacy.

EP.07.30 Preop-Intraop Consistency in Thoracic Surgery: MRMC Reanalysis of Surgical Planning Accuracy

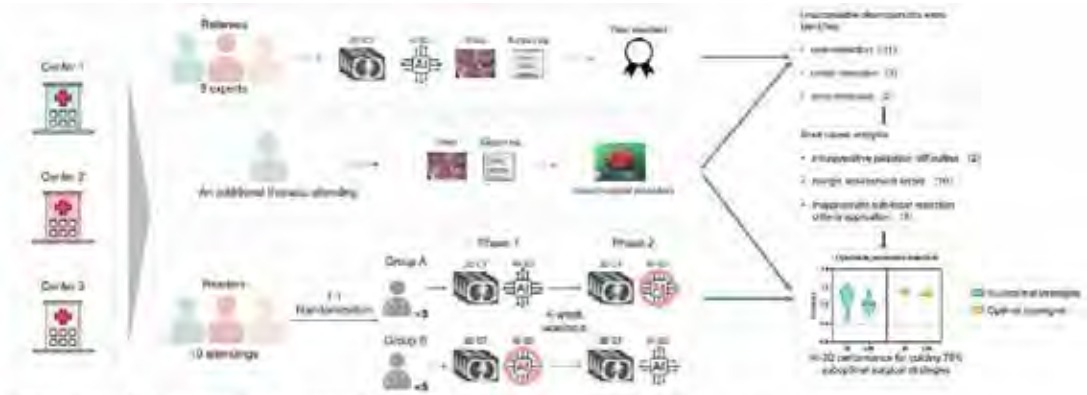
H. Zhao[1,2,3,4,5], R. Li[1], J. Geng[1], C. Dai[6], M. Peng[7], D. Wang[8], X. Chen[1,2,3,4,5]
[1]Department of Thoracic Surgery, Peking University People's Hospital, Beijing/CN ,[2]Thoracic Oncology Institute, Peking University People's Hospital, Beijing/CN ,[3]Research Unit of Intelligence Diagnosis and Treatment in Early Non-small Cell Lung Cancer, Chinese Academy of Medical Sciences, Peking University People's Hospital, Beijing/CN ,[4]Institute of Advanced Clinical Medicine, Peking University, Beijing/CN ,[5]Beijing Key Laboratory of Innovative Application of Big Data in Lung Cancer, Peking University People's Hospital, Beijing/CN ,[6]Shanghai Pulmonary Hospital, Shanghai/CN ,[7]The Second Xiangya Hospital of Central South University, Changsha/CN ,[8]Infervision Medical Technology Co., Ltd, Beijing/CN

Introduction: Three-dimensional (3D) reconstruction enhances spatial awareness to improve anatomical variant identification, with demonstrated surgical benefits in urological surgery and other specialties, though its impact on pulmonary surgical planning remains unsubstantiated. Building upon our prior multi-center, multi-reader, multi-case (MRMC) retrospective study, we employed gold-standard surgical planning panels and AI-driven 3D reconstruction to systematically evaluate the performed surgical procedures and identify cases amenable to procedural optimization through 3D guidance.

Methods: The MRMC study assessed an artificial intelligence (AI) system for preoperative planning. Three expert surgeons from three centers established the gold standard using surgical logs, videos, CT scans, and manual 3D reconstructions. Ten surgeons as readers were randomized into two groups for two rounds of fully crossed pre-operative planning simulations (4-week interval) with or without AI-derived 3D pulmonary vessel reconstructions. Surgical videos and anesthesia/surgical records from all patients were independently reviewed by an additional senior thoracic surgeon unaffiliated with the original procedures to determine actual procedures. Discrepancies between executed surgical procedure and gold-standard plans were classified into three categories: over-resection (exceeding planned resection margins), under-resection (insufficient anatomical coverage), and error-resection (fundamentally altered surgical approaches).

Results: A total of 140 patients were consecutively enrolled across three tertiary centers. Surgical video analysis identified 62 lobectomies and 78 segmentectomies. Comparison with gold-standard plans revealed 21 discrepancies (15.0%): 5 clinically justified (2 multifocal cancers requiring extended resection, 1 compromised sub-lobar resection in an octogenarian, 2 sub-segmental resections exceeding anatomical resolution standards) and 16 protocol deviations (11.4%). Deviations included: 11 over-resections (5 conversions to lobectomy, 6 extended segmentectomies), 3 under-resections (lobectomy-to-segmentectomy conversions), and 2 error-resections (adjacent-segment substitutions). Root cause analysis attributed discrepancies to intraoperative palpation difficulties (2 cases), margin assessment errors (10), and inappropriate sub-lobar resection criteria application (4). Among 12 cases involving palpation or margin errors, preoperative planning accuracy improved from 52% (2D CT) to 76% with AI-3D across 10 readers.

Conclusions: Our study demonstrates that even at leading Chinese tertiary hospitals, surgical plans relying solely on 2D CT exhibit optimization potential in 11.4% (16/140) of pulmonary resections, primarily due to spatial misinterpretations of complex anatomy. Cases with non-palpable nodules or ambiguous margins—representing 75% (12/16) of suboptimal strategies—were identified as prime candidates for 3D reconstruction-guided refinement. These findings underscore AI-3D's critical role in enhancing precision for thoracic surgical planning, particularly in anatomically challenging scenarios requiring enhanced intraoperative decision support.



The workflow of the MRMC study and Consistency Analysis of Surgical Procedures.
The multi-center, multi-reader, multi-case (MRMC) study was conducted as a novel two-phase crossover design. In the initial phase, half of the readers utilized standard 2D CT imaging, while the remainder utilized both 2D CT images and AI-enhanced 3D reconstructions. Following a 28-day washout period, the groups switched methodologies. Each reader was tasked with determining the extent of resection. Three expert surgeons from three centers established the golden standard based on collected surgical logs, videos, CT scans, and manually constructed 3D reconstructions. Surgical videos and anesthesia/surgical records were reviewed by an additional senior thoracic to determine actual procedures. Through comparison with gold-standard surgical plans, clinically unacceptable discrepancies were identified and yielding quantitative discrepancy profiles and root cause. At last, Subgroup analysis was conducted in Readers group, the performance of AI-3D to guide surgical strategy was shown.

Inclusion criteria for readers and golden standard referee
1.Certified attending physician in thoracic surgery department.
2.Practicing thoracoscopic surgery independently for at least one year.
3.Physicians with national license for clinical practicing.
4.Physicians with a good clinical practice certificate.
5.The expert group consists of thoracic surgeons with associate senior clinical titles or above, and their professional directions lobectomy and segmentectomy.

Keywords: lung surgery, 3D reconstruction, artificial intelligence

EP.07.31 A Comparative Analysis of Sublobar Versus Lobar Resection for Early-Stage Non-Small Cell Lung Cancer in Octogenarian Patients

S. Yun[1], T. Yun[1,2], J.H. Park[2], B. Na[1,2], K.J. Na[1,2,3], S. Park[1,2], I.K. Park[1,2], C.H. Kang[1,2], Y.T. Kim[1,2,3]
[1]Seoul National University, Seoul/KR ,[2]Seoul National University Hospital, Seoul/KR ,[3]Seoul National University College of Medicine, Seoul/KR

Introduction: In octogenarian patients with early-stage non-small cell lung cancer (NSCLC), careful consideration of the extent of pulmonary resection is crucial due to increased operative risks associated with age-related functional decline and comorbidities. This study aimed to compare the outcomes of sublobar resection and lobectomy in this demographic.

Methods: A retrospective analysis was conducted on patients aged 80 years or older who underwent curative surgery for clinical stage II or less NSCLC between 2011 and 2022. The primary endpoint was overall survival (OS), while secondary endpoints included recurrence-free survival (RFS), and cumulative incidence of lung cancer-related mortality and noncancer-related mortality.

Results: Among 220 patients, 48 (22%) underwent sublobar resection (wedge resection - 30, segmentectomy - 18), and 172 underwent lobectomy. No significant differences were observed in performance status or pulmonary function between the two groups. However, clinical (P < 0.001) and pathological stage (P < 0.001) were significantly higher in the lobectomy group. The postoperative complication rate was significantly higher after lobectomy (18.8% vs 38.4%, P = 0.047). At a median follow-up of 4.1 years, the 5-year OS indicated a trend towards better survival following sublobar resection, though not statistically significant (80.4% vs 64.6%, P = 0.35). The 5-year RFS were not different significantly between the two groups (81.5% vs 72.7%, P = 0.32). The 5-year cumulative incidence of lung cancer-related mortality (0% vs 12.5%, P = 0.47), and noncancer-related mortality (9.3% vs 18.6%, P = 0.75) did not differ significantly between the groups (Figure 1). Sublobar resection was not a prognostic factor for OS, lung cancer-related mortality and noncancer-related mortality (Table 1).

Conclusions: Sublobar resection demonstrated long-term oncologic outcomes comparable to those of lobectomy. Given the higher complication rate after lobectomy, sublobar resection may be considered the preferred surgical option for octogenarians with early-stage NSCLC.

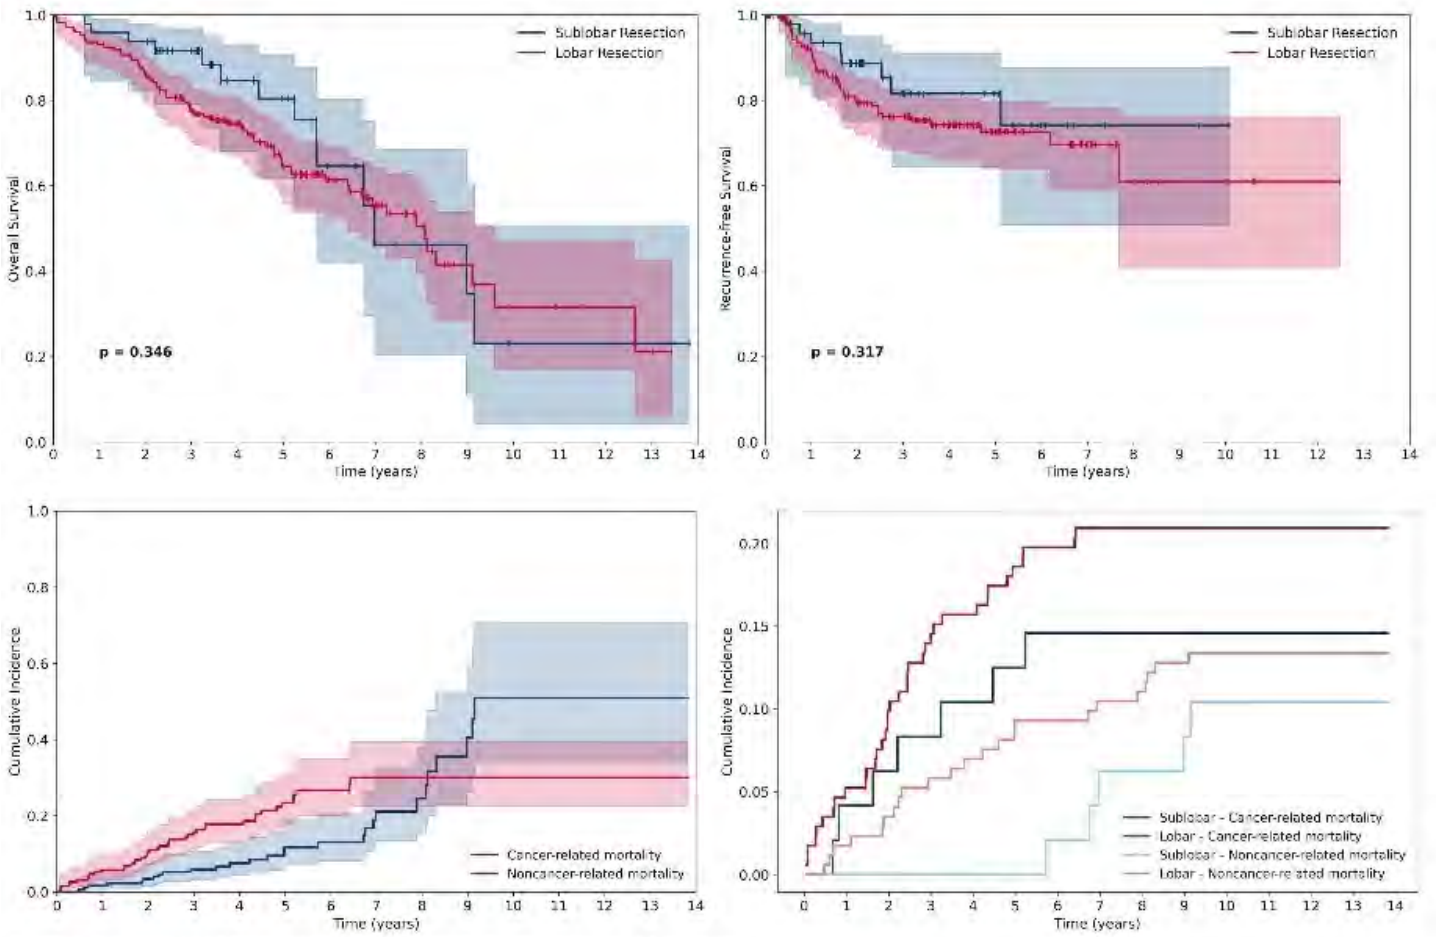


Figure 1. Comparison of Clinical Outcomes after Sublobar Resection and Lobectomy

Table 1. Univariable and Multivariable Regression Analysis for All-Cause Mortality, Lung Cancer-Related Mortality, and Noncancer-Related Mortality

- All-cause mortality was analyzed using Cox regression analysis.
- Lung cancer-related death and non-lung cancer-related death were analyzed using the Fine-Gray subdistribution method to account for competing risks.
- For multivariable regression, variables with $P < 0.2$ in the univariable analysis were included in the model. Backward selection was performed by sequentially removing variables with $P \geq 0.1$ until only those with $P < 0.10$ remained.

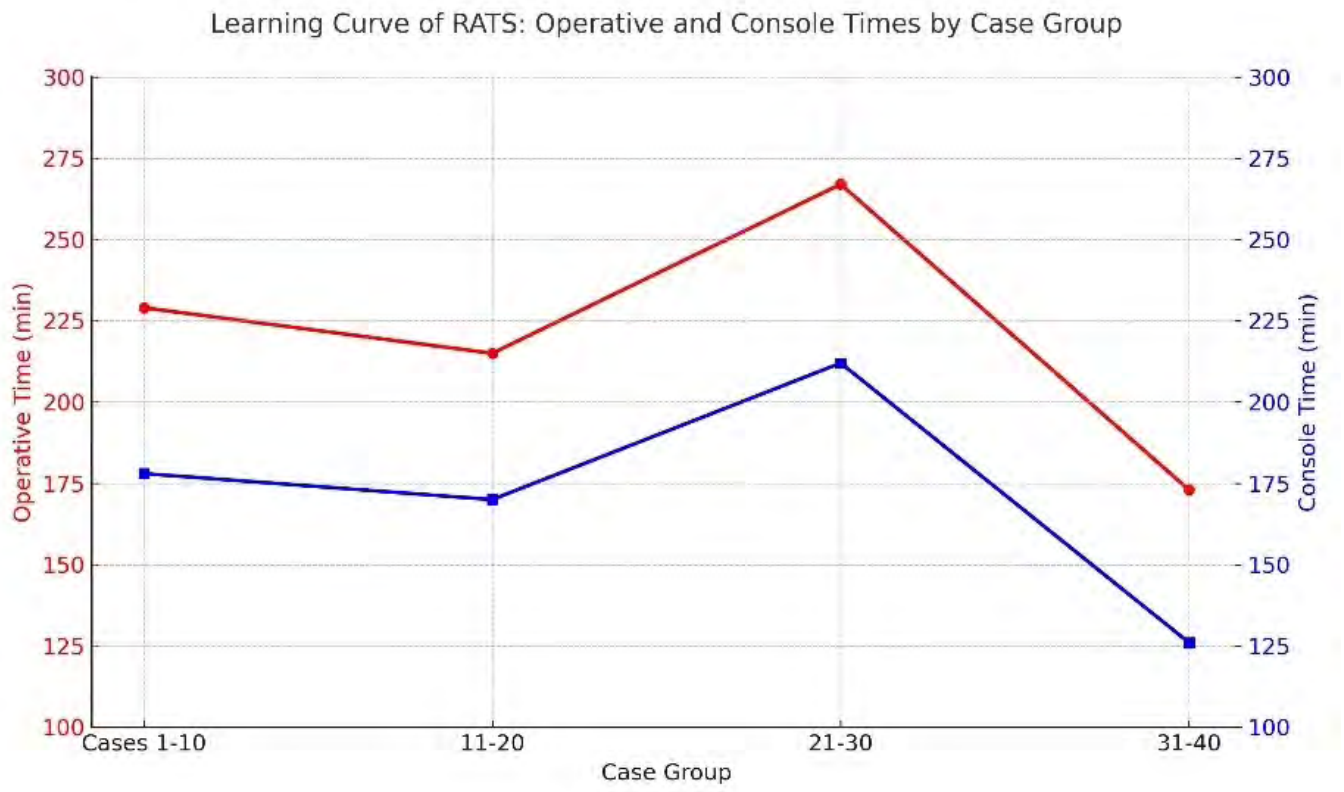
EP.07.32 Initial Experience With Robot-Assisted Thoracic Surgery for Anatomical Lung Resection: A Case Series of 40 Patients From a Japanese Regional Hospital

T. Shima, H. Aoki
Ashikaga Red Cross Hospital, Tochigi/JP

Introduction: Robot-assisted thoracic surgery (RATS) has become an increasingly utilized minimally invasive option for anatomical lung resection. However, evidence regarding the early-phase implementation of RATS in regional Japanese hospitals remains scarce. We aimed to report our institutional experience with the first 40 RATS cases, focusing on perioperative outcomes and learning curve analysis.

Methods: This retrospective case series was conducted at Ashikaga Red Cross Hospital, a 555-bed regional hospital in Japan. The institution had existing robotic surgery programs in urology and gastrointestinal surgery. A RATS program was launched in November 2023 using the da Vinci Xi system. All procedures were performed by a single board-certified thoracic surgeon. The first 10 cases were proctored by an external thoracic surgeon certified as a robotic surgery proctor; subsequent cases were performed independently with institutional staff. Forty patients (18 male, 22 female) underwent RATS anatomical lung resections for clinical stage 0-IIB primary lung cancer between November 2023 and March 2025. The median age was 73 years (range: 49-85). Surgical procedures included 29 lobectomies and 11 segmentectomies. Outcomes evaluated included operative time, console time, blood loss, complications, and hospital stay. Median values were analyzed across four consecutive 10-case groups.

Results: No conversions to thoracotomy were observed. The overall median operative time was 220 minutes, and console time was 162 minutes. The median estimated blood loss was 6 mL (range: 0-1111 mL). Postoperative complications classified as Clavien-Dindo grade ≥ IIIa occurred in 2 patients (5%), and no 30-day mortality was observed. Median operative times by group were 229, 215, 267, and 173 minutes, respectively. Median console times were 178, 170, 212, and 126 minutes. A significant reduction in both operative and console times was noted in the final group, indicating procedural optimization. Figure 1 illustrates this trend.



Conclusions: Our findings suggest that RATS for anatomical lung resection across clinical stages 0 to IIB can be safely introduced in a regional hospital setting with structured support and multidisciplinary collaboration. The data support a moderate learning curve with clear efficiency gains after 30 cases.

Figure 1: Learning curve analysis showing median operative and console times in consecutive 10-case groups.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.33 The Pictorial Fit Frail Scale as a Preoperative Risk Stratification Tool in Lung Resection Patients

F. Pezeshkian, A. Singh, C. Adhikarla, E. Fulton, M. McAllister, V. Wang, C. Vega, M.J. Pommerening, M.T. Jaklitsch, L. Frain
Brigham and Women's Hospital, BOSTON/MA/USA

Introduction: Pictorial Fit Frail Scale (PFFS) is a validated, self-administered, and easy frailty assessment tool that is understudied in thoracic surgery. Our objective was to evaluate whether PFFS can be used to risk-stratify patients undergoing lung resection.

Methods: All patients evaluated for lung surgery between October 2020 and February 2025 were given PFFS for preoperative frailty assessment. Patients who underwent lung resection were divided into 'fit' (PFFS score: 0-0.2) or 'frail' cohorts (PFFS score:0.21-1) based on validated scores. Surgeons were not provided with PFFS scores for surgical decision-making. Descriptive and parametric analysis was used to compare the perioperative characteristics and outcomes between the two groups. P-value <0.05 was considered statistically significant.

Results: During the study period, 272 patients underwent lung resection and completed a PFFS preoperatively. Within the cohort, 201(74%) patients were classified as 'fit' and 71(26%) as 'frail' by PFFS. The median age was 71 and 74 years in the 'fit' and 'frail' cohort, respectively (P=0.006). 'Fit' patients had a higher preoperative FEV1% (93% vs. 83%, P=0.05) compared to 'frail' patients; 'frail' patients had a higher rate of wedge resections (53% vs. 44%, p=0.4). Postoperative adverse events were more frequently noted in the 'frail' group (23% vs. 17%, P=0.3). Major adverse events were comparable between the two groups (Table 1). The median length of stay for both groups was 2 days, however, there was more variability amongst the 'frail' cohort reflected in the higher interquartile range. In addition, frail patients were more frequently discharged to a rehab facility compared to fit peers (1% vs. 4.2%), although this was not statistically significant. Intrahospital mortality was observed in 1/201 fit patients and 1/71 frail patients. The 30- and 90-day mortality was comparable between the two groups. One-year overall survival was 96.5% and 97.2% in 'fit' and 'frail' patients, respectively. Although statistically insignificant, increasing PFFS scores (indicating increased frailty) were associated with longer hospitalizations (β:2.12[95%CI:-2.9-7.1], p=0.4).

Conclusions: Frailty assessment tools such as PFFS have the potential to identify subclinical frailty and improve risk stratification for patients undergoing lung surgery. Although surgical decision-making was not based on PFFS, 'frail' cohort had higher rates of wedge resection compared to 'fit' peers. Hospital length of stay was similar between the groups; however, 'frail' patients were more likely to be discharged to a facility postoperatively. Future work will focus on performing analyses with larger sample sizes to identify significant associations with PFFS scores and postoperative outcomes.

Table 1. Characteristics of the overall cohort were categorized by patients who were classified as fit (PFFS score 0 – 0.2) and frail (PFFS score 0.21 – 1).

Variables; median [IQR] or n (%)	Total N=272	Non-frail (PFFS≤0.2) N=201(73.9%)	Frail (PFFS>0.2) N=71(26.1%)	P value*

EP.07.34 A Study of Lung Cancer Patients Who Survived for More Than 5 Years After Incomplete Resection

F. Hoshi, M. Kawamura, Y. Suzuki, T. Hasumi
Sendai Medical Center, Sendai/JP

Introduction: Complete resection is important for long-term survival in lung cancer. The development of imaging equipment such as thin slice CT and PET decreased the number of cases deemed unresectable during surgery. Even so, there are a certain number of cases of incomplete resection. On the other hand, advances in drug therapy have allowed some cases to survive for longer periods after incomplete resection.

Methods: To explore the pathological and clinical trends of long-term survivors who have undergone incomplete resection.We retrospectively examined 33 patients who survived for more than 5 years after incomplete resection of lung cancer at our hospital between January 2000 and December 2017, inclusive.

Results: Of the 33 cases, 21 were male and 12 were female, with an average age of 69 years. Twenty-five cases of histology were adenocarcinoma, four cases of squamous cell carcinoma, one case of large cell carcinoma, one case of pleomorphic carcinoma, and two cases of small cell carcinoma. The causes of incomplete resection were pleural dissemination in 7 cases, metastatic lymph node remnant in 4 cases, chest wall invasion in 1 case, bronchial stump positive in 1 case, malignant pleural effusion in 4 cases, and pleural lavage cytology positive in 15 cases. Twenty-nine patients underwent lobectomy, three underwent partial resection, and only one was limited to exploratory thoracotomy.

Conclusions: Long-term survivors had a higher percentage of females and positive effusion-positive cases. In addition, there are many driver mutation-positive cases, suggesting that drug therapy with TKIs facilitates long-term survival.

EP.07.35 Comparative Analysis of Anterior and Posterior Approaches in Robotic Pulmonary Resection

A. Osoegawa, M. Abe, N. Haratake, E. Kudo, T. Sato, K. Kamada, Y. Takumi, K. Sugio
Oita University Faculty of Medicine, Yufu/JP

Introduction: Robotic pulmonary resection (RPR) is generally performed via either an anterior or a posterior approach, with institutional preferences varying. Our institution employs both approaches, and this study aims to compare their outcomes.

Methods: We retrospectively analyzed 85 consecutive cases of RPR performed between November 2020 and February 2025. The da Vinci system was used, with the Si model utilized until August 2023 and the Xi model thereafter. The median patient age was 71 years (range, 25-86 years); there were 35 males, and procedures included 75 lobectomies and 10 segmentectomies. Clinical staging was as follows: IA in 71 cases, IB in 4, IIB in 6, IIIA in 1, with 3 cases of metastatic lung tumors. Four console surgeons performed the procedures, with 39 cases employing the anterior approach and 46 using the posterior approach. We compared console time, number of stapler firings, blood loss, and postoperative complications between the two groups using the Mann-Whitney test. The learning curve was evaluated using the cumulative sum (CUSUM) method.

Results: The posterior approach group had a significantly higher median age (72.5 vs. 67 years, p=0.01) and a greater proportion of segmentectomies. There were no significant differences in operative time, console time, blood loss, or postoperative complications between the groups. However, the number of stapler firings was significantly higher in the posterior approach group (median of 7 vs. 5, p<0.001). Among the three surgeons who performed at least 10 cases, proficiency was achieved by the third to fourth case, with no differences noted between the two approaches.

Conclusions: Short-term outcomes, learning curves, and complication rates did not differ significantly between the anterior and posterior approaches in RPR. The increased use of staplers in the posterior approach is likely attributable to the utilization of the da Vinci stapler.

EP.07.36 Introduction of Dural-Port Robot Assisted Thoracoscopic Lung Disection - Aiming for Reduce-Port RATS That Anyone Can Do

H. Numanami, M. Yamaji, T. Akiyama, R. Imazu
Daiyukai General Hospital, Ichinomiya/JP

Introduction: Reduce-port surgery always attracts many surgeons, however a surgical operation needs to be ensured safety and curability. We develop the "Dual-port Robot assisted thoracoscopic (RATS) lung dissection for lung cancer" as a minimally invasive and easy operation. In this study, we introduce Dual-port RATS (DRATS) lung dissection to confirm safety.

Methods: Under general anesthesia with single-lung ventilation, the patients were placed in the lateral decubitus position. The da Vinci Xi Surgical SystemR was positioned at the patient's head side. The cross of the laser was placed at the camera port and conventional targeting was not necessary. From 4 to 4.5 cm diameter working port was created in the sixth intercostal space (ICS) along the middle axillary line as a main window. A camera port was placed at the anterior edge of the window, and an instrument port was placed at the posterior edge. To avoid collisions, we did not use all four arms. The assistant inserted two devices between the ports of the main window. A 12mm diameter port was inserted at the anterior end of the 8th ICS for the stapler. We used the only four devices: a curved dissector, a fenestrated bipolar, SynchrosealR, and SureformR.

Results: Four operations were performed using the DRATS lung dissection for 3 months. The mean operation time was 200.8 min. The mean console time was 149.8 min. The blood loss was 27.5 g. The duration of chest tube drainage was 2.75 days, and mean postoperative stay was 4.5 days.

Conclusions: Our method is safe and easy to perform. This is because an assistant can easily operate two devices and provide appropriate support. We will increase the number of cases to evaluate safety and oncological outcomes.

EP.07.37 An Initial Experience of Resectable Non Small Cell Lung Cancer From a Tertiary Care Center

S. Raikwar[1], A. Yadav[2], A. Agarwal[2], R. Purohit[2], A. Jakhetiya[2]
[1]Geetanjali Cancer Centre, Udaipur/IN ,[2]Geetanjali Cancer Center, Udaipur/IN

Introduction: Lung cancer is the second most common malignancy and the leading cause of cancer death for both sexes worldwide. In western Rajasthan people face the exposure of mines, marbles and stones as a major risk factor for lung and thoracic malignancies . Here, we present an initial experience of managing patients with a resectable lung cancer at our center. The main goal was to see the surgical outcomes and compare them to the guidelines as per the best standard of care.

Methods: This is a Retrospective analysis of a prospectively maintained data base from January 2020 to December 2024.

Results: A total of 12 patients underwent thoracic surgery for a resectable lung cancer.The median age was 52.5 years (Range 24 to70 years). A male predominance was seen with eight male and four female patients. Patients had a median duration of symptoms of seven months (range 4-8 months) before presentation. Cigarette smoking in synergism with occupational exposure to mines and marbles was a major risk factor. All the females were non smoker.The upper lobe was the most common subsite with six patients having disease in right upper (03) and left upper lobe (03), followed by lower lobe (04) and two involving fissure.All the pre operative core biopsies revealed Non Small Cell on histology and molecular profile including five squamous cell, four adenocarcinoma, two carcinoids and one alveolar rhabdomyosarcoma. Ten patients underwent upfront surgery. Two patients were operated after 4# of neoadjuvant chemotherapy (paclitaxel +carboplatin). Surgical approach included a thoracotomy followed by resection with mediastinal node dissection. Ten patients underwent Lobectomy. A bi lobectomy and an apical segmentectomy were done in one patients each. Mean blood loss was 250ml. The median duration of hospital stay was 10 days. Major post operative complications were pneumonia (02) and seroma(03). One mortality was seen on postoperative day five. The post surgery pathological staging revealed median tumor size to be 4cm (range 2 to 11cm) with eight patients in early stage and node negative status and four patients with a locally advanced disease. Three patients were given adjuvant radiation of (55 Gy in 20# over 5 weeks) and one was put on targeted therapy.At a median follow up of 18 months two patients had developed locoregional relapse.

Conclusions: The end result of the present study demonstrated a relatively high overall survival in two years after multimodal treatment. The ability to perform surgery with R0 resection in all cases with a low complication rate, represents the importance of a dedicated thoracic oncology team. Encompassing all possible modalities to extend patients 'survival and quality of life is the ultimate goal of our team in future.

EP.07.38 Immune Checkpoint Inhibitors May Not Fully Mitigate the Adverse Prognostic Impact of PD-L1 Expression in Early Lung Cance

K. Onodera, H. Notsuda, S. Kumata, T. Watanabe, Y. Watanabe, T. Suzuki, T. Hirama, H. Oishi, Y. Okada
Institute of Development, Aging and Cancer, Tohoku University, Sendai/JP

Introduction: PD-L1 expression is thought to correlate with the grade of malignancy in lung cancer. On the other hand, immune checkpoint inhibitors have emerged as an option for recurrence after lung resection and are expected to be highly effective in patients of lung cancers with PD-L1 expression. In this study, we investigated the impact of treatment with immune checkpoint inhibitors after recurrence on postoperative prognosis in early stage lung cancer patients.

Methods: We analyzed 141 patients with stage pI non-small cell lung cancer who underwent complete resection at Tohoku University Hospital from January 2017 to December 2018. We retrospectively evaluated pathological factors and the treatment after recurrence and examined recurrence-free and overall survival rates according to PD-L1 expression.

Results: PD-L1 expression was classified as high (≧50%) in 19 patients, low (1-49%) in 50 patients, and negative in 72 patients; with increasing PD-L1 expression, the rates of pleural invasion, vascular invasion, and lymphatic invasion increased. Recurrence patterns included local recurrence in 8 patients, distant recurrence in 5 patients, and both local and distant recurrence in 4. Patients with negative PD-L1 expression had better OS and RFS than those with positive expression. Patients who bared lung cancer with PD-L1 expression and without driver mutations were predominantly treated with immune checkpoint inhibitors after relapse, but two of the five patients were untreatable after recurrence.

Conclusions: PD-L1 expression in early-stage lung cancer appears to be associated with the grade of oncological malignancy. Treatment with immune checkpoint inhibitors may not sufficiently mitigate the adverse prognostic implications of PD-L1 expression despite its high efficacy for lung cancers with PD-L1 expression.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.39 Simply the Best: Analysis Of 1000+ Patients Comparing Single-Fraction to Three-Fraction Lung SBRT for Early-Stage Inoperable Lung Cancer

G. Videtic[1], C. Reddy[2], K. Stephans[2]
[1]Cleveland Clinic Foundation: Cleveland Clinic, CLEVELAND/OH/USA ,[2]Cleveland Clinic, CLEVELAND/OH/USA

Introduction: A never-realized cooperative group phase III trial had planned to compare single fraction (SF) to three fraction (TF) lung stereotactic body radiotherapy (SBRT) for inoperable early-stage lung cancer (ESLC) patients (pts), with a primary endpoint of overall survival (OS). We analyzed our large single institution database to investigate this question and other relevant cancer- and treatment-related outcomes.

Methods: We surveyed our institutional review board-approved prospective lung SBRT data registry from 2003 to 2024 for ESLC pts treated with SF and TF SBRT, on and off protocols. Rates of local failure (LF), distant failure (DF) and toxicity were assessed, as well as OS. Prognostic factors for LF and DF were identified with competing risk regression with all-cause mortality defined as a competing event. Factors associated with OS were identified with Cox proportional hazards regression.

Results: For the 21-year interval, 1094 pts met study criteria for this retrospective analysis, with the SF cohort having 676 pts (61.8%) and the TF 418 pts (38.2%). 37.2% pts were alive at analysis. Median follow up for all, SF, and TF pts was 29.3, 24.4 and 39.8 months, respectively (p= <0.0001). Patient characteristics included: female (51%); median age 73.9 years, median KPS 80; 25% still smoking; inoperability by lung co-morbidities in 53.1%; with no differences by fractionation (Fx). Tumor characteristics included: median size 1.8 cm; median PET SUVmax 6.6; 64.2% with biopsy proven cancer and the majority adenocarcinoma at 44.1%; with no differences by Fx. SF SBRT consisted of 34 Gy for 88.2% and 30 Gy [with homogeneous planning (HP)] 11.8%. TF SBRT consisted of 60 Gy [with HP] for 82.3% and 54 Gy 17.7%. Grade 3 and higher toxicity was reported in 2.4% pts, with no significant difference by Fx (p=0.40). Grade 3 and higher chest wall toxicity was: SF 0.3% and TF 1%. Each Fx cohort had grade 5 in 1 pt (both as pneumonitis). At 5 years, failure patterns by SF and TF were: LF 5.2% vs. 3.1% (p=0.05) and DF 20.1% vs. 24.1% (p=0.16), respectively. Median and 5-year OS by SF and TF were: 43.6 months and 37.5%; 44.7 months and 41.3%, respectively(p=0.27). Multivariate analysis (MVA) for LF revealed no pt, tumor or treatment associations. DF was associated with histology on MVA (p=0.0039). MVA for OS was significantly associated with age at SBRT (p=0.0015), KPS (p=<0.0001), gender (p=<0.0001) and tumor size (p=0.0002).

Conclusions: In this analysis of over 1000 pts treated in a single center, there were no differences seen in OS between SF and TF lung SBRT pts. Rates of high-grade toxicity including of the chest wall were similar between Fx schedules, as were LF and DM rates. These results suggests that SF may be the preferred lung SBRT option for ESLC, potentially offering logistical and resource advantages.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.40 Efficacy of Re-Irradiation With SABR of Lung Cancer After Primary SABR: A Single Centre Experience

N. Balaramal, S. Briggs, L. Jaques, N. Hatton, P. Bhatnagar
Leeds Cancer Centre, Leeds Teaching Hospital NHS Trust, Leeds/GB

Introduction: While incidents of second primary lung cancers (SPLC) are on the rise, there is a scarcity of data that investigates the effectiveness of re-irradiation with stereotactic ablative body radiotherapy (SABR) following primary SABR. This study evaluates progression-free survival (PFS), local control (LC), and overall survival (OS) following re-irradiation with SABR.

Methods: An ongoing retrospective review of 1033 distinct patients with SABR to the lung from January 2015 to December 2020 examined demographics, radiotherapy data, and outcomes from the electronic patient record. Patients were considered for analysis if they had a SABR re-irradiation for SPLC after 2 years following primary SABR. 28 patients were identified for analysis.

Results: The median age was 72.7, and 46.5% of the patients had a Charlson Comorbidity Index (CCI) of 5 or more. While 75% of patients included in the final analysis were diagnosed with Stage 1 lung cancer, all of the patients had active or past tobacco use. The median time interval between both SABR treatments is 33.5 months, with all treatments delivering BED (10) of 81Gy and more. 55Gy in 5 fractions was the most commonly used fractionation regimen in both primary & re-irradiation settings. The median OS from the 2nd SABR is 30 months (14.0 - 46.0 CI 95%), while the median PFS from the 2nd SABR is 23.0 months (11.7 - 34.3 CI 95%). SABR re-irradiation shows a 92.9% LC rate, comparable to 92.7% LC at 1-year in the primary SABR setting [1].

Conclusions: This study demonstrates the effectiveness of SABR re-irradiation following primary SABR. Further analysis is planned on a larger cohort and will investigate treatment failure patterns, radiation dosimetry & toxicities.

EP.07.41 Individualized SBRT for Ultra-Central NSCLC Achieves Optimal Tumor Control With Minimal Toxicity

D. Liu, S. Yang, C. yun, M. Liu, R. Zhao, M. Hu, B. Su, Q. Wu, H. Wu, H. Liu, Y. Xu
shanghai pulmonary hospital, Shanghai/CN

Introduction: Stereotactic body radiation therapy (SBRT) provides excellent outcomes for early-stage non-small cell lung cancer (NSCLC). However, treating ultra-central NSCLC (UCNLC)-tumors adjacent to critical organs at risk (OARs)-remains challenging due to potential toxicities. Advances in personalized radiotherapy planning may help overcome these challenges. This study evaluates the efficacy and safety of tailored SBRT approaches for UCNLC.

Methods: We reviewed 66 patients with stage I-II unresectable UCNLC treated with SBRT at Shanghai Pulmonary Hospital (January 2020-December 2023). UCNLC was defined as a planning target volume (PTV) abutting or overlapping the proximal bronchial tree, esophagus, heart, great vessels, or pulmonary vessels, or within 1 cm of these structures. Rigorous OAR constraints (maximum dose and volumetric thresholds) were used to protect critical structures. Individualized SBRT plans incorporated non-uniform PTV modifications (e.g., PTV_crop and PTV_high/low) to meet these stringent constraints. Primary endpoints were local control (LC) and progression-free survival (PFS), while secondary endpoints included regional control (RC), distant control (DC), overall survival (OS), and treatment-related toxicity.

Results: Non-uniform PTV modifications were employed in 45.5% of patients, enabling 53.3% to achieve a biologically effective dose (BED10) of 100 Gy while adhering to strict OAR constraints. After a median follow-up of 23.7 months, median PFS was 42.9 months (95% CI: 34.5-51.3), with 1- and 3-year PFS rates of 93.9% and 67.0%, respectively. LC rates reached 98.5% at 1 year and 81.4% at 3 years; corresponding OS rates were 98.5% at 1 year and 92.8% at 3 years. Toxicities were minimal, with grade 1 and 2 radiation pneumonitis in 28.8% and 7.6% of patients, respectively, and only one grade 3 pneumonitis case (1.5%). Long-term toxicities were also mild, including grade 1 pulmonary fibrosis in 9% and one case of grade 2 fibrosis. No severe toxicities (> grade 3) were observed. Importantly, non-uniform PTV modifications did not compromise survival outcomes.

Conclusions: Tailored SBRT that incorporates non-uniform PTV modifications alongside rigorous OAR constraints achieved excellent tumor control with minimal toxicity in UCNLC. These findings underscore the feasibility and effectiveness of personalized radiotherapy planning, affirming SBRT as a safe and viable treatment option for challenging ultra-central tumors.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.42 Stereotactic Body Radiation Therapy Versus Surgery in Early-Stage Non-Small Cell Lung Cancer. How Does Comorbidity Impact?

Lung Cancer. How Does Comorbidity Impact?
L. Martinez-Avila[1], S. Mosteiro-Molina[1], L. PAreja Fernandez[1], M. Nuñez-Fernandez[1], S. Padrones-Sanchez[2], Y. Lin-Lin[2], M. Moretti[2], M. Ruiz-Dominguez[2], S. Aso-Gonzalez[2], J. Ribes-Puig[1], A. Navarro-Martin[1]
[1]Hospital Duran i Reynals, Barcelona/ES ,[2]Hospital Universitario Bellvitge, Barcelona/ES

Introduction: Surgery remains the standard treatment for early-stage non-small cell lung cancer (ES-NSCLC). For patients unfit for surgery, stereotactic body radiation therapy (SBRT) offers high local control with low toxicity. This study aimed to compare overall survival (OS) between surgery and SBRT in early-stage NSCLC, considering comorbid burden.

Methods: A cohort study of patients with clinical ES-NSCLC diagnosed between 2019 and 2021, identified through Tumor Registry Database was made. Patients were stratified by age (<75, ≥75), treatment (surgery, SBRT), and comorbidity by Charlson Comorbidity Index (CCI), categorized as no, low or high comorbidity. Variables: age, sex, histology, hospital admissions before NSCLC diagnosis, follow-up and survival. Kaplan-Meier and hazard ratios were used for survival analysis.

Results: 713 patients were included (mean age 68y, 70.7% male). Most patients were diagnosed at stage I (79.1%), and 83.6% received surgery while 16.4% were treated with SBRT. Based on the CCI, 40.5% had no comorbidity, 35.2% low and 24.3% high. Median follow-up was 28 months. In patients without comorbidity, OS did not significantly differ between surgery and SBRT. However, in those with comorbidities, surgery was associated with improved OS. In the high-comorbidity subgroup, 1-year OS for <75y was 95.7% for surgery vs 84.6% for SBRT, and 80.0% vs 73.3% respectively in ≥75y. SBRT patients had significantly more hospital admissions related to comorbidities prior to cancer diagnosis, suggesting greater baseline fragility.

Conclusions: SBRT provides comparable OS to surgery in early-stage NSCLC patients without comorbidities. In patients with comorbidity, surgery was associated with better outcomes. The higher pre-diagnosis healthcare utilization in SBRT patients suggests a degree of frailty not fully captured by conventional comorbidity indices. The CCI may therefore be insufficient in differentiating surgical from non-surgical candidates. These results highlight the need for more nuanced and clinically meaningful tools to guide treatment individualized decisions in ES-NSCLC

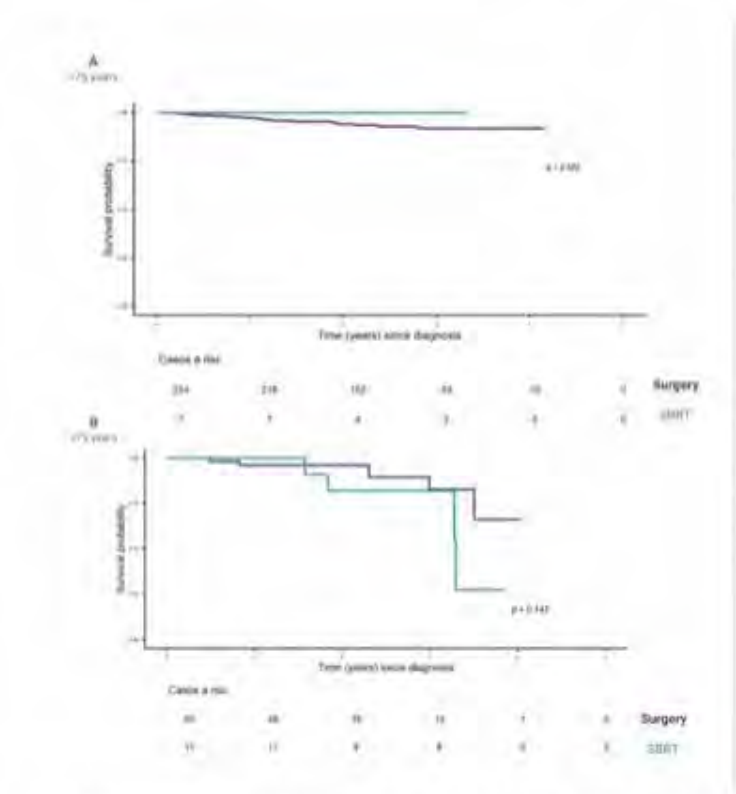

Figure 1. OS according to treatment (surgery vs SBRT) for each group of patients [<75 years (A) and ≥75 years (B)] with **no-comorbidity** by CCI.

Table 1

	Surgery	SBRT
Chronic pulmonary disease	0.7 (0.62-0.75)	1.4 (1.2-1.63)
Diabetes	0.4 (0.38-0.49)	0.9 (0.77-1.12)
Peripheral vascular disease	0.3 (0.21-0.29)	0.4 (0.31-0.55)
Mild liver disease	0.1 (0.11-0.17)	0.1 (0.07-0.2)
Myocardial infarction	0.2 (0.13-0.2)	0.4 (0.28-0.51)

Table 1. Hospital admissions per patient (mean, CI95%) by the five most popular comorbid condition in our patients represented by CCI in surgery and SBRT groups.

EP.07.43 The Role of FDG-PET/CT SUVmax in Predicting Treatment Outcomes and Progression Risk in SBRT for ES-NSCLC

G. Guardia, N. Gascón, G. Sánchez Naranjo, M. Temes, P. Alcaide Córdoba, F. García Luque, S. Pedraza, S. Ruiz, M.Á. Perez Escutia
Hospital Universitario [12] de Octubre, Madrid/ES

Introduction: Stereotactic body radiation therapy (SBRT) is the standard of care for medically inoperable early-stage non-small cell lung cancer (ES-NSCLC). FDG-PET/CT, widely used for pre-treatment staging, provides critical metabolic information and is employed as a diagnostic tool for managing pulmonary lesions without histological confirmation. This study investigates the predictive value of pre-treatment FDG-PET/CT, specifically the relationship between lesion SUVmax and the risk of disease progression, as well as treatment response to SBRT.

Methods: Retrospective study included ES-NSCLC patients treated with SBRT between 2016 and 2023 who underwent pre-treatment FDG-PET/CT imaging. Tumor characteristics and FDG-PET/CT SUVmax of the primary lesion were recorded. Radiological response at three months of SBRT, and progression (type and timing) were also collected. The relationship between FDG-PET/CT variables and treatment response/progression was analyzed with statistical significance set at $p < 0.05$.

Results: A total of 49 patients were included in the study, of whom 91.6% were male. Former smokers comprised 73.5% of the cohort, and 69.4% had a history of emphysema or pulmonary obstructive disease (EPOD). Histological confirmation was available for 57.1% of lesions. Tumor location was central in 34.7% and peripheral in 65.3% of cases. The median SUVmax of the primary lesion was 9.94 (SD 7.2). The most common treatment regimen was 8×750 cGy (32.7%), followed by 5×1000 cGy (22.4%) and 5×1100 cGy (20.4%). At the first post-SBRT assessment, 40.8% of patients had a stable primary lesion response and 44.9% had a partial response. Median follow-up time was 1.5 years. Median progression-free survival was 1 year. A total of 23 patients experienced disease progression; among them, 52.2% had local and/or nodal progression, while the remainder developed distant metastases. The SUVmax values in primary lesions were not associated with increased risk of progression ($p = 0.3$). Interestingly, patients with stability of the primary lesion at first follow-up had significantly lower baseline SUVmax values (mean 7.6 SD 6.9), with statistical significance ($p = 0.04$). Of these patients, 60% lacked histological confirmation of malignancy. No significant differences were observed in progression patterns or treatment fractionation schedules.

Conclusions: We not found relationship between SUVmax values and an increased risk of progression of ES-NSCLC, although further studies specifically addressing this question are needed. The finding that most patients with stable disease at the first follow-up had low SUVmax values and lacked histological confirmation may suggest potential overtreatment of these lesions.

EP.07.44 Perioperative Treatment Patterns and Clinical Outcomes in Early-Stage NSCLC: A Real-World Study (Peri-R-02)

H. Zhong[1], Q. Chu[2], B. Zhang[1], F. Liu[2], J. Teng[1], W. Zhang[1], R. Qiao[1], Y. Zhang[1], M. Li[1], J. Xu[1], J. Qian[1], Y. Kuang[1], L. Cheng[1], S. Wang[1], F. Qian[1], L. Zhang[1]

[1]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN ,[2]Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN

Introduction: The perioperative management of resectable non-small cell lung cancer (NSCLC) has evolved significantly with the integration of immunotherapy. However, perioperative treatment patterns and clinical outcomes in real-world clinical practice remain inadequately characterized.

Methods: The Peri-R-02 study (NCT06610240) was a real-world study in patients with stage I-III NSCLC who underwent radical surgery and received neoadjuvant therapy from two medical centers in China between January 2020 and Feb 2025. The primary endpoint was pathologic complete response (pCR), and the secondary endpoints were objective response rate (ORR), major pathologic response (MPR) and event-free survival (EFS).

Results: In the Peri-R-02 study, a total of 609 patients were analyzed and divided into the immunotherapy checkpoints inhibitor based neoadjuvant cohort (ICI, n=507) and EGFR/ALK tyrosine kinase inhibitor-based neoadjuvant cohort (TKI, n=57) and chemotherapy alone neoadjuvant cohort (Chemo, n=45). After neoadjuvant therapy, surgical outcomes showed comparable R0 resection rates (ICI:97.6%, TKI:96.5%, Chemo:88.9%) and adjuvant therapy administration rates (ICI:79.3%, TKI:86.4%, Chemo:73.3%). Baseline characteristics revealed distinct cohort profiles, ICI and Chemo cohort were predominantly male (ICI, 93.5%; Chemo, 75.6%) and squamous histology (ICI, 70.2%; Chemo, 63.1%), TKI cohort have higher female proportion (57.9%), non-squamous histology (98.2%) and driver gene mutations (EGFR:77.2%, ALK:15.8%). Disease stage (stage III: ICI, 86.4%; TKI, 78.9%; Chemo, 91.1%) and age (>65%: ICI, 43.2%; TKI, 42.1%; Chemo, 42.2%) showed comparable distributions across all three cohorts. ICI cohort demonstrated significant benefits in pCR rate (36.5% vs 7.0% vs 6.7%; P<.001) and MPR (61.4% vs 26.1% vs 12.9%; P<.001) compared to TKI cohort or chemo cohort. ICI cohort and TKI cohort showed significant higher ORR (60.5% vs 60.1% vs 25.5%; P<.001) compared to Chemo cohort. With a median follow-up time of 16.2 months, an EFS benefit trend favoring ICI cohort (HR= 0.44 [95% CI: 0.26, 0.74]; P=0 0.002) and TKI cohort (HR=0.42 [95% CI: 0.20, 0.90]; P=0.025) was observed compared to Chemo cohort.

	ICI cohort N=507	TKI cohort N=57	Chemo cohort N=45
Neoadjuvant therapy regimens, %	ICIs+Chemo, 96.6% ICIs + Anlotinib/Beva, 2.6% ICIs mono, 0.8%	EGFR/ALK TKI + chemo, 42.1% EGFR/ALK TKI, 57.9%	Chemotherapy, 88.9% Chemo+beva, 11.1%
Neoadjuvant Treatment cycles/time, median(range)	3 cycles (1-9)	2 months (1-13)	2cycles (1-6)
R0 resection rate, n (%)	495 (97.6%)	55 (96. 55%)	40 (88.9%)
Adjuvant Treatment Rate, n (%)	402(79.3%)	49(86.0%)	33(73.3%)
pCR, n (%)	185(36.5%)	4(7.0%)	3(6.7%)
ORR	325(60.6%)	36(63.2%)	9(20.0%)

ICI, immunotherapy checkpoints inhibitor; TKI, tyrosine kinase inhibitor; Chemotherapy, chemo; pCR, pathologic complete response; ORR, objective response rate.

Conclusions: In real-world practice, ICI-based neoadjuvant therapy showed greater utilization frequency than TKI or chemo regimens, achieving significantly higher pathological response rates versus both TKI or chemo regimens, while demonstrating EFS benefit trend over conventional chemotherapy. Continued follow-up is being conducted to assess long-term efficacy and safety.

EP.07.45 Single-Cell Analysis Revealed the Characteristics of Tumors With Different Responses to Neoadjuvant Chemo Immunotherapy in Stage II-IIIB NSCLC

M. Zhuo[1], H. Chen[1], B. Jia[1], J. Wang[1], W. Yan[1], S. Yan[1], R. Nuersulitan[1], Y. Chi[1], X. Zhai[1], X. Yang[1], M. Ma[1], L. Li[2], X. Gao[2]
[1]Peking University Cancer Hospital & Institute, Beijing/CN ,[2]Geneplus-Beijing Institute, Beijing/CN

Introduction: Neoadjuvant chemo-immunotherapy (NCIT) has shown promising results in patients with non-small cell lung cancer (NSCLC). However, resistance to treatment remains a constraint to fully understanding treatment responsiveness.

Methods: In this study (ChiCTR2300069552), patients diagnosed with stage II-IIIB NSCLC without EGFR/ALK/ROS1 gene variations were enrolled. Neoadjuvant tislelizumab plus platinum-based doublet chemotherapy for up to 4 cycles was administered. We comprehensively characterized the tumor and immune cell states within the tumor microenvironment (TME) across multiple sequential single-cell samples grouped by pathological complete remission (pCR) and non-pCR based on pathology results. This was achieved by analyzing the single-cell transcriptomes of a total of 473,192 cells from 20 patients, both pre- and post-NCIT, along with their corresponding paracancerous tissues.

Results: From February 2023 to September 2024, 30 patients were enrolled. The overall response rate was 83.3%, and the disease control rate was 100%. Among patients who underwent surgery, the major pathological remission (MPR) rate was 66.7%, and pCR was 50%. We first observed a significantly higher proportion of cytotoxic T cells, TH17 cells, and type II alveolar cells in the pCR group compared to the non-pCR group. In contrast, the proportion of T regulatory cells and exhausted T cells in the non-pCR group was significantly higher than in the pCR group. Secondly, we found that while the proportion of cytotoxic T cells in the pCR group decreased, the proportion of NKT cells significantly increased after NCIT, suggesting that NKT cells may be associated with treatment efficacy. Tumor-associated fibroblasts increased significantly after treatment in the non-pCR group, which may be associated with poor efficacy. Finally, tumor cell trajectory analysis showed that the pCR and non-pCR groups exhibit different evolutionary trajectories.

Conclusions: Our study provides novel insights into the different cellular and molecular components that correspond to NSCLC NCIT responsiveness, which will benefit future personalized chemo-immunotherapy.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.46 Clinical and Radiologic Factors Associated With Surgical Eligibility After Neoadjuvant Chemoimmunotherapy in Stage II-III NSCLC

J. Lee, D.Y. Jeong, J. Son, Y.J. Jeon, S.Y. Park, J.H. Cho, Y.S. Choi, J. Kim, S. Park, H.A. Jung, J-M. Sun, S-H. Lee, J.S. Ahn, M-J. Ahn, H.Y. Lee, H.K. Kim
Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul/KR

Introduction: Neoadjuvant chemoimmunotherapy (NCIT) has demonstrated improved resectability and survival in patients with stage II-III non-small cell lung cancer (NSCLC). However, some patients are not eligible for surgery after NCIT. This study evaluates real-world data to identify baseline clinical and radiologic characteristics associated with surgical eligibility following NCIT.

Methods: We retrospectively analyzed 100 patients with stage II-III NSCLC who received NCIT at Samsung Medical Center between November 2022 and December 2023. Clinical variables included performance status, pulmonary function (DLCO, FEV1), and comorbidities. Radiologic parameters—assessed by experienced thoracic radiologists using CT and PET/CT scans before and after NCIT—included tumor location, bronchial or vascular abutment, necrosis, cavitation, extranodal extension, and metabolic activity. Multivariable logistic regression identified independent predictors of non-surgical treatment decisions.

Results: The mean age of the study population was 64.8 years, with 86% male and 87% ever-smokers. NCIT was completed in 98% of patients. Surgery was performed in 82% of patients. Among those who did not undergo surgery, the main reasons included impaired cardiopulmonary function (n = 9), disease progression (n = 3), and patient refusal (n = 3). Among those who performed surgery, clinical downstaging occurred in 56.1% (n = 46), no change in 40.2% (n = 33), and upstaging in 3.7% (n = 3). Multivariable analysis revealed that ECOG ≥1 (OR 10.89, p = 0.027), DLCO <60% (OR 13.65, p = 0.035), tumor abutment to the main bronchus (OR 10.20, p = 0.035), and incomplete NCIT (OR 0.01, p = 0.013) were significantly associated with a shift away from surgery.

Conclusions: Pre-treatment clinical, imaging, and pulmonary function parameters are key predictors of surgical eligibility following NCIT in stage II-III NSCLC. Identifying these factors may help guide individualized treatment planning in real-world practice. Further validation and development of predictive models across different cohort may improve treatment strategies and outcomes.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.47 Real-World Implementation of Neoadjuvant Chemo-Immunotherapy in Resectable Non-Small Cell Lung Cancer

H. Hemead[1,2], R. Hoffman[1], C. Escriu[3], O. Fakih[3], M. Smith[1], S. Love[1], A. Brunswicker[1], J. McLouhghlin[1], J. Asante-Siaw[1], S. Woolley[1], M. Shackcloth[1]
[1]Liverpool Heart and Chest Hospital, Liverpool/GB ,[2]Alexandria Main University Hospital, Alexandria/EG ,[3]Clatterbridge Cancer Centre, Liverpool/GB

Introduction: In alignment with the recommendation of National Institute of Health and Care Excellence (NICE), nivolumab combined with chemotherapy is currently used for selected patients with resectable non-small cell lung cancer (NSCLC). However, real-world data on outcomes and implementation are limited. Therefore, we aimed to capture real-world data on safety, efficacy and feasibility of chemoimmunotherapy in resectable NSCLC.

Methods: Between 22 March 2023 and 29 October 2024, we retrospectively reviewed patients referred for neoadjuvant chemo-immunotherapy at Liverpool Heart and Chest Hospital, following publication of the NICE guidance. Data collected included demographics, treatment adherence, adverse events, surgical outcomes, pathological response, peri-operative complications and mortality.

Results: During this period, 978 patients underwent surgery for primary lung cancer. Of 184 patients referred to neoadjuvant treatment, 145 patients commenced neoadjuvant treatment and 136 underwent surgery (attrition rate 6%). Adherence to chemoimmunotherapy was excellent;133 patients (92%) completed three cycles. Minimally invasive surgery was performed in 113 patients (83%) with 12 conversions (10%). Standard lobectomy was performed in 92% of cases and pneumonectomy rate was 2%. Complete pathological response was achieved in 41 (30%) and major pathological response in 21 patients (15%). The 90-day mortality in the surgical cohort was 4%.

Conclusions: Neoadjuvant chemo-immunotherapy is feasible and well tolerated in a real-world setting, with low attrition and encouraging pathological response rates. The high utilisation of minimally invasive surgery and low peri-operative complications, along with low mortality, support its integration into the standard care for selected patients with resectable NSCLC.

EP.07.48 The Impact of Sarcopenia on Neoadjuvant Chemoimmunotherapy in Earlier Stage Resectable NSCLC

V. Di Noia[1], R. Castellana[1], F. Fusco[1], I. Sperduti[1], N. Porciello[1], V. Stati[1], D. Marinelli[1], F.L. Cecere[1], L. Sanchez[1], A. Torchia[1], F. Gallina[1], S. Buglioni[1], E. Melis[1], P. Nistico[1], L. Landi[1], A. Vidiri[1], F. Cappuzzo[1]*
[1]IRCCS Regina Elena National Cancer Institute, Rome/IT

Introduction: Immunotherapy (IO) targeting programmed death (PD) 1 and PD ligand(L)-1 has been recently introduced in the neoadjuvant [combined with chemotherapy (CT)] and adjuvant setting to enhance outcomes in resectable NSCLC and improve the chances of achieving a cure. The interplay between nutritional status and anticancer immunity represents an emerging and intriguing area of research. This study explored the influence of sarcopenia on the pathological response to the neoadjuvant CT-IO in resectable non-small-cell lung cancer (NSCLC).

Methods: A retrospective analysis was performed of patients with earlier stage resectable NSCLC receiving neoadjuvant CT-IO at our institution from August 2021 to August 2024. Body composition parameters at third lumbar level were assessed by applying an arti artificial intelligence (AI)-powered-software to computed tomography (CT) performed at baseline and before surgery (T1). Sarcopenia was defined according to Skeletal Muscle Index (SMI) sex-based cut-offs of the International definition. Primary endpoint was the pathological complete response (pCR) rate; secondary endpoints were Major Pathological Response (MPR) rate and event-free-survival (EFS).

Results: Data from 34 patients were collected, including 20 (58%) females and 14 (42%) males. The median age was 65.5 years (range 45-80). The median Body Mass Index (BMI) was 24.6 kg/m2. At baseline, 16 (47%) patients were sarcopenic and the majority of them (10/16, 63%) were classified as normal-weight by BMI. The PCR rate was significantly higher in patients without sarcopenia compared with sarcopenic patients (66.7 vs 31.3%, OR 4.4, 95%CI 1.04-18.59; p=0.039). Also PD-L1 high-expression (≥50%) was significantly associated with pCR rate (p=0.021). No significant differences in term of pCR and MPR were observed according to SMI and fat tissue indices. Multivariate regression analysis confirmed significantly higher likelihood of pCR rate with non-sarcopenia status (OR 4.2 , 95% CI.0.83-21.14, p=0.081) and PD-L1 high-expression (OR 7.48, 95% CI 1.16-48.19, p=0.034). Out the 29 evaluable patients at T1, sarcopenia was present in 18 (62%) cases, including 2 patients who were non-sarcopenic at baseline. Difference of SMI and fat tissue-related indices between T1 and baseline were not significantly associated with pCR and MPR. After a median follow-up 12.6 months (mo), a better EFS trend was observed in patients without sarcopenia at baseline (not reached vs 23.7 mo, HR 0.23, 95%CI 0.04-1.37, p=0.106).

Conclusions: Non-sarcopenic status may represent an intriguing predictive markers of pathological response to CT-IO in the potentially-curative setting of resectable NSCLC. Prospective data on larger population are needed to validate this easy-assessable clinical biomarker.

EP.07.49 Neoadjuvant Sunvozertinib for Early-Stage NSCLC Patients With EGFR Exon 20 Insertion Mutation: A Case Series

J. Chen, D. Zhao, Z. Zhou
Peking University Cancer Hospital & Institute, Beijing/CN

Introduction: Sunvozertinib is an oral, potent, highly selective EGFR-TKI approved in China for the treatment of advanced NSCLC with EGFR exon 20 insertion (exon20ins) mutation. Few reports describe the advantages of this therapeutic strategy in a neoadjuvant setting. Here, we firstly report a real-world series showing the encouraging clinical activity of sunvozertinib as neoadjuvant therapy in early-stage NSCLC patients harboring EGFR exon20ins mutation.

Methods: We retrospectively collected profiles of NSCLC patients with EGFR exon20ins mutation receiving sunvozertinib as neoadjuvant treatment. TNM staging was based on AJCC 9th Edition. The data analyzed by investigators included response assessment by RECIST 1.1 and safety outcomes. The data cutoff was March 21, 2025.

Results: At data cutoff, three NSCLC patients with EGFR exon20ins mutation were retrospectively collected. All the patients received sunvozertinib as neoadjuvant treatment and achieved obvious partial response (PR) before surgery. Then all the patients underwent surgery successfully. Patient 1, a 67-year-old male patient was diagnosed with stage IIIB lung adenocarcinoma. The patient received a therapy of sunvozertinib 300 mg QD for 3 months then 150mg QD for another 3 months as neoadjuvant treatment. The preoperative CT scan showed significant reduction by about 80%. At data cutoff, the patient has undergone surgery successfully. No intolerable adverse event was observed. Patient 2, A 54-year-old female patient was diagnosed with stage IIIA lung adenocarcinoma. The patient received sunvozertinib 300 mg QD as neoadjuvant treatment for 3 months. The preoperative CT scan showed that the primary lesion achieved obvious PR and then the patient underwent surgery successfully. There were no drug-related adverse events during the neoadjuvant treatment. Patient 3, A 78-year-old male patient was diagnosed with stage IIB lung adenocarcinoma. The patient received sunvozertinib 300 mg QD orally for 3 months. The preoperative CT scan showed obvious tumor shrinkage by about 50%. Then the patient underwent surgery successfully. The safety profile of sunvozertinib in this patient was good.

Conclusions: In this real-world case series, neoadjuvant sunvozertinib showed encouraging clinical benefit in early-stage NSCLC patients with EGFR exon20ins mutation and all the three patients achieved obvious PR before surgery. In addition, the safety profile was acceptable. Prospective studies with larger sample sizes of sunvozertinib in early-stage NSCLC patients are worth further investigation.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.50 Real-World Treatment Strategy and Postoperative Prognosis for Clinical Stage II/III NSCLC: A Multicenter Study

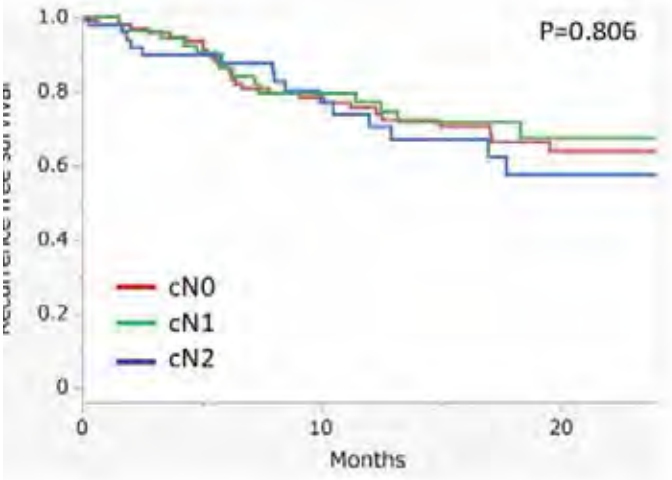
T. Matsubara[1], A. Hashinokuchi[1], K. Matsudo[1], T. Nagano[2], K. Kosai[3], S. Wakasu[4], F. Kinoshita[1], M. Yamaguchi[3], M. Takenoyama[5], K. Yamazaki[2], M. Hamatake[4], T. Takenaka[1]
[1]Kyushu University Hospital, Fukuoka/JP ,[2]Kyushu Medical Center, Fukuoka/JP ,[3]NHO Kyushu Cancer Center, Fukuoka/JP ,[4]Kitakyushu Municipal Medical Center, Kitakyushu/JP ,[5]Red Cross Matsuyama Hospital, Matsuyama/JP

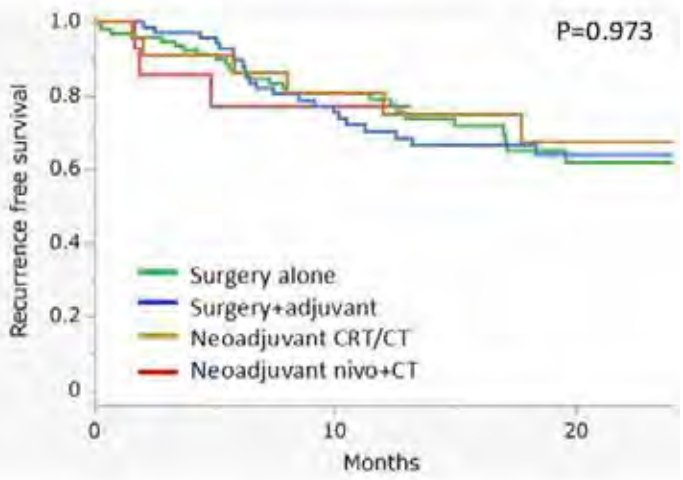
Introduction: For stage II/III non-small cell lung cancer (NSCLC), postoperative tyrosine kinase inhibitors, postoperative immune checkpoint inhibitors (ICIs), and recently, neoadjuvant ICI have become standard treatment options. We conducted a multicenter retrospective observational study to investigate the real-world treatment patterns and prognostic outcome for clinical stage II/III NSCLC in this era of perioperative personalized medicine.

Methods: We retrospectively analyzed 201 cases of clinical stage II/III NSCLC (based on the 9th edition of the TNM classification) who underwent surgery at 5 institutions in Japan between March 2022 and August 2024. The primary endpoint was the treatment strategy based on clinical factors (N status or clinical stage). Postoperative prognosis was also examined.

Results: The median age was 72 years, and 68% of the patients were male. The distribution of clinical N stages was cN0/1/2 in 48%, 27%, and 25% of cases, respectively, and cStage II/III in 61% and 39%, respectively. Among all cases, 82% underwent upfront surgery, while 18% received neoadjuvant therapy (11% were chemoradiotherapy (CRT) or chemotherapy (CT), and 7% received nivolumab+CT). Among the upfront surgery cases, 70 patients (42%) received adjuvant therapy. The rate of neoadjuvant therapy increased from 10% to 24% (P=0.0154) following neoadjuvant first approval of neoadjuvant nivolumab+CT regimen in Japan (from 6% to 24% in cN1 cases, from 33% to 50% in cN2 cases). Finally, we analyzed recurrence-free survival (RFS). No significant difference in RFS was observed based on clinical stage, N status, or treatment modality. The 1-year RFS rates for clinical stage II and III were 76% and 73%, respectively (P=0.866). The 1-year RFS rates for cN0, cN1, and cN2 were 76%, 77%, and 71%, respectively (P=0.806). Based on treatment modality, the 1-year RFS rates were 79% for surgery alone, 70% for surgery plus adjuvant therapy, 75% for the neoadjuvant CRT/CT group, and 77% for the neoadjuvant nivo+chemo (P=0.973).

Conclusions: The introduction of neoadjuvant therapy has increased for cN1/N2 cases following neoadjuvant nivolumab+chemotherapy regimen approval . Due to the impact of neoadjuvant therapy, the short-term prognosis of cN1/N2 cases was comparable to that of cN0 cases. Further follow-up is needed to assess long-term outcomes by treatment modality.





EP.07.51 Long-Term Egfr-Tki as Neoadjuvant Therapy Effectively Achieved Depth of Pathological Response

Y.D. Cheng, L.F. Li, C.F. Zhang, X.Z. Li, L.Q. Lu
Xiangya Hospital of Central South University, Changsha/CN

Introduction: Emerging evidence suggest that neoadjuvant therapy is capable of improving R0 resection rate, controlling regional recurrence and distant metastasis in NSCLC. Nevertheless, the NEOS trial reported limited pathological response (MPR 15%, PCR 0%) with 6-week third-generation EGFR-TKI in EGFR-mutant NSCLC. Given EGFR-TKI exerts its effect by inhibiting the growth of tumor cells instead of inducing cytotoxic effects, we assumed that prolonged duration of neoadjuvant therapy may be a promising approach to improve the depth pathological response for EGFR-mtated NSCLC patients.

Methods: We retrospectively analyzed stage IA-IVA(AJCC 9th) NSCLC patients harboring EGFR mutations without prior anti-tumor treatment from 2022 to 2024 in Xiangya hospital. All the patients were treated with regular dose of third-generation EGFR-TKI at least 3 months as neoadjuvant therapy. The primary endpoint was pDepOR (pathologically depth of response). Secondary endpoints included PFS, ORR, DCR and safety.

Results: In total, 13 patients were enrolled and analyzed with the median age of 60 years old (range 53-76). Among them, two patients were clinically diagnosed as stage IVA due to possible lesions localized in contralateral lung reported by PET-CT. Eight patients received neoadjuvant therapy over half year. 84.6% of candidates reached pDepOR to varying degrees. The pDepOR distribution: >95% (30.8%), 50-95% (53.8%), 26-50% (15.4%). The ORR was 46.2% and the DCR was 100%. No grade ≥3 AEs occurred before surgery. As for surgery, long-term EGFR-TKI as neoadjuvant therapy did not increased the difficulty nor complications. The operation time of 11 patients was within 2 hours and all the patients were discharged within 5 days. The majority of patients (84.6%) had intraoperative blood loss was no more than 50ml. The post-op drainage was around 200-400ml and the drainage tube can be pulled off within 4 days.

Conclusions: Long-term 3rd-generation EGFR-TKI as neoadjuvant therapy can effectively shrink the depth of tumor without making surgery more complicated. Enrollment will continue for further analyses.

Keywords: EGFR-mutant NSCLC, Long-term neoadjuvant therapy, targeted therapy

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.52 PD-L1 Tumor Expression Changes in Non-Small Cell Lung Cancer After Neoadjuvant Chemoimmunotherapy and the Relation With Pathologic Response

M. Polaczek[1], R. Langfort[1], A. Wozniak[2], T. Orlowski[1], C. Piwkowski[2], K. Stencel[2]
[1]National Tuberculosis and Lung Diseases Research Institute, Warsaw, Poland, Warsaw/PL ,[2]Wielkopolska Center of Pulmonology and Thoracic Surgery of Eugenia and Janusz Zeyland, Poznan/PL

Introduction: Programmed death-ligand 1 (PD-L1) expression on cancer cells remains the most important predictive factor for checkpoint inhibitors in non-small cell lung cancer (NSCLC). The use of PD-1/PD-L1 antibodies in combination with chemotherapy as neoadjuvant or perioperative treatment for NSCLC is not dependant on PD-L1 expression level and PD-L1 does not correlate so strong with treatment outcomes as it does in the palliative setting. Chemotherapy was believed to increase the level of PD-L1 expression and to boost the mechanisms of response to checkpoint inhibitors. The effects of neoadjuvant chemoimmunotherapy on the PD-L1 expression on tumour cells and the correlation between pathological response and the PD-L1 status-change remain unknown.

Methods: We investigated 18 cases of patients diagnosed with locally advanced NSCLC and found resectable, who were treated with neoadjuvant chemoimmunotherapy in routine clinical practice. We retrospectively recorded demographics, initial stage, histology, regimen used, baseline PD-L1 (bPD-L1) expression and pathological response with percentage of vital cancer cells in the resected specimen. We also conducted prospective PD-L1 expression assessment in the resected specimen (yPD-L1), with the initial results blinded from the pathologist, we excluded cases with pathological complete response (pCR). We used SP263 clone for PD-L1 stain. Collected data was analysed, change is presented in percentage points (p.p.) and numbers are rounded to two decimal places. All patients consent to study participation.

Results: Our cohort included 9 females and 9 males; the median age was 67 years at the day of treatment introduction. There were 10 cases of squamous cell carcinoma and 8 cases of adenocarcinoma. Median bPD-L1 expression was 73% (average 54%, SD=0.42, range 0-100%). Clinical stage IIIA was predominant, with N2 positive in 9 cases. Most patients received nivolumab (13/18), the rest got durvalumab and pembrolizumab (3 and 2 accordingly) in combination with histology specific chemotherapy. 16 patients completed the whole planned neoadjuvant treatment. Major pathological response (MPR) rate was 61% (11/18) and the median percetage of remaining living cancer cells in resection specimen (LCCSp) was only 10% (average 23%). 17 cases were node-positive (N+) at baseline, only 6 remained N+ after neoadjuvant phase. LCCSp had very low negative linear correlation with bPD-L1 (r= -0.249), but median bPD-L1 in pCR group was 80%. Median yPD-L1 expression was 10% (average 25%, change from baseline (-)63 p.p.for median value and (-)31 p.p. for average value) and change from baseline in the evaluable-only group was (-)14 p.p. The potency of-PD-L1 stain was decreased in resection specimens and in cases when living cancer cells proportion was low the assessment was less reliable.

Conclusions: Very high PD-L1 expression is a good predictive factor to complete pathologic response after neoadjuvant treatment with chemoimmunotherapy of NSCLC. PD-L1 expression decreases after neoadjuvant chemoimmunotherapy for NSCLC which may explain smaller (or uncertain) benefit from adjuvant phase of perioperative treatment observed in recent registration trials. Further investigation is needed.

Keywords: PD-L1, neoadjuvant, chemoimmunotherapy

EP.07.53 Impact of Subcutaneous Fat on the Relative Dose Intensity of Adjuvant Chemotherapy in Patients With Non-Small Cell Lung Cancer

I. Takada
Kanagawa cancer center, Kanagawa/JP

Introduction: Maintaining a high relative dose intensity (RDI) is important for enhancing the efficacy of chemotherapy in various cancers. Reduced or delayed administration of anticancer drugs may result in poor prognosis. This study examined the effect of subcutaneous fat on the RDI of platinum-based agents during postoperative adjuvant chemotherapy in patients with pathological stage II-III non-small cell lung cancer (NSCLC).

Methods: Toward this, 101 patients subjected to adjuvant platinum chemotherapy after complete resection of pathological stage II-III NSCLC at our institution between 2017-2019 were included in this study. RDI was defined as the ratio of the actual dose (mg/m2/week) to the planned dose (mg/m2/week) of platinum agents (cisplatin and carboplatin) used in adjuvant chemotherapy. The area of subcutaneous fat (SFA) was measured with a Synapse Vincent (FUJIFILM, Tokyo, Japan) using preoperative CT at the level of the third lumbar vertebra. Cutoff values of subcutaneous fat area were determined using receiver operating characteristic (ROC) analysis to predict the completion of four courses of adjuvant chemotherapy. A logistic regression model was used to perform multivariable analysis of factors related to the RDI, including SFA, as a variable.

Results: Median age was 64 (35-78) years, median BMI 22.9 (16.9-29.7) kg/m2, 72 patients had adenocarcinoma, and 51 (50.1%) had pathological stage III NSCLC; 75 patients received four courses of adjuvant chemotherapy and 83 received cisplatin, and the median RDI was 75 (range 23-100) %. There were 34 patients (33.7%) with low RDI (RDI < 70 %). There were no significant differences in clinicopathological factors, including age (62.8 vs 62.3, p=0.773), BMI (23.5 vs 22.8, p=0.269), and gender (male: 67.6% vs. 76.1%, p=0.476), between the low- and high-RDI groups. The number of patients with high SFA (>137 cm2) was significantly higher in the low-RDI group than in the high-RDI group (32.4% vs. 10.4%, p=0.012). The 5-year RFS rates were 42.5% and 60.4% in the low- and high-RDI groups, respectively (p=0.084). Multivariable analysis revealed SFA as an independent predictive factor associated with low RDI (HR 4.120, 95%CI 1.39-12.2, p=0.01).

Conclusions: High subcutaneous fat area was associated with low RDI in platinum-based adjuvant therapy in patients with pathologic stage II-III NSCLC.

Keywords: Adjuvant chemotherapy, relative dose intensity, subcutaneous fat

EP.07.54 Lymphatic Permeation as a Key Risk Factor for Recurrence in Pathological Stage IIA NSCLC Under the 9Th TNM Classification

Y. Kudo[1], Y. Shimada[1], T. Mimae[2], T. Nagashima[3], M. Hagiwara[1], M. Kakinaha[1], T. Ohira[1], H. Ito[3], M. Okada[2], N. Ikeda[1]
[1]Tokyo Medical University, Tokyo/JP ,[2]Hiroshima University, Hiroshima/JP ,[3]Kanagawa Cancer Center, Kanagawa/JP

Introduction: In the 9th edition of the TNM classification, T1N1 non-small cell lung cancer (NSCLC), previously classified as stage IIB, has been redefined as stage IIA. This stage, which originally included only T2bN0 tumors, now comprises both node-negative and node-positive disease, resulting in a more heterogeneous population. While some clinical guidelines recommend adjuvant therapy for all patients with stage IIA, others limit its use to those with high-risk features, which remain inconsistently defined. Thus, identifying robust pathological risk factors for recurrence is essential to inform appropriate postoperative management.

Methods: We retrospectively analyzed 724 patients with pathological stage II NSCLC (based on the 9th edition TNM classification) who underwent curative resection between 2010 and 2022. The data were collected from the HITOKA3 database, which comprises cases from three institutions: Hiroshima University, Tokyo Medical University, and Kanagawa Cancer Center. Clinicopathological characteristics and survival outcomes were evaluated.

Results: Among the 724 patients (men:women = 508:216; median age 64), 672 underwent lobectomy, 46 segmentectomy, and 6 pneumonectomy. Stage IIA and IIB included 258 and 466 patients, respectively. Within stage IIA, 144 were T1N1 and 114 were T2bN0. The 5-year overall survival (5yOS) was 73.4% for IIA and 64.2% for IIB. The 5-year recurrence-free survival (5yRFS) was 54.2% (IIA) and 47.2% (IIB), showing no significant difference. In stage IIA, 5yRFS was 50.0% in T1N1 and 58.8% in T2bN0 (p = NS). Multivariate analysis was performed including postoperative TNM factors and pathological invasive features such as tumor size, lymph node metastasis status, vascular invasion, pleural invasion, and histology. Among these, lymphatic permeation (ly) was identified as the only independent risk factor for recurrence (p = 0.009), with 5-year recurrence-free survival (5yRFS) of 41.2% in ly-positive and 63.0% in ly-negative cases.

Conclusions: Lymphatic permeation represents a significant prognostic factor for recurrence in patients with pathological stage IIA NSCLC. It may serve as a valuable criterion for stratifying patients who are likely to benefit from adjuvant therapy within the framework of the revised TNM classification.

EP.07.55 Adjuvant Sunvozertinib for Early-Stage NSCLC Patients With EGFR Exon 20 Insertion Mutation: A Case Series

X. Chen, Y. Wang, Y. Ma, P. Xia, J. Ye, W. Lv, L. Wang, J. Hu
The First Affiliated Hospital of Zhejiang University, Hangzhou/CN

Introduction: Disease recurrence in early-stage non-small cell lung cancer (NSCLC) often peaks around one year post-surgery, with poorly differentiated tumors and other high-risk factors increasing recurrence likelihood. Notably, NSCLC patients harboring EGFR exon 20 insertion (EGFR exon20ins) mutations exhibit higher malignancy, underscoring the importance of adjuvant treatment for these patients. Sunvozertinib is an oral, potent, highly selective epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) approved in China for the treatment of advanced NSCLC with EGFR exon20ins mutations. Here, we firstly present a real-world case series highlighting the clinical efficacy and safety of sunvozertinib as adjuvant treatment in early-stage NSCLC patients with poorly-differentiated pathological type harboring EGFR exon20ins mutation.

Methods: A retrospective review was conducted on medical records from January 2024 to January 2025, identifying patients with poorly-differentiated NSCLC harboring EGFR exon20ins mutation detected through postoperative next-generation sequencing (NGS) and subsequently treated with sunvozertinib as adjuvant therapy. TNM staging was based on IASLC 9th Edition. The data analyzed by investigators mainly included disease-free survival (DFS) and safety outcomes. The data cutoff was March 20, 2025.

Results: Three poorly-differentiated NSCLC patients with EGFR exon20ins mutation were retrospectively collected and the detailed information were in Table 1. All the patients underwent complete tumor resection, followed by six months of adjuvant treatment with sunvozertinib 150 mg once daily. Patient 1, a 56-year-old male patient was diagnosed with stage IA1 poorly-differentiated lung adenocarcinoma. At the data cutoff, the patient did not relapse and the DFS reached 13 months. Only grade 1 oral mucositis occurred during treatment which improved after symptomatic treatment. Patient 2, a 72-year-old male patient was diagnosed with stage IA2 poorly-differentiated lung adenocarcinoma. This patient did not experience a relapse at data cut off with a DFS of 12 months. No intolerable adverse event was observed. Patient 3, a 55-year-old female patient was diagnosed with stage IIB poorly-differentiated lung adenocarcinoma. At the data cutoff, the DFS of this patient reached 10 months with no disease recurrence. The patient developed a mild rash during treatment which improved after applying hormone ointment.

Table 1. Case summary (Data cutoff: March 20, 2025)

Patient case	Sex	Age	Stage	EGFR exon20ins mutation subtype	Concurrent mutation	Pathological type	High-risk factors	Adjuvant treatment	Adverse events	Recurrence	DFS (months)
1	Male	56	IA1	p.S768_D770dup	PTEN	Poorly-differentiated adenocarcinoma	Airway spread	Sunvozertinib monotherapy	Oral mucositis	None	13
2	Male	72	IA2	p.D770_N771insG	TP53	Poorly-differentiated adenocarcinoma	Micropapillary component	Sunvozertinib monotherapy	None	None	12
3	Female	55	IIB	p.A763_Y764insFQEA	TP53; MGMT	Poorly-differentiated adenocarcinoma	Vascular invasion, airway spread	Sunvozertinib monotherapy	Rash	None	10

Conclusions: For NSCLC patients with EGFR exon20ins mutation, sunvozertinib showed sustained efficacy and safety benefits as adjuvant treatment after surgery. Adjuvant treatment with sunvozertinib helped these patients pass the 1-year peak period of disease recurrence successfully. Prospective studies of sunvozertinib in early-stage NSCLC patients are worth further investigation.

EP.07 EARLY-STAGE NON-SMALL CELL LUNG CANCER

EP.07.56 Efficacy and Safety of Postoperative Adjuvant Chemotherapy and Atezolizumab and Osimertinib Maintenance Therapy for NSCLC at Our Hospital

M. Ota[1], N. Hara[1], Y. Yoshii[1], S. Okazaki[1], R. Sasaki[1], Y. Koujitani[1], S. Hontsu[1], K. Yamanashi[1], R. Miyata[1], T. Kawaguchi[1], M. Hamaji[1], S. Muro[1], M. Takeda[1]
[1]Nara Medical University, Kashihara, Nara/JP[1]

Introduction: Atezolizumab was shown to be effective in the IMpower010 trial and osimertinib in the ADAURA trial as maintenance therapy after adjuvant chemotherapy for non-small cell lung cancer, and they are now available in clinical practice.

Methods: Patients who underwent surgery at our hospital and received postoperative adjuvant chemotherapy and subsequent atezolizumab maintenance or osimertinib maintenance by March 2025 at our department and affiliated hospitals were retrospectively reviewed.

Results: A total of 24 patients were included, 11 were negative for EGFR mutations and 13 were positive for EGFR mutations. Of the 11 EGFR mutation-negative patients, 10 were men and 1 was a woman, with a median age of 68 years (58-78). 8 of the 11 patients were switched to atezolizumab maintenance therapy, including 1 case of early relapse after 3 courses of maintenance therapy, 1 case of discontinuation due to irAE liver damage (Grede2) after 1 course of maintenance therapy, 3 cases of completion of treatment after 1 year and 3 cases of ongoing treatment. Of the 13 EGFR mutation-positive patients, 2 were men and 11 were women, with a median age of 72 years (60-77). 2 of the 13 patients could not start osimertinib maintenance therapy after CDDP+VNR therapy due to recurrence of brain metastasis or AKI during CDDP+VNR therapy, 1 patient was on CDDP+VNR therapy and the remaining 10 patients started osimertinib maintenance therapy. 2 of the 10 patients started osimertinib maintenance therapy without CDDP+VNR. 1 of the 10 patients on osimertinib maintenance therapy had a recurrence of bone metastasis, but was judged to be oligo-metastasis and continued on osimertinib maintenance therapy.

Conclusions: Atezolizumab maintenance and osimertinib maintenance also resulted in one recurrence each, and in cases of early recurrence during atezolizumab maintenance, MAPK gene deletion/amplification and TP53 gene mutation were found in the cancer gene panel test, suggesting that these gene mutations may be involved in early recurrence. These mutations may have contributed to early recurrence. If comprehensive gene analysis can be carried out in each group in the future to investigate the characteristics of gene expression in recurrent and non-recurrent cases, this may contribute to the development of superior adjuvant therapy.

Keywords: adjuvant chemotherapy, atezolizumab, osimertinib

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER
TUESDAY, SEPTEMBER 9, 2025

EP.08.01 Surgery for Resectable Lung Cancer With Radiographic Disease Control After Chemoimmunotherapy: A Retrospective Cohort Study

B. Lu[1], G. Zheng[1], T. Tian[1], S. He[2], C. Chen[1]
[1]Affiliated Hospital of Zunyi Medical University, Zunyi/CN ,[2]The Second Affiliated Hospital of Zunyi Medical University, Zunyi/CN

Introduction: Immune checkpoint inhibitors have achieved breakthrough progresses in perioperative treatment for non-small cell lung cancer (NSCLC) and have become one of the standard regimens for patients with resectable NSCLC. However, whether surgery is needed for patients with resectable NSCLC who achieve radiographic disease control after chemoimmunotherapy remains controversial.

Methods: We retrospectively collected medical records of patients with stage IIB-IIIB (AJCC 8th edition) resectable NSCLC who received 2-6 cycles tislelizumab plus platinum-based doublet chemotherapy and achieved radiographic disease control in the Affiliated Hospital of Zunyi Medical University from November 2021 to January 2024. The radiographic disease control was defined as patients achieved complete remission, partial remission, or stable disease after chemoimmunotherapy per RECIST v1.1. Based on whether surgery, patients were divided into surgery group or non-surgery group. The surgery group and non-surgery group were both received tislelizumab monotherapy as maintenance therapy until disease progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS). The secondary endpoints included objective response rate (ORR) and overall survival (OS).

Results: A total of 56 patients (28 in each group) were enrolled, with a median age of 59.0 years (IQR: 56.0-66.75). As of February 2025, the median follow-up duration was 19.67 months (IQR: 15.54-27.79). Neither group reached the median PFS. The surgery group improved average PFS versus the non-surgery group (37.2 months vs. 27.4 months; stratified hazard ratio 0.16 [95% CI: 0.03-0.77]; one-sided p = 0.02). The 12-month PFS rates were 100% vs. 85.7%, respectively. The ORR was 85.7% in the surgery group and 67.9% in the non-surgery group. The surgery group demonstrated a better OS benefit trend than the non-surgery group (HR = 0.096 [95% CI: 0.012-0.79]; one-sided p = 0.029). The surgical group showed superior 12-month OS rates compared to the non-surgical group (100% vs. 88.9%). No grade 3-4 adverse events were observed in either group. The data are still being followed up.

Conclusions: For patients with resectable stage IIB-IIIB NSCLC who achieved radiographic disease control after tislelizumab combined with chemotherapy, surgical intervention may provide additional survival benefits. The long-term follow-up data and large sample prospective studies are required for further validation.

Keywords: non-small-cell lung cancer, surgery, chemoimmunotherapy

EP.08.02 A Study of Patients With Lung Cancer Complicated With Ipf Who Underwent Partial Pulmonary Resection

M. Toyoda[1], H. Arai[1], S. Nakamura[1], Y. Mishina[1], T. Sawazumi[1], M. Matsumura[1], T. Iwasawa[1], K. Okudela[2], A. Saito[3]
[1]Kanagawa Cardiovascular and Respiratory Center, Yokohama/JP ,[2]Saitama Medical University, Iruma-gun/JP ,[3]Yokohama City University, Yokohama/JP

Introduction: Wedge resection is often the only feasible option for the surgical treatment of lung cancer that has been complicated by idiopathic pulmonary fibrosis (IPF). In this study, we investigated the prognosis of patients with lung cancer and concurrent IPF who underwent wedge resection.

Methods: We conducted a retrospective analysis of six patients with lung cancer and IPF that underwent wedge resection at our institution between January 2015 and December 2017. Postoperative acute exacerbation (AE) of IPF was defined as occurring within 30 days after surgery.

Results: Among these six patients, five were male, with a median age of 73.5 years. Five patients had a history of smoking, with a median Brinkman Index (BI) of 1,147.5. All cases had a performance status (PS) of 0. The rationale for choosing partial resection included: hypoxemia in four cases, a history of contralateral lower lobectomy in one case, and history of AE in one case. Patients underwent Video-Assisted Thoracoscopic Surgery (VATS) with automatic staplers. Intraoperative frozen section analysis confirmed negative surgical margins in all resected specimens. Histological findings included five cases of squamous cell carcinoma and one large cell neuroendocrine carcinoma. Pathologic assessment of the resected specimens revealed tumor invasion diameters of ≤20 mm in one case, ≤30 mm in four cases, and ≤70 mm in one case. Among these, two cases had positive surgical margins, and four had negative margins. At follow up, one patient remained alive with recurrence of the disease, four died from lung cancer progression, and one developed local recurrence but ultimately died from IPF exacerbation. Median recurrence-free survival (RFS) was 11.2 months, and median overall survival (OS) was 22.2 months. All four lung cancer-related deaths involved metastases: one patient developed liver metastasis, two developed intrapulmonary metastasis, and one exhibited both local margin recurrence and intrapulmonary metastases. The only long-term survivor experienced recurrence at the surgical margin but achieved long-term survival of 97.5 months postoperatively with chemotherapy. This patient later developed metachronous lung cancer in the subpleural area of the ipsilateral lung, which was successfully treated with another wedge resection, and remains recurrence-free. None of the patients experienced postoperative AE.

Conclusions: There is little literature related to research involving the prognosis of lung cancer patients complicated with IPF who were deemed unsuitable for lobectomy and underwent wedge resection. Currently, there are no established guidelines regarding surgical procedures for lung cancer in patients with IPF. At our institution, the surgical resection strategy is determined through multidisciplinary board discussions involving thoracic surgeons and pulmonologists. The balance between oncological radicality and parenchymal preservation remains a therapeutic challenge. Our findings demonstrate elevated recurrence rates, particularly in cases with multifocal intrapulmonary metastases, suggests wedge resection may provide inadequate oncological radicality. Nevertheless, the absence of postoperative AE and presence of a long-term survivor in our cohort indicate that wedge resection remains a viable treatment option for patients with IPF and lung cancer when radical surgery is contraindicated. When choosing a surgical approach, close collaboration with IPF-specialized pulmonologists is essential for optimal outcomes.

Introduction: Immunotherapy (IO) has revolutionized the treatment landscape for non-small cell lung cancer (NSCLC). However, its influence on surgical outcomes remains uncertain. This study aimed to evaluate surgical outcomes in patients undergoing neoadjuvant or perioperative (chemo)-IO protocols.

Methods: A systematic review and meta-analysis were conducted using PubMed and Embase up to December 2024. Prospective trials investigating preoperative IO, with or without chemotherapy, in neoadjuvant or perioperative settings were included. Two independent reviewers (P.B. and F.G.) screened studies and extracted data.

Primary outcomes included postoperative complications, minimally invasive surgery (MIS), and pneumonectomy rate.

Results: Twenty-seven studies involving 4,505 patients were analyzed; 2,691 patients in experimental arms were included. Ten studies used perioperative protocols, 17 used neoadjuvant protocols. The pooled proportion of surgery delayed beyond protocol-defined timeframes was 0.09 (95% CI 0.05-0.14). The use of MIS and conversion rates varied significantly among the studies; the pooled proportion of MIS was 0.47 (CI 0.32-0.62), with a conversion pooled proportion of 0.18 (CI 0.10-0.26). MIS use was higher in perioperative trials, though not significantly. However, conversion was less frequent in the perioperative group, although not significantly (p=0.08). Comparing IO vs. chemo-IO (CTIO), MIS use was significantly higher with IO alone (40.1%, CI 35-45%) versus CTIO (31.9%, CI 28.0-37.0; p=0.017), while conversion rates were similar (9.0% vs. 6.6%; p=0.208).The pooled pneumonectomy proportion was 0.11 (95% CI 0.09-0.13), with no significant difference between neoadjuvant and perioperative protocols (p=0.180), although slightly higher in IO trials (p=0.054). Pooled proportion for intraoperative and postoperative complications was 0.04 (CI 0.01-0.08) and 0.26 (CI 0.19-0.34), respectively. Both were significantly higher in CTIO vs. IO (p<0.001 and p=0.021, respectively). The pooled postoperative mortality rate was consistently low at 0.01 (CI 0.00-0.01) with no significant difference according to protocol (p=0.170) or treatment (p=0.150).

Conclusions: Surgical outcomes among (chemo)-IO trials vary widely. While MIS is increasingly adopted, conversion rates remain notable. Chemo-immunotherapy is associated with higher complication rates.

Greater adoption of IO-based strategies may improve surgical feasibility and reduce morbidity by enabling wider MIS implementation.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.04 Reducing Medication Burden and Accelerating Recovery Through Tubeless Thoracic Surgery: A Large-Scale Real-World Study

Z. Liu, R. Wang, H. Liang, J. Shi, Y. Zhao, J. He
The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Thoracic surgery has evolved from open procedures to minimally invasive approaches, with video-assisted thoracoscopic surgery (VATS) becoming the preferable care for early-stage non-small cell lung cancer and other thoracic conditions. Tubeless thoracic surgery represents a paradigm shift in surgical and anesthetic management, eliminating the need for endotracheal intubation while potentially enabling faster recovery, though evidence remains limited. We conducted a large-scale real-world cohort to validate its impact on perioperative outcomes.

Methods: We collected data from patients who underwent VATS for lung cancer between June 2019 and January 2025. Patients were divided into tubeless or intubated VATS groups and matched 1:1 using propensity score matching (PSM). Surgical outcomes, anesthesia medication use, and ventilatory parameters were compared to evaluate their roles in this approach.

Results: 45,619 patients were screened for eligibility, and 36,705 patients were included. After PSM, each group contains 8,146 patients. The tubeless approach demonstrated remarkable reduction in medication use (standardized mean dosages), including muscle relaxants (rocuronium: 256.81 vs 931.12; cisatrocurium: 47.13 vs 204.02), opioids (sulfentanil: 163.08 vs 258.57; remifentanil: 6076.43 vs 7873.43), and sevoflurane used (335 vs 4119 patients) (all P<0.001). Recovery was faster, with shorter time to airway device removal (33.40 vs 36.88 min), Post Anesthesia Care Unit (PACU) stay (83.07 vs 90.46 min), and postoperative hospital stay (3.11 vs 3.84 days) (all P<0.001). Ventilatory parameters were also more favorable in the tubeless group, with lower plateau pressure (8.58 vs 17.24 cmH2O) and minute volume (3.64 vs 4.80 L/min) (all P<0.001).

Conclusions: Based on the largest dataset to date, our findings demonstrate that tubeless VATS enables dramatically faster recovery through substantial reductions in medication use and ventilation pressures, while promoting remarkable resource efficiency. This study provides new evidence for the tubeless approach.

EP.08.05 Minimally Invasive Approaches for Pancoast Tumor Resection: A Comparative Analysis of Surgical Techniques and Outcomes

F. Watanabe[1], M. Shinoda[1], K. Adachi[1], D. Yamaguchi[2], S. Sinohara[2], K. Fujinaga[2], D. Ito[3], T. Kawaguchi[3], S. Kaneda[3], K. Kawaguchi[3]
[1]Mie Chuo Medical Center, Tsu/JP ,[2]Anjo Kosei Hospital, Anjo/JP ,[3]Mie University Hospital, Tsu/JP

Introduction: Pancoast tumors arise from within the superior sulcus, with most clinical manifestations occurring due to mass effect on surrounding structures. Symptoms include shoulder and arm musculoskeletal pain, Horner's syndrome, and various neurological complications. Although these tumors often mimic musculoskeletal conditions, they originate from lung tissue. Due to their location, surgical treatment frequently necessitates extensive chest wall resection and intercostal dissection, which can lead to decreased respiratory function and postoperative morbidity. Advances in minimally invasive techniques, including robot-assisted thoracic surgery (RATS) and uniportal video-assisted thoracic surgery (U-VATS), have been explored as potential alternatives to traditional open thoracotomy to reduce surgical trauma and preserve lung function.

Methods: We conducted a retrospective analysis of nine patients with Pancoast tumors who underwent surgical resection between 2018 and 2024, using data from the Mie Thoracic Surgery Database (MiTSD), a multi-center registry. The surgical approaches included open thoracotomy (n=7), robot-assisted thoracic surgery (RATS) with a lateral incision (n=2), and uniportal video-assisted thoracic surgery (U-VATS) with a high lateral incision (n=1). Eight cases involved lobectomy, while one underwent left upper division segmentectomy. Preoperative chemoradiation therapy was administered in both the RATS and U-VATS groups to reduce tumor burden and facilitate resection.

Results: Of the nine cases, eight patients were male and one was female. Surgical procedures included six right upper lobectomy two left upper lobectomy and one left upper division segmentectomy. The mean operative time and blood loss for each approach were as follows: open thoracotomy (n=6): 370 minutes, 660 mL; RATS (n=2): 524 minutes, 719.5 mL; and U-VATS (n=1): 402 minutes, 734 mL. The operative time was longer in the RATS group due to revascularization; however, blood loss did not differ significantly among the three groups. Postoperative complications in the open thoracotomy group included neuropathy (n=2), pleural effusion reaccumulation (n=2), and upper extremity elevation failure (n=1). In the RATS group, one patient developed an infection requiring reoperation. The U-VATS had postoperative infection necessitating drain reinsertion. In a segmentectomy case, the predicted postoperative FEV1.0 was calculated as follows: left lobectomy vs. left upper division segmentectomy = 971 mL / 1100 mL. Similarly, the predicted postoperative DLCO was 46.1% / 52.3%, indicating a potential advantage in preserving lung function with segmentectomy.

Conclusions: Due to the typical midline-to-posterior location of Pancoast tumors, the posterior approach is frequently utilized. When lesions are located dorsally, a high posterolateral or posterior transaxillary (hook) approach is often preferred. The hook approach provides clear visualization of the subclavian artery, facilitating resection and reconstruction with minimal technical difficulty. In contrast, the posterior approach offers dorsal visualization but limits anterior access, making direct observation of critical structures more challenging.The use of RATS and U-VATS enables enhanced visualization within the thoracic cavity and minimizes muscle dissection, which may help preserve respiratory function. In the method described here, dorsal dissection was limited to the rhomboid and vastus lateralis muscles, reducing trauma to surrounding tissues. Incorporating RATS and U-VATS techniques into Pancoast tumor surgery may provide a less invasive alternative while maintaining oncologic efficacy and improving postoperative recovery.

EP.08.06 Survival Analysis and Nomogram for Postoperative Pulmonary Sarcomatoid Carcinoma Patients: SEER Database Analysis and External Validation

Z. Hu, C. Jia, H. Liu, J. Chen
Tianjin Medical University General Hospital, Tianjin/CN

Introduction: Pulmonary sarcomatoid carcinoma (PSC) is a rare and deadly form of aggressive lung cancer. This study aims to develop a nomogram to predict the overall survival (OS) of PSC patients undergoing surgery.

Methods: The model was developed using 481 PSC patients from the SEER database (training cohort) and 45 surgical cases from Tianjin Medical University (external validation). Twelve standardized clinical factors were analyzed. Discrimination was assessed via time-dependent ROC curves (AUC), C-index, and calibration. DCA compared prognostic performance between the nomogram and 9th AJCC-TNM staging. Cox regression identified independent prognostic factors.

Results: LASSO regression was used to identify potential clinical variables for inclusion in the nomogram (Figure 1.A/B). Then univariate (Figure 1.C) and multivariate (Figure 1.D) Cox regression analyses were used to assess the impact of clinical factors on patient outcomes. The multivariate analysis identified age, pathological subtype, T stage, lymph node metastasis, and distant metastasis as independent prognostic factors for patient outcomes. Then, a nomogram were constructed with the relevant variables (Figure 1E). The concordance index (C-index) of the nomogram was 0.657 (95% CI, 0.638 to 0.676) in the training cohort and 0.716 (95% CI, 0.671 to 0.761) in the external validation cohort. In the training cohort, the AUC values for the 1-year, 3-year, and 5-year survival rates were 0.696, 0.710, and 0.663. In the external validation cohort, the AUC values for the 1-year, 3-year, and 5-year survival rates were 0.809, 0.765, and 0.785. Both the C-index and AUC indicate strong discriminatory ability of the nomogram. DCA suggested that the nomogram outperforms the 9th AJCC-TNM staging system in predicting OS, indicating its potential clinical utility.

Conclusions: A survival analysis and a nomogram with robust C-index and AUC values was developed and the validated model demonstrates certain clinical value.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.07 The Role of Surgery After Neoadjuvant Immunotherapy in NSCLC : Refining the Multimodal Paradigm

A. Libreros Niño[1], S. Chavarria Murillo[1], J. Belda Sanchis[1], E. Martinez Tellez[1], G. Planas Canovas[1], G. Ros Brasó[1], J. Hernández Ferrandez[1], A. Rodríguez[2], R. Aguiló[2], L. Grando[2], A. Barba[1], M. Majem[1], S. Martínez[1], M. Portu[1], E. Arriola[2], A. Taus[2], J.C. Trujillo Reyes[1]
[1]Hospital de la Santa Creu i Sant Pau, Barcelona/ES ,[2]Hospital del Mar, Barcelona/ES

Introduction: Neoadjuvant immunotherapy (IO) has emerged as a promising therapeutic approach for selected patients with resectable non-small cell lung cancer (NSCLC). This study evaluates the outcomes of induction IO followed by surgical resection in patients with resectable or potentially resectable NSCLC.

Methods: We conducted a retrospective analysis of patients with resectable or potentially resectable NSCLC who underwent induction chemotherapy (CT) plus IO, followed by surgical resection between January 2017 and January 2025.Collected data included demographics, surgical details, pathological response, postoperative complications, overall survival (OS), local recurrence-free survival (LRFS), and distant recurrence-free survival (DRFS).Continuous variables were reported as mean ± SD, and categorical variables as absolute numbers and percentages. Survival analysis was performed using the Kaplan-Meier method.

Results: Among 37 patients, 10 were excluded due disease progression prior surgery, incomplete treatment, or enrollment in placebo arms.The final cohort included 27 patients (63% male; median age: 64).Histology was predominantly squamous cell carcinoma (48%) and adenocarcinoma (41%).PD-L1 was >1% in 19 cases, with PD-L1 >50% in six; two had concurrent KRAS mutations.Neoadjuvant IO included nivolumab (n=15), pembrolizumab (n=9), and durvalumab (n=3).Clinical staging included cIIA (4%), cIIB (7%), cIIIA (70%), and cIIIB (19%); all cN2 cases (37%) were pathologically confirmed.

Restaging was performed using CT (48%), PET/CT (37%), PET/CT + EBUS (7.5%), and PET/CT + mediastinoscopy (7.5%). Post-induction clinical staging showed ycIA (22%), ycIB (19%), ycIIA (4%), ycIIB (22%), ycIIIA (33%); with downstaging observed in 92% (n=25). Surgical procedures included 23 lobectomies (85%), 3 lobectomies with wedge resections (11%), and 1 bilobectomy (4%). A minimally invasive approach was used in 70% of cases (Video-Assisted Thoracoscopic Surgery 63%, Robotic-Assisted Thoracic Surgery 7%). The mean operative time was 240 ± 97 minutes, and the mean drainage duration was 7 ± 4 days.The mean number of biopsied lymph nodes was 9 ±5, and mean of biopsied lymph node stations was 4 ± 1. Postoperative complications occurred in 11 patients (41%), mainly respiratory (37%), including persistent air leak (19%), respiratory infection (7%), pleural effusion (4%), hemothorax (4%), and empyema (4%). One patient required reoperation for hemothorax. Pathologic stging was yp0 (41%), ypI (41%), and ypII (18%). Pathologic complete response (pCR) was achieved in 41%, major pathologic response (MPR) in 41%, and partial response in 18%.Among cN2 patients (n=10), 80% (n=8) were downstaged to ypN0. Adjuvant therapy was administered in 74% of cases (IO 75%, CT+IO 20%, RT 5%). At follow-up, one patient developed both local and distant recurrence (at 8 and 20 months, respectively). There was no 90-day mortality. All patients who underwent CT+IO+R0 resection (without adjuvant treatment) remained alive and recurrence-free at one year.

Conclusions: - Surgery following induction immunotherapy in resectable NSCLC is safe and associated with excellent pathological response rates and early survival outcomes. - These findings support its integration as a key component of the multimodal strategy in the management of resectable or potentially resectable NSCLC - Additionally, it is crucial to standardize and homogenize the definition of resectability in this setting to ensure consistent patient selection, optimize outcomes, and facilitate comparisons across studies.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.08 Complex Tracheobronchial Reconstruction for Locally Advanced T4N2M0 Non-Small Cell Lung Cancer Using Three-Dimensional Models

S. Yeskov[1], S. Krasny[1], A. Sukalinskaya[1], T. Filipava[1], A. Hulenka[1], S. Kremeneuski[1], N. Paramonava[1], Y. Tsarkouskaya[1], P. Famianok[1], V. Fiankevich[2], I. Yeskov[3]
[1]N.N. Alexandrov National Cancer Centre of Belarus, Minsk/BY ,[2]Belarussian State University, Minsk/BY ,[3]Gymnasium No. [12], Minsk/BY

Introduction: Organ-preserving surgery for centrally located lung cancer is a proven approach, even in cases involving trachea or superior vena cava. Success depends on perioperative therapy and completeness of surgery.

Methods: We present three cases of T4N2M0 non-small cell lung cancer treated with preoperative platinum-based chemotherapy or chemoimmunotherapy. 3D-modeling, utilizing the open-source 3D Slicer software, was employed for precise surgical planning based on pretreatment tumor borders. Detailed data is provided in Table 1 and Figure 1.

Results: All patients underwent R0 resection. One patient underwent coronary artery bypass surgery before lung cancer surgery, achieving 39 months of relapse-free survival without adjuvant therapy. Another patient with EGFR mutant adenocarcinoma developed pleural dissemination nearly three years after surgery despite osimertinib treatment. Pathology revealed a pathological complete response of the primary tumor following chemoimmunotherapy in the third patient, though residual subcarinal lymph node metastasis was detected. Planned treatment includes two cycles of carboplatin and paclitaxel, followed by 12 months of atezolizumab.

Conclusions: Despite significant progress in drug therapy, surgery remains vital for achieving tumor elimination. Preoperative chemoimmunotherapy shows promise as a treatment option for locally advanced T4 NSCLC. Accurate 3D-modeled planning is an essential tool for surgeon, helping to ensure the resection line is correctly positioned outside pretreatment tumor borders, minimizing errors and maximizing surgical success.

EP.08.09 Aggravation of Tumor Necrosis After Transbronchial Biopsy in Lung Cancer: A Fatal Complication Despite Rescue Surgery

S. Hattori, T. Saito, Y. Takeyasu, N. Makihara, T. Utsumi, N. Maru, A.K. Kobayashi, K.J. Fukumoto, H. Matsui, Y. Taniguchi, T. Kurata, T. Murakawa
Kansai Medical University Hospital, Hirakata, Osaka/JP

Introduction: Infectious complications following transbronchial biopsy (TBB), often linked to the aggravation of preexisting tumor necrosis, can delay lung cancer treatment and worsen survival outcomes. While emergency surgery may be required in severe cases, data on its clinical outcomes remain unclear. This study aims to evaluate the clinical characteristics and prognosis of patients undergoing emergency rescue surgery for post-TBB complications associated with aggravated tumor necrosis.

Methods: A retrospective review was conducted on 2,717 patients who underwent bronchoscopic procedures at Kansai Medical University Hospital between January 2016 and February 2024. Patients included in the study had histologically confirmed lung cancer and required emergency rescue surgery for post-TBB complications, such as lung abscess or hemoptysis, associated with aggravated tumor necrosis.

Results: Nine patients (0.3%) met the inclusion criteria, with complications including lung abscesses (n=7) and hemoptysis (n=2). The median age was 72 years, with clinical stages II/IIIA (n=5) and IIIB/IV (n=4). Tumors had a median diameter of 6.0 cm on CT, all with low-attenuation areas (≤30 Hounsfield units). Median preoperative CRP and albumin levels were 7.0 mg/dL and 2.4 g/dL, respectively. Surgical procedures included lobectomy (n=6), bilobectomy (n=2), and pneumonectomy (n=1), with a median operative time of 123 minutes and blood loss of 940 mL. Pathological staging revealed stage II/IIIA in 6 patients (all R0 resections) and stage IIIB/IVA in 3 patients. Histological subtypes included squamous cell carcinoma (n=4), pleomorphic carcinoma (n=2), adenosquamous carcinoma (n=2), and large cell carcinoma (n=1). Tumor necrosis was observed in all resected specimens, while 55.6% (n=5) of TBB specimens showed necrosis. Additionally, bacterial cultures identified oral commensal bacteria in 7 cases. The 30-day mortality rate was 0%, however, the 90-day mortality rate was 33.3% (n=3). The cause of death included sepsis (n=2) and shock associated with ileus (n=1). One-year survival rates were 44% for stage II/IIIA and 50% for stage IIIB/IV (Figure).

Conclusions: Patients requiring rescue surgery for post-TBB complications were characterized by large tumor size (≥3 cm), low-attenuation CT features, and preexisting necrosis. Despite surgical intervention, the high mortality rate highlights the need for preventive strategies, including upfront surgical resection for high-risk patients. Future studies are necessary to validate these approaches.

EP.08.10 N3 Stage May no Longer Be Considered Unresectable in Anaplastic Lymphoma Kinase(ALK)-Positive Non-Small Cell Lung Cancer: A Case Series

H. Guo[1], X. Yang[2], J. Zhang[2]
[1]GuangDong Provincial Peoples Hospital, Guang Zhou/CN ,[2]Guangdong Provincial People's Hospital, Guang Zhou/CN

Introduction: In recent years, the development of ALK-tyrosine kinase inhibitors (ALK-TKIs) has significantly improved the survival of patients with unresectable locally advanced ALK-positive disease. Some of these patients may become eligible for surgery after induction targeted therapy. However, whether this treatment paradigm—conversion from unresectable to resectable disease—provides a survival benefit remains uncertain, particularly for patients with N3 disease in whom supraclavicular and contralateral lymph nodes are not dissected during surgery.

Methods: N3 stage NSCLC patients with ALK detected by next-generation sequencing (NGS) received concomitant oral crizotinib or alectinib.

Results: Three patients were retrospectively reviewed: 1) a 45-year-old female patient was diagnosed with stage T1bN3M0 IIIB lung adenocarcinoma. The patient first received three cycles of docetaxel plus cisplatin, and the treatment response was evaluated as stable disease (SD).After multidisciplinary team (MDT) discussion, the treatment regimen was modified to crizotinib. After 150 days of treatment, CT imaging showed a significant reduction in the volume of the primary lesion, and the treatment response was evaluated as partial response (PR). The patient subsequently underwent conversion thoracotomy with lobectomy and mediastinal lymph node dissection. Postoperative pathological evaluation confirmed a pathological complete response (pCR). The patient experienced disease recurrence on March 1, 2020, with a stage rT0N0M1b (brain), IVA. The progression-free survival(PFS) was 12.0 months. By the time of manuscript submission, the overall survival(OS) was 83.0 months. 2)a 57-year-old male patient was diagnosed with stage T1cN3M0 IIIB lung adenocarcinoma. After 225 days of induction targeted therapy with alectinib, the treatment response was evaluated as PR.The patient subsequently underwent pulmonary wedge resection and lymph node biopsy. Postoperative pathological evaluation achieved non-major pathological rsponse(non-MPR). Adjuvant targeted therapy with alectinib was continued postoperatively. By the time of manuscript submission, the patient had not experienced recurrence, with PFS and OS of 64.0 months. 3)a 51-year-old male patient was diagnosed with stage T1cN3M0 IIIB lung adenocarcinoma.NGS revealed an ALK mutation. After 135 days of induction targeted therapy with alectinib, the treatment response was evaluated as PR. The patient subsequently underwent sublobar resection and lymph node dissection. Postoperative pathological evaluation confirmed pCR. Adjuvant targeted therapy with alectinib was continued postoperatively. By the time of manuscript submission, the patient had not experienced recurrence, with PFS and OS of 38 months.

Conclusions: These case sheds light on the feasibility and safety of alectinib and crizotinib as a conservsion treatment and the efficacy of for stage N3 NSCLC patients with ALK rearrangement.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.11 Multimodality Approach for Locally Advanced Lung Cancer, When Is Surgery Most Beneficial in a Resource-Constrained Environments

R. Abdel Jalil
King Hussein Cancer Center, AMMAN/JO

Introduction: Stage III non-small cell lung cancer (NSCLC) is a complex and challenging disease due to its heterogenicity and the absence of standardized treatment protocols. This study aimed to investigate the role of surgical resection as part of a multimodal treatment approach to improve overall survival (OS) and disease-free survival (DFS) in resource-limited settings.

Methods: The medical records of 309 patients who underwent surgery for confirmed primary lung cancer at the King Hussein Cancer Center (KHCC) in Amman, Jordan, between 2016 and 2022 were reviewed. 59 of them diagnosed with Stage III NSCLC underwent curative surgery. Patients were grouped into three categories: surgery alone, neoadjuvant therapy followed by surgery, and surgery combined with adjuvant therapy. Demographic, clinical, and survival data were statistically analyzed to compare the outcomes across these groups.

Results: The study cohort consisted predominantly of males (86.4%), with adenocarcinoma being the most common histological subtype (54.2%). Patients who underwent surgery alone had the lowest recurrence rate (8.8%), whereas those who underwent surgery alone had the highest three-year OS and DFS rates (66.7%). Improved OS and DFS were observed in patients with pN0 status and no evidence of lymphovascular invasion (LVI). Minimally invasive surgical approaches such as VATS were associated with better perioperative outcomes than open surgery.

Conclusions: Surgical resection, particularly when achieving negative margins (R0) in patients with N0 disease, is critical for improving survival in patients with Stage III NSCLC. Multimodal strategies can enhance these benefits further. However, challenges related to healthcare access in resource-limited settings highlight the need for customized treatment protocols and broader access to advanced medical therapies.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.12 Occult Lymph Nodal Metastasis in Sub-Centimeter Lung Cancer: A Report of Seven Cases and Review of Literature

X. Wang
Nanjing Drum Tower Hospital, Medical School of Nanjing University, Nanjing/CN

Introduction: Occult lymph node metastasis (OLNM) after surgery for stage IA sub-centimeter lung cancer is an extremely rare clinical situation, with few reported cases in the literature. Further investigation is warranted into the clinical characteristics of patients and the radiological features of lung nodules. Here, we aim to provide a comprehensive insight into this tumor type.

Methods: We present cases that sub-centimeter non-small cell lung cancer (NSCLC) patients who underwent surgery at our center and were found to have OLNM in postoperative pathology. This is the first time such cases have been reported. We reviewed the existing literature on this rare event and collected detailed clinical, histopathological, and radiological data for analysis.

Results: A total of 7 sub-centimeter lung cancer patients were diagnosed with OLNM based on routine pathology, including 1 male and 6 females, with an average age of 58.7±9.3 years. All patients had no clinical symptoms and were found by physical examination, with follow-up durations ranging from 1 week to 3 years. Among these patients, 4 exhibited mediastinal lymph node metastasis. Preoperative chest CT in all patients showed pure-solid nodules (PSN), and 6 patients changed the surgical procedure based on intraoperative frozen sections results. Routine pathology revealed that all adenocarcinoma patients presented high-risk factors for recurrence, including visceral pleural invasion (VPI), spread through air spaces (STAS), vascular invasion, and poorly differentiated tumor.

Conclusions: Sub-centimeter lung cancers with radiological feature of PSN are at risk for lymph node metastasis. Surgeons should pay close attention to intraoperative rapid pathology results to prevent inadequate surgical treatment. Adenocarcinoma patients often present with one or more high-risk factors for recurrence, active adjuvant treatment and follow-up are necessary.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.13 Machine Learning Prediction of Overall Survival in Stage III Unresectable NSCLC: Data Analysis From a Single Center Prospective Cohort

E. Ippolito[1], V. Marè[1], C. Talocco[1], C. Greco[1], M. Fiore[1], D. Carlotti[1], A. Iurato[1], G. Meffe[1], E. Molfese[1], S. Ramella[1]
[1]Fondazione Policlinico Universitario Campus Bio-Medico, Roma/IT

Introduction: The standard treatment for stage III unresectable NSCLC patients, is concurrent chemo-radiotherapy (cCRT) followed by Durvalumab immunotherapy (IT). Radiotherapy to uninvolved mediastinal nodes as well as to lymphocytes in the blood pool can to induce lymphopenia and affect immune response. This study aims to describe the outcome of CRT followed by IT and to explore the ability of a random forest (RF) model to predict overall survival (OS) in these patients including in the model planning data potentially involved in the negative immunologic impact of RT.

Methods: A retrospective analysis of a prospective cohort of 45 patients with stage III locally advanced, non-oncogene-addicted NSCLC (PDL-1 ≥1%) treated since 2019 with cCRT (60 Gy in 30 fractions) followed by Durvalumab IT was conducted.Treatment plans were reviewed by 2 radiation oncologist with > 10 years of experience and mediastinal nodal stations (involved and uninvolved) were contoured according to JLCS-JASTRO CT atlas and the relative received dose collected. OS was evaluated using KM curves. The choice of RF model was related to its reliability in small sized dataset. All patients were divided chronologically into the training (32 patients) and validation (13 patients) groups. Death was defined as the end point. The prediction performance was quantified by the area under the curve (AUC).

Results: The mean age was 77 (range: 52-86); 70% patients were current or former smokers. 53% of patients had adenocarcinoma. Most patients had stage IIIB (47%). All underwent cCRT followed by Durvalumab, completing a median of 15 cycles (range 1-26).Grade 3 pneumonitis occurred in 10.0% of patients, G3 esophagitis in 2.2%, and G3 thrombocytopenia in 11.1%. The median Overall Survival (OS) was 53.5 months (95% CI: 32.85-74.14). 1-2-5 year OS was 94.7%, 80.4% and 39.3% respectively. A Mean Heart Dose (MHD) of <5.2 Gy (predictor of radiation- related lymphopenia), was associated with improved survival (p-value = 0.05). The RF model achieved an AUC of 0.8667 (95%IC: 0.8333-0.9666). The most important predictor variables (figure 1), were represented by MHD, dose to nodal stations S1, S3P, S4L, CTV cc, mean incidental dose to “non target” nodal stations.

Conclusions: Concurrent chemo-radiotherapy followed by Durvalumab shows promising outcomes for stage III locally advanced NSCLC in real life setting. The RF model showed a good performance in predicting OS in these patients, highlighting the importance of the mediastinal RT dose and OARs dose. Optimizing radiotherapy planning is essential for enhancing treatment efficacy.

Tata Memorial Hospital, Homi Bhabha National Institute, Mumbai/IN

Introduction: Concurrent Chemoradiation (CTRT) followed by Durvalumab is the standard of care for unresectable locally advanced lung cancer (LC). During RT, tumor volume and position changes necessitate adapting radiotherapy (ART) planning. ART may offer dosimetric and clinical advantages, however, its clinical utility remains under investigation. This study aimed to evaluate outcome comparison in patients treated with ART and those who did not need ART.

Methods: A retrospective analysis was conducted on patients with LALC treated with CTRT between January 2017 and December 2019. All patients underwent 18F-FDG PET-CT and brain MRI for baseline staging, and treatment decisions were taken after a multidisciplinary tumor board. All patients routinely undergo weekly audit, and the need for ART was identified based on tumor response, resolution of atelectasis, or disease progression. Clinical details were extracted from electronic medical records and the treatment planning system. Progression-free (PFS) and overall survival (OS) were defined from the diagnosis date until progression/death and death, respectively. Loco-regional recurrence-free survival (LRFS) was defined from RT starting till loco-regional recurrence or death, whichever is earlier. Survival comparisons between the ART and non-ART cohorts were performed using the log-rank test, with significance set at a p-value of < 0.05.

Results: A total of 156 patients were included. The median age was 59 years (range: 28-80), males (78%), and smokers (65%). Adenocarcinoma (46.2%), squamous cell carcinoma (40.4%), and small cell carcinoma (13.5%). The median planning target volume (PTV) was 444 cc (IQR: 284-606). Median lung-PTV V20 was 18.5% (IQR: 13.8-23.6), and mean lung dose (MLD) was 11.13 Gy (IQR: 9.75-13.1). ART was required in 35 patients (22.4%), due to tumor shrinkage (74%), resolution of atelectasis (20%), or progression (6%), at a median dose of 26 Gy (range: 14-36). The median time to deliver the ART plan was 5 days (IQR: 3.5-7.5). After a median follow-up of 23 months (range: 11-46), the median OS, PFS, and LRFS for entire cohort was 28 months (IQR: 14-54), 17 months (IQR: 15-50), and 28 months (IQR: 27-51), respectively. Median and 2-yr OS in ART vs non-ART groups were 25m (IQR:15-50) & 54.3% (95%CI: 37.9-70.7) vs 31m (IQR: 13-55) & 58% (95%CI: 49.2-66.8) (p=0.54). Median and 2-yr PFS were 15m (IQR: 6-41) & 38% (95%CI: 21.3-54.5) vs 20m (IQR: 9-54) (p=0.5) & 43.6% (95%CI: 33.8-53.4). Median and 2-yr LRFS were 39m (IQR: 29-52) & 61.6% (95%CI: 44.2-79) vs 27m (IQR: 36-52) & 53.8% (95%CI: 43.6-63.9)(p=0.9), (p=0.9). There was no difference in LRF between ART (45.7%) and non-ART (43%). ART modestly increased lung-PTV V20 (+3.7%) and MLD (+4.5%) (p=0.158), but significantly reduced heart V20 (−18.3%) and spinal cord Dmax (−6.7%), (p=0.005). Grade ≥2 acute toxicities included pneumonitis (5.2%), skin toxicity (11.8%), and esophagitis (16.3%).

Conclusions: One-fourth of patients do require ART during CTRT. Adaptive RT was not associated with inferior loco-regional control or overall survival. While ART demonstrated dosimetric advantages in sparing critical organs, these did not translate into significant clinical benefit. Pre-emptive anticipation of the need for ART through weekly audits may be considered for precision CTRT.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.15 Predicting Locations of In-Field Failure Leading to Proton Re-Irradiation for NSCLC

S. Saad[1], S. Lazarev[2,3], N. Shaverdian[2,4], J. Fox[1,2], A. Shepherd[2,5], H. Lin[2], I. Choi[2,4], C. Simone[2,4], N. Ohri[1,2]
[1]Montefiore Medical Center, Bronx/NY/USA ,[2]New York Proton Center, New York/NY/USA ,[3]The Mount Sinai Hospital, New York/NY/USA ,[4]Memorial Sloan Kettering cancer center, New York/NY/USA ,[5]University of Washington, Seattle/WA/USAM. Früh[1]

Introduction: Previous single-institution studies have suggested that in-field disease progression following chemo-radiotherapy for locally advanced non-small cell lung cancer (LA-NSCLC) most often occurs at sites with bulky disease. We aimed to validate that finding using a cohort of patients who underwent reirradiation for recurrent NSCLC.

Methods: We reviewed records of consecutive patients with LA-NSCLC treated between 2019 and 2024 at a large proton center with thoracic radiotherapy (RT) for recurrent disease following prior chemotherapy and photon RT. Volumes of pulmonary tumors and lymph nodes initially treated with photon RT were tabulated, and lesions that required reirradiation with protons were identified. Volumes of lesions that required reirradiation were compared with volumes of lesions that did not require reirradiation using Kruskall-Wallis testing. A previously identified volume cutoff (25 cc) was tested as a predictor of in-field disease recurrence using logistic regression.

Results: Twenty-seven patients met selection criteria for this analysis. Fourteen patients (52%) had squamous cell carcinoma, and 13 (48%) had adenocarcinoma. The median initial RT dose was 60Gy (range: 45 to 66 Gy), and the median initial dose per fraction was 2 Gy (range: 1.8 to 3 Gy). The median interval between radiotherapy courses was 23 months (range: 7 to 92 months). Median age at the time of reirradiation was 68 years (range: 49 to 86 years). Twenty-five patients (93%) required reirradiation of a tumor or lymph node region previously treated with RT, and for 24 of those patients (96%), only one tumor or lymph node region required reirradiation. Among those 24 patients who required reirradiation of a single tumor or lymph node, for 22 patients (92%), it was the largest tumor or lymph node at the time of initial treatment that required reirradiation. The median initial volume of targets that required reirradiation was 89 cc (IQR: 49 to 123 cc). The median initial volume of targets that did not require reirradiation was 20 cc (IQR: 8 to 36 cc). Using the a priori volume cutoff of 25 cc , larger tumors and lymph nodes were significantly more likely to require reirradiation than smaller lesions (OR=8.0, p<0.001) (Figure 1).

Conclusions: Sites of local disease recurrence may be predictable, and the benefits of selectively applying local treatment intensification to more bulky sites could warrant investigation.

Figure 1

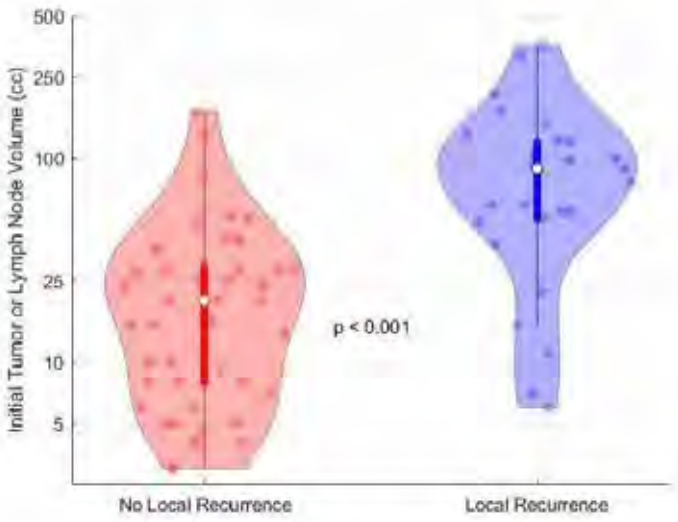

Figure 1: The violin plot: x-axis represents two groups, No local Recurrence and local Recurrence; y-axis represents log scale initial lesion volume (cc). The white dot represents the median lesion volume. P-value <0.001 from Kruskall-Wallis test suggests that the difference in lesion volume between the two groups is statistically significant. Patients in the local Recurrence group tend to have larger lesion volumes compared to those in the No local Recurrence group.

Introduction: Lung cancer remains the leading cause of cancer-related deaths worldwide. Radiotherapy plays a fundamental role in treatment, and recent studies emphasize the importance of personalized dose escalation strategies based on tumor histology. This study investigates how pathological subtypes and radiation dose escalation impact survival outcomes in lung cancer patients treated at a single institution between 2020 and 2025.

Methods: We conducted a retrospective analysis of 103 lung cancer patients treated with radiotherapy. Patients were classified by histological subtype: adenocarcinoma, squamous cell carcinoma, and other subtypes. Radiation doses ranged from 50 to 70 Gy (mean: 62 Gy). Pulmonary dosimetric parameters, including mean lung dose (MLD), V20, and Dmax, were recorded. Survival outcomes were evaluated using Kaplan-Meier analysis, and independent prognostic factors were identified through Cox proportional hazards models, adjusting for age, disease stage, comorbidities, and smoking history. Treatment-related toxicities (≥grade 3) were assessed following CTCAE v5.0 guidelines.

Results: Patients who received ≥65 Gy had a significantly higher 1-year survival rate (72.5%) compared to those treated with <65 Gy (61.2%; $p<0.05$). The median overall survival (OS) for the entire cohort was 17.8 months, with an overall survival rate of 64.1%. Adenocarcinoma patients had better OS than those with squamous cell carcinoma (median: 20.1 vs. 15.6 months; HR 0.79, 95% CI: 0.63-0.95). Higher MLD and V20 were associated with increased rates of ≥grade 3 pneumonitis (8.1%) and esophagitis (6.3%). Multivariate analysis confirmed that histology and radiation dose were independent predictors of survival.

Conclusions: Personalized radiotherapy strategies that account for tumor histology and optimized dose escalation can significantly improve survival outcomes in lung cancer patients. Notably, adenocarcinoma patients demonstrated a greater survival benefit from higher radiation doses. Additionally, the growing evidence of the synergy between radiotherapy and immunotherapy suggests that combining these approaches may enhance the antitumor response and prolong survival, particularly in selected subgroups. These findings align with recent international studies and reinforce the need for prospective trials incorporating molecular biomarkers, immunotherapy, and advanced radiotherapy techniques to further refine lung cancer treatment strategies.

EP.08.17 Patterns of Recurrence and Eligibility for Salvage Therapy After Curative Intent Treatment for Unresectable Stage III NSCLC

E. Bhang[1], M.F. D'amours[2], A. Chan[2], F. Usman[2], M-H. Denault[2], J. Feng[2], J. Laskin[2], S. Sun[2], B. Leung[2], B. Melosky[2], H. Carolan[2], S. Raman[2], M. Liu[2], C. Ho[2]
[1]University of British Columbia, Vancouver/BC/CA ,[2]BC Cancer, Vancouver/BC/CA

Introduction: Definitive chemoradiotherapy (CRT) followed by durvalumab is the standard of care for unresectable stage III non-small cell lung cancer (NSCLC). Patterns of recurrence determine options for salvage therapy. For oligo-recurrence, stereotactic radiosurgery to the brain (SRS) or stereotactic body radiotherapy (SBRT) may be used alone, as an alternative to surgery or in conjunction with systemic treatment. This study aimed to analyze the patterns of recurrence and amenability to salvage SRS/SBRT or surgery following curative intent treatment for patients with unresectable stage III NSCLC.

Methods: Patients with unresectable stage III NSCLC treated at BC Cancer, British Columbia, Canada from January 2018-December 2021 were identified. A retrospective chart review was performed including patient characteristics, surveillance compliance, initial treatment, recurrence patterns (detected on imaging), number of sites of metastases and salvageability. Patients eligible for salvage treatment were determined by multidisciplinary assessment, defined as those amenable to salvage SRS/SBRT or surgery for intrathoracic recurrence, extrathoracic recurrence in the body or recurrence in the central nervous system (CNS).

Results: 433 of 459 patients completed CRT as planned with a median follow up of 31.4 months. Patients were median age 68 years, male 54%, never/ever smoking history 10/90%, adenocarcinoma 61%, stage IIIA/B/C 48/45/7%. Median radiation dose was 60 Gy with 63% receiving platinum/etoposide and 37% receiving carboplatin/paclitaxel. 63% received at least 1 dose of durvalumab consolidation. 271/433 patients had recurrence. There was no difference in pattern or number of sites of recurrence based on durvalumab treatment. Of patients with recurrence, 269 received body imaging while 139 received CNS imaging. Most recurrences were intrathoracic only in 137/269 or 51%, compared to extrathoracic only (excluding CNS) 10%, 31% of patients had both intrathoracic/extrathoracic and 61/139 or 44% of patients had CNS recurrence. 44% of patients had 1-5 body metastatic sites at recurrence compared to >5 sites (47%). Relatively higher proportions of CNS recurrences were limited to 1-5 sites (75%) vs 25% with >5 sites. 51/271 were deemed eligible for salvage therapy.

Conclusions: In this retrospective cohort of patients treated with CRT for unresectable stage III NSCLC, the recurrence rate was 62% after a median duration of 31.4 m of follow up. Intrathoracic only recurrence was noted in 51% of patients and 19% were potentially amenable to salvage therapy with SRS/SBRT or surgery. The possibility of salvage therapy supports the routine surveillance imaging for timely detection of such cases for patients who have completed first-line curative intent chemoradiotherapy.

Pattern of first recurrence	Total	CRT only	CRT followed by durvalumab	P value
BODY	**n=269 with imaging**	**n=109**	**n=160**	
Intrathoracic only	137 (51%)	55 (50%)	82 (51%)	0.89
Extrathoracic only	27 (10%)	10 (9%)	17 (11%)	0.69
Intra/extrathoracic	84 (31%)	37 (34%)	47 (29%)	0.43

EP.08.18 Concurrent Chemoradiotherapy (ConCRT) in Locally Advanced (LA) Non-Small Cell Lung Cancer (NSCLC)In the Durvalumab Era

S. Loizides[1], P. Vogazianos[2], Z. Kordatou[1], G. Fotopoulos[1], E. Xenophontos[1], D. Vomvas[1], N. Katodritis[1], M. Georgiou[1], D. Ntaskagiannis[1], A.M. Shiarli[1], I. Porfyridis[1], C. Symeonidou[1], H. Charalambous[1]
[1]Bank of Cyprus Oncology Centre, nicosia/CY ,[2]European University Cyprus, Nicosia/CY

Introduction: Following the presentation of the PACIFIC trial, we adopted ConCRT, followed by Durvalumab maintenance, for patients with unresectable, LA NSCLC without disease progression after CRT and PD-L1 expression >1%, as per the EMA approval. We compare outcomes of this approach with our historical series of conCRT from 2005 to 2017. This analysis examines a register of all patients consecutively assigned to conCRT since 2018, conducted in an intent-to-treat manner.

Methods: From March 2018 to May 2024, we assigned ConCRT followed by 1 year Durvalumab maintenance to 37 consecutive patients with LA NSCLC who were deemed unresectable and had PD-L1 expression >1%. 19 patients with PD-L1-negative disease received only conCRT. Patients had ECOG performance status 0-2 and were treated mainly with either weekly carboplatin-paclitaxel or Cisplatin/Carboplatin-Vinorelbine (with dose reduction of Vin to 15mg/m2 during the concurrent phase). We report outcomes for both cohorts of PD-L1 positive and negative patients, and compare to our pre-2018 series (JTO 13(10):S854. DOI:10.1016/j.jtho.2018.08.1533).

Results: For the conCRT Durva series, 5-year progression-free survival (PFS) and overall survival (OS) rates were 37% (95%CI, 18,8%-55,3%) and 39,3% (95%CI, 18,4%-59,8%), respectively whilst for the conCRT, 5-year PFS and OS rates were 34,7% (95%CI, 12,9%-57,8%) and 38% (95%CI, 15%-61%). 5-year PFS and OS rates for our historical CRT series were 25% and 28,2%, respectively. For the conCRT Durva series, median PFS (mPFS) was 22,3 months and median OS (mOS) was 33,6 months, whilst for the conCRT series, mPFS was 10,7 and mOS 27,2 months. mPFS and mOS for our historical CRT series of 86 patients treated pre-2018, were 14,1 months and 24,8 months, respectively. Further information in table 1 and PFS and OS curves.

Conclusions: ConCRT with and without Durvalumab produced encouraging results, compatible with the PACIFIC data, and better than our historical series before the introduction of Durvalumab.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.19 Timing and Predictors of Lymphopenia in Lung Cancer Patients Undergoing Proton and Photon Chemoradiotherapy

E.Y. Akdemir, R. Kotecha, S. Gurdikyan, R. Herrera, A.N. Gutierrez, A. Wroe, F. Albrecht, M.P. Mehta, R.H. Press
Miami Cancer Institute, Miami/FL/USA

Introduction: Treatment-induced lymphopenia is a well-known and clinically significant adverse effect observed in patients undergoing proton or photon chemoradiotherapy (PT-CRT or PH-CRT) for lung cancer, especially given the increasing use of adjuvant immune checkpoint inhibitors. Although PT may provide dosimetric advantages by reducing integral body dose, direct comparisons remain limited. This study aimed to assess the timing and identify factors associated with grade 3 lymphopenia (G3L) in patients treated definitively with PT-CRT or PH-CRT.

Methods: We performed a retrospective analysis of patients with locally advanced or recurrent lung cancer who underwent definitive PT-CRT or PH-CRT at a single institution. All patients received conventionally fractionated radiotherapy alongside chemotherapy, and lymphopenia was graded per CTCAE version 5.0. We analyzed the timing of G3L and its association with clinical and dosimetric factors, including age, gender, pre-treatment absolute lymphocyte count (ALC), tumor histology, concurrent chemotherapy regimen, induction chemotherapy (ICT), treatment volume (planning target volume [PTV] or clinical target volume [CTV], lung V5, and mean lung dose (MLD). Group comparisons used Mann-Whitney U and Chi-square tests, Kaplan-Meier estimates assessed time to G3L, and univariate/multivariate Cox regression identified factors associated with G3L.

Results: A total of 68 patients (PT-CRT: 47, PH-CRT: 21) were evaluated. Both groups were comparable in terms of median age (76 years [range, 54-88] vs. 72 years [range, 51-83]), gender (male: 55.3% vs. 71.4%), histological subtype (adenocarcinoma: 55.3% vs. 52.4%), and type of concurrent chemotherapy (paclitaxel/carboplatin: 80.9% vs. 85.7%), in PT-CRT and PH-CRT, respectively, all p>0.05. Median PTV/CTV was similar (292.3 cc PT-CRT vs. 331.2 cc PH-CRT, p>0.05). Across the entire cohort, the median delivered dose was 60 Gy/GyE (range, 59-70 Gy/GyE) in 30 fractions (range, 30-35). Despite the similar target volumes and radiation doses, median MLD was significantly lower in PT-CRT (10.7 Gy vs. 15.0 Gy, p=0.01). Median time to G3L was longer in PT-CRT (31 vs. 21 days, p=0.07). Larger PTV/CTV (p=0.015) and radiotherapy modality (p=0.08) correlated with G3L in univariate cox-regression analysis, but only PTV/CTV remained significant in multivariate analysis (p=0.015).

Conclusions: G3L was common in both PT-CRT and P-CRT, strongly associated with larger PTV. Although PT-CRT showed a trend toward delayed lymphopenia onset, significance of radiation modality was lost in multivariate analysis, likely due to the interplay effect of other variables, such as treatment volume or sample size limitations. Given the expanding use of immune checkpoint inhibitors, optimizing radiation planning and target volume management to minimize lymphopenia is crucial

EP.08.20 Comparative Survival Post-Radiotherapy in Small Vs. Non-Small Cell Lung Cancer: Revisiting Prognostic and Dosimetric Factors

R.A.B. Aguiar[1],[2], T.R. Dias[3], M.L.T. Bento[3], J.S. Pavão[3], L.B. Assunção[3], G.L.F. Cunha[3], R. Ferrari[1], G. Barbosa[1], E. Fuks[1], L. Oliveira[1], P. Canary[1], C.E. De Almeida[1], M. JV.[4], D. Przybysz[1]
[1]RadioSerra Radiation Therapy, Petrópolis/BR ,[2]Petropolis Medical School - FMP, Petrópolis/BR ,[3]RadioSerra Radiation Therapy, Petropolis Medical School, Petrópolis/BR ,[4]Centro de Terapia Oncológica, Petrópolis/BR

Introduction: This study aimed to critically compare survival rates, recurrence patterns, and radiotherapy outcomes between Small Cell Lung Cancer (SCLC) and Non-Small Cell Lung Cancer (NSCLC), assessing prognostic variables and exploring how radiotherapy dosimetry influences clinical outcomes.

Methods: A retrospective analysis was conducted on lung cancer patients treated with radiation therapy, evaluating demographic characteristics, tumor staging, and key dosimetric parameters. The study focused on identifying differences in survival, recurrence patterns, and potential impacts of radiotherapy planning on clinical outcomes. The dosimetric parameters analyzed included mean total dose and fractions of each different histological type.

Results: A total of 207 patients were analyzed, with a mean age of 66 years (range 29-92) and a balanced gender distribution (50,2% male, 49,8% female). Smoking history was recorded in 81,16% of patients, averaging 55.28 pack-years. The majority presented with advanced-stage disease (86,47% Stage III or IV), and 56,04% were Stage IV. The cohort consisted of 191 NSCLC (92.3%) and 16 SCLC (7.7%) patients. Overall mortality was 24.6% (51 deaths). Notably, SCLC patients exhibited higher survival rates (75.4%) with lower recurrence (37,5%, 6 patients), contrasting with the 74,87% survival and 67,54% recurrence in NSCLC. These results substantially diverge from established literature, which consistently reports poorer outcomes in SCLC, typically characterized by rapid recurrence and low 5-year survival (<10%). Dosimetric analysis revealed that patients with non-small cell lung cancer (NSCLC) received a median dose of 3292.68 cGy administered in 10 fractions, while patients with small cell lung cancer (SCLC) received higher doses (3853.33 cGy) with a median of 9 fractions. Despite receiving higher doses in fewer fractions, patients with SCLC in our cohort demonstrated unexpectedly higher survival rates and lower recurrence compared to patients with NSCLC. The subgroup analysis indicated that the one-year progression-free survival (PFS) rate was 58.3% in SCLC versus 41.2% in NSCLC (p=0.021), suggesting a potential advantage of the therapeutic approach employed in the analyzed cohort. Additionally, NSCLC patients treated with escalated-dose radiotherapy (>4,000 cGy) demonstrated a modest survival benefit, with a median overall survival of 19.8 months vs. 16.2 months (p=0.034), indicating that personalized dosimetry may improve clinical outcomes.

Conclusions: Contrary to existing literature, SCLC patients in this cohort demonstrated higher survival and lower recurrence post-radiotherapy compared to NSCLC. This may reflect earlier diagnosis, intensified multimodal treatment, and higher-dose, hypofractionated radiotherapy in SCLC. In NSCLC, escalated-dose radiotherapy was associated with modest survival gains, supporting personalized dosing strategies. Comparative assessments by histologic subtype are key to refining treatment decisions. Concurrent evaluation of survival, recurrence, and dosimetric data offers critical insight into therapeutic response. These findings challenge conventional prognostic models and suggest that individualized radiotherapy may improve outcomes. Prospective studies with integrated dosimetric analysis are needed to confirm and translate these insights into practice.

EP.08.21 Sequential Radiotherapy Following Induction Immunochemotherapy/Chemotherapy for Unresectable Stage III Non-Small Cell Lung Cancer

Y. Yang[1], L. Zhu[1], J. Li[2], F. Xue[1], D. Huang[3], Y. Pan[4], L. He[5], L. Liu[1]
[1]Affiliated Hospital of Guilin Medical University, Guilin/CN ,[2]Liuzhou People's Hospital, Liuzhou/CN ,[3]Liuzhou Worker's Hospital, Liuzhou/CN ,[4]Nanxi Mountain Hospital of Guangxi Zhuang Autonomous Region, Guilin/CN ,[5]Guilin Medical University, Guilin/CN

Introduction: The use of immune checkpoint inhibitors (ICIs) during concurrent chemoradiotherapy (CCRT) has been established as the standard of treatment forunresectable stage III non-small cell lung cancer (NSCLC) by previous studies, including the PACIFICtrial. Inductionimmunochemotherapy was addedbefore CCRT in the PACIFIC-BRAZIL study,improving progression-free survival (PFS). However,4% of patients showed disease progression during induction immunochemotherapy, which raises concerns regarding the bestfollow-up treatment. In this research,the safety and efficacy of sequential radiotherapy were retrospectivelyevaluated in patients who didnot establish remission with induction therapies in real-world settings.

Methods: A multicenterretrospective researchwas conducted on 29 patients withunresectable stage III NSCLC who hadsequential radiotherapy after inductiontherapy failed to produce remission.Induction immunochemotherapy wasadministered to 18 patients,while induction chemotherapy wasgiven to 11. Log-rank tests wereused for univariate analysis,and progression-free survival(PFS) and overall survival(OS)were assessed using Kaplan-Meier analysis.Multivariate Cox regression was used to determineprognostic factors.

Results: The disease control rate (DCR) was 96·6%, while the objectiveresponse rate (ORR) was 37·9%. Themedian overall survival (MOS) was 32·7(95%CI 30·1-35·3) months, and the median progression-free survival (MPFS) was 5·1(95%CI 3·9-6·3) months overall, with 6·6 months in the immunochemotherapy group and 3·7months in the chemotherapy group($\chi 2$=7·68,P=0·006).Theone-year survival rate was 82·%(95%CI68·1%-97·4%).Although OS did not vary significantly across subgroups,progression-freesurvival was significantly better in the immunochemotherapy group(immunochemotherapygroup vs. chemotherapy group,HR:0·174,95%CI 0·054-0·566,P=0·004).No patient had any disease progression while receivingradiotherapy.The proportion of patients whoreceived immunotherapymaintenance as a re-challenge after induction immunochemotherapywas 88·9%,with a 12-month survival rate of 87·5%. There were 16(55·2%) cases of radiation pneumonitis and 2(6·9%)cases of radiation pneumonitis that were grade III orhigher. One patient passed away from radiationpneumonitis,although the cause of deathcould not be associatedwith radiation pneumonitis since the patient had a pre-existingPneumocystis infection before receiving radiotherapy.

Conclusions: For unresectable stage IIINSCLC patients who arenot responsive to induction treatments, sequential radiation is a feasibleand effective method that offers better PFS with a manageable safety profile. These results also demonstrate thepossible advantages of immunotherapy re-challengeafter successful radiotherapy.

EP.08.22 Treatment Patterns and Clinical Outcomes in South Korean Patients With Unresectable Stage III EGFRm NSCLC Undergoing CRT

J.B. Lee[1], M-J. Ahn[2], S-W. Kim[3], K.L. Davis[4], M. Jimenez[4], F. Nasirova[5], Y. Kim[6]
[1]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University, Seoul/KR ,[2]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR ,[3]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul/KR ,[4]Real-World Data & Analytics, RTI Health Solutions, Research Triangle Park, Durham/NC/USA ,[5]Global Medical Affairs Oncology, AstraZeneca, Cambridge/GB ,[6]Oncology Outcomes Research, AstraZeneca, Mississauga/ON/CA

Introduction: In the Phase III LAURA study (NCT03521154), osimertinib demonstrated statistically significant and clinically meaningful progression-free survival (PFS) benefit versus placebo, post-definitive CRT in patients with unresectable stage III EGFRm NSCLC (PFS hazard ratio [HR] 0.16; p<0.001). Real-world treatment patterns and clinical outcomes are important to evaluate the impact of new treatments. Here, we report data from the South Korean cohort of a global, retrospective, real-world study in this setting.

Methods: Data were extracted from medical records of patients (aged ≥19 years) with unresectable stage III EGFRm (Ex19del/L858R) NSCLC diagnosed between Jan 2016 and Dec 2019, who underwent CRT as standard of care at selected sites in South Korea. The primary study outcome was real-world PFS (rwPFS); secondary outcomes included mutation testing and treatment patterns, real-world time to next treatment or death (rwTTNTD) and real-world overall survival (rwOS). Data cut-off: 31 Dec 2022.

Results: In total, 60 patients from South Korea were enrolled across three sites: median age 65 years; 50% female; 93% ECOG PS 0-1; 38% current/former smokers; 68% Ex19del/32% L858R. Most patients (38 [63%]) underwent sequential CRT (sCRT); 22 (37%) patients underwent concurrent CRT (cCRT) (Table). The most common chemotherapy regimen was platinum + paclitaxel: 54/60 (90%) all patients; 34/38 (89%) sCRT; 20/22 (91%) cCRT. Overall, 56 patients (93%) underwent CRT alone, three (5%) received CRT + durvalumab and one patient (2%) received CRT + EGFR-TKI + IO as first treatment. In total, 57 patients received a subsequent treatment upon disease progression, of which EGFR-TKIs were the most commonly used (45/57; 79%). Median (95% CI) rwPFS, rwTTNTD and rwOS were 8.0 months (6.0, 9.0), 9.0 months (7.0, 9.5) and 54.9 months (36.9, 64.9) respectively, in patients who underwent CRT alone. By CRT type, median (95% CI) rwPFS, rwTTNTD and rwOS were 7.5 months (6.0, 9.0), 9.0 months (6.1, 9.4), 54.9 months (36.9, 64.9) and 8.6 months (2.8, 11.0), 8.8 months (3.5, 13.1), 61.5 months (15.5, 69.9) in patients who underwent sCRT or cCRT, respectively.

Conclusions: In this real-world analysis of patients from South Korea with unresectable stage III EGFRm NSCLC, most patients underwent CRT alone as first treatment, most commonly sCRT. The majority of patients received EGFR-TKIs as first subsequent treatment. The rwPFS observed highlights the need for alternative first treatment options in this patient population; the prolonged rwOS observed may be attributed to subsequent use of EGFR-TKIs.

Table: Summary of treatment patterns.

	All patients (N=60)
First treatment, n (%)	
sCRT	**38 (63)**
Cisplatin + paclitaxel*	30 (79)

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.23 EMS to Lung Cancer Patients Receiving Platinum Doublet Concomitant Chemoradiotherapy

A.I. Saito
Juntendo University Urayasu Hospital, Urayasu/JP

Introduction: To determine feasibility and effect of electrical muscle stimulation (EMS) to patients with lung cancer receiving platinum doublet concomitant chemoradiotherapy (CCRT).

Methods: After IRB approval, from August 2014 to December 2016, lung cancer patients receiving CCRT were assigned to either EMS group (EG) or control group (CG). Eligibility criteria were histologically proofed lung cancer, CCRT for curative intent, performance status (PS) 2 or better, and age 20 or older. The quadriceps muscle of both legs were stimulated using biphasic pulsed current, constant current impulses with a pulse width of 400 μs and a frequency of 75 Hz for 18 minutes, twice daily every day through the whole CCRT period. For EG, patients were allowed to raise the electrical current of the machine as high as they can endure. However, for CG patients, electrical current was only increased until the patient could feel a tingling sensation and no muscle contraction was visible or palpable. Grade 2 or higher adverse effects were evaluated and compared between the two groups. Regarding the survival, because stage IV patients (after a good response to chemotherapy or gamma knife to the brain) or patients with recurrence after surgery were also included in this study, these patients were excluded to make the population more homogeneous.

Results: Eligible patients were 63. Out of them, 36 agreed to participate (EG, 17; CG, 19). The following parameters were all balanced well between the two groups; gender, age, PS. Concomitant to chemotherapy, all patients with non-small lung cancer received 60 Gy in 30 fractions and all patients with small cell lung cancer received 45 Gy in 25 fractions (two times a day). Statistically significantly ($p=0.02$) fewer patients with grade 2 or higher serum albumin loss were observed in EG and a trend ($p=0.08$) of fewer patients with grade 2 or higher neutropenia were observed in EG. There were no adverse effect caused by the EMS intervention. There were 6 stage IV patients and 5 patients receiving CCRT after recurrence, who were excluded from survival evaluation. These decreased the population to 25 patients. There was no difference in overall survival ($p=0.71$) and progression free survival ($p=0.12$) between the two groups.

Conclusions: EMS is feasible and could be effective in preventing cancer cachexia and may prevent neutropenia in patients receiving CCRT, but no survival benefit was observed in this study.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.24 Pattern of Care in Locally Advanced NSCLC in India

A. Ravi[1], S. Pathy[1], S. Mallick[2], P.S. Malik[1], S. Kumar[1], R.K. Malhotra[3]
[1]All India Institute of Medical Sciences, New Delhi/IN ,[2]National Cancer Institute, Jhajjar/IN ,[3]All India Institute of Medical Sciences, Delhi/IN

Introduction: Locally advanced NSCLC group requires a multi-disciplinary management. Surgery is the standard of care treatment if resectable otherwise concurrent chemo-radiation (CCRT) is preferred. This audit aims to analyse various treatment strategies in real-world settings and their resultant outcomes.

Methods: Medical records of patients presented to the lung cancer clinic from 2014 to 2018 were retrieved. Stage III NSCLC were included in this retrospective analysis. Demographic and clinical data, treatments with outcomes and side effects were analysed. The PFS and OS were computed using Kaplan- Meier survival curves. Cox proportional hazard model (univariate and multivariate) was used to assess factors affecting PFS and OS.

Results: A total of 396 patients were eligible for demography; 53% were > 60 years of age and male-to-female ratio was 4:1. The proportion of squamous cell carcinoma and adenocarcinoma were 55.8% and 31.3% respectively. Survival analysis was limited to 310 patients who received any form of cancer treatment. The intent of treatment was decided to be curative in 240 of them. Upfront surgical resection was performed in 28 patients (11.6%) with 22 receiving adjuvant chemotherapy. Pre- operative chemotherapy followed by surgery was offered to 20 patients (8.3%). The majority of patients taken for definitive chemo- radiation (CTRT) were treated by induction chemotherapy followed by concurrent CTRT (46 patients= 19.2%). Sequential CTRT (SCRT) was opted for 30 patients (12.5%). Concurrent CTRT (CCRT) was received by only 12 patients (5%). Neoadjuvant chemotherapy (NACT- including preoperative and induction chemotherapy before definitive radiotherapy or CTRT) was administered to 200 patients (83.3%). Of these, 104 patients (43.3%) of NACT were not amenable to curative local treatment later on due to poor performance status(PS), comorbidities, poor cardiopulmonary reserve, or logistic issues. The median follow-up was 30.7 months. Survival was assessed by intention to treat analysis. The median PFS and median OS of the curative intent group were 11.9 months (95%CI= 8.99-14.81), and 30.7 months (95%CI= 24.42-36.98) respectively. Upfront resectable patients had longer survival when compared to NACT followed by surgery. Survival outcomes for NACT followed by CCRT were superior to CCRT or SCRT. Both median OS and PFS were found to be superior with surgery plus adjuvant therapy in comparison to definitive CTRT. Long-term survival outcomes were also better with surgical resection. No significant differences in survival outcomes were observed between CCRT and SCRT approaches, likely due to the limited number of patients in the CCRT group. Overall adherence to treatment protocols was 56.7% and adherence to chemotherapy protocols was 50.4%. PS and reception of intended treatment were significant prognostic factors in multivariate analysis for survival. The median PFS and OS of the patients treated with palliative intent were 6.5 months (95% CI: 4.2- 12.7), and 9.1 months (95% CI: 3.1- 15.7) respectively.

Conclusions: Whenever feasible, curative intent treatment should be offered to fit LA- NSCLC patients. Although stage-wise comparison was not performed, it was seen that survival is longer when tumor is resectable. Homogenous treatment protocols and well-equipped cancer facilities must be in place to avoid deviations from standard recommendations.

Introduction: Despite the prevalence of unresectable/inoperable locally advanced Non-Small Cell Lung Cancer (LA NSCLC) and wide use of chemoradiotherapy (CRT) as the gold standard there were no real- world data about patients' characteristics, diagnostics approaches, CRT patterns and outcomes in Russia. The study set out to evaluate patients' characteristics and explore the patterns of routine clinical management of LA NSCLC in Russia.

Methods: This is an ongoing multi-center, non-interventional study set out to enroll patients with unresectable/inoperable LA NSCLC (stage II-III, incl. locoregional recurrence and patient's refusal to undergo surgery) receiving CRT in the largest oncology centers in Russia. The primary endpoint was demographic and clinical characteristics of the population. The secondary endpoint was evaluation of diagnostic, treatment approaches and short-term outcomes.

Results: From 31 March 2023 to 22 August 2024, 504 patients (97,4% primary diagnosed) were enrolled from 35 centers. Median age (Q1, Q3) was 65 (60, 70) years. 83,5% were current/former smokers. 91.9% had 0-1 ECOG performance status. 491 patients (97,4%) had primary unresectable NSCLC. Of the enrolled patients 92.1% were diagnosed with Stage III (IIIA 31,55%; IIIB 48,21%; IIIC 12,3%). 73,0% had squamous NSCLC and 24,8% had adenocarcinoma. PD-L1 expression level was evaluated in 26,8% of patients, EGFR - in 47,2%. Concomitant diseases were diagnosed in 79.96% of patients with cardiac (62.5%) and vascular (23.4%) disorders being the most common. CT (94,8%) with further additional PET-CT (61,7%) and fibrobronchoscopy with biopsy/puncture (95,8%) and pathomorphological examination (99%) were the commonly used methods for diagnosis and identification of lymph node involvement. Among 265 (52.6%) patients with N2 invasive staging was performed in 21.5% while 14,3% of patients used both PET-CT and invasive methods. 12,7% of patients with N2 stage whom diagnosis was based only on the CT had bulky or conglomerate lymph nodes. Brain MRI was performed on 49,6% patients. Of the 82,9% of patients without PD, 1.8% had CR, 45.6% - PR, 35.5% - SD. Only 6.4% had PD during or immediately after CRT, and 10.7% patients were unevaluable for response. ORR was reached in 239/504 (47.4%) patients and was higher in the cCRT group (53,1%) than in the sCRT group.

Conclusions: Obtained results will make an important contribution to the necessity of wider use of invasive staging for more precise local disease control and extend cCRT (vs sCRT) use in the routine clinical practice to achieve greater OS in unresectable/inoperable LA NSCLC.

Table 1. CRT Characteristics

CRT Characteristics		
Type of CRT (n = 473), n (%)	Concurrent (cCRT)	309 (65.3)
	Sequential (sCRT)	164 (34.7)
Type of CT (n = 473), n (%)	Induction	80 (15.9)

EP.08.26 Blood Inflammatory Biomarkers Dynamics in Neoadjuvant Chemoimmunotherapy vs Chemotherapy Alone in Non-Small Cell Lung Cancer

X. Michavila[1], A. López[1], N. Quiroga[1], I. Botías[1], M. Boada[1], A. Ureña[1], Á. Guirao[1], I. Bello[1], R. Guzmán[1], L. Grando[1], A. Calderón[1], L. Molins[1], R. Ramos[1]
[1]Hospital Clínic de Barcelona, Barcelona/ES

Introduction: Immunotherapy can modulate the tumor microenvironment, activating T lymphocytes and reversing immunosuppression, but it can also generate resistance mechanisms and adverse immune-mediated responses by regulating cells such as neutrophils, monocytes, and lymphocytes. Inflammatory response in cancer is also closely related to tumor genesis, disease progression, and patient prognosis. Different inflammatory biomarkers have been proposed as predictors of response to immunotherapy, including the neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (PLR), monocyte-lymphocyte ratio (MLR), and the immune inflammation index (SII). The objective of this study is to explore the evolution of inflammatory markers in patients undergoing neoadjuvant treatment followed by surgery and to determine whether there are differences depending on the addition of immunotherapy.

Methods: A retrospective cohort study was performed in a single center setting between January 2018 to December 2024. Fifty-two patients who were diagnosed with resectable stage IIB-IIIB NSCLC treated with neoadjuvant treatment followed by radical resection were included. Groups were formed between patients treated with chemotherapy alone (ChT) or chemotherapy plus immunotherapy (ChIT). Differences in perioperative characteristics and treatment response were compared. Baseline, post-neoadjuvant treatment and post-surgery neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), monocyte-to-lymphocyte ratio (MLR) and systemic immune-inflammation index (SII) were calculated and analyzed for correlation with neoadjuvant treatment groups and level of response.

Results: Both groups had similar percentages of comorbidities, pulmonary function tests, and tumor size. The ChIT group had a higher frequency of squamous cell carcinoma (43% vs. 13%, p=0.023) and a higher frequency of N0 and N1 tumors (25% and 12.5% vs. 0%, p=0.002). Neoadjuvant chemoimmunotherapy was associated with an increased major pathologic response (MPR) and complete pathologic response (cPR) compared to chemotherapy alone (65.6% vs 17.4%, p<0.001; 50% vs 13%, p=0.009). No significant differences were shown after neoadjuvant treatment. No differences were observed in the evolution of inflammatory markers according to the neoadjuvant regimen. Besides, no differences were reported in the progression of markers based on the presence of response to treatment. After surgery, significantly elevated levels of PLR, NLR and SII, and decreased levels of LMR were observed in both groups.

Conclusions: Our study shows no differences in the evolution of inflammatory markers associated with neoadjuvant treatment, regardless of the systemic treatment regimen or the degree of response to it. A significant increase in inflammatory status was observed exclusively associated with surgery as published in previous studies.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.27 Exploration of Targeted Sequential Surgery Combined Therapy for ROS1-Rearranged Non-Small Cell Lung Cancer

L. Jiang, j. Kang, w. Zhong
hospital, guangzhou/CN

Introduction: With advances in molecular subtype-guided precision therapy, the clinical management of ROS1-rearranged non-small cell lung cancer (NSCLC) (incidence: 2.6%) faces new challenges. Approximately 50% of newly diagnosed ROS1-rearranged patients present with stage IV disease. Current research primarily focuses on systemic therapy for advanced stages, while the transformative potential of targeted therapy followed by surgery remains underexplored.

Methods: This retrospective study enrolled 20 ROS1-rearranged NSCLC patients (confirmed by next-generation sequencing, NGS) from Guangdong Provincial People's Hospital (2020-2024) who received first-line tyrosine kinase inhibitors (TKIs) followed by surgery. The median preoperative TKI treatment duration was 5.6 months, with 7 patients undergoing dynamic circulating tumor DNA (ctDNA) monitoring for minimal residual disease (MRD). Primary endpoints included pathological response (major pathological response [MPR]: viable tumor ≤10%), while secondary endpoints were event-free survival (EFS) and safety.

Results: Among 20 patients (10 male, 10 female; median age 41.5 years [range 28-67]), initial staging was I/II/III/IV in 1/4/7/8 cases, respectively. Baseline characteristics were balanced between the crizotinib and entrectinib treatment groups(crizotinib 250mg bid, entrectinib 600mg qd). By RECIST 1.1 criteria, the objective response rate (ORR) reached 100% (17 partial responses [PR], 3 stable disease [SD]). R0 resection under video-assisted thoracoscopic surgery (VATS) was achieved in 19 patients (95%; 1 converted to thoracotomy). Postoperative pathology revealed a pathological complete response (pCR) rate of 20% (4/20) and MPR rate of 50% (10/20). Notably, 70% (14/20) exhibited nodal downstaging, with 40% (8/20) achieving Nx→N0 conversion. Regarding safety, 5 patients experienced treatment-related adverse events during preoperative TKI therapy, including 1 case of grade 3 hepatic impairment, with no surgery delays. Kaplan-Meier analysis (median follow-up: 24.6 months) showed median EFS was not reached. Among 7 patients with MRD monitoring, 3 were MRD-positive preoperatively, but all turned negative 1 month post-surgery. Importantly, the MPR rate was significantly higher in patients receiving ≥3 months of TKI therapy versus <3 months (66.7% vs. 0%, P=0.032), and 75% (3/4) of pCR patients received ≥6 months of treatment. No significant difference in MPR rates was observed between TKI agents (P=1.0).

Conclusions: This study is the first to demonstrate that ROS1-TKI induction therapy enables R0 resection in early-to-intermediate-stage NSCLC patients deemed initially unresectable or potentially resectable in advanced stages, with favorable tolerability and no impact on subsequent TKI sequencing. Dynamic ctDNA monitoring effectively guides therapeutic decisions, recommending preoperative TKI therapy for ≥3 months to optimize pathological response. These findings provide novel evidence for multidisciplinary management of ROS1-positive NSCLC.

EP.08.28 Referral Rates to Medical Oncology Before Lung Cancer Surgery: A Quality Improvement Study in the Era of Perioperative Chemoimmunotherapy

J.E. Meir[1], R. Epstein[2], K.E. Pinto Chengot[1], N.E. Seetharamu[1]
[1]Zuckerberg Cancer Center, Lake Success/NY/USA ,[2]Northwell Health, Northwell Health/Hofstra School of Medicine/NY/USA

Introduction: Fifty percent of all patients with non-small cell lung cancer (NSCLC) are diagnosed with localized (20%) or loco-regional disease (30%). Immunotherapy with checkpoint inhibitors along with chemotherapy administered in the perioperative setting has been shown to decrease the risk of distant relapse and surgical outcomes. A meta-analysis of eight phase 2 and 3 randomized clinical trials demonstrated that neoadjuvant chemo-immunotherapy improves pathologic complete response and two-year event-free survival, regardless of treatment-related factors such as chemotherapy type and PD-L1 status. We present a quality improvement project aimed at increasing rates of referral to medical oncology at Northwell Health/Zuckerberg Cancer Center prior to surgical resection in patients with resectable NSCLC.

Methods: The study included 50 patients with pathologically confirmed stage of IB-IIIB NSCLC who underwent surgical resection January - May 2024. Patient charts were retrospectively reviewed for referral to medical oncology prior to surgery for discussions on neoadjuvant chemo-immunotherapy and whether they were presented at the thoracic tumor board. Pre-intervention findings are presented here. We intend to distribute questionnaires and hold multidisciplinary focus groups to identify the reasons for not referring. Through use of Pareto charts, we aim to identify key factors affecting the referral process and create fishbone diagrams to analyze root causes, and then implement se Pareto charts to identify key factors affecting referrals and fishbone diagrams to analyze root causes, then implement Plan, Do, Study, and Act (PDSA) cycles to test and refine improvements.

Results: Among the 50 patients with stage IB-IIIB NSCLC, 11 (22%) were referred to medical oncology for evaluation of neoadjuvant chemotherapy, and 12 (24%) were presented at the tumor board prior to resection. Table 1 provides a breakdown of each stage of NSCLC. Most of the patients referred to medical oncology pre-operatively had stages IIB-IIIB where the referral rates were up to 40% and even amongst those referred to medical oncology, <55% received neoadjuvant chemoimmunotherapy.

Conclusions: Our study found a reduced rate of medical oncology referrals for stage IB-IIIB NSCLC at a major academic center. Suboptimal utilization of perioperative approach was also reflected in a recent real-world study which reported <3% use of stage I and 40% use at stage III. Our findings highlight the need for quality initiatives to identify potential barriers to optimal management of resectable lung cancer to homogenize with evolving standards. These initiatives may also be appropriate for other institutions given global underutilization of perioperative therapies for resectable lung cancer.

Table 1. Rates of medical oncology and tumor board referral in all patients with pathologic stage of IB to IIIB non-small cell lung cancer.

TNM stage	Med Onc Referral (%)	Tumor Board Present (%)	Neoadjuvant (%)

Introduction: Neoadjuvant chemoimmunotherapy has shown promising activity in locally advanced non-small cell lung cancer (NSCLC). However, data comparing it with conventional neoadjuvant chemoradiotherapy (nCCRT) in resectable stage III-N2 disease remain limited. This study aimed to evaluate clinicopathologic characteristics and pathologic response following neoadjuvant treatment.

Methods: We retrospectively reviewed patients with clinical stage III-N2 NSCLC confirmed to be EGFR-wild type and ALK-negative, treated between November 2021 and December 2024 at a single institution. Patients received either nCCRT or neoadjuvant chemoimmunotherapy (nCIT), followed by multidisciplinary evaluation for curative-intent surgery. Clinicopathologic variables were compared using t-test or chi-square test. Major pathologic response (MPR) was defined as ≤10% viable tumor, and pathologic complete response (pCR) as no residual viable tumor.

Results: Among the 279 patients included, 229 (82.1%) underwent surgery while 50 (17.9%) did not. Of the 171 patients treated with nCCRT, 146 (85.4%) proceeded to surgery, compared to 83 out of 108 (76.9%) in the nCIT group. In the surgical cohort, baseline characteristics were comparable between groups. PD-L1 high expression (≥50%) was more frequent in the nCIT group (p = 0.009). Minimally invasive surgery (VATS or robotic) was performed in 81.9% of nCIT patients and 35.6% of nCCRT patients (p < 0.001). Lobectomy was the predominant resection type in both groups, and pneumonectomy was rare (p = 0.122). R0 resection was achieved in all patients in the nCCRT group and in 97.6% of the nCIT group (p = 0.091). MPR was observed in 68.7% versus 48.1% (p = 0.034), and pCR in 17.8% versus 28.3% (p = 0.041), for nCCRT and nCIT groups, respectively.

Table 1 . Patients' clinicopathologic characteristics comparing neoadjuvant CCRT group with neoadjuvant chemoimmunotherapy

	Neoadjuvant CCRT (n=146)	Neoadjuvant ChemoIO (n=83)	p-value

pCR	26 (17.8%)	22 (36.1%)	0.008

Conclusions: Distinct patterns of pathologic response were observed between treatment groups. Neoadjuvant chemoimmunotherapy was associated with a higher rate of pathologic complete response, whereas concurrent chemoradiotherapy led to more frequent major pathologic response. These findings highlight differing biological effects of induction strategies in resectable stage III-N2 NSCLC without targetable mutations. Further follow-up is warranted to evaluate long-term survival outcomes associated with each strategy.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.30 The Outcome of Preoprerative Therapy for Resectable NSCLC Patients With EGFR PACC Mutations

W. Yan, M. Fan, H. Fu, Y. Fang, J. Zhang, X. Yang, M. Zhuo, K-N. Chen
Peking University Cancer Hospital, Beijing/CN

Introduction: The PACC mutation represents a rare subtype among the driver gene EGFR mutations in NSCLC. Second-generation TKIs, such as afatinib, are recommended for treating advanced lung cancer patients harboring this specific mutation. However, there is currently no data regarding preoperative treatment for resectable patients with PACC mutation. This study retrospectively reviewed cases of patients with PACC mutations who underwent preoperative treatment.

Methods: Consecutive patients with EGFR PACC mutations who underwent preoperative treatment and radical resection between 2017 and 2024 were selected from the prospective database of the Department of Thoracic Surgery at Peking University Cancer Hospital. The rates of major pathological response (MPR), pathologic complete response (pCR), and the safety of perioperative treatment in this cohort following neoadjuvant therapy were analyzed.

Results: A total of 11 patients participated in this study, including 7 males (63.6%) with an average age of 61 years; among them, 6 were smokers (54.5%). The clinical stages included stage I in one case (multiple primary lung cancer), stage II in six cases, and stage III in four cases. The specific EGFR mutation sites identified for G719X in three cases, S786I alone in two cases, L858R combined with S786I in two cases, G719S combined with S768I in one case, L747P in one case, and L861Q combined with L718Q in one case. Neoadjuvant treatment primarily consisted of targeted therapy: four patients received targeted therapy alone, four underwent a combination of targeted therapy and chemotherapy, two received chemotherapy combined with immunotherapy, and one was treated with chemotherapy alone. The overall response rate (ORR) for the entire cohort was 36.4% (4/11), while five patients (45.5%) achieved downstaging. The R0 resection rate reached 100% (11/11), as all patients underwent video-assisted thoracoscopic surgery (VATS) for radical lung cancer resection. Assessment results indicated that there was no pathological complete response (pCR) across the group; however, the major pathological response (MPR) rate stood at 9.1% (1/11). Notably, no grade 3 or higher adverse events occurred within the cohort.

Conclusions: The preoperative management of patients harboring EGFR PACC mutations presents a formidable challenge in clinical practice, necessitating the development of innovative treatment regimens to enhance therapeutic efficacy.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.31 Phase II Trial and Correlative Genomic Analysis of Neoadjuvant Sintilimab Plus Chemotherapy in EGFR-Mutant Non-Small Cell Cancer

C. Zhang[1], B-Y. Jiang[1], L-X. Yan[2], X-N. Yang[1], Q. Zhou[1], Y-L. Wu[1], W-z. Zhong[1]
[1]Guangdong Lung Cancer Institute, Guangzhou/CN ,[2]Guangdong Provincial People's Hospital, Guangzhou/CN

Introduction: We have previously reported the encouraging short-term outcome of the phase 2 prospective trial (NCT05244213). Herein, we report the updated survival analysis as well as an integrated comprehensive genomic analysis with multi-cohorts involved.

Methods: This is an open-label, phase 2 prospective trial with Simon two-stage design. 35 patients with stage IIB-IIIB (N2) and EGFR mutation including non-sensitive mutations were enrolled, and up to 3 cycles sintilimab plus chemotherapy would be provided followed by surgery and observation for stage I cohort or adjuvant osimertinib for stage II cohort. Comprehensive genomic profile of this cohort and other cohorts upon different neoadjuvant treatment modalities were included for subsequent analysis (N=104).

Results: With a median follow-up of 22.5 months for the two-stage cohorts, 12 out of 35 (25.7%) patients experienced disease relapse/progression. The most common relapsed sites were brain (50.0%) and intrapulmonary metastasis (33.3%). The median event-free survival (EFS) was 25.3 months, with 12-month and 24-month EFS rates of 88.6% and 60.0%, respectively. Although there was no significant difference in EFS based on pathological response status, patients who achieved pCR showed a favorable trend in EFS (p=0.27). Specifically, patients with EGFR L858R exhibited better pathological and radiological response as well as survival benefit compared to EGFR 19del and other uncommon subtypes. No overall survival (OS) events were observed so far in this study. For patients who received adjuvant osimertinib or first-line osimertinib after disease relapse, no severe immune-related toxicities were observed with numerically higher incidence of paronychia and ALT/AST elevation when compared with ADAURA. The ORR for those patients who received first-line osimertinib was 87.5%. The most common co-mutations among four EGFR-mutated cohorts were TP53 (60.9%), RB1 (15.2%), RBM10 (9.5%), CDK4 (6.5%) and MDM2 (5.4%). By comparing the radiological response among CTONG2104 cohort, neoadjuvant osimertinib and neoadjuvant erlotinib cohorts, patients with co-mutated RB1 (p=0.29), RBM10 (p=0.06) and MDM2 (p=0.19) tended to not respond well to neoadjuvant EGFR-TKIs while patients with TP53 (p=0.13), RB1 (p=0.37) and RBM10 (p=0.51) co-mutation tended to response well to neoadjuvant immunochemotherapy. Pre-treatment genomic and chromosomal instability could help identify beneficiaries while patients with 12q amplification might not benefit from immunochemotherapy.

Conclusions: Neoadjuvant sintilimab plus chemotherapy yielded encouraging clinical activity in patients with localized EGFR-mutant NSCLC. Comprehensive genomic testing might help inform personalized neoadjuvant treatment strategy. Upfront immunochemotherapy for localized EGFR-mutant NSCLC did not add sever immune toxicity or impact clinical response to adjuvant or first-line osimertinib.

EP.08.32 Real-World Outcome of Neoadjuvant-Intent Therapy vs Concurrent Chemoradiation for Locally Advanced Non-Small Cell Lung Cancer

Y. Fakhari Tehrani[1], A. Abhyankar[2], M. Ramesh[1], N. Nassour[1], M. Alharbi[2], R. McCauley[2], A. Buradkar[2], R. Thakur[2], M. Burwinkel[1], P. Jain[2], G. Dy[2], E. Yau[2], M. Farrugia[2], C. Nwogu[2], N. Malik[2], B. Fitzgerald[2]
[1]University at Buffalo, Buffalo/NY/USA ,[2]Roswell Park Cancer Center, Buffalo/NY/USA

Introduction: Increasingly in real-world practice, some patients with localized or locally advanced non-small cell lung cancer (NSCLC) who would have historically been offered upfront concurrent chemoradiation (CCRT) followed with consolidation immunotherapy are now being treated with a neoadjuvant intent approach (NAI). In clinical trials, rates of not proceeding to surgery after NAI therapy range from 17-22%, and in clinical practice rates will likely be higher.In this retrospective analysis of patients recently treated at a high-volume comprehensive cancer center, we assessed survival outcomes for patients treated with NAI who did not proceed to surgery with those who received upfront CCRT.

Methods: Patients diagnosed with locally advanced NSCLC from 2019 onward were identified through the bioinformatics shared resource at Roswell Park Cancer Institute. Manual chart reviews were conducted to verify demographics, tumor characteristics, treatments, and survival outcomes. Survival outcomes were defined from start of first treatment to progression, death, or last known follow up. Group comparisons were conducted using an unpaired t-test and chi-squared/Fisher's exact test with statistical significance set at $p < 0.05$. Survival outcomes were analyzed using the Kaplan-Meier method.

Results: A cohort of 309 patients with localized or locally advanced NSCLC were identified, of whom 133 received NAI therapy and 95 underwent upfront CCRT. Baseline characteristics are reported in table 1. Within the NAI group, 36 patients (26.5%) did not proceed to surgery, with 18 ultimately completing CCRT. At the time of data lock, with average follow up time of 685 days, median overall survival (OS) was 535 days for NAI patients who did not undergo surgery versus 1177 days for patients receiving upfront CCRT(p = 0.53). Median progression-free survival (PFS) was 449 days in the NAI group versus 843 days in the CCRT group (p = 0.22) (figure 1).

*Multidisciplinary Conference: Weekly Thoracic Oncology "tumor board" consisting of thoracic surgery, thoracic medical oncology, pathology, radiology, radiation oncology, pulmonology and interventional pulmonology representatives.

‡3 patients with unknown bronchoscopic staging

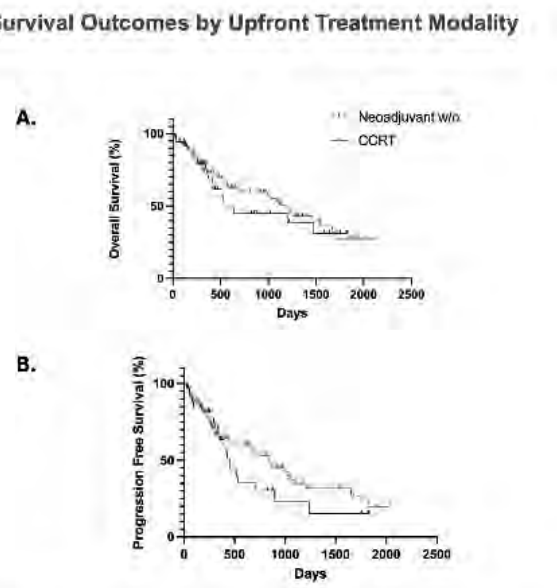

Figure 1: Survival outcomes among upfront neoadjuvant chemoimmunotherapy w/o surgery group vs CCRT. Median Overall survival (OS) (A), was 535 days in the neoadjuvant group vs 1177 days in the upfront CCRT group (p=0.53). Median PFS (B) in the upfront neoadjuvant group was 449 days vs 843 days in the CCRT group(p= 0.22).

Conclusions: Compared to large clinical trials, our institutional experience demonstrates a higher proportion of patients receiving neoadjuvant therapy who ultimately did not proceed to surgery (26.5%), possibly related to high levels of multistation N2 disease in this cohort. There was a numerical trend towards improved survival with CCRT that did not meet threshold for statistical significance. 75% of patients treated with NAI without surgery had at least one case presentation at a multidisciplinary conference (MDC), underlining the importance of close multidisciplinary collaboration in these patients. Our cohort is limited by its retrospective nature and limited follow up time; continuing assessment at our institution is ongoing.

Keywords: neoadjuvant therapy, concurrent chemoradiation

EP.08.33 A Real-World Study of Resectable NSCLC Following Neoadjuvant Immunotherapy: Should Postoperative Adjuvant Immunotherapy Be Recommended?

M. Li, F. Sun, M. Feng, L. Tan, Q. Wang
Zhongshan Hospital Fudan University, Shanghai/CN

Introduction: This study aims to evaluate the impact of postoperative adjuvant immunotherapy in resectable NSCLC patients who received neoadjuvant chemotherapy combined with immune checkpoint inhibitors (ICIs), focusing on whether extending immune checkpoint inhibition beyond the perioperative period improves survival outcomes.

Methods: A retrospective cohort study was conducted on resectable NSCLC patients treated with NAC combined with ICIs at Zhongshan Hospital, Fudan University, from January 2019 to June 2024. Pathological responses (pCR, MPR, or partial response) were assessed, and event-free survival (EFS) and overall survival (OS) were compared between those receiving postoperative adjuvant ICI therapy and those who did not.

Results: Of 186 patients, 106 received adjuvant ICI therapy and 80 did not. Patients who achieved pCR or MPR showed no significant difference in EFS or OS between the two groups (EFS: p=0.282, OS: p=0.330). In contrast, patients without pCR or MPR experienced significantly improved EFS (p=0.004) with adjuvant ICI therapy, though no clear OS benefit was observed (p=0.108). Multivariable analysis identified age, smoking history, advanced clinical stage, PD-L1 expression, and pathological response as independent predictors of survival. An AI-based decision tree model developed to predict the need for postoperative adjuvant immunotherapy showed strong performance (accuracy: 85%, AUC: 0.82), with key predictors including pathological response, age, clinical stage, and PD-L1 expression. The model suggested that patients with incomplete responses (non-pCR/MPR) were more likely to benefit from adjuvant ICI therapy, and younger patients were more likely to tolerate and benefit from it.

Conclusions: Postoperative adjuvant ICI therapy significantly improves EFS in resectable NSCLC patients, particularly in those without pCR or MPR. However, its impact on OS remains uncertain. These findings suggest the need for personalized treatment strategies, with adjuvant ICI offering greater benefit in patients with incomplete responses. Further prospective studies are needed to clarify its role and optimize treatment sequencing.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.34 To Resect or Not to Resect: The Evolving Landscape of Definitive Therapy for Stage III NSCLC: Implications for Service Demand in Ireland

C. Moloney[1], O.M. Fitzpatrick[1], R. Clarke[1], D. O'Reilly[1,2], M.L. O'Connor[1], J. Moyle[1], O. Breathnach[1], P.G. Morris[1], A. Murphy[1], M.Y. Teo[1], B.T. Hennessy[1], L. Grogan[1], J. Naidoo[1,2]
[1]Beaumont Hospital, Dublin/IE ,[2]Royal College of Surgeons Ireland, Dublin/I

Introduction: Lung cancer is the leading cause of cancer-related mortality in Ireland. Non-small cell lung cancer (NSCLC) constitutes 80-85% of cases, with approximately one quarter presenting with stage III (locally advanced) disease at diagnosis. Traditionally, surgery followed by adjuvant platinum-based chemotherapy was the standard approach for resectable stage III NSCLC, with definitive chemoradiotherapy (dCRT) +/- maintenance immunotherapy. In recent years, several phase III trials have demonstrated a benefit for perioperative chemoimmunotherapy in a subset of patients with stage III NSCLC (EGFR-WT, ALK-WT, PD-L1>1%), based on improved pathologic complete response rates, event-free survival, and overall survival. These advances potentially expand the pool of patients eligible for surgery. In this study, we aim to identify the proportion of stage III NSCLC patients considered eligible for perioperative therapy and surgery, in a tertiary referral centre in Ireland.

Methods: We retrospectively reviewed patients with stage III NSCLC discussed at the Beaumont RCSI Cancer Centre lung cancer tumour board (2012-2023). Patient features, diagnostic testing, treatment and survival (OS) were analysed. Stage was assessed by IASLC TNM version 8, and resectability defined by EORTC consensus criteria and ECOG PS 0-1. Differences in patient features, treatment, and outcome were analysed across three time periods (2012-2015; 2016-2019; 2020-2023).

Results: A total of 422 patients with stage III NSCLC (209 male, 213 female) were identified. Patients with stage IIIA NSCLC accounted for 48% (203/422), stage IIIB 41% (173/422), and stage IIIC for 11% (46/422) of cases. Median OS was 17.4 months for stage IIIA, 13.4 months for stage IIIB, and 7.9 months for stage IIIC NSCLC. There was an increasing proportion of stage IIIA disease over time, rising from 42.7% in 2012-2015 to 50.8% in 2020-2023. Histologically, the majority of patients had non-squamous NSCLC at 54.4% (204/422) followed by squamous NSCLC at 45.6% (171/422). EGFR/ALK/ROS1 were available in 80% of patients with non-squamous NSCLC across all time periods, while PD-L1 was obtained in 69.2% from 2020-2023. dCRT was the primary treatment recommendation for 38.2% (161/422) of patients, with 8.5% (36/422) recommended palliative radiation alone, 20.9% (88/422) palliative chemotherapy alone, and 10.9% (46/422) best supportive care. Surgical resection was recommended for 34% (n=69) of stage IIIA and 9.2% (n=16) of stage IIIB NSCLCs. Applying the 2024 EORTC resectability criteria, would have meant that 66% (n=134) of stage IIIA and 26.6% (n=46) of stage IIIB cases with an ECOG PS of 0-1 could have been considered for surgery.

Conclusions: In this study, we identify that in a large tertiary cancer centre, more than half of historical patients with stage IIIA NSCLC and a quarter of patients with stage IIIB NSCLC patients may have been eligible for perioperative chemoimmunotherapy and curative surgery based on 2024 international recommendations and regulatory approvals. This change in treatment approach will require investment in rapid biomarker and related diagnostic testing, and surgical services. Next steps include conducting an analysis based on National Cancer Registry of Ireland (NCRI) data on stage III NSCLC incidence projections, to evaluate anticipated service demands nationally.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.35 Accurate Pathologic Response Assessment of Lung Squamous Cell Carcinomatreated With Neoadjuvant Immunochemotherapy therapy

S. li, C. Wu, L. Hou, Z. Dong, J. Lin, W. Chen, Y. Huang
Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai/CN

Introduction: The pathological response assessment system in lung cancer surgical specimens post-neoadjuvant therapy includes the cPRC method recommended by IASLC for all treatment regimens and the immune-related pathologic response criteria (irPRC) for immunotherapy. However, there is a lack of sufficient comparative research data on the application value of these two assessment systems in the pathologic response assessment.

Methods: A total of 83 LSCC patients who received neoadjuvant immunochemotherapy and underwent complete resection at Shanghai Pulmonary Hospital between 2019 and 2023 were enrolled. All surgical specimen H&E sections (778 sections) were digitized using Motic scanning software, and the Aperio ImageScope ×64 software was used to manually annotate the tumor bed, residual viable tumor (RVT), and necrotic areas in the H&E-stained sections. We compared the consistency of the IASLC-recommended calculation method (cPRC method, RVT% = viable tumor cell area / tumor bed area) and the irPRC assessment calculation method (RVT% =A1*S1/S+A2*S2/S+A3*S3/S+·····+An* Sn/S) in evaluating the pathological response.

Results: Using the IASLC multidisciplinary-recommended cPRC and irPRC methods, we assessed the pathological response in 83 LSCC patients treated with neoadjuvant immunochemotherapy. The results revealed that 28 cases (33.7%) achieved complete pathological response (CPR), 28 cases (33.7%) achieved major pathological response (MPR), and 27 cases (32.5%) were classified as non-MPR. For these non-CPR cases, the average absolute difference in RVT% calculated by the two assessment methods was 0.95% (range: 0% to 7.90%). Specifically, 41 cases (74.5%) showed a difference of 0% ≤ |RVT% difference| ≤ 2%, eight cases (14.5%) had a difference of 2% < |RVT% difference| ≤ 4%, and six cases (10.9%) exhibited a difference of |RVT% difference| > 4%. Among the cases with |RVT% difference| > 4%, five were non-MPR patients and one was an MPR patient. The consistency between the two methods in pathological response assessment grouping was excellent, with a Kappa coefficient of one indicating strong agreement.

Conclusions: Both the cPRC and irPRC methods are suitable for assessing pathological response in surgical specimens following neoadjuvant immunotherapy. However, when significant discrepancies in RVT% values exist across different wax blocks, the cPRC method is more significantly impacted in pathological response assessment compared to the irPRC method. Additionally, the irPRC method provides enhanced precision in pathological response evaluation when RVT% approaches the 10% threshold.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.36 Vebreltinib as Neoadjuvant Therapy in Three Cases of MET Exon 14 Skipping Mutation-Positive NSCLC: A Case Series

Y. Zhou, D. Bian#, P. Zhang#
Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: MET exon 14 skipping mutation were discovered in non-small cell lung cancer (NSCLC) and the efficacy of MET-targeted treatment in these patients has been established. However, neoadjuvant therapy in these patients has limited treatment options.

Methods: Clinical data were obtained from the Shanghai Pulmonary Hospital. Reverse transcription-polymerase chain reaction (RT-PCR) was performed to detect gene mutation. Tumor and adjacent normal tissue were collected during surgery for postoperative pathological assessment.

Results: Three patients were prospectively enrolled. Case 1: A 70-year-old female patient was diagnosed with stage T3N1M0 (IIIA) NSCLC, CT scan revealed a 56.76mm tumor tissue mass in the basal segment of the upper lobe of the left lung with left hilar lymph nodes metastasis. RT-PCR identified a MET exon 14 skipping mutation. The patient was administered Vebreltinib 200mg twice daily. After 4 cycles of treatment, the CT scan showed a 48.4% reduction in the primary lesion volume, shrinking to 29.31mm, and the clinical evaluation was partial response (PR) according to RECIST 1.1. Video-assisted thoracoscopic surgery (VATS) left upper lobectomy was planned following neoadjuvant treatment, but transformed to open thoracotomy due to tissue adhesion during operation. Postoperative pathological examination revealed the residual tumor was 8%, achieving a major pathological response without lymph node invasion, and the postoperative pathological stage was ypT1cN0Mx. The treatment-related adverse events (AE) were decreased leucocyte count, decreased neutrophil count, peripheral edema and rash, which all for grade 2 according to CTCAE 5.0. Case 2: A 61-year-old male patient was diagnosed with stage T4N0M0 (IIIA) NSCLC. CT scan revealed a 57.06mm tumor tissue in the right upper lobe of lung with invasion of the mediastinum. RT-PCR identified MET exon 14 skipping mutation. After administering 4 cycles of Vebreltinib 200mg twice daily, the CT scan revealed tumor shrinkage of 26.4%, and the clinical evaluation indicated stable disease (SD). The patient underwent VATS right upper lobectomy. Postoperative pathological examination revealed a stage of T1cN1Mx with 75% residual tumor cells. There were no other AE except Grade 1 anemia. Case 3: A 62-year-old male patient was diagnosed with stage T4N2M0 (IIIB) NSCLC. PT-PCR revealed MET exon 14 skipping mutation. The patient received Vebreltinib treatment (200 mg bid po) 4 cycles for neoadjuvant treatment. CT images on C4 of the treatment showed 34% shrinkage of the primary tumor, assessed as PR. There were no other drug-related side effects except Grade 2 peripheral edema. This patient is undergoing preoperative evaluation.

Conclusions: These cases highlight the potential therapeutic benefit of MET-targeted therapy as neoadjuvant treatment for MET exon 14 skipping mutation-positive IIIA-IIIB NSCLC. Our findings suggest that highly sensitive MET-TKI may confer clinical benefits for these patients and the toxicity profile is tolerable. However, tissue adhesion should be noted during surgery.

Keywords: Met exon 14 skipping mutation, neoadjuvant, non-small cell lung cancer

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.37 Treatment Strategies for Unresectable Stage IIIA Lung Cancer After Neoadjuvant Therapy

P. Rodriguez Hernaez, A. Cardeña-Gutiérrez, I. Castellano-Carneiro, A. Herrero-Márquez, L. Herrera-Gorrín, J.L. DeRozas-Gutiérrez, M. Harpalani-Manghnani, J.J. Martín-Ortega, F. Mujica-Arencibia, M. Vera-Dumpiérrez, M. Gutiérrez-Gordo, K. Medina-Sánchez
Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife/ES

Introduction: Stage III non-small cell lung cancer (NSCLC) is a heterogeneousdisease and accounts for 22% of all cases of NSCLC. Neoadjuvant treatment in patients with resectable stage IIIA is changing the paradigm of locally advanced disease and is recommended in the major treatment guidelines. However, among patients undergoing neoadjuvant treatment, 7-17% are unable to undergo subsequent surgical treatment. In these patients, management is uncertain.

Methods: This case report highlights three cases of stage IIIA lung adenocarcinoma candidates for neoadjuvant therapy and surgical treatment, in which surgery could not be performed due to patient contraindications, and radical chemoradiotherapy was proposed. Patient data were reviewed confidentially and anonymized for presentation.

Results: Patient A: 73-year-old woman diagnosed in March 2023 with stage IIIA squamous cell lung adenocarcinoma (cT4N1M0). PD-L1 <1%. Neoadjuvant treatment with Cisplatin - Gemcitabine and nivolumab, according to CheckMate 816 trial regimen. Partial response after 3 cycles. Thoracic surgery was proposed, but the patient declined. Finally, sequential radiotherapy was chosen. Carboplatin (AUC 5) and Paclitaxel (175 mg/m^2), followed by 66 Gy of sequential radiotherapy. Partial response after treatment. Last follow-up in February 2025 with maintained partial response. Patient B: 49-year-old woman, diagnosed in May 2023 with stage IIIA lung adenocarcinoma (cT2N2M0). PD-L1 80%. KRAS G12V mutation. Neoadjuvant treatment with Carboplatin - Paclitaxel - Nivolumab, according NADIM II regimen. Stable disease after 4 cycles. Proposed for pneumonectomy but inoperable patient due to cardiac pathology. As an alternative, concomitant chemoradiotherapy (Carboplatino (AUC5) -Paclitaxel (175mg/m^2) plus sequential radiotherapy, 56 Gy total doce) followed by Durvalumab as maintainance treatment, leading to a complete response. Finished Durvalumab in October 2024 maintaining complete response until the most recent follow-up in February 2025.Patient C: 70-year-old man diagnosed in March 2023 with stage IIIA lung adenocarcinoma (cT3N1M0). PD-L1 5%. Neoadyuvant treatment with Cisplatino-pemetrexed- Nivolumab according Checkmate 816 regimen. Partial metabolic response in PET-TC after 3 cycles. Surgical contraindication due to high probability of pneumonectomy and patient comorbidity. Given PD-L1 5%, Pemetrexed - Pembrolizumab was proposed as maintenance. After 3 cycles, complete metabolic response in PET-TC. Proposed for sequential radiotherapy, total dose of 66 Gy. Sustained partial response with Pemetrexed-Pembrolizumab until February 2025.

Conclusions: Neoadjuvant chemoimmunotherapy has demonstrated significant benefits, with nearly 20- 40% of patients achieving complete responses and between 80-90% of patients reaching curative surgery. There is no established evidence regarding the management of patients who remain inoperable after neoadyuvant treatment. Concurrent or sequential chemoradiotherapy followed by consolidation immunotherapy could be a beneficial approach, as evidenced by the clinical cases reported earlier. However, both this approach and other concerns, such as the selection of the appropiate immunotherapy for consolidation (same immunotherapy as in neoadjuvant therapy or different) remain uncertain. Further studies are needed in this area.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.38 Real-World Data of Adjuvant Therapy With Aumolertinib for EGFR-Mutated NSCLC Patients

H. Liu, M. Xing, L. Tong, H. Duan, X. Dong, Y. Zhang, C. Ke, K. Zhang, X. Yan
The 2nd Affiliated Hospital of Air Force Medical University of PLA, Xi'an/CN

Introduction: Aumolertinib is the first innovative third-generation Epidermal Growth Factor Receptor (EGFR) tyrosine kinase inhibitor (TKI) in China. In previous clinical trials, it has shown excellent efficacy and safety in advanced NSCLC patients (pts), especially with central nervous system (CNS) metastases. However, there is still lack of research on the adjuvant therapy of pts after radical surgery. Here, we conducted a retrospective real-world study to investigated the efficacy and safety of aumolertinib for stage IA2-IIIB NSCLC after R0 resectiona with EGFR mutations.

Methods: Pts who underwent radical surgery with EGFR-mutant were enrolled and received a daily dose of aumolertinib 110 mg up to 3 years, depended on the pts's pathologic stage and physical conditions. The disease-free survival (DFS), overall survival (OS), safety and tolerability were evaluated.

Results: The study retrospectively analyzed 62 pts with stage IA2-IIIB who underwent radical surgery and were pathologically confirmed to have EGFR mutation (mostly exon 19 deletion or L858R, 6.4% rare mutation; 24% pts with EGFR co-mutations and 16% with TP53 co-mutation). Among them, 21 pts (33.9%) were accompanied by multiple pulmonary nodules.As of October 2024, the median follow-up time was 33.3 months. The 1-year DFS rate was 100%, the 2-year DFS rate was 93.5%, and the 3-year DFS rate was similar to the results of ADAURA study, reaching 84.2%. However, it is important to note that our study included 2 pts (3.2%) with stage IIIB, whereas the AUAURA study excluded this population. In terms of overall survival (OS), both 1-year and 2-year OS rates in this study were 100%. The 3-year OS rate of aumolertinib was 98.3% (2 pts died, one from COVID-19 and the other died in a car accident, both unrelated to lung cancer treatment), compared with 85% for Osimertinib in the ADAURA study. Notably, in further analysis, there was no statistical difference in DFS rates among multiple important subgroups(preoperative multiple nodules vs. Single lesions, p=0.99; Ex19del vs. L858R, p=0.246; with or without TP53 mutations, p=0.38). We observed a total of 33 pts (53.2%) with high-risk factors in postoperative pathology, including poorly differentiated carcinoma, Vascular invasion, pleural invasion, and with micropapillary and solid components, etc. There was no statistically significant difference in DFS rate (p=0.313) and OS rate (p=0.90) among pts with or without high-risk pathological factors after surgery.No grade≥3 adverse events occurred during aumolertinib treatment. The most common side effects were rash and mouth ulceration. No pts withdrew from therapy due to adverse drug reactions.

Conclusions: Our real-world study data reinforces the remarkable effectiveness of aumolertinib as a postoperative adjuvant treatment for NSCLC with an excellent safety profile. Although 5-year OS data were not available in this study, the findings suggest that aumolertinib has the potential to improve pts outcomes.

Keywords: EGFR mutant NSCLC, adjuvant therapy, Aumolertinib

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.39 Adjuvant Therapy With Furmonertinib Significantly Reduces the Recurrence Rate in Lung Cancer Patients With Exon 20 Insertion Mutations

J. Chen, J. Fan
Shanghai General Hospital, Shanghai/CN

Introduction: Exon 20 insertion mutations in the EGFR gene are a rare subtype of non-small cell lung cancer (NSCLC) with limited treatment options and poor prognosis. Postoperative recurrence remains a significant challenge in these patients. Furmonertinib, a third-generation EGFR tyrosine kinase inhibitor (TKI), has shown promise in targeting exon 20 insertion mutations. We report a series of cases evaluating the efficacy of Furmonertinib as adjuvant therapy in reducing recurrence rates in NSCLC patients with exon 20 insertion mutations.

Methods: We retrospectively identified 5 patients from Shanghai General Hospital who underwent curative surgery for NSCLC with confirmed exon 20 insertion mutations and received Furmonertinib as adjuvant therapy between 2020 and 2024.

Results: The 5 patients had a median age of 73 (range, 41-75) years, with 4 (80%) being female. All patients received adjuvant therapy with Furmonertinib after surgery(One of the patients switched to Sunvozertinib after one year of Furmonertinib treatment). During a median follow-up of 24 months, 1 (20%) patients experienced disease recurrence(the patient who discontinued Furmonertinib midway and switched to Sunvozertinib). The most common adverse events were mild diarrhea (40%) and leukopenia (20%), with no grade 3 or higher toxicities reported. Disease-free survival (DFS) at 2 years was 80%, significantly higher than expected for this mutation subtype.

Conclusions: This case series highlights the potential of Furmonertinib as an effective adjuvant therapy in reducing recurrence rates in NSCLC patients with exon 20 insertion mutations. Further prospective studies are warranted to confirm these findings and to better understand the long-term efficacy and safety of Furmonertinib in this population.

EP.08.40 Immunotherapy Extended Survival in Patients With Recurrent Pulmonary Pleomorphic Carcinoma Following Surgery

W. Nagase, Y. Kudo, J. Matsubayashi, S. Takahashi, K. Murakami, H. Furumoto, Y. Shimada, M. Hagiwara, M. Kakihana, T. Ohira, T. Nagao, N. Ikeda
Tokyo medical university, Tokyo/JP

Introduction: Pulmonary pleomorphic carcinoma (PC) is a rare histological type of lung cancer, accounting for approximately 0.4% of all cases, and is known for its aggressive nature. PC is resistant to conventional treatment however, programmed death-ligand 1 (PD-L1) expression in PC is reported to be high in most cases. This study aims to investigate factors associated with recurrence and evaluate the efficacy of ICIs after recurrence in patients with surgically resected PC.

Methods: A total of 71 patients with PC who underwent pulmonary resection at Tokyo Medical University Hospital between 2008 and 2022 were retrospectively analyzed.

Results: The median age at the time of surgery was 71 years (range: 43-85), and the majority of patients were male (59 patients, 83%). 64 patients (90%) had smoking history. The median pathological tumor size was 4.2 (range: 0.4-12.0) cm and pathological stage I/II/III/IV (8th edition) was 17 (24%), 28 (39%), 25 (35%), and 1 (1%), respectively. PD-L1 expression (28-8 clones) was positive in 62 patients (87%), of which 22 patients (33%) showed PD-L1 expression levels of ≥50%. The 5-year overall survival rate was 48.6%.Postoperative recurrence occurred in 38 patients (54%), with a median recurrence-free survival of 19.4 months. Treatment after recurrence was administered to 24 patients (63%), and ICIs were administered to 10 patients (26%). Thirteen patients (34%) did not receive any treatment and 7 of them, due to poor PS by progressive disease.The overall response rate of patients treated with ICIs was significantly higher (5 out of 10 patients, 50%) than that of patients treated without ICIs (1 out of 14 patients, 7%). Among the 5 patients with high responses to ICIs (complete response or partial response), 4 patients showed high PD-L1 expression (≥50%). The 3-year survival rate after relapse was significantly higher in patients treated with ICIs compared to those without ICIs (65.6% vs. 14.3%, Log-rank p = 0.007) (Figure 1).

Conclusions: Recurrence in the early postoperative period and rapid progress of PC were observed and conventional systemic treatment was in effective. ICIs after recurrence in PC improved prognosis compared to other treatment, and favorable outcomes were observed in cases with high PD-L1 expression. Careful postoperative follow-up, and early intervention at the time of recurrence, are crucial for this aggressive type of lung cancer.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.41 Tislelizumab Combined With Chemotherapy for Conversion Therapy in Stage III-N3 Non-Small Cell Lung Cancer: A Phase 2, Single-Arm Trial

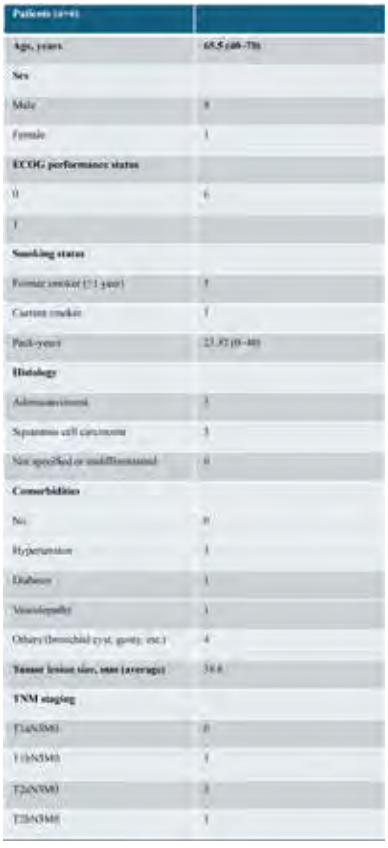
S. Lin[1], K. Ma[1], Z. Yu[1], X. Yu[1], F. Ll[1], H. Xiao[1], J. Feng[1]
[1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital and Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, Shenzhen city/CN

Introduction: Stage III non-small cell lung cancer (NSCLC) is a disease with significant heterogeneity, and selecting an effective treatment strategy is a challenge faced by clinicians. There are already some studies exploring whether surgical treatment is suitable for N3 patients. In recent years, immunotherapy has achieved continuous success in the perioperative treatment of early-stage resectable NSCLC, demonstrating significant tumor shrinkage effects and Event-Free Survival (EFS) benefits. This study is designed to investigate whether technically resectable Stage III-N3 NSCLC patients can be converted to surgically resectable after treatment with tislelizumab (PD-1 inhibitor) in combination with chemotherapy.

Methods: This was an open-label, single-arm, phase 2 trial. Eligible patients were aged 18 years or older with histologically or cytologically documented, untreated Stage III-N3 NSCLC. N3 lymph node metastasis is diagnosed through pathological examination using EBUS (endobronchial ultrasound), EUS (endoscopic ultrasound), thoracoscopy, mediastinoscopy, or fine-needle aspiration biopsy. Patients received conversion treatment with nab-paclitaxel (260mg/m^2) and Cisplatin (75 mg/m^2) or Carboplatin (AUC 5) plus Tislelizumab (200 mg) on day 1 of each 21-day cycle, for 3-4 cycles before surgical resection, followed by standard adjuvant therapy. The primary endpoints were R0 rate, assessed in the intention-to-treat population, and MPR, evaluated in the surgical patients. The Secondary endpoints were pCR, TTDM, EFS, OS, and Surgical-related outcomes. Safety was assessed in the intention-to-treat population. This study is registered with ClinicalTrials.gov under the registration number: ChiCTR2400081493, and is ongoing.

Results: Between February 2024 to February 2025, we screened 7 patients for eligibility, of whom 6 patients were enrolled and received conversion treatment (Fig 1). Among them, 5 patients completed 4 cycles of conversion treatment, and 4 patients underwent surgery. one case recently completed conversion therapy and evaluated for surgery 4-6 weeks later. All surgical patients achieved R0 resection, and 3/4 achieved MPR, 1/4 achieved pCR. The downstaging rate of T classification after conversion therapy reached 100%, and the downstaging rate of pathological N classification reached 3/4. During the conversion therapy, any treatment-related adverse events were Grade 1-2.

Conclusions: This ongoing clinical study has shown exciting preliminary efficacy. As more data to be collected, surgery following conversion therapy with immunotherapy combined with chemotherapy is becoming a new direction in the clinical research of N3 locally advanced lung cancer.



Keywords: Conversion Therapy, Stage III-N3 NSCLC, Tislelizumab

EP.08.42 A Prognostic Marker for Consolidation Therapy With Durvalumab After Concurrent Chemoradiotherapy in NSCLC: The Utility of Serum CYFRA 21-1

M. Ito, R. Ariyasu, S. Fujishima, H. Iso, T. Nemoto, K. Nibuya, M. Sugai, R. Tsugitomi, Y. Amino, K. Uchibori, N. Yanagitani, M. Nishio
The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo/JP

Introduction: Following concurrent chemoradiotherapy (cCRT), consolidation therapy with durvalumab has become a standard treatment for locally advanced non-small cell lung cancer (NSCLC). However, potential risks associate with durvalumab necessitate the identification of biomarkers to predict patient outcomes. Serum CYFRA 21-1, recognized for its high sensitivity and specificity in detecting squamous cell carcinoma, has been highlighted as an indicator of treatment response and prognosis in advanced NSCLC treated with immune checkpoint inhibitors. However, effectiveness as a prognostic biomarker for consolidation therapy with durvalumab after cCRT in locally advanced NSCLC remains unclear.

Methods: We conducted a retrospective study of patients with locally advanced NSCLC who underwent durvalumab consolidation therapy following cCRT with curative intent, between July 2018 and November 2024. Patients without serum CYFRA 21-1 measurements were excluded. For comparison, serum CEA levels were also measured. The threshold values were established at CYFRA 21-1 ≥3.5 ng/mL and CEA ≥5.0 ng/mL. To assess the overall survival (OS) and progression-free survival (PFS), Kaplan-Meier curves were utilized, and comparisons were made using the log-rank test. Both univariate and multivariate analyses were conducted using Cox proportional hazards models, with statistical significance determined at $p < 0.05$.

Results: A total of 124 patients were analyzed, with a median age of 69 years (range: 40-86). Of these, 95 were male and 29 female. Regarding performance status (PS), 67 patients had a PS of 0, while 57 had a PS ≥1. The histological analyses revealed 47 cases of squamous cell carcinoma and 77 cases of non-squamous cell carcinoma. 66 patients were at stage IIA-IIIA, while 58 were at stage IIIB-IIIC. 9 patients had EGFR mutations. Elevated levels of CYFRA 21-1 were found in 34 patients, and CEA levels were elevated in 59 patients. Patients with elevated CYFRA 21-1 levels had significantly shorter OS compared to those with normal levels (median OS: 45.5 months vs. not reached, $p < 0.05$, hazard ratio (HR) 2.12). No significant difference in OS was observed between patients with elevated and normal CEA levels (median OS: not reached vs. not reached, $p = 0.74$, HR 1.11). Furthermore, the analysis restricted to patients with non-squamous cell carcinoma demonstrated a similar trend (median OS: 45.5 month vs. not reached, $p = 0.104$, HR 2.15). Multivariate analysis which included tumor stage, which represents tumor volume, histological type and CYFRA 21-1 levels showed CYFRA 21-1 emerged as an independent prognostic factor (HR = 2.07, $p < 0.05$). Regarding PFS, the CYFRA 21-1 high group was shorter than that of the normal group (median PFS: 15.7 vs. 31.5 months, $p = 0.08$, HR1.55). PFS was similar between patients with high and normal CEA levels (median PFS: 24.6 vs. 27.6 months, $p = 0.37$, HR1.24).

Conclusions: Serum CYFRA 21-1 levels may be a useful prognostic biomarker for patients with locally advanced NSCLC treated with durvalumab consolidation therapy following cCRT. Considering the analysis restricted to non-squamous NSCLC and results of multivariate analysis, serum CYFRA 21-1 levels may be a prognostic factor independent of histological type and tumor volume.

Keywords: CYFRA 21-1, durvalumab, chemoradiotherapy

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.43 Surgical Stress After Lung Cancer Surgery Triggers the Outgrowth of Distant Metastases

Y. Kawaguchi, M. Yden, K. Ueda, Y. Kataoka, D. Ishihara, T. Shiratori, J. Hanaoka
Shiga University of Medical Science, Otsu, Shiga/JP

Introduction: Patients with lung cancer have a high incidence of tumor recurrence even after curative surgical resection. Some reports have indicated that immunosuppressive cells induced by surgical stress can contribute to tumor recurrence after surgery. Circulating tumor cells (CTCs) float in the blood and reach metastatic sites not only in advanced lung cancer, but also in early stage lung cancer that can be curatively resected. Usually, most CTCs are eliminated by the host antitumor immune response, and only a few become dormant tumor cells. When dormant tumor cells recruit immunosuppressive cells, they begin to grow and metastasize. However, the specific immunosuppressive cells involved have not been identified and their dynamics after surgery are not fully understood.

Methods: We first investigated which immunosuppressive cells are increased in the blood after surgery and correlated with cancer recurrence in patients with non-small cell lung cancer (NSCLC). Next, we established a mouse model of lung cancer recurrence after tumor resection. We then analyzed the mechanisms of post-operative recurrence via immunosuppressive cells using this model.

Results: Using the mouse model of recurrent lung cancer, we showed that the serum level of monocyte chemoattractant protein-1 (MCP-1) increased immediately after tumor resection, subsequently recruiting monocytes from the bone marrow into the blood. These blood monocytes rapidly migrated into distant micrometastases and became tumor growth-promoting tumor associated macrophages (TAMs). Furthermore, even after blood MCP-1 and monocyte levels decreased after tumor resection, TAMs remained enriched in micrometastases because MCP-1 secreted by the micrometastases continued to recruit monocytes around the tumor. Consequently, tumor resection triggers the outgrowth of distant metastases via the MCP-1-monocyte-TAM axis. When we administered an MCP-1 inhibitor to lung cancer recurrent model mice, blood monocytes and TAMs in micrometastases decreased after tumor resection. Finally, peri- and postoperative treatment of model mice with an MCP-1 inhibitor decreased distant metastases after surgery.

Conclusions: To the best of our knowledge, this is the first study to explore the immunological mechanisms and therapeutic potential of the MCP-1-monocyte-TAM axis in lung cancer recurrence. The findings of this study provide the following insights. First, surgery causes dynamic changes in the immune status of both systemic and local metastatic regions. After surgery, CTCs that adhere to metastatic organs recruit an increasing number of blood monocytes that differentiate into TAMs, resulting in metastatic outgrowth. Second, an MCP-1 inhibitor decreases the number of monocytes and TAMs in micrometastases, leading to reduced metastatic recurrence after surgery. Our results suggest that the risk of metastatic recurrence after surgery can be reduced by developing a therapeutic method targeting the MCP-1-monocyte-TAM axis. These results also suggest that increased post-operative blood monocyte levels are a risk factor for tumor recurrence in patients with NSCLC.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.44 The Prognosis of NSCLC Patients Who Received Neoadjuvant Immunotherapy

B. Zhou

National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijin

Introduction: Immune checkpoint inhibitors (ICIs) have been incorporated into diverse neoadjuvant therapy regimens for the treatment of non-small cell lung cancer (NSCLC). Nevertheless, the efficacy of ICIs as a neoadjuvant treatment remains largely unexplored in real-world clinical data.

Methods: Between April 01, 2018 and June 30, 2022, We have retrospectively enrolled 171 NSCLC patients treated with neoadjuvant immunotherapy and subsequent surgery in this cohort study. We performed Cox proportional hazards regression analysis and Kaplan-Meier survival analysis to evaluate the prognosis of patients in this cohort. Subgroup analysis was conducted to evaluate the efficacy of neoadjuvant immunotherapy between different subgroups.

Results: The median follow-up time of patients in our cohort was 23.4 months. Among patients undergoing neoadjuvant immunotherapy, the 1-year overall survival (OS) and event-free survival (EFS) rates were 98.8% and 95.9%, respectively. And the 2-year OS and EFS rates were 96.5% and 91.8%, respectively. We also screened for the beneficial subpopulation for neoadjuvant immunotherapy via the subgroup analysis. Patients who achieved pathological complete response (pCR) have longer survival time than the others. The survival benefits (OS and EFS) were also observed among patients who did not achieve pCR. In addition, we did not observe significant differences in prognosis for patients receiving different types of ICIs.

Conclusions: Neoadjuvant immunotherapy resulted in a favorable prognosis for NSCLC patients, suggesting the potential value of multiple ICIs in the treatment of NSCLC patients.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.45 Real-World Long-Term Outcomes of First-Line Pembrolizumab in Advanced NSCLC and PD-L1 =50%: A Systematic Review and Meta-Analysis

G. Franceschini machado[1], F. Santos Passos[2], I. Teles Costa Grillo[3], V. Trasatti Romao[4], P.D. D'ambrosio[5]
[1]Hospital San Paolo, São Paulo/BR ,[2]Materdei Hospital, Salvador/BR ,[3]University of Buenos Aires, Buenos Aires/AR ,[4]Faculdade Anhembi Morumbi, São Paulo/BR ,[5]Universidade de Sao Paulo, São Paulo/BR

Introduction: Pembrolizumab has revolutionized first-line treatment for advanced non-small cell lung cancer (NSCLC) with high PD-L1 expression (≥50%), but pivotal trials such as KEYNOTE-024 or KEYNOTE-042 often restrict the population to match randomization. These excluded populations, however, reflect those most commonly seen in our clinical practice. Pooled real-world data and long-term outcomes remain crucial to validate the external validity of clinical trial findings and inform treatment decisions for these broader and more representative patient populations.

Methods: We performed a systematic review and meta-analysis of real-world studies reporting outcomes of pembrolizumab monotherapy in patients with advanced NSCLC (non-EGFR/ALK-mutated) and PD-L1 ≥50%, ECOG 0-2. A comprehensive search was conducted in PubMed, Embase, and the Cochrane Library from inception to February 2025 and identified five eligible studies (n = 2,888) that met our inclusion criteria. Analyses were conducted using R software (random-effects model), and heterogeneity was assessed via the I^2 statistic.

Results: Across studies, the mean age was 70.6 years, with 65.6% male and 77.2% identified as current or former smokers. Our meta-analysis reported a pooled mean overall survival (OS) of 22.56 months (95% CI: 19.13-26.56), with individual study means ranging from 19.10 months (Velcheti 2024) to 29.00 months (Cvijic 2023). Mean progression-free survival (PFS), pooled from four studies (n = 1,593), was 12.22 months (95% CI: 5.75-18.70), with study-level means ranging from 7.90 to 22.00 months. These real-world outcomes are notably consistent with KEYNOTE-024 (median OS: 26.3 months).

Conclusions: This is the first meta-analysis to assess long-term real-world outcomes of pembrolizumab in this high-risk population with advanced NSCLC and PD-L1 ≥50%. Our findings suggest that the survival benefits observed in clinical trials may extend to broader and real-world populations, including those typically excluded from randomized studies. These results provide real-world evidence that may support the use of first-line pembrolizumab as a standard treatment option, reaffirming its potential role as immunotherapy in NSCLC with high PD-L1 expression.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.46 Neoadjuvant Immunotherapy Improves Recurrence-Free Survival in Resectable Non-Small Cell Lung Cancer - a 10-Year Institutional Experience

T. Ermer, S.Y. Kim, S. Goldberg, J. Blasberg, D. Boffa, R. Herbst, K. Politi, K. Schalper, S. Dacic, G. Woodard
Yale New Haven Hospital, New Haven/CT/USA

Introduction: Clinical trials have shown improved short-term survival with neoadjuvant immunotherapy + chemotherapy (NAIO) vs platinum-based chemotherapy (CT). Long-term real-world experiences remain understudied.

Methods: Stage IB-IV NSCLC patients who underwent NAIO or NACT and surgical resection at YNHH from October 2015 - January 2025 were included. Demographics, stage, treatment data, pathologic information, and survival outcomes were compared by Chi-square or Fisher's exact test, and Kaplan-Meier survival curves using SAS 9.4.

Results: Among 107 consecutive patents (39 NACT, 68 NAIO), demographics were similar between groups (Table 1). NAIO recipients more often had high PD-L1 expression (30.9 vs 18%, p=0.02). Surgical treatment and pathological outcomes did not differ significantly (Figure 1); however, the NAIO group more frequently received adjuvant immunotherapy (41.2 vs 18%, p=0.01) and the NACT group more frequently received adjuvant radiation (23.1 vs 6%, p=0.01). The difference in overall survival between NAIO and NACT did not reach statistical significance, but the curves diverged notably after 20 months (Figure 2). NAIO patients had a higher likelihood of recurrence-free survival than NACT (0=0.02). PCR was not associated with improved survival.

Conclusions: In this 10-year institutional experience, NAIO recipients had improved recurrence-free but not overall survival compared to NACT recipients, irrespective of pCR.

1 Lobectomy or less = any type of sublobar lung resection (e.g., wedge, segment) or lobectomy, bilobectomy = either two complete lobes or one complete lobe + sublobar lung resection of an additional lobe
2 Sleeve resection means a more complex lung resection with circumferential excision of involved lung tissue around a bronchus or pulmonary artery branch
3 VATS= video-assisted thoracoscopic surgery, RATS = robotic-assisted thoracoscopic surgery
4 Conversion means that a surgery that was initially started minimally invasively (i.e., VATS or RATS) was converted to an open thoracotomy intraoperatively for any reason. Common reasons include lack of exposure due to scars, or uncontrollable bleeding.
* Percentages do not add up to 100% as variable expressions were analyzed as separate variables.

EP.08.47 Consolidation Immunotherapy Impact in Non-Small Cell Lung Cancer: A Descriptive Analysis

M. Quintana Déniz, A. Mañes García, B. Gutiérrez García, G. Molina Osorio, A. Álvarez Gracia, L.M. Álvarez González, I. Vargas Parada, L.M. Díaz Galindo, E. Luguera Sánchez, J. Molero Savall, J. Jové Teixidó
Catalan Institute of Oncology- Germans Trias i Pujol Hospital, Barcelona/ES

Introduction: Consolidative immunotherapy (CIT) after concurrent chemoradiotherapy (CCRT) is the new standard for treating unresectable non-small cell lung cancer (NSCLC) following better outcomes in the Pacific trial. We aim to review our treatment outcomes with this new standard in recent years.

Methods: We have retrospectively analyzed 120 NSCLC patients treated with CCRT between February-2018 and June-2024, all receiving volumetric arc therapy (VMAT) and platin-based chemotherapy. Sixty-seven patients (55.8%) received CIT following Pacific schedule. Toxicity was assessed according to CTCAE 5.0. Overall survival (OS) and progression-free survival (PFS) were analyzed.

Results: With a median follow-up of 27.4 months, median OS (mOS) was 39 months for all patients (95% CI: 28.1 to 49.8). Patients treated with CIT achieved better mOS (46m, 95% CI: 35.7 to 49.4) than those who only received CCRT (34m, 95% CI: 32.1 to 50.3), although not statistically significant (p=0.37). The mPFS was 39 months in CIT group (95% CI: 24.5-53.5), whereas in those who only receive CCRT, it was 13 months (95% CI: 9-17) (p=0.05). Of the 67 patients treated with CIT, 36 (53.7%) couldn´t complete one-year treatment. Eighteen patients prematurely discontinued CIT due to toxicity (50% pneumonitis, 16% hepatitis, 11% nephritis, 11% myopericarditis), 13 due to disease progression, 3 due to intercurrent deaths and 1 due to other causes. Patients who didn't complete 1-year CIT have a mOS of 15 months (95%CI: 10.9 to 19), significantly worse than those who completed it (mOS not reached; OS at 2y: 90.3%) and those treated with CCRT alone (mOS: 34 months; 95%CI: 17.4 to 50.5) (p<0.05). Consolidative immunotherapy administered for 3, 6 or 9 months showed less benefit than completing 1-year treatment.

Conclusions: Consolidative immunotherapy has demonstrated to have a positive impact on survival in NSCLC patients when at least 1-year treatment is completed.

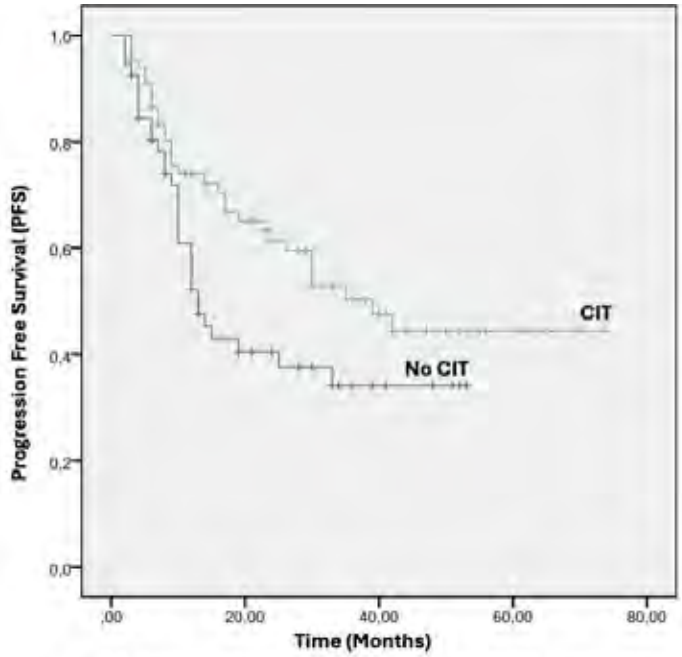

Fig 1. Progression Free Survival (PFS) according to receiving or not receiving CIT.

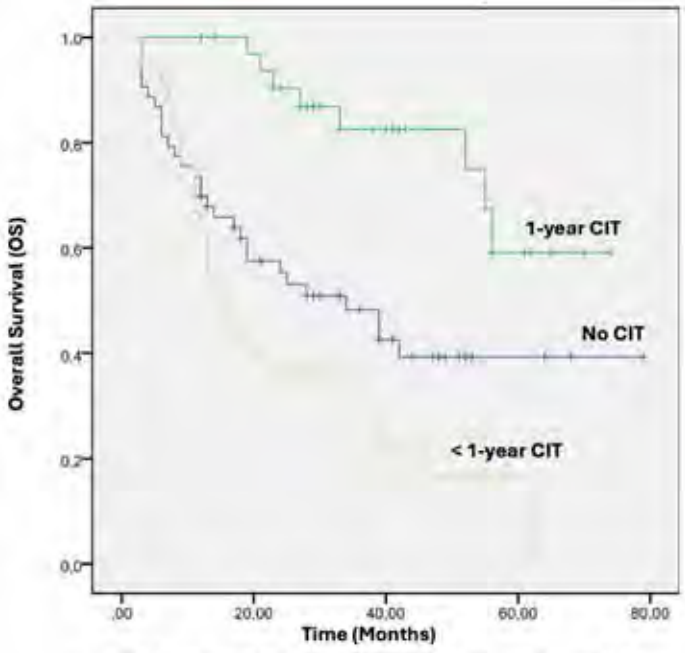

Fig 2. Overall survival (OS) according to receiving 1-year CIT, <1-year CIT or not receiving CIT.

EP.08.48 PD-L1 Expression and Efficacy of Durvalumab Consolidation in Stage III EGFR-Mutant Non-Small Cell Lung Cancer: A Multicenter Real-World Study

I. KIM
Dong-A university hospital, Busan/KR

Introduction: Durvalumab consolidation therapy after concurrent chemoradiotherapy (CCRT) improves outcomes in unresectable stage III non-small cell lung cancer (NSCLC). However, its benefit in patients with epidermal growth factor receptor mutations (EGFR M+) remains controversial, particularly in relation to programmed death-ligand 1 (PD-L1) expression. This study aimed to evaluate the real-world efficacy of durvalumab according to EGFR mutation and PD-L1 expression status.

Methods: This retrospective multicenter study included 249 patients with unresectable stage III NSCLC treated with durvalumab following CCRT across 11 tertiary hospitals in South Korea. Patients were categorized into four cohorts: A (EGFR M-, PD-L1 ≥50%), B (EGFR M-, PD-L1 <50%), C (EGFR M+, PD-L1 ≥50%), and D (EGFR M+, PD-L1 <50%). Progression-free survival (PFS) was the primary endpoint; overall survival (OS) and adverse events were also evaluated.

Results: Among 249 patients, 31 (12.4%) had EGFR M+ NSCLC. Median PFS and OS did not significantly differ between EGFR M+ and M- groups (PFS: 16.6 vs. 18.7 months; OS: 37.4 vs. 35.7 months). Cohort A showed significantly longer PFS compared to cohort D (23.7 vs. 15.2 months; p=0.045). In multivariate analysis, cohort D had a worse PFS than cohort A (adjusted HR=2.27, 95% CI: 1.11-4.66, p=0.025). No significant OS difference was found among the four cohorts. Durvalumab-related adverse events did not differ by EGFR mutation status.

Conclusions: Durvalumab consolidation provided comparable benefit in EGFR-mutant NSCLC patients with high PD-L1 expression (≥50%) to EGFR wild-type patients. However, those with EGFR mutations and low PD-L1 expression showed poorer PFS. These findings suggest PD-L1 may serve as a predictive biomarker for durvalumab efficacy in EGFR-mutant stage III NSCLC, and consolidation therapy should be considered in selected EGFR M+ patients with high PD-L1 expression.

Table 1. Cox regression analyses of progression-free survival in durvalumab-treated patients

	Univariate		Multivariate

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.49 Accurate Pathologic Response Assessment of Lung Adenocarcinoma Treated With Neoadjuvant Targeted Therapy

S. Li, C. Wu, L. Hou, W. Wu, Y. Huang
Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai/CN

Introduction: Distinguishing the residual viable tumor cells (RVT) from the non-neoplastic reactive proliferative epithelium of neoadjuvant targeted therapy resection specimens is challenging. This study aims to improve the accuracy and reproducibility of assessing residual viable tumor cells (RVT) by integrating H&E staining, immunohistochemical and molecular detection.

Methods: A total of 32 patients who received neoadjuvant targeted therapy and underwent complete resection at Shanghai Pulmonary Hospital between 2018 and 2023 were enrolled. All patients with oncogenic abnormality including ALK rearrangement (n=18), EGFR mutations (n=12), and ROS1 fusions (n=2) were identified pre-treatment. The pathologic response of tumor bed and metastatic lymph nodes (mLN) was evaluated by H&E staining, ALK Ventana-D5F3 immunohistochemistry (for patients with ALK rearrangement) and PCR detection (for patients with EGFR and ROS1 abnormality).

Results: Pathologic response assessment of the 32 patients on H&E images were non-major pathologic response (non-MPR, n=11), major pathologic response (MPR, n=9) and complete pathologic response (CPR, n=12). Among the non-MPR and MPR group, there were 11 patients with ALK rearrangement, eight patients with EGFR mutations, and one patient with ROS1 mutation, respectively. The pathologic response assessment of the tumor bed and mLN was consistent by H&E staining, immunohistochemical staining and molecular detection. In the CPR group on H&E images, there were seven patients with ALK rearrangement, four patients with EGFR mutations, and one patient with ROS1 fusion, respectively. Among the seven patients with ALK rearrangement, four cases showed slightly atypical epithelial cells surrounding the regression tumor bed on H&E images(Figure 1A, 200x), which were confirmed as RVT by ALK(D5F3) immunohistochemistry(Figure 1B, 200x). In the four patients with EGFR mutation, there were two challenging cases where there was controversy as to whether these were neoplastic tumor cells or reactive pneumocyte hyperplasia(Figure 1C, 200x), which were ultimately shown to be reactive changes by PCR detection(Figure 1D, 200x).

Conclusions: In most cases, H&E staining is a simple and time-saving approach to assess the pathologic response of lung adenocarcinoma patients with neoadjuvant targeted therapy. The accuracy and reproducibility of RVT assessment is improved by integrating H&E staining, ALK Ventana-D5F3 immunochemistry or PCR detecting for patients with different oncogenic abnomality.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.50 Excellent Response to Osimertinib-Based Regimens in Choroidal Metastasis in Patients With EGFR Exon 19 Deleted Non-Small Cell Lung Cancer a Case Series

N. Shammas[1], S. Bhatti[2]
[1]CHI St. Vincent, Hot Springs/AR/USA ,[2]University of Arkansas for the Medical Sciences, Little Rock/AR/USA

Introduction: Symptomatic choroidal metastasis leading to vision loss is an unusual presentation in metastatic non-small cell lung cancer (NSCLC). Osimertinib is a third-generation tyrosine kinase inhibitor (TKI) approved for first-line treatment for NSCLC patients with exon 19 deletions and L858R epidermal growth factor receptor (EGFR) mutation.

Methods: Here, we describe two cases of patients with EGFR exon 19 deletions and symptomatic choroidal metastasis at baseline who responded to Osimertinib-based regimens.

Results: In case 1, a 66-year-old male presented to the hospital with right-sided vision loss. Visual acuity in the right eye was reduced to 20/200. An ophthalmologic examination revealed a 6 mm x 6mm choroidal mass superior to the optic nerve with an exudative retinal detachment of the right macula. MRI of the brain and orbits with and without contrast demonstrated thickening in the right posterior globe. He was eventually diagnosed with non-small cell lung cancer with liver, bone and choroidal metastasis. A blood-based next-generation sequencing (NGS) panel revealed an exon 19 EGFR deletion. He received systemic therapy with first-line Osimertinib 80 mg once daily with palliative intent. After one month of treatment, his visual acuity improved to 20/30 in the right eye. A detailed eye exam showed complete resolution of subretinal fluid, with shrinkage of the right choroidal mass, consistent with disease response to single agent Osimertinib. In case 2, a 67-year-old female was diagnosed with non-small cell lung cancer with diffuse liver and bone metastasis. While awaiting NGS and PDL-1 results, she received one cycle of chemotherapy. Around the same time, the patient saw an ophthalmologist for worsening vision changes in the left eye for over one month and was diagnosed with choroidal metastasis to the left eye. She could only count her fingers at 1 foot with her left eye. MRI of the orbits showed mild nodular thickening and enhancement of the choroidal layer along the posterior aspect of the left globe, consistent with metastatic involvement. Once NGS results revealed an exon 19 deletion in EGFR, Osimertinib was added to chemotherapy, based on FLAURA-2 trial results. She had a repeat ophthalmologic exam about two weeks after initiation of Osimertinib. By then, her left eye's vision had improved to 20/80. A detailed fundoscopic exam showed resolution of the choroidal metastasis consistent with a quick and excellent disease response.

Conclusions: Osimertinib is a third-generation EGFR TKI currently approved for first-line treatment for patients with EGFR exon 19 deletions and L858R mutation, with and without chemotherapy. Symptomatic choroidal metastasis is an uncommon presentation of non-small cell cancer and represents a therapeutic dilemma. Our above case series provides evidence that osimertinib-based regimens are an effective treatment option for controlling both systemic and intraocular disease burdens, which can replace the need for local therapy.

Keywords: Osimertinib, Choroidal mass

EP.08.51 Impact of KRAS Mutations on Outcomes in Stage III Non-Small Cell Lung Cancer Treated With Chemoradiation and Durvalumab

N. Mankuzhy[1], J.Y. Shin[1], D.Y. Gelblum[1], A.J. Wu[1], T.L. Chaunzwa[1], J. Ma[1], D. Billing[1], P. Iyengar[1], C.B. Simone II[1,2], M. Offin[1], A.J. Schoenfeld[1], D.R. Gomez[1], J.E. Chaft[1], N. Shaverdian[1]
[1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]New York Proton Center, New York/NY/USA

Introduction: KRAS is the most common mutated oncogenic driver in non-small cell lung cancer (NSCLC) of non-squamous histology and is associated with inferior prognosis. Patients with unresectable stage III non-squamous NSCLC harboring KRAS mutations are currently treated with standard concurrent chemoradiation (cCRT) and consolidative durvalumab. Given the association of KRAS mutations with resistance to immunotherapy, we hypothesized that patients with KRAS-mutant non-squamous NSCLC would have inferior progression-free survival (PFS) after cCRT and durvalumab.

Methods: We conducted a retrospective, single-institution analyses of consecutive patients with stage III non-squamous NSCLC who underwent KRAS driver mutation testing with institutional next-generation sequencing (MSK-IMPACT) or other assays. All patients received definitive cCRT and initiated consolidative durvalumab. We estimated PFS and overall survival (OS) from the start of cCRT with the Kaplan-Meier method and compared using the log-rank test. Cumulative incidences of locoregional recurrence (LRR) and distant metastases were estimated for the first progression event with competing risk methodology and compared with Gray's test. For the KRAS-mutant cohort with MSK-IMPACT, top co-mutated genes were summarized.

Results: From 2017-2022, 115 patients met inclusion criteria and 51 were KRAS-mutant (G12C, n=24). The median age was 67 years, 55% were male, and 96% had smoking history. Histology was adenocarcinoma in 102 (89%) patients - 54 (84%) KRAS-wildtype and 48 (94%) KRAS-mutant - and the remaining had unspecified poorly-differentiated carcinomas. Stage was IIIA in 30 (26%), IIIB in 59 (51%), and IIIC in 26 (24%) with more IIIC in KRAS-mutant disease (33% vs 14%, p=0.01). Programmed death ligand 1 (PD-L1) status was high (>50%) in 38 (36%), low (>1-49%) in 24 (23%), negative in 44 (42%), and untested in 9 patients, with no difference by KRAS status. Median PFS was 27 months (95%CI 18-31) overall and 19 months (95%CI 11-30) for KRAS-mutant vs 31 months (95%CI 19-NA) for KRAS-wildtype (p=0.02, Figure 1). There was no difference in OS (p=0.80) or LRR (p=0.34) by KRAS status, but the KRAS-mutant cohort had an increased incidence of distant metastases (2-year: 45% [95%CI 31%-58%]) compared to KRAS-wildtype (2-year: 32%, [95%CI 21%-44%], p=0.03). Of the KRAS-mutant cohort with MSK-IMPACT (n=46), top co-mutations were: TP53 (n=25), TERT (n=10), CDKN2A (n=10), CDKN2B (n=8), and STK11 (n=8).

Conclusions: In stage III non-squamous NSCLC treated with cCRT and consolidative durvalumab, KRAS mutations are associated with inferior PFS and increased incidence of distant metastases. Further research in optimizing treatments for this patient population, including the use of KRAS-targeting therapies, are needed.

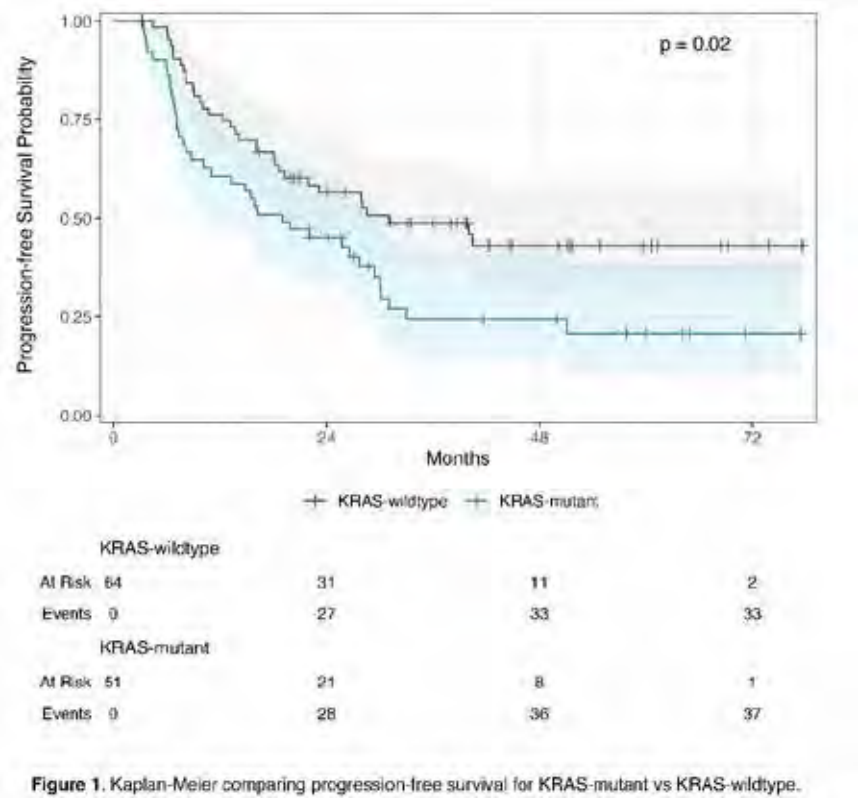

Figure 1. Kaplan-Meier comparing progression-free survival for KRAS-mutant vs KRAS-wildtype.

EP.08 LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER

EP.08.52 Is Attrition to Surgery Even Less in a Real-World Setting After Neoadjuvant Chemo-Immunotherapy for Non-Small Cell Lung Cancer?

R.S. Werner, K. Chiffi, U. Richter, S. Hillinger, D. Schneiter, I. Opitz
University Hospital Zurich, Zurich/CH

Introduction: Neoadjuvant and perioperative immune checkpoint inhibition (ICI) has been shown to provide excellent outcomes within recently published phase III trials on resectable non-small cell lung cancer (NSCLC). However, high preoperative attrition rates of up to 20% after neoadjuvant ICI remain a central challenge and real-world data that support the treatment protocols are scarce. In this study, we aimed to report real-world data after neoadjuvant and perioperative ICI.

Methods: By review of the prospectively maintained clinical NSCLC database, we identified patients with resectable UICC stage II-III NSCLC of all histologic subtypes who underwent 3-4 cycles of induction ICI (all agents) within a neoadjuvant or perioperative regimen with intended surgical resection between March 2017 and November 2024. Patients treated within ongoing or blinded clinical trials were excluded.

Results: The analyzed cohort of 25 patients included 3 clinical stage IIB, 18 stage IIIA and 4 stage IIIB cases. Clinical T4 disease was present in 12 cases and clinical N2 disease was found in 10 patients. ICI was performed with nivolumab in 15, durvalumab in 6 and pembrolizumab in 4 patients. Attrition to surgery occurred in 12% (progressive disease in 2, cardiac failure in 1 case). 22 patients underwent surgical resection including 14 lobectomies, 3 bilobectomies and 5 pneumonectomies. Surgery was performed minimally invasive in 46% (6 RATS and 4 VATS cases). Surgical complexity was increased due to a high percentage (73%) of patients with hilar fibrosis. R0 resection was achieved in 100% and pathological complete response (pCR) was found in 27%. Among 10 patients with clinical N2 disease who underwent surgery, nodal downstaging to ypN0 occurred in 4 patients (40%). In patients who underwent surgical resection, median EFS was 37 months and median OS was 50 months. Median OS was significantly longer in patients who underwent resection when compared to non-resected patients (50.0 [33.6-72.5] vs. NR [1.2-NR] months; p=0.007).

Conclusions: Our single-center experience, confirms the findings from the phase III trials in a real-world setting and demonstrates R0-resection in 100% of the patients, as well as excellent pCR rates and long-term survival. With a minimally invasive rate of 46%, our results are comparable to the reported MIS rates of the Checkmate 816 trial (39%) and the AEGEAN trial (48%). In our limited sample size, the attrition rate of 12% is lower than the reported rates in clinical trials, nevertheless highlighting the importance of precise patient selection.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.01 Feasibility of High Pressure Continuous Positive Airway Pressure to Reduce Respiratory Motion in Thoracic Irradiation

S. Appel[1], Z. Symon[1], Y.R. Lawrence[1], J. Bar[1], J. Goldstein[2]
[1]Sheba Medical Center, Ramat Gan/IL ,[2]Sourasky Medical center, Tel Aviv/IL

Introduction: Motion management in Lung radiotherapy (RT) can be challenging with no one standard solution. Reducing the tumor motion and reducing the radiation to the lungs are goals of motion management and can improve tumor control and reduce toxicity compared to treating in free breathing. We have previously studied high pressure Continuous Positive Airway Pressure (HP-CPAP) ventilator as a new method for motion management. HP-CPAP increases lung volume in passive manner and reduces tumor motion and thus reduces dose to the lungs and heart in thoracic and breast RT. have shown that using high pressure (HP)-CPAP-ventilator to pressure of 15cm H2O during RT treatment can decrease intrathoracic organ motion and reduce tissue irradiation. Here we study the safety and of compliance regular use of HP-CPAP in patients receiving thorax compared with breast RT.

Methods: Our database included cases treated with RT to lung, mediastinum and breast with HP-CPAP at Sheba Medical Center. Data extracted from electronic medical files included indication for RT, fractionation, compliance and toxicity with HP-CPAP. We grouped patients according to treatment indications and radiation techniques using breast RT as reference.

Results: Between 2014-2024, 404 patients received 512 courses of HP-CPAP RT/SBRT delivered in 4816 fractions. The cohort included 105 breast RT pts., 209 SBRT, pts., and 90 fractionated-RT pts., of them 37 received concomitant-chemotherapy-RT (CCRT). Compliance with breast RT and SBRT was excellent (1-1.9% discontinuation). Most interruptions occurred when receiving fractionated RT to the chest or mediastinum (n=9/90, 10%), particularly in combination with chemotherapy (CCRT) (n= 8/37 21.6%). 13 refused HP-CPAP prior to RT due to discomfort or chest pain. Fourteen patients (3.5%) discontinued CPAP after starting RT due to toxicity that may be related to CPAP including presyncope/weakness (n=3), syncope (n=2), dyspnea (n=2) hypertension (n=2), hoarseness (n=1), or discomfort (n=4).

Conclusions: Compliance of HP-CPAP for respiratory motion management in thoracic and breast RT was excellent, with minimal complication rate. Most interruptions occurred in CCRT group. HP-CPAP can be used as one of the options for motion management.

EP.09.02 Consolidative Hypofractionated RT for Oligometastatic NSCLC

B.K. Bae, J. Park, S.Y. Lee, S-S. Yoo, S.H. Choi
Kyungpook National University, Daegu/KR

Introduction: This study aimed to evaluate the role of consolidative hypofractionated radiotherapy in the management of oligometastatic non-small cell lung cancer (NSCLC).

Methods: We retrospectively reviewed patients who received consolidative hypofractionated radiotherapy for oligometastatic NSCLC at Kyungpook National University Chilgok Hospital between 2013 and 2024. Hypofractionated radiotherapy was defined as a biologically effective dose (BED) of ≥ 50 Gy delivered in fewer than 10 fractions. A total of 216 patients (267 radiotherapy sites) met the inclusion criteria. Treatment outcomes, including local control (LC), progression-free survival (PFS), widespread PFS (WSPFS), and overall survival (OS), were analyzed.

Results: The median time to oligometastasis from diagnosis was 1.6 years. Patient disease status was categorized as synchronous (23 patients, 10.6%), metachronous/repeat (118 patients, 54.6%), or induced (75 patients, 34.7%). Oligometastatic sites were predominantly lung (207 lesions, 77.5%) and regional lymph nodes (22 lesions, 8.2%). Various dose fractionation regimens were employed, with 48 Gy in 4 fractions (52 lesions, 19.5%), 50 Gy in 4 fractions (47 lesions, 17.6%), and 60 Gy in 4 fractions (31 lesions, 11.6%) being the most common. The median BED was 105.6 Gy (range, 51.3-151.2 Gy). One-year LC, PFS, WSPFS, and OS rates were 87.3% (median, not reached), 51.2% (median, 1.0 year), 62.6% (median, 1.5 years), and 80.0% (median, 2.6 years), respectively (Figure 1). Grade ≥ 2 radiation pneumonitis occurred in 13 patients (6%) but was safely managed in all cases.

Conclusions: Consolidative hypofractionated radiotherapy for oligometastatic NSCLC can achieve good local control and may offer survival benefits with acceptable toxicity.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.03 Survival and Neurotoxicity of WBRT Vs. SRS in Individuals With Brain Metastases From Lung Cancer: Retrospective Study

G.L.F. CUNHA[1,2], T.R. Dias[1,2], M.L.T. Bento[1,2], J.S. Pavão[1,2], L.B. Assunção[1,2], R.A.B. Aguiar[1,2], C.E. De almeida[1], R. Ferrari[1], L. Oliveira[1], E. Fuks[1], P. Canary[1], G. Barbosa[1], M. JV[1,3], D. Przybysz[1]
[1]RadioSerra Radiation Therapy, Petrópolis - RJ/BR ,[2]Petropolis Medical School - FMP, Petrópolis - RJ/BR ,[3]Centro de Terapia Oncológica, Petrópolis - RJ/BR

Introduction: Brain metastases (BM) in individuals with lung cancer significantly impact prognosis and quality of life. This retrospective study analyzes survival outcomes, treatment patterns, toxicity profiles, and predictive factors influencing treatment efficacy and safety in patients treated at our institution between 2020 and 2025. Additional variables, including detailed dosimetric parameters, tobacco exposure history (pack-years), and extracranial metastasis patterns, were incorporated to enhance predictive modeling.

Methods: A retrospective review of 208 lung cancer patients identified 53 (25%) with BM. Data collected included demographics, ECOG performance status, smoking burden (median 55.3 pack-years), tumor staging, number and volume of brain metastases, extracranial disease burden, and treatment modalities (Whole Brain Radiotherapy [WBRT], Stereotactic Radiosurgery [SRS], and Stereotactic Body Radiotherapy [SBRT]). Dosimetric parameters such as D95% (mean 6307.8 cGy), D98% (mean 1928.4 cGy), heterogeneity index (HI: 0.09), and volume irradiated (V5%: 1.62%, V20%: 0.17%) were analyzed for correlation with outcomes and toxicity (CTCAE v5.0). Kaplan-Meier methods and Cox proportional hazards models were applied for survival and correlation analyses.

Results: The median age was 66.4 years (range: 29-87), with an equal gender distribution. Among BM patients, 27.5% received WBRT, 17.6% underwent SRS, and 54.9% had concurrent extracranial metastases. Metastases outside the CNS were found in 37.4% of patients, while 25% had exclusive BM.Median overall survival (OS) was estimated as 8.0 months (95% CI: 5.6-10.4) for SRS compared to 4.9 months (95% CI: 3.5-6.3) for WBRT (p=0.04). One-year survival rates favored SRS (35%) over WBRT (18%) (p=0.03).Improved OS correlated with:

Higher ECOG performance status (0-1) (HR 0.55, p=0.02)Smaller BM volume (HR 1.45, p=0.01)Lower extracranial metastatic burden (HR 1.62, p=0.005)

Dosimetric analysis revealed that higher HI (mean: 0.09; range: 0.045-0.14) and increased total radiation dose were correlated with higher rates of neurotoxicity (p=0.02). V5% (mean: 1.62%) and V20% (mean: 0.17%) were predictive of increased lung toxicity. Grade 3-4 neurotoxicity occurred in 15% of WBRT patients vs. 5% in SRS patients (p=0.01). Higher cumulative radiation exposure correlated with increased treatment-related toxicity.

Conclusions: SRS provides superior survival benefits and reduced neurotoxicity compared to WBRT in carefully selected lung cancer patients with BM. The inclusion of dosimetric parameters, pack-years, and extracranial disease burden enhances the prognostic model, emphasizing the need for personalized treatment approaches. These findings reinforce the role of SRS as the preferred treatment when clinically feasible. Patient selection based on performance status, lesion volume, smoking burden, and extracranial disease involvement is critical for optimizing outcomes. Further prospective trials are needed to refine treatment decision-making.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.04 Ablative RT Use and Systemic Therapy Duration in Metastatic EGFR-Mutated NSCLC: A Population-Based Analysis

M. Yan[1], A. Parmar[2], N. Coburn[2], L. Nguyen[3], A. Louie[2]
[1]Princess Margaret Cancer Centre, Toronto/ON/CA ,[2]Sunnybrook Health Sciences Centre, Toronto/ON/CA ,[3]Institute of Clinical and Evaluative Sciences, Toronto/ON/CA

Introduction: Advances in systemic therapy have improved survival for patients with EGFR-mutated non-small cell lung cancer (NSCLC). Randomized trials have shown that adding stereotactic body radiation therapy (SBRT) to EGFR-targeted tyrosine kinase inhibitors (TKIs) may improve progression-free survival (PFS) and overall survival (OS). Prospective studies also suggest that SBRT to oligoprogressive sites may prolong the duration of the same line of systemic therapy. This study evaluates these outcomes in a real-world setting using a population-based healthcare administrative database.

Methods: We analyzed data from the provincial Institute for Clinical Evaluative Sciences (ICES), a repository of linked health administrative databases, identifying all patients diagnosed with non-squamous NSCLC between 2002 and 2022, in Ontario, Canada. Eligible patients received EGFR-targeted therapy with Gefitinib or Osimertinib, with treatment start/stop dates and radiotherapy (RT) data recorded. Patients younger than 18 or those with a prior cancer diagnosis within five years of NSCLC diagnosis were excluded. SBRT was defined as any radiotherapy course delivering ≥5Gy per fraction in ≤8 fractions to non-cranial targets, except for single-fraction treatments ≤8Gy. Patients who received SBRT during EGFR-targeted therapy were classified in the SBRT cohort, while all others comprised the palliative RT cohort. The primary outcome was the duration of first-line systemic therapy from time of systemic therapy initiation. Baseline and treatment characteristics were summarized descriptively, and OS was estimated via the Kaplan-Meier method from the date of drug start. Propensity score matching using logistic regression adjusted for baseline factors influencing systemic therapy duration, including age, sex, rurality index, Charlson and Elixhauser comorbidity indices, income quintile, and treatment year. A sensitivity analysis excluded patients treated before 2013, since ~90% of patients were treated after this year.

Results: A total of 898 patients met inclusion criteria, with 185 receiving SBRT and 713 receiving palliative RT. SBRT use increased in later years (2019-2022). The median duration of first-line systemic therapy was 683 days in the SBRT cohort versus 400 days in the palliative RT cohort ($p < 0.001$). Median OS was 35.3 months (95% CI 27.2-77.5) for SBRT and 23.1 months (25.4-32.4) for palliative RT ($p < 0.01$ log rank test). After excluding patients treated before 2013, 797 patients remained (SBRT: 171, palliative RT: 626). Median first-line systemic therapy duration was 692 vs. 393 days, respectively ($p < 0.01$), and median OS was 35.6 (95% CI 31.4-41.2) vs. 23.1 months (95%CI 21.2-24.5) ($p < 0.01$ log rank test). After propensity score matching (n=364, 184 per cohort), standardized mean differences were balanced (<0.1). The SBRT cohort maintained a longer median first-line therapy duration (683 vs. 431 days, $p < 0.01$) and improved median OS (35.3 vs. 23.7 months) ($p < 0.01$ log rank test).

Conclusions: SBRT was associated with prolonged first-line systemic therapy duration and improved OS compared to palliative RT in stage IV EGFR patients treated with targeted therapy. These findings remained consistent after propensity score matching and sensitivity analysis. SBRT may help extend the effective duration of systemic therapy in carefully selected patients.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.05 Efficacy and Prognostic Factors of Radiotherapy in Brain Metastases From Non-Small Cell Lung Cancer Patients:A Retrospective Study

H. Zhou[1], C. Xu[1,2], P. You[1], S. Wu[1], L. Yao[1], L. Cai[1,2], Z. Feng[1,2], J. Ke[1,2], C. Tong[1,2]
[1]Department of Thoracic Surgery, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou [510080], China., Guangzhou/CN ,[2]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou/CN

Introduction: To evaluate the efficacy of radiotherapy and prognostic factors in non-small cell lung cancer with brain metastases (NSCLC-BM).

Methods: This retrospective study included 113 NSCLC-BM patients treated with standard cranial radiotherapy at Guangdong Provincial People's Hospital (January 2020-October 2024). Prognostic factors (demographics, KPS score, metastasis features, molecular markers, GPA score, and radiotherapy parameters) were analyzed. Primary and secondary endpoints were intracranial progression-free survival (iPFS) and disease control rate (DCR), respectively. Statistical analyses included Cox regression, Kaplan-Meier, and log-rank tests.

Results: With a median follow-up of 7.7 months, 49 patients (43.4%) experienced endpoint events. Median iPFS was 9.2 months (95% CI: 7.53-16.6), with 6-, 12-, and 18-month iPFS rates of 63.0%, 42.7%, and 38.0%, respectively. Univariate Cox analysis identified brain lesions ≥3 cm (HR=2.632, P=0.016), age ≥60Y (HR=1.921, P=0.028), KPS >2 (HR=6.345, P=0.001), GPA ≤2 (HR=2.070, P=0.020), spinal metastases (HR=22.255, P=0.006), single dose >3 Gy (HR=2.037, P=0.015), total dose <30 Gy (HR=1.757, P=0.049), and biologically effective dose (BED) ≥40 Gy (HR=1.867, P=0.032) as predictors of reduced iPFS. Multivariate Cox analysis confirmed KPS >2 (HR=11.362, P=0.001), lesions ≥3 cm (HR=7.356, P=0.004), spinal metastases (HR=21.957, P=0.036), and BED ≥40 Gy (HR=11.484, P=0.034) as independent risk factors. Increased brain metastases (2-3, ≥4) correlated with reduced iPFS (HR=3.425, P=0.016). Only KPS >2 correlated with reduced DCR (OR=4.727, P=0.027).

Conclusions: KPS >2, brain lesions ≥3 cm, number of brain metastases >1, spinal metastases, and BED ≥40 Gy are independent predictors of worse intracranial control and shortened iPFS post-radiotherapy.

EP.09.06 Consolidative High-Dose Thoracic Radiotherapy in NSCLC Without Progression After First-Line Systemic Therapy With ICIs

M. Galaverni, F. Colombo, C. Dell'Anna, E. Lattanzi, C. Grondelli, F. Salaroli, G. Ceccon, S. Gianni, M.L. Bergamini, G. Mazzaschi, A. Leonetti, M. Tiseo, N. D'Abbiero, N. Simoni
University Hospital of Parma, Parma/IT

Introduction: Consolidative thoracic radiotherapy (CTRT) demonstrated to improve oncological outcomes in patients with advanced and metastatic non-small-cell lung cancer (NSCLC) that did not progress after first-line chemotherapy (CT). However, potential toxicity and clinical benefit of high-dose CTRT in patients treated with prior immune checkpoint inhibitors (ICIs) are yet to be defined. This study aims to investigate clinical results of CTRT in patients with NSCLC and previously treated with (CT-)ICIs.

Methods: Patients treated at our Institution with CTRT after first-line systemic treatment with (CT-)ICIs were retrospectively analyzed. Primary endpoint was acute lung toxicity (≤6 months from CTRT completion). Secondary endpoints were local failure free survival (LFFS), progression free survival (PFS) and overall survival (OS).

Results: A total of 40 patients treated from 2019 to 2024 were included (Table 1).

Table 1. Patients and treatment characteristics

Patients, n		40
Sex, n (%)	Female	11 (27.5)
	Male	29 (72.5)
Age, median (range)		69 (44-84)
BMI, median (range)		25.1 (18.3-33.6)
Performance status, n (%)	ECOG 0	19 (47.5)

COPD, n (%)	Yes	8 (20.0)
	No	32 (80.0)
Smoking history, n (%)	Yes	38 (95.0)
	No	2 (5.0)
Cycles of ICIs before CTRT, median (range)		7 (1-31)
ICI type, n (%)	PD-1 inhibitors	36 (90.0)
	PD-L1 inhibitors	4 (10.0)
Concurrent systemic therapy, n (%)	Yes	20 (50.0)
	No	20 (50.0)
ICIs after CTRT, n (%)	Yes	25 (62.5)
	No	15 (37.5)
Cycles of ICIs after CTRT, median (range)		5 (0-19)
Radiation EQD2 (Gy), median (range) *		51.5 (42.3-70.0)
Radical CTRT schedule, n (%)	54-60 Gy/30 fractions	9 (22.5)
	55 Gy/20 fractions	4 (10.0)
	51 Gy/17 fractions	4 (10.0)
	Others	4 (10.0)
Subradical CTRT schedule, n (%)	45 Gy/15 fractions	15 (37.5)
	Others	4 (10.0)
CTV volume (cc) , median (range)		121 (5.5-560)
PTV volume (cc) , median (range)		243 (24.3-1025)
MLD (Gy), median (IQR) ^		7.5 (0.8-17.4)
V20 (Gy), median (IQR) ^		11.1 (2.4-32.8)
V5 (Gy), median (IQR) ^		33.9 (3.5-77.6)

BMI: body mass index; ECOG: Eastern Cooperative Oncology Group Performance Status; ADK: adenocarcinoma; SCC: squamous cell carcinoma; COPD, chronic obstructive pulmonary disease; ICIs: immune checkpoint inhibitors; PD-1: programmed death 1; PD-L1: programmed death ligand 1; CTRT, consolidative thoracic radiotherapy; EQD2: equivalent dose in 2 Gy fractions; CTV, clinical target volume; PTV, planning target volume; IQR: interquartile range; MLD: mean lung dose; Vx: volume of lung receiving ≥ xGy.
* Assuming an α/β of 10.
^ Following conversion of all dose-fractionation schemes to EQD2 based on the linear-quadratic model, assuming an α/β of 3.

NSCLC presentation was locally advanced not-suitable for definitive radio-chemotherapy and low-burden metastatic in 18 (45%) and 22 (55%) cases, respectively. ICIs were PD-1 inhibitors in 36 (90.0%) patients administered for a median of 7 cycles (range 1-31) prior to CTRT. Radical and subradical CTRT was administered in 21 (52.5%) and 19 (47.5%) patients, respectively, at a median Equivalent Dose in 2 Gy Fractions (EQD2) of 51.5 Gy (58.4 Gy radical and 48.8 Gy subradical CTRT). Acute radiation pneumonitis (aRP) G≥2 rate was 30%, occurring at a median time of 2 months (95% CI 2-4 months) from CTRT, with G3 and G5 aRP observed in 4 (10%) and 1 (2.5%) patients, respectively. aRP G≥2 occurrence correlated with number of pre-CTRT ICIs cycles (7.5 % ≤6 cycles vs 22.5% ≥7 cycles, p = .09), but not with CTRT prescribed dose (15% radical vs 15% subradical, p = .84). Considering all pulmonary acute adverse events (radiation-induced, ICI-induced, infectious, and/or multifactorial pneumonitis), G≥2 rate was 35%, with G3 and G5 toxicities observed in 10% and 7.5% of patients, respectively. At a median estimated follow-up time of 31.6 months (95% CI 23.6-55.0 months), overall local control (LC) was 77.5%, with a 1- and 3-year LFFS rates of 86.1% (95% CI 75.5-98.2%) and 71.9% (95% CI 56.2-92.1%), respectively. Median PFS and OS were 20.2 months (95% CI 9.6 months-NR) and 30.2 months (95% CI 16.1 months-NR), respectively.

Conclusions: In patients with advanced NSCLC that did not progress after first-line systemic therapy with ICIs, high-dose CTRT is associated with promising oncological outcomes and acceptable aRP rate. A careful monitoring of all pulmonary acute adverse events should be recommended.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.07 Cardiac Dosimetry and Clinical Outcomes in Individuals With Lung Cancer Undergoing Thoracic Radiotherapy: Retrospective Study

G.L.F. Cunha[1,2], T.R. Dias[1,2], M.L.T. Bento[1,2], J.S. Pavão[1,2], L.B. Assunção[1,2], R.A.B. Aguiar[1,2], C.E. De almeida[1], R. Ferrari[1], L. Oliveira[1], E. Fuks[1], P. Canary[1], G. Barbosa[1], M. JV[1,3], D. Przybysz[1]
[1]RadioSerra Radiation Therapy, Petrópolis - RJ/BR ,[2]Petropolis Medical School - FMP, Petrópolis - RJ/BR ,[3]Centro de Terapia Oncológica, Petrópolis - RJ/BR

Introduction: Cardiac radiation exposure has emerged as an independent prognostic factor in thoracic radiotherapy (RT) for individuals with lung cancer. Increased cardiac doses have been associated with higher rates of non-cancer-related mortality and decreased survival. This study investigates the relationship between cardiac dosimetric parameters and clinical outcomes in persons receiving RT for lung cancer.

Methods: A retrospective review was conducted of 211 individuals with lung cancer treated at a single institution between 2020 and 2025. Clinical data included demographics, treatment modality (RT alone, chemoradiotherapy, or RT combined with immunotherapy/targeted therapy), and clinical endpoints: overall survival (OS), progression-free survival (PFS), and metastasis incidence. Cardiac dosimetric parameters collected included V5%, V20%, V35%, V50%, and V60%. Survival analyses were performed using Kaplan-Meier estimates and Cox proportional hazards models. Differences in cardiac dosimetry between individuals who survived and those who did not were assessed using Mann-Whitney U tests.

Results: The median age was 66.4 years (range: 29-90). Treatment modalities included RT alone (58%), concurrent chemoradiotherapy (30%), and RT with immunotherapy or targeted therapy (12%). Among the 35 individuals with available cardiac dosimetric data, the mean cardiac exposures were: V5% 1.62% (±7.02%), V20% 0.17% (±0.13%), V35% 0.15% (±0.19%), V50% 0.093% (±0.14%), and V60% 0.034% (±0.064%). No statistically significant associations were observed between cardiac dose-volume parameters and OS or PFS. However, persons who survived exhibited numerically higher V5% exposure compared to those who did not survive (2.37% vs. 0.54%, p = 0.24). Similar non-significant trends were noted for V20% and V35%. Most individuals were exposed to low cardiac radiation doses, consistent with modern treatment planning standards and the use of cardiac-sparing techniques

Conclusions: Although no statistically significant associations were observed, the data suggest a trend toward improved outcomes with higher V5% exposure—possibly reflecting treatment selection bias or an underpowered subgroup analysis. These findings support further prospective evaluation of cardiac dosimetric thresholds in thoracic RT. Ongoing efforts to minimize cardiac exposure remain essential, and techniques such as IMRT, VMAT, and proton therapy should be considered standard in advanced-stage lung cancer RT planning.

EP.09.08 Outcomes of SBRT in the Management of Adrenal Metastases From Lung Cancer - Retrospective Data From Tertiary Cancer Centre of India

M.D. Ngasepam, A. Tipdewal, G. Maheshwari, G. Khatavkar, S. Yewle, S. Pedapathi, K. Prabhash, J.P. Agarwal
TATA MEMORIAL HOSPITAL, Mumbai/IN

Introduction: Adrenal gland metastases (AGM) from lung cancer pose a therapeutic challenge, with optimal management strategies still evolving. Stereotactic Body Radiation Therapy (SBRT) has emerged as a promising non-invasive treatment modality. This study evaluates the clinical outcomes of SBRT in AGM.

Methods: From 2017-2024, all consecutive patients of AGM from lung cancer who were treated with SBRT were included in this retrospective study. The case details were retrieved from the electronic medical records and treatment planning system. All patients underwent either CECT of thorax and abdomen or whole-body PET-CECT. All patients were treated with VMAT technique using motion management strategies. Local control (LC) was defined as the absence of radiological progression from the date of adrenal SBRT till the date of adrenal progression or last follow up. Progression free survival (PFS) and overall survival (OS) were calculated using Kaplan-Meier method from SBRT starting date till the date of progression or death, respectively. P-value of <0.05 was considered statistically significant. Toxicities were graded using CTCAE v5.0. Prognostic factors for outcomes were identified using univariate and multivariate analysis (MVA).

Results: A total of 20 patients (16 males, 4 females) with adrenal metastasis from lung primaries (18 NSCLC, 2 SCLC) were included. The median age was 62.5 years (range, 48-71), with synchronous presentation at diagnosis in 70% and oligometastatic (≤3 sites) disease (OM) in 80% of the patients. Nearly 50% had targetable driver mutations. The main indication for SBRT of AGM was oligoprogression (50%), out of which 60% warranted change of systemic therapy. Majority (n=17) received systemic therapy 4 weeks prior to or after SBRT. The median time from lung cancer diagnosis to adrenal SBRT was 9.9 months (range, 1.3-35.6). The median GTV was 12 cc (range, 3.7- 30) and PTV was 33.3 cc (16.4- 75.1). The median total dose and dose per fraction was 38 Gy (30-50 Gy) and 6-10 Gy, respectively with a median biologically effective dose (BED10) of 65.75 Gy (57-100 Gy). At a median follow-up of 13.4 months, 1-year and 2-year LC rates were 90% and 75%, respectively. The median PFS was 11.8 months, with 1-year & 2-year PFS rates of 50% and 12%, respectively. The 1-year & 2-year OS after adrenal SBRT was 61% and 21%. The median OS for metachronous and synchronous AGM was 25.7 and 6.8 months, (p=0.02). Univariate analysis showed a statistical significance favouring metachronous presentation for OS and GTV <12 cc (p=0.02) for PFS. However, MVA did not yield any significance. Grade 1-2 fatigue (10%) and diarrhoea (10%) were observed. No cases of renal injury or any ≥Grade 3 toxicity were reported.

Conclusions: SBRT for adrenal metastases demonstrated excellent local control with minimal toxicity, especially with small tumor size and metachronous OM presentation. However, larger studies will be required for better prognostication of adrenal gland metastases.

Keywords: adrenal metastases, SBRT, oligoprogression

EP.09.09 Evaluation of Radiotherapy Use in Patients With Metastatic Solid Tumors: An Analysis of Real-World Data

S.V. Mendes[1], E.P. Lima[2], L.D. Faroni[1], C.S.d.R. Baldotto[1], L. Raez[3]
[1]IDOR - Instituto D'Or de Pesquisa e Ensino, Rio de Janeiro/BR ,[2]Universidade Estácio de Sá - UNESA, Rio de Janeiro/BR ,[3]Memorial Cancer Institute, Florida/FL/USA

Introduction: This study aimed to evaluate the use of stereotactic body radiotherapy (SBRT) in treating metastatic lung cancer in the Brazilian population and to analyze different scenarios of its application, with a particular focus on oligometastatic disease. The authors declare no conflicts of interest related to this article.

Methods: This is a retrospective cohort study using medical record data from patients diagnosed and treated with SBRT at Oncologia D'Or between 2019 and 2023. Data were extracted from the electronic medical record system and entered into a form (RedCap). Exploratory data analysis was performed using IBM SPSS 29.0 software.

Results: Among the 85 patients included in the study, 25.9% (n = 22) received treatment with palliative intent, 34.1% (n = 29) for oligoprogression control, 29.4% (n = 25) for oligometastatic control, and 10.6% (n = 9) for oligopersistence control in the setting of the first SBRT. Regarding the best treatment response, 35.8% (n = 29) of patients achieved a complete response, and the median time from the first radiotherapy treatment to systemic therapy change was 5 months. At the time of evaluation, 32.9% (n = 28) of patients had died, with lung cancer being the cause in 85.7% (n = 24) of cases. The median overall survival (OS) of patients who underwent at least one radiotherapy treatment was 12 months (95% CI: 6.004 - 17.996), while the median survival time after the last radiotherapy treatment was 8 months (95% CI: 3.003 - 12.997).

Conclusions: This study provided a comprehensive analysis of different clinical scenarios involving the use of SBRT in lung cancer. Its application was predominantly observed in the context of oligometastatic disease and oligoprogression, where it played a role in sustaining a specific line of treatment. Furthermore, the study assessed SBRT outcomes about distinct driver mutations. Despite the limitation of a small sample size, this represents the first study to evaluate oligometastatic disease in the Brazilian population.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.10 Salvage Surgery After Nonoperative Treatment of Initially Unresectable Stage IIIB-IV Non-Small Cell Lung Cancer

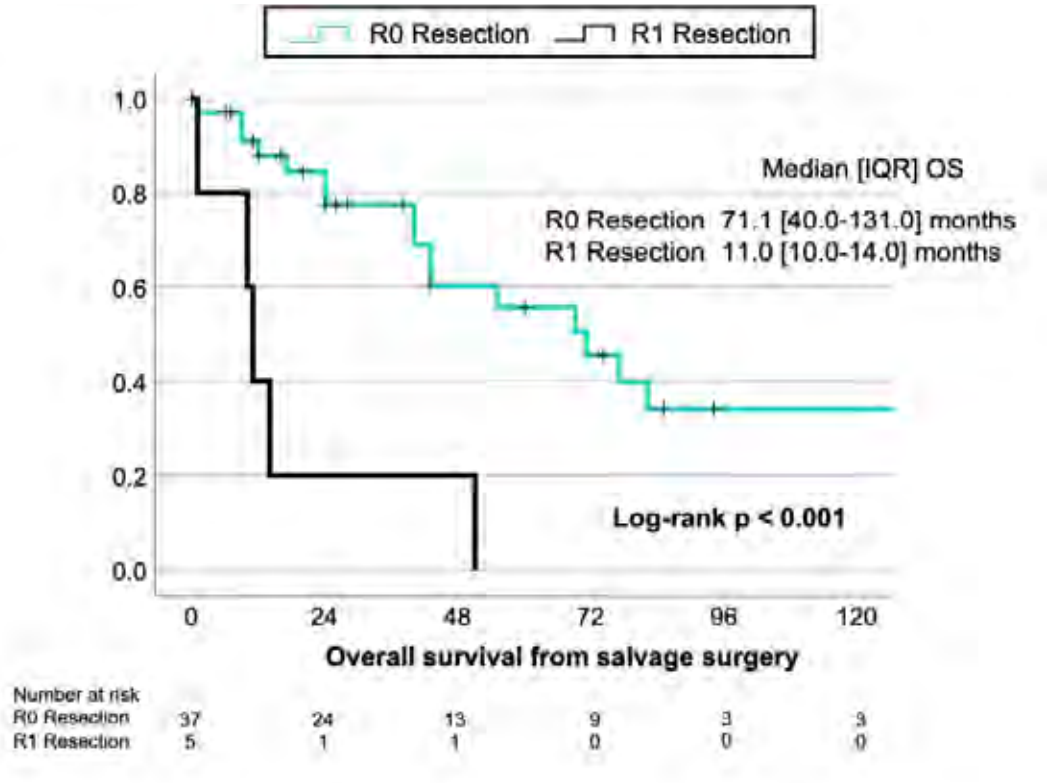
R.S. Werner, K. Furrer, S. Hillinger, D. Schneiter, I. Opitz
University Hospital Zurich, Zurich/CH

Introduction: Despite the current advancements in systemic treatment, cancer persistence, progression or recurrence remain common after nonoperative treatment of unresectable non-small cell lung cancer (NSCLC). In this situation, lung resection frequently remains among the last options to achieve local cancer control. We aimed to assess the outcomes of salvage lung resection in patients with stage IIIB-IV NSCLC.

Methods: Patients with stage IIIB-IV NSCLC who underwent anatomical lung resection between 2003 and 2024 after initial nonoperative treatment were identified from a prospectively maintained single-center database.

Results: 42 patients were included in the analysis. Median age was 61.5 (IQR 51.8 - 67.5) years and 57.1% were male. The cohort included 9 UICC stage IIIB/C patients and 33 stage IV patients. Nonoperative treatment included definitive chemoradiotherapy in 19 cases (45.2%), immuno- or chemoimmunotherapy in 21 cases (50%) and targeted therapy in 10 cases (23.8%). The indication for lung resection was local recurrence in 4 (9.5%) patients, (oligo) progression under active treatment in 9 (21.4%) patients and (oligo)persistence under active treatment in 29 (69%) patients. Resections included 1 segmentectomy, 14 standard lobectomies, 15 extended lobectomies (incl. sleeve resections, intrapericardial resections, resections of diaphragm, pericardium, large vessels or chest wall), 2 bilobectomies and 10 (extended) pneumonectomies. 66.7% (n=28) of all resections were performed by thoracotomy, 16.7% (n=7) by VATS and 16.7% (n=7) by RATS. Median overall survival was 27.0 months (IQR 11.0-69.5 months), median progression-free survival 22.0 months (IQR 5.0-NR months) and median follow-up was 46.0 months (IQR 29.0-78.5 months). R0-resection was achieved in 88.1% of all cases. Overall survival was significantly improved if R0-resection was achieved (median OS 71.0 [40.0-131.0] months versus 11.0 [10.0-14.0] months, p<0.001).

Conclusions: Salvage surgery remains a valuable option for patients with advanced NSCLC and cancer persistence, progression or recurrence after initial nonoperative treatment and can provide a substantially prolonged long-term survival. In this heavily pretreated population, extended resections with high surgical complexity are common. The achievement of R0-resection is essential as further treatment options are often limited.



Keywords: Salvage Surgery

EP.09.11 Prognostic Impact of Nodal Downstaging After Neoadjuvant Therapy on Survival in Oligometastatic Non-Small Cell Lung Cancer

N. Steinmann, R. Werner, I. Opitz
University of Zurich, Zurich/CH

Introduction: At the initial diagnosis of stage IV non-small cell lung cancer (NSCLC), an estimated 25-50% of patients present in an oligometastatic state, characterized by limited metastatic spread and low systemic tumor burden. Multimodal strategies incorporating systemic therapy and local ablative treatment to the primary tumor and all metastatic sites have led to encouraging outcomes. However, patient selection and timing of local ablative treatment remain central challenges. In this study, we retrospectively analyzed a cohort of oligometastatic NSCLC patients with hilar and/or mediastinal nodal involvement who received neoadjuvant systemic therapy before anatomical lung resection as part of a local ablative approach. We investigated the prognostic implications of nodal response on overall survival (OS) following local treatment.

Methods: We retrospectively identified patients with synchronous or metachronous oligometastatic NSCLC who received upfront systemic therapy and subsequently underwent local ablative treatment, including anatomical lung resection, between 2002 and 2020. All patients had hilar and/or mediastinal nodal involvement prior to treatment. Oligometastatic disease was defined as ≤5 distant metastases in ≤3 organs.

Results: Twenty-four patients with oligometastatic NSCLC and nodal involvement were included. The median age at diagnosis was 59 years (IQR: [52.5-66]); 16 patients (67%) were male. Most had an ECOG performance status of 0 (67%) and presented with metachronous metastases (58%). Adenocarcinoma was the predominant subtype (75%). The majority had one metastasis (71%) confined to a single organ (92%), and 88% had ≤3 metastases. Common metastatic sites included the brain (54%), bone (29%), and adrenal gland (13%). All patients received neoadjuvant systemic therapy: 20 (83%) with chemotherapy, 3 (13%) with immunotherapy, and 1 (4%) with targeted therapy. According to RECIST 1.1, 14 (58%) achieved partial response, 8 (33%) had stable disease, and 2 (8%) showed progression. Nodal downstaging, defined as conversion from positive to negative nodal status at surgery, occurred in 8 patients (33%). Among partial responders, 8 (57%) experienced nodal downstaging. OS was comparable between patients with nodal downstaging and those with persistent nodal disease (median OS [95% CI]: 72.8 [37.8-107.9] vs. 116.0 [70.0-162.1] months, p=0.98).

Conclusions: In this cohort, nodal downstaging after neoadjuvant therapy was not associated with OS. Local ablative treatment, including resection, may yield excellent survival even with persistent nodal disease. Further research is needed to identify predictive biomarkers for local therapy in oligometastatic NSCLC.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.12 Pleurodesis in cM0sM1a Lung Adenocarcinoma With Pleural Metastasis: Impact on Pleural Effusion Control and Survival Outcomes

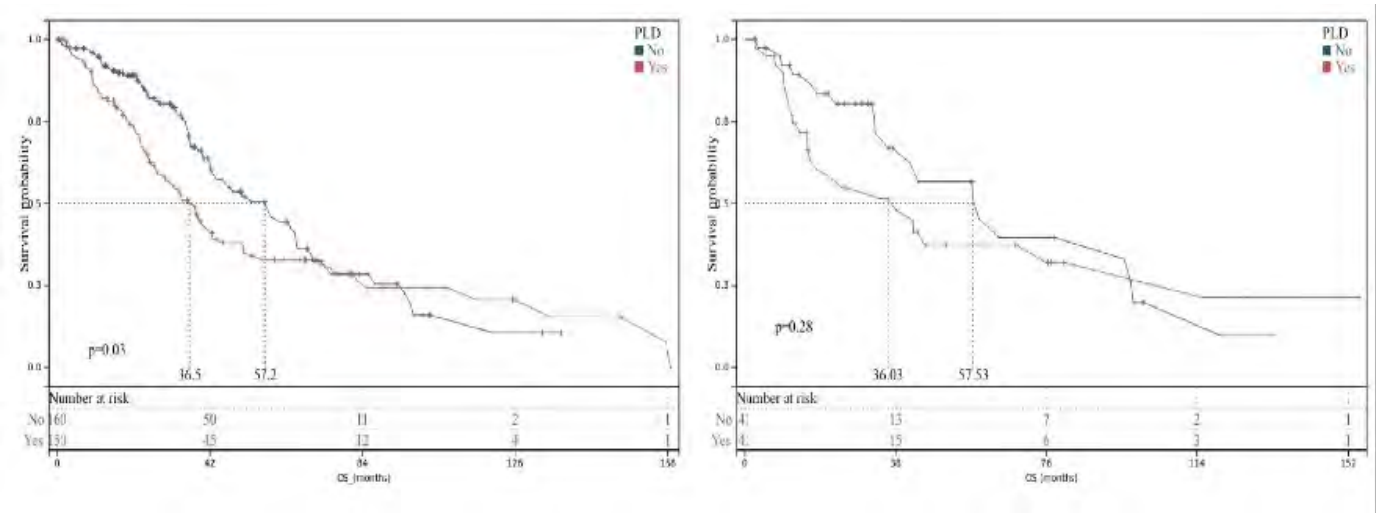
J. Tian, S. Liang, Y. Yang
Sun Yat-sen University Cancer Center, GuangZhou/CN

Introduction: Pleurodesis (PLD) is a procedure to treat recurrent malignant pleural effusion (MPE) via pleural adhesion induction. However, its clinical application remains unclear in cM0sM1a lung adenocarcinoma (LUAD) where pleural metastasis is unexpectedly identified during surgery despite negative preoperative imaging. This study aims to assess procedural safety, effusion control efficacy, and survival outcomes of PLD in cM0sM1a LUAD.

Methods: This retrospective study analyzed 310 cM0sM1a LUAD from Sun Yat-sen University Cancer Center (November 2008 to December 2023), categorized into PLD and non-PLD groups. Perioperative outcomes included hospitalization/ICU stay duration, 6-month pleural effusion control efficacy, 30-/90-day mortality and other parameters. Propensity score matching addressed baseline confounders. Perioperative metrics were compared before and after matching; overall survival (OS) was analyzed via Kaplan-Meier methodology and Cox proportional hazards regression.

Results: In 160 non-PLD and 150 PLD surgically treated patients, PLD demonstrated superior malignant pleural effusion control (41.3% vs. 25.6%, p<0.001) but prolonged postoperative hospitalization (6.50 vs. 5.10 days, p<0.001), without differences in fever, ICU readmission, mortality (30-/90-day), repeat thoracentesis, or chest tube duration (p>0.05). Importantly, these findings persisted after 1:1 PSM (n=82), with PLD maintaining superior effusion control (36.59% vs. 9.76%, p=0.008) and longer hospitalization (6.56 vs. 4.78 days, p=0.018). Multivariate Cox regression showed PLD lacked independent prognostic significance (HR=1.02, p=0.93), while intraoperative pleural effusion (HR=2.10, p<0.001) and smoking history (HR=1.49, p=0.028) conferred elevated mortality risk. Pre-matching survival analysis favored non-PLD (median OS 57.2 vs. 36.5 months; p=0.03), but this difference disappeared post-matching (p=0.28).

Conclusions: PLD safely and effectively controls malignant pleural effusion in cM0sM1a LUAD patients despite extended hospitalization. Crucially, PLD exhibited no long-term survival impact. These findings support prophylactic PLD as a viable surgical strategy for alleviating effusion-associated symptoms in M1a disease, while exemplifying the expanding role of surgical interventions in M1a LUAD to complement systemic therapies through symptom control and locoregional management.



EP.09.13 Prognostic Analysis of Patients With Incidentally Diagnosed Pathological Stage IVA Non-Small Cell Lung Cancer After Anatomical Resection

R. Matsuyama, Y. Kakuraki, I. Takada, C. Kanno, T. Isaka, T. Nagashima, H. Ito
Kanagawa Cancer Center, Yokohama/JP

Introduction: The reported 3-year survival rate of clinical stage IVA non-small cell lung cancer (NSCLC) is approximately 35%. This study aimed to evaluate the prognosis of patients with pathological stage IVA NSCLC who underwent anatomical resection at our institution.

Methods: Among patients who underwent lobectomy with mediastinal lymph node dissection at our institution between January 2010 and December 2021, 13 cases diagnosed with pathological stage IVA NSCLC were retrospectively analyzed for their clinicopathological characteristics and postoperative prognosis.

Results: The median age of the patients was 68 years, and 11 were male. Two cases were preoperatively diagnosed as clinical stage I or earlier. Seven cases were adenocarcinoma. The median PET-SUVmax was 8.8. Lymphatic invasion was observed in 6 cases, vessel invasion in 12 cases, pleural invasion in 13 cases, and nodal metastasis in 13 cases. EGFR mutations were detected in 3 cases. The reasons for pathological stage IVA were pleural dissemination in 8 cases (single pleural lesion in 6 cases, multiple pleural lesion in 2 cases) and malignant pleural effusion (Class V in cytology) in 5 cases. Postoperative systemic therapy was administered in 6 cases, and EGFR-TKI therapy was given in 1 case. The median progression-free survival was 15 months (range: 0-46 months), and the median overall survival was 27 months (range: 9-112 months). The 3-year survival rate was 38.5%. Recurrence or disease progression sites included lung metastases in 5 cases, pleural effusion in 3 cases, brain metastases in 2 cases, mediastinal lymph node metastasis in 1 case, and pericardial metastasis in 1 case. Notably, one patient remained progression-free for 46 months postoperatively. This patient had preoperative clinical stage IIB adenocarcinoma and was diagnosed intraoperatively with malignant pleural effusion.

Conclusions: Overall survival rate after anatomic resection for p-stage IVA NSCLC was similar to that previously reported for c-stage IVA patients. These results suggest that anatomic resection for p-stage IVA NSCLC patients does not appear to improve prognosis.

Keywords: pathological stage IVA, Dissemination or Malignant Pleural Effusion

EP.09.14 Efficacy and Safety of Intrathecal Pemetrexed in NSCLC Patients With Leptomeningeal Metastases: A Retrospective Study

T. Zhang
Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Nanjing/CN

Introduction: Leptomeningeal metastasis (LM), a devastating complication of advanced non-small cell lung cancer (NSCLC), poses therapeutic challenges due to limited effective interventions. This study aimed to evaluate the efficacy and safety profile of premetrexed-based intrathecal chemotherapy in non-small cell lung cancer (NSCLC) patients with leptomeningeal metastasis (LM), while identifying prognostic biomarkers and evaluating the impact of anti-angiogenic therapy.

Methods: We retrospectively analyzed 133 NSCLC patients with LM who received pemetrexed-based intrathecal chemotherapy at Nanjing Drum Tower Hospital affiliated of Nanjing University Medical School, from January 2017 to June 2024. Clinical parameters (age, Karnofsky Performance Status [KPS], genetic alterations), treatment regimens, and survival outcomes were collected. The overall survival (OS), clinical response rate and adverse events (AEs) were evaluated. Prognostic factors were identified through multivariate Cox regression analysis.

Results: The cohort demonstrated a median OS of 14.2 months with 6-month and 1-year OS rates of 83.5% and 56.6%, respectively. Clinical improvement was observed in 91.7% of patients, accompanied by a 64.3% regression or stabilization in leptomeningeal foci. The most common AEs were myelosuppression (57.9%) and elevation of hepatic aminotransferases (25.6%). 12 (9.0%) patients experienced grade 4 adverse events. Subgroup analyses revealed prolonged OS in patients with EGFR common mutations (19del or L858R) versus rare variants (15.9 vs. 11.7 months, p=0.037) and those with KPS ≥ 60 versus <60 (15.8 vs. 11.7 months, p=0.005). Multivariate Cox analysis identified low levels of baseline serum CEA, Cyfra21-1, and cerebrospinal fluid (CSF) Cyfra21-1, as well as use of combined anti-angiogenic therapy were associated with better prognosis.

Conclusions: Pemetrexed-based intrathecal chemotherapy exhibits promising efficacy and manageable toxicity in NSCLC patients with LM. The integration of anti-angiogenic agents and serum/CSF tumor markers (CEA, Cyfra21-1) may optimize therapeutic strategies. These findings warrant prospective validation to establish personalized treatment paradigms for this aggressive malignancy.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.15 CT-Guided Microwave Ablation as an Alternative Treatment for Non-Surgical Lung Cancer Patients: A Clinical Evaluation of Benefits and Risks

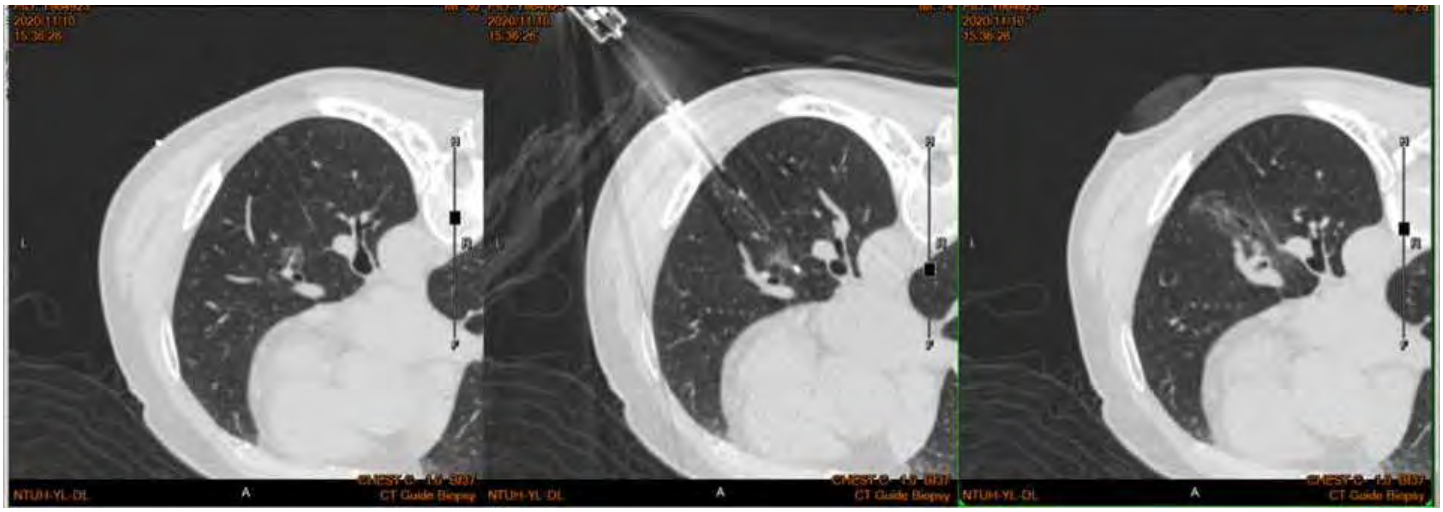
H-C. Peng[1], K-H. Lian[1], J-D. Ye[1], C-Y. Chen[1], K-Y. Chen[2]
[1]National Taiwan University Hospital Yunlin Branch, Douliou/TW ,[2]National Taiwan University Hospital, Taipei/TW

Introduction: For lung cancer patients ineligible for surgical resection, stereotactic radiotherapy and image-guided thermal ablation are alternative treatments. However, the clinical outcomes and risks associated with CT-guided microwave ablation (MWA) require further investigation.

Methods: This prospective cohort study evaluated 23 lung cancer patients who underwent CT-guided MWA between October 2020 and September 2023 using Medtronic's Emprint™ ablation device. Patients had early-stage (I-II) lung cancer or postoperative local recurrence unsuitable for surgery.

Results: The median patient age was 69.5 years (range 46-86), with 43.5% male. Squamous cell carcinoma was observed in 21.7%, while 69.6% had post-treatment recurrence. Tumor size averaged 19.2 mm (range 5-42 mm). Complications included pneumothorax (47.8%), pneumonia (43.5%), chest pain (30.4%), and hemoptysis (8.7%), with severe adverse events in 34.8% of patients. Male gender, right upper lobe tumor location, larger tumor size, and higher energy usage were associated with increased complications. Recurrence occurred in 56.5% of cases, significantly correlated with tumor sizes > 15 mm. Median disease-free survival was 18.4 months, with a 13.0% mortality rate due to severe complications or disease progression.

Conclusions: CT-guided microwave ablation offers a viable treatment option for lung cancer patients who cannot undergo surgery, with promising survival outcomes. However, careful consideration of tumor size and patient-specific risk factors is crucial to minimize complications and optimize results.



Keywords: microwave ablation, complications, survival

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.16 Airway Stenting for the Treatment of Airway Stenosis in Advanced Lung Cancer; a Study of 20 Patients With Advanced Lung Cancer

A. Baba[1], H. Endo[1], Y. Abe[1], S. Matsui[1], E. Takehara[1], K. Fujimoto[1], T. Takeuchi[1], N. Miyamoto[1], A. Morishita[1], N. Kawakita[1], H. Toba[1], H. Takizawa[1], A. Tsuji[1]
[1]Biomedical Sciences, Tokushima University Graduate School, Tokushima/JP

Introduction: Advanced lung cancer is often complicated by airway stenosis, fistula formation, and airway hemorrhage, leading to significantly reduced quality of life and lethal situations. Many of these are oncological emergencies that require a rapid treatment. This study aims to clarify the location and type of stents, efficacy, prognosis and complications.

Methods: We retrospectively reviewed patients who underwent airway stenting for central airway stenosis due to advanced lung cancer at our institution between 2005 and 2024.

Results: Twenty patients with advanced lung cancer underwent airway stenting. The mean age was 62.9 (±12.2) years, 19 (95%) were male and 1 (5%) female. 14 (70%) were stage III and 6 (30%) were stage IV. Subjective symptoms were dyspnea in 17 patients (75%) and bloody sputum in 3 patients (15%). All patients had airway stenosis, including 1 (5%) with fistula formation and 4 (20%) with hemorrhage. The stenosis was located in the main bronchus in 12 patients (60%) and in the carina of trachea in 8 patients (40%). Systemic therapy was initiated prior to stenting in 18 patients (90%) and untreated in 2 patients (10%). Four patients (20%) required ventilator management and one patient (5%) required ECMO management prior to stenting. The mean pre-stent PS was 2.95 and the mean MRC breathlessness scale was 4.15. Metallic stents, silicone stents, and both stents were placed under general anesthesia in 13 (65%), 5(25%), and 2 (10%) patients, respectively. Rigid bronchoscope was used only in 5 (25%) patients. After stent placement, both the PS and MRC breathlessness scales showed significant improvement with mean scores of 2.25 and 3.4, respectively ($p<0.01$). Respiratory support was no longer required in all patients after stent placement. Four patients (20%) had sputum retention as an acute complication requiring bronchoscopic clearance. One patient (5%) experienced stent displacement. Median survival for all patients after airway stenting was 198.5 days. Patients who received adjuvant therapy after stenting had a median survival of 418 days, while patients who did not receive adjuvant therapy had a median survival of 88 days, a trend toward longer survival with adjuvant therapy, but not a significant difference ($p=0.179$). There was no difference in survival between metal and silicone stents. Late complications included frequent pneumonia and atelectasis due to granulation in one patient with a metallic stent, which resulted in decreased quality of life and required stent removal.

Conclusions: PS and MRC were improved by airway stenting. In recent years, medical therapy for advanced lung cancer has progressed, and there have been cases of long-term survival after stenting. Because of granulation formation due to long-term implantation, it is necessary to consider the therapeutic intervention after airway stenting when selecting a stent in the future. The risk of complications should also be considered in each case, and the treatment method should be selected on a case-by-case basis.

EP.09 METASTATIC NON-SMALL CELL LUNG CANCER – LOCAL THERAPIES

EP.09.17 Permanent Local Control After Orbital Cryoablation for Ocular Metastasis From Lung Cancer

N.N. Mederos Alfonso[1], T. Nguyen-Ngoc[1], M. Christofis[1], A. Serena[1], K. Abdelhamid[1], N. Ferahta[1], V. Mosimann[1], A. Stamatiou[1], M-L. Meyer[1], H. Bouchaab[1], S. Peters[1], R. Duran[1]
[1]Lausanne University Hospital, Lausanne/CH

Introduction: Choroidal metastases are the most common intraocular malignancies, occurring in approximately 2-7% of patients with metastatic cancer. Lung carcinoma is a major cause of choroidal metastasis, second only to breast cancer. Such lesions frequently threaten vision and significantly affect quality of life. Standard treatment for choroidal metastasis generally combines systemic therapy with local treatments, predominantly external beam radiotherapy, which achieves high tumor regression rates (approximately 85-93%). However, radiotherapy carries risks of ocular complications such as radiation retinopathy and cataracts, and typically requires multiple treatment sessions. Ocular enucleation, involving the complete surgical removal of the eye, is generally reserved as a last-resort intervention for severe, treatment-refractory ocular tumors, including choroidal metastasis from lung cancer. This procedure may result in significant psychological distress due to aesthetic changes and emotional impacts on self-image, as well as rare but possible physical complications such as orbital infection, haemorrhage, or implant extrusion. Consequently, clinicians increasingly prefer conservative, eye-preserving therapies whenever clinically feasible. Cryoablation, a targeted therapy employing tissue-freezing to destroy tumors while preserving healthy ocular structures, offers a promising alternative that potentially avoids enucleation, preserves ocular anatomy, minimizes visual loss, and significantly reduces patient distress. Here, we present two clinical cases of lung cancer patients treated with orbital cryoablation for choroidal metastases, primarily to avoid ocular enucleation.

Methods: Case 1 was a 64-year-old female with active tobacco use diagnosed in 2018 with stage IVA lung adenocarcinoma, featuring molecular mutations (KRAS, TP53, CDKN2A) and PD-L1 expression (40%). She initially underwent systemic treatment following the KEYNOTE-189 phase III study protocol, followed by multiple systemic therapies and stereotactic radiotherapy for orbital metastatic progression leading to visual loss. In April 2021, rapid progression of a right intraorbital metastasis infiltrating the optic nerve and symptomatic exophthalmia prompted orbital cryoablation. Case 2 was a 32-year-old male with active tobacco use diagnosed in May 2021 with a rare NUT carcinoma of the left lower lung lobe (stage IVA), initially presenting with a choroidal metastasis and serous retinal detachment with visual loss. After thoracic surgery, chemo-immunotherapy, and orbital stereotactic radiotherapy, persistent ocular metastatic progression led to orbital cryoablation in November 2021. Both cryoablation procedures utilized targeted orbital freezing through double freeze-thaw cycles directly applied to the metastatic lesions.

Results: Both patients achieved definitive local tumor control after cryoablation. Case 1 demonstrated partial regression of the orbital lesion with symptomatic relief and maintained ocular integrity without significant adverse events. Case 2 achieved a complete local response with no residual enhancement. Neither patient required ocular enucleation. Although both eventually experienced systemic disease progression, local ocular disease control was maintained until their deaths.

Conclusions: These cases represent the first documented use of orbital cryoablation specifically for choroidal metastases from lung cancer, demonstrating effective local tumor control and ocular preservation. Cryoablation emerges as a valuable local therapy alternative in selected ocular metastatic cases, particularly when avoiding enucleation significantly impacts patients' quality of life.

EP.10 METASTATIC NON-SMALL CELL LUNG CANCER – ANTIBODY-DRUG CONJUGATE AND CYTOTOXIC THERAPY

EP.10.01 Retrospective Study of Pemetrexed Monotherapy for Non-Small Cell Lung Cancer Patients by Renal Function

T. Koyanagi, T. Tamura
NHO Iwakuni clinical Center, Iwakuni City/JP

Introduction: Pemetrexed (PEM) is one of the commonlyused cytotoxic anticanceragents for non-squamous non-small cell lung cancer (NSCLC). Efficacy of pemetrexed has been shown for non-squamous NSCLC , and PEM is a renally excreted drug and its pharmacokinetics correlate linearly with creatinine clearance (Ccr). Patients whose renal function deteriorated to a Ccr of less than 45 mL/minwere excluded from clinical trials, and the efficacy and safety of PEM have not been established.The purpose of this study is to determine whether the efficacy and safety of PEM in NSCLC patients with reduced renal function differs from that in patients with normal renal function.

Methods: From July 2010 to March 2024, 420 NSCLC patients were treated withpemetrexed at our hospital. Of these, 88 patients were treated with PEM alone, and 72 patients were evaluated retrospectively, excluding 4 patients for whom PEM was administered again and 12 patients for whom the effect of treatment was not evaluated.

Results: 72 patients received PEM monotherapy. Of the 72 patients, 53 had Ccr>45mL/mim and 19 had Ccr<45mL/min, and propensity score matching was performed on these patients. The median progression-free survival estimated at baseline for the Ccr>45 mL/min and Ccr<45 mL/min groups was 71 and 112 days, respectively (p = 0.322), and the median overall survival was 198 and 131 days, respectively (p = 0.912), which were not significantly different. The incidence of febrile neutropenia, an adverse event, was 18.8% and 25.0% (p = 1.000), also not significantly different.

Conclusions: Neither the efficacy nor the safety of PEM for non-squamous NSCLC differed by renal function.Pemetrexed monotherapy may be an option for use as a salvage line even with starting Ccr<45 mL/min, as treatment efficacy and adverse events were similar to those in the group with good renal function.

Keywords: NSCLC, Pemetrexed , reduced renal function

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.01 The Challenge of Immunotherapy in Advanced Lung Cancer Patients With HIV: A Systematic Review of Case Reports

T. Franchina[1], P. Carroccio[1], G. Ciappina[1], J.A. Portillo Funes[1], A. Picone[2], C. Infurna[1], F. Bignoli[1], F. Monaco[3], G.F. Pellicanò[4], M. Berretta[1]
[1]Medical Oncology Unit, Department of Human Pathology "G. Barresi", University of Messina, MESSINA/IT ,[2]Medical Oncology Unit, University Hospital "G. Martino", MESSINA/IT ,[3]Section of Thoracic Surgery, Department of Biomedical, Dental, Morphological and Functional Imaging Sciences, University of Messina, MESSINA/IT ,[4]Unit of Infectious Diseases, Department of Clinical and Experimental Medicine, University of Messina, MESSINA/IT

Introduction: Immunotherapy has significantly revolutionized the treatment landscape for lung cancer, demonstrating both effectiveness and a favourable safety profile. Patients with concurrent HIV and lung cancer face considerable differences in their treatment approaches and clinical outcomes. This specific group has a significantly higher mortality rate. Recent studies have yielded important findings regarding the use of immune checkpoint inhibitors in this patient cohort. However, the available data remains insufficient, and there are recognized barriers and limitations to the use of these therapies in cancer care. Real-world data and clinical practice reports are crucial, as they offer essential perspectives that enhance the sharing of clinical experiences and assist in making complex management decisions. To better assess individual patient management and to analyse the multidisciplinary approach utilized, we have excluded studies and case series, including only case reports in our analysis.

Methods: Following PRISMA guidelines, in March 2025, we searched the MEDLINE, Web of Science, and Scopus databases in the English language. Titles and abstracts were reviewed by 2 independent reviewers; disagreements were resolved by a third. All identified full papers were assessed independently by three researchers. Included studies were required to be case reports and evaluate immunotherapy in advanced lung cancer patients with HIV. The Newcastle Ottawa Scale (NOS) was used to assess the quality of studies included in the systematic review.

Results: The systematic search of the literature identified 8 case reports meeting the selection criteria to analyse in qualitative synthesis.The cases analysed, although limited, illustrate the different settings in which immunotherapy is used. Most notably, there is a clear emphasis on careful infectious disease monitoring throughout the immunotherapy treatment process. The observed heterogeneity in CD4 count variations during treatment underscores the importance of adopting a personalized approach with rigorous multidisciplinary monitoring. The reported responses highlight the need for more appropriate treatments for newly diagnosed HIV-positive patients to enhance prognosis and ensure equitable access to care.

Conclusions: The notable positive outcomes observed in these patients underscore the critical importance of a multidisciplinary strategy and the cooperative efforts of oncologists and HIV specialists.

STUDY	ICI	ANTIRETROVIRAL TREATMENT DURING ICI	CD4 COUNT VARIATION	HIV VIRAL LOAD VARIATION	BEST RESPONSE	irAEs
Hentrich et al., 2017	Second-line nivolumab	Dolutegravir and ritonavir-boosted darunavir	Decrease	Stable (below the limits of detection)	PD	No toxicities reported

EP.11.02 Four Year-Experience With Immunotherapy in First Line Treatment of Advanced Lung Cancer in Patients With High and Very High Expression of PD-L1

E.I. Morcillo[1], Ó. Valle[1], J. Marchal[1], S. Sequero[1], C. Rubio[1]
[1]Hospital Universitario Clínico San Cecilio, Granada/ES

Introduction: Immune checkpoint inhibitors (ICIs) targeting programmed cell death 1 (PD-1) or its ligand (PD-L1), have changed the treatment paradigm of metastatic non-small cell lung cancer (NSCLC), specially in tumours with PD-L1 expression ≥50%. This study analyzed demographic and disease-related characteristics, as well as outcomes after first-line ICI treatment in a group of NSCLC patients with PD-L1 ≥50%. We also compared these results between patients with PD-L1 expression 50-89% and those with very high PD-L1 expression (≥90%).

Methods: - Retrospective data from patients with metastatic NSCLC, diagnosed between January 2020 and January 2024. - Objective response rate (ORR) based on iRECIST 1.1 classification. - Survival analysis using Kaplan-Meier method and Cox proportional hazards model.

Results: We present data from 53 patients whose clinical-demographic characteristics are shown in table 1. 44 patients (83%) were treated with Pembrolizumab, 5 with Cemiplimab (9.4%) and 4 with Atezolizumab (7.5%). By the cut-off date, 4 patients were still on treatment. Characteristics between the high PD-L1 expression and very high expression groups, were balanced, except for brain metastasis, which were more prevalent in the PD-L1 ≥90% group. We observed an ORR of 30.19%, a median PFS of 5 months and a median OS of 9 months. In patients with PD-L1 ≥90% (41.5%), median PFS was 6 months and for PD-L1 50-89% (58.5%), 5 months (HR 0.86, 95%CI 0.4-1.5). Median OS was 8.5 and 9 months respectively (HR 0.86, 95%CI 0.4-1.6).

Conclusions: First-line ICI monotherapy for NSCLC in patients with PD-L1 ≥50% has demonstrated a substantial benefit in ORR, PFS and OS in several randomized clinical trials. Our real-world results suggest that there may be a group of patients who don't benefit from this therapy. Therefore, identifying the clinical and biological characteristics of this patients is crucial to seek alternative treatments that achieve better outcomes in this subgroup.

Table 1. Clinical-demographic characteristics of patients with NSCLC

	General population (n=53)	Very high expression of PD-L1 (≥90%) (n=22)	High expression of PD-L1 (50-89%) (n=31)
Sex (n, %)			
Male	37(69.8)	11 (50)	26 (83.9)

[1]A.O.R.N. Antonio Cardarelli, Naples/IT ,[2]A.O.R.N. Ospedale dei Colli, Naples/IT ,[3]A.O.U. Federico II, Naples/IT ,[4]A.O.U. San Giovanni di Dio e Ruggi d'Aragona, Salerno/IT ,[5]A.O.R.N. Moscati, Avellino/IT

Introduction: In metastatic NSCLC TPS PDL1<50%, squamous cell carcinoma or non oncogene addicted adeno-carcinoma, chemo-immunotherapy is the first choice of treatment. Currently there are two different therapeutic regimens: platinum based chemotherapy with anti-PD1 Pembrolizumab or with Nivolumab plus anti CTLA4 Ipilimumab. A comparison end to end between these two strategies is lacking. The aim of our multicentric observational study is to identify potential prognostic factors useful in clinical decision making.

Methods: We retrospectively analyzed 363 metastatic NSCLC patients with programmed cell-death ligand (PD-L1) TPS <50%, who received chemo-immunotherapy between march 2022 and october 2023 in the following institutions: A.O.R.N. Cardarelli, A.O.R.N. dei Colli and A.O.R.N. Moscati. We stratified for therapeutic regimens, PD-L1 <1% vs 1-49%, histotypes, distant sites of metastasis, Neutrophils to Lymphocyte Ratio (NLR), presence/absence in NGS of patogenic KRAS mutations, sex and age. We evaluate univariate Kaplan Meier estimated overall survivall and multivariate Cox Regression Hazard Ratio.

Results: At a median follow-up of 12 months, no statistically significant differences were revealed in median OS between patients treated with chemotherapy plus Nivolumab and Ipilimumab or with chemotherapy plus pembrolizumab. A clinically but not statistically significant improvement in median OS has emerged in PD-L1 positive vs negative patients, regardless chemo-immunotherapy regimen. Bone metastasis were associated with a worse prognosis vs no bone metastasis patients (median OS 6.4 vs 13.2 months, log rank test p value = 0.0002). Liver metastasis also resulted in a bad prognosis with a median OS of 4.9 months vs 11.4 months of no liver metastasis patients. (p value = 0.011). NLR from the pretreatment complete blood counts reflected a poor treatment benefits if equal or higher than 3.8. Finally, presence of pathogenetic KRAS gene variants did not have a negative impact on prognosis.

Conclusions: High NLR, Bone and Liver metastasis are associated to significantly shorter overall survival in previously untreated patients with NSCLC with lower or negative expression of PD-L1 and treated in first line with chemo-immunotherapy.

EP.11.04 Camrelizumab-Induced Immune-Related Toxic Epidermal Necrolysis in Lung Adenocarcinoma: A Case Report and Literature Review

M. Sun, H. Zhou, D. Zang, J. Chen
The Second Hospital of Dalian Medical University, Dalian/CN

Introduction: Immune checkpoint inhibitors (ICIs), such as Camrelizumab, have revolutionized the treatment of non-small cell lung cancer (NSCLC), offering significant improvements in survival outcomes. However, ICIs are associated with immune-related adverse events (irAEs), including rare but severe cutaneous toxicities like toxic epidermal necrolysis (TEN). Here, we report a case of Camrelizumab-induced immune-related TEN in a patient with lung adenocarcinoma (LUAD), highlighting the clinical challenges in diagnosis and management.

Methods: This study presents a case report of a 58-year-old female with stage IV LUAD who developed TEN after receiving Camrelizumab monotherapy. Comprehensive clinical data, including patient history, laboratory results, treatment regimen, and follow-up, were collected and analyzed. A literature review was conducted to contextualize the findings and explore the current understanding of ICI-induced TEN.

Results: The patient developed widespread erythematous rashes, blisters, and epidermal necrosis within 8 days of Camrelizumab treatment. Despite initial management with methylprednisolone, the skin lesions rapidly progressed, involving nearly 70% of the body surface area. The patient was treated with high-dose corticosteroids and intravenous immunoglobulin (IVIg), resulting in gradual improvement. Immunological analysis revealed increased IL-10 levels and reduced T cell, CTL, and NK cell counts after immunotherapy. No significant tumor progression was observed during the treatment period.

Conclusions: Camrelizumab-induced TEN is a life-threatening irAE requiring immediate cessation of ICI therapy and aggressive immunosuppressive treatment. This case emphasizes the need for early recognition of severe cutaneous reactions during ICI treatment. Further research is warranted to understand the underlying mechanisms and develop predictive biomarkers for severe irAEs.

EP.11.05 Prognostic Value of Hb/RDW and Its Correlation With Immune-Inflammatory Profile in NSCLC Receiving First-Line Immunotherapy

F. Pecci[1], G. Mazzaschi[2], A. Dodi[3], P. Tamarozzi[2], M. Manini[3], M. Peroni[3], S. D'Agnelli[3], M. Pluchino[3], M. Verzè[3], R. Minari[3], F. Perrone[3], P. Bordi[3], A. Leonetti[3], F. Quaini[2], N. Sverzellati[2], S. Buti[3], M. Tiseo[3]
[1]University of Parma, Parma/IT ,[2]University of Parma, Department of Medicine and Surgery/IT ,[3]University Hospital of Parma, Medical Oncology Unit/IT

Introduction: The Hemoglobin to Red cell Distribution Width Ratio (Hb/RDW) is a simple and reliable tool directly influenced by factors such as inflammation, nutritional deficiencies, and bone marrow disorders, and a low Hb/RDW seems to be associated with a higher risk of death in patients with cancer. Here, we explored the prognostic role of Hb/RDW and its correlation with blood immunophenotypes and cytokines to provide an easily available non-invasive tool to predict the survival from first-line immune checkpoint inhibitors +/- chemotherapy (ICI+/-CT) in metastatic NSCLC (mNSCLC).

Methods: Clinicopathological data were collected from a monocentric prospective cohort of patients with mNSCLC treated with first-line ICI+/-CT. Baseline blood samples were collected for the assessment of Hb/RDW, relevant immunophenotypes (flow-cytometry) and cytokines (multiplex array). High and low Hb/RDW subgroups were defined according to the median value of Hb/RDW. Correlations of Hb/RDW with survival outcomes in terms of progression-free/overall survival (PFS/OS) and circulating immune-inflammatory benchmarks were analyzed.

Results: Among the 153 patients included, 76% received first-line treatment with ICI + chemotherapy, 31.5% had a PD-L1 tumor proportion score (TPS) ≥ 50%, 71.9% had adenocarcinoma histology, and 43.5% harbored a KRAS mutation. Regarding Hb/RDW, 49.3% of patients had levels equal or below the median (≤0.94). Clinicopathologic characteristics, including age, PD-L1 TPS, performance status, histology, smoking history, and number of metastatic sites, were well balanced between the low and high Hb/RDW subgroups. However, the low Hb/RDW group had a higher proportion of male patients (p = 0.01) and lower median total blood cholesterol levels (p = 0.03), particularly lower median HDL levels (p < 0.001), compared to the high Hb/RDW group. Additionally, patients with low Hb/RDW were more likely to have a baseline concurrent diagnosis of diabetes mellitus (p = 0.02). Hb/RDW did not correlate with baseline derived neutrophil-to-lymphocyte ratio (dNLR) (R = 0.08, p=0.9). At a median follow-up of 27.4 months (95% CI 22.9-32.0), while no meaningful difference regarding median PFS was found, significantly shorter OS was observed in patients with low Hb/RDW compared to patients with high Hb/RDW (11.3 months vs 26.2 months, hazard ratio [HR]: 1.5, p=0.04). The multivariable analysis (adjusting for sex, age, performance status, histology, PD-L1 TPS, metastatic sites, treatment type, dNLR) confirmed the prognostic impact of Hb/RDW in terms of OS (HR 1.6, p=0.03). Compared to patients with high Hb/RDW, patients with low Hb/RDW showed higher baseline blood levels of IL-12 (p=0.04), TNF alpha (p=0.02), IL-6 (p=0.01), and soluble PD-L1 (p= 0.01). In addition, higher baseline immune suppressor cell populations characterized patients with low Hb/RDW, with significantly higher PD-1-positive Natural Killer cells (p=0.05) compared to patients with high Hb/RDW.

Conclusions: In patients with mNSCLC receiving first-line ICI +/- CT, a low Hb/RDW is associated with a higher comorbidity burden, including diabetes mellitus and an unfavorable cholesterol profile, reduced OS and a compromised systemic immune-inflammatory status. As a simple, non-invasive circulating biomarker, Hb/RDW can provide valuable insights into overall patient health, emphasizing its potential role in baseline prognostic stratification.

EP.11.06 First-Line Immunotherapy for PD-L1 =50% Advanced NSCLC vs EGFR-TKIs in EGFR-Mutant NSCLC: A Retrospective Single-Center Study

S. Futamura[1], K. Kunimasa[1], A. Miyazaki[1], K. Komuta[1], T. Tanaka[1], T. Kawamura[1], T. Inoue[1], M. Tamiya[1], K. Nishino[1], A. Kubota[2]
[1]Osaka International Cancer Center, Osaka-shi/JP ,[2]Department of Biomedical Statistics and Bioinformatics, Kyoto University Graduate School of Medicine,, Kyoto/JP

Introduction: Immune checkpoint inhibitors (ICIs) have demonstrated durable responses and prolonged survival in some patients with advanced non-small cell lung cancer (NSCLC). We conducted a retrospective single-center analysis to compare the prognostic impact of first-line ICIs and EGFR tyrosine kinase inhibitors (EGFR-TKIs) in patients with advanced NSCLC.

Methods: We collected the following data from patients' medical records: age, sex, ECOG performance status (PS), smoking history, histologic subtype, clinical stage, PD-L1 tumor proportion score (TPS), chemotherapy regimen, and overall survival (OS). The data cutoff was August 31, 2024. OS was defined as the time from the first dose of systemic therapy until death from any cause or the last date of follow-up. Data analyses were performed from January 2017 to December 2022.

Results: A total of 1,368 patients with advanced NSCLC were identified, among whom 979 received systemic chemotherapy. PD-L1 expression was <1% in 263 tumors (26.9%), 1%-49% in 336 (34.3%), ≥50% in 318 (32.5%), and unknown in 62 (6.3%). EGFR mutations were detected in 268 patients (27.4%), all of whom received EGFR-TKIs. The median OS among these 268 patients was 41.9 months (95% CI, 35.7-54.3). Among patients treated with ICI-based regimens, the median OS was: 36.4 months (95% CI, 24.0-48.1) in 128 patients receiving pembrolizumab monotherapy (13.1%), 31.3 months (95% CI, 24.7-46.4) in 111 patients receiving pembrolizumab plus chemotherapy (11.3%), 26.9 months (95% CI, 15.2-NA) in 54 patients receiving ipilimumab plus nivolumab ± chemotherapy (5.5%), 21.5 months (95% CI, 16.2-27.2) in 86 patients receiving atezolizumab plus chemotherapy (8.8%). In the subgroup with PD-L1 ≥50% (n=157) who received pembrolizumab ± chemotherapy, the median OS was 42.15 months (95% CI, 26.7-62.6). Compared with the OS of 41.9 months (95% CI, 35.7-54.3) for the 268 patients who received EGFR-TKIs (hazard ratio [HR], 1.04; 95% CI, 0.80-1.35), there was no significant difference in survival benefit. Restricted mean survival time (RMST) analysis also showed no significant difference.

Conclusions: In this retrospective single-center study, regimens including pembrolizumab for patients with PD-L1 ≥50% advanced NSCLC achieved an OS benefit comparable to that of EGFR-TKIs in patients with EGFR-mutant NSCLC.

Keywords: ICI, EGFR-TKI, OS

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.07 Type2 Diabetes Mellitus Affect Prognosis and Immune Checkpoint Inhibitor Treatment Efficacy for Advanced Non Small Cell Lung Cancer

Y. Kato[1], T. Okano[2], E. Kuramochi[2], R. Yamaguchi[2], E. Mikami[2], K. Shinbu[2], J. Aoyama[2], M. Seike[1]
[1]Nippon medical school, Tokyo/JP ,[2]Nippon medical school Chiba-Hokuso hospital, Chiba/JP

Introduction: The effect of type 2 diabetes mellitus (T2DM) on systemic treatments, especially immune check point inhibitor (ICI) for advanced non-small cell lung cancer (NSCLC) remained unclear issue. We conducted retrospective analysis of the effect of T2DM on each type of systemic treatment, ICI, molecular targeted therapy (MTT), and cytotoxic chemotherapy, for advanced NSCLC as multi-cohort retrospective study.

Methods: We reviewed medical charts of patients initiated any systemic treatments after diagnosed advanced NSCLC at Nippon Medical School Chiba-Hokuso hospital from April 2018 to August 2024. Clinicopathological character, treatment effect, and adverse events in these patients were investigated retrospectively

Results: Of 257 patients diagnosed advanced NSCLC and initiated on systemic treatment, 76 (29.6%) patients were diagnosed with T2DM. The numbers of T2DM and non-T2DM patients who initiated immune checkpoint inhibitor (ICI) therapy, molecular targeted therapy (MTT), and cytotoxic chemotherapy were 37 and 78, 30 and 86, 9 and 17, respectively. The overall survival of total patients T2DM patients was significantly worse than total patints without T2DM (34.5 months vs. 19.3 months, hazard ratio [HR] 1.76, P-value 0.0014). Similarly, patients with T2DM in ICI and MTT cohorts was significantly worse than without T2DM (ICI cohort 34.2 months vs. 11.5 months, HR 2.13 [95% CI 1.24-3.66], P-value 0.0049; MTT cohort 43.4 months vs. 27.4 months, HR 1.81 [95% CI: 1.05-3.13], P-value 0.031). Multivariate analysis identified T2DM as an independent poor prognostic factor in the total patients. Median progression-free survival (PFS) was significantly poor for T2DM patients in the ICI cohort (12.5 vs. 5.7 months, hazard ratio [HR] 1.60, P=0.036). However, a significant difference was not found for the MTT cohort (12.7 vs. 13.3 months, HR 1.02, P=0.94). In the ICI cohort, HbA1c was significantly higher in patients with dNLR>3. A similar trend was observed in the NLR in the ICI cohort. In contrast, no association was found between activation of systemic inflammation and glycaemic control in the MTT cohort. However, Multivariate analysis for the PFS in T2DM patients showed specialist consultation was identified as a factor that improved PFS after ICI therapy.

Conclusions: Our research suggests T2DM is one of the prognostic factor for advanced NSCLC and affects ICI treatment efficacy through systemic inflammation acceleration. In addition, our results highlights the importance of strict glycemic control by T2DM specialist intervention.

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.08 Comparison of Efficacy and Safety of Combination Therapy With Atezolizumab and Chemotherapy in Non-Small Cell Lung Cancer

T. Isobe[1], A. Ohiwa[1], H. Yuda[1], T. Nishimura[2], H. Fujimoto[3], T. Sakaguchi[4], A. Fujiwara[5], H. Nakahara[6], T. Kobayashi[3]
[1]Kuwana City Medical Center, Kuwana city/JP ,[2]Mie Chuo Medical Center, Z city/JP ,[3]Mie University School of Medicine Hospital, Z city/JP ,[4]Matsusaka Municipal Hospital, Matsusaka-city/JP ,[5]Mie Prefectural General Medical Center, Yokkaichi-city/JP ,[6]Suzuka General Hospital, Suzuka-city/JP

Introduction: Combination therapy with carboplatin, nab-paclitaxel and atezolizumab (ACnP) and combination therapy with carboplatin, paclitaxel, bevacizumab and atezolizumab(ABCP) can be used in patients with renal dysfunction or EGFR-TKI resistance. However, differences in background factors, efficacy, and safety between the two treatment groups are unclear. In this study, we performed a retrospective comparative analysis of the efficacy and safety of the ACnP andABCP in patients with non-small cell lung cancer.

Methods: This study enrolled patients with non-small cell lung cancer (NSCLC) treated withACnP regimen or ABCP regimen from May 2018 through December 2023 in 6hospitals in Japan. The characteristics, the efficacy and the incidence ofadverse events were compared between the two regimens. The hazard ratios of subgroup analysis were analyzed after adjusting for factors including age, gender, Eastern Cooperative Oncology Group performance status (ECOG PS), smoking history, histology, EGFR with inverse probability of treatment weighting using propensity score.

Results: Ninety-one patients were enrolled. There were 40 patients in the ACnP group and 51 patients in the ABCP group. There were differences between the two groups in age, gender, smoking history, histology, EGFR status, and TTF-1 status. The objective response rate was 55.0% in the ACnP group and 45.1% in the ABCP group. The median time to treatment failure was 5.5 months and6.6 months, the progression-free survival was 5.5 months and 6.9 months, the median overall survival was 16.2 months and 18.3 months in the ACnP group and ABCP group, respectively. Subgroup analysis after inverse probability weighting adjustment for progression-free survival and overall survival showed patients with brain metastases, liver metastases, EGFR positive, PD-L1 positive, and CCr < 45 significantly favored the ABCP regimen for progression-free survival. For overall survival, patients with brain and liver metastases significantly favored ABCP regimen. Among the adverse events we evaluated, neutropenia, peripheral neuropathy, and skin rash were significantly less frequent with the ACnP group.

Conclusions: In this study, the ABCP regimen was found to be effective in liver metastases,brain metastases, and EGFR-positive cases.

Keywords: Atezolizumab, ABCP, ACnP

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.09 Predictive Value of Markers of Systemic Inflammation in Patients With Advanced NSCLC Treated With First-Line Immune Checkpoint Inhibitors

K. Ljujic, F. Djordjevic, A. Kojic, D. Kolovic, N. Stanic, J. Spasic
Institute for Oncology and Radiology of Serbia, Belgrade/RS

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionised treatment of NSCLC over the past several years, both in early and advanced stage. Markers of host systemic inflammation, such as neutrophile-to-lymphocyte ratio (NLR), Lung immune Prognostic Index (LIPI) and Glasgow Prognostic Score (GPS) have been proposed as potential predictive markers of ICI response and resistance.

Methods: In this retrospective analysis, we evaluated the relationship of pre-treatment values of NLR, LIPI and GPS on the survival of patients with metastatic NSCLC and PD-L1≥50% treated with first-line pembrolizumab at the Institute for Oncology and Radiology of Serbia. Data from 100 consecutive patients were obtained from hospital medical records. NLR was calculated as the absolute neutrophil/lymphocyte count from complete blood count. LIPI was developed by the association between the derived NLR (dNLR) and the blood level of lactate dehydrogenase (LDH). It is divided into three subsets: good, with dNLR ≤3 and LDH≤ upper limit of normal (ULN); intermediate, with dNLR >3 or LDH >ULN and poor, dNLR >3 and LDH>ULN. GPS is calculated from C-reactive protein (CRP) and serum albumin. GPS is 0 when CRP ≤10 mg/L and albumin ≥3.5 g/dl, 1 when CRP ≤10 and albumin <3.5 or CRP >10 and albumin ≥3.5 and 2 when CRP >10 and albumin <3.5. Cut-off values were determined using ROC curves. Correlation with progression-free survival (PFS) and overall survival (OS) was examined by the Kaplan-Meier method and Cox regression.

Results: Patients with NLR under the cut-off value of 4.46 had a median PFS of 20.70 months (CI 95%, 14.09-27.37), in those with NLR over 4.46 mPFS was 12.45 (CI 95%, 0.0-34.15); p=0.332. Median OS in patients with NLR ≤4.46 was 25.40 months (CI 95%, 9.12-41.67) in those with NLR>4.46 mOS 15.05 (CI 95%, 7.56-22.53), p=0.090. 14 patients had good LIPI score, 46 intermediate and 40 poor LIPI. Median PFS in the good group was not reached, for the intermediate group it was 16.43 months (CI 95%, 6.95-25.9), and for the poor group 12.45 (CI 95%, 0.54-24.36), p=0.13. Median OS in the group with good LIPI was not reached, in the intermediate group was 18.17 (CI 95%, 12.58-23.25),in the poor group 11.04 months (CI 95%, 0-25.02), p=0.28. Also, 24 patients had GPS 0, 52 GPS 1 and 24 had GPS 2. Median PFS in patients with GPS 0 was 23.53 months (CI 95%, 7.17-39.86), with GPS 1 14.29 (CI 95%, 2.46-26.11) and with GPS 2 21.02 (CI 95%, 8.63-33.42), p=0.882. Median OS was 31.73 months (CI 95%, 5.29-58.17) for the group with GPS 0, 19.15 (CI 95% 10.44-27.86) for GPS 1 and 18.16 (CI 95%, 0.00-37.96), p=0.64.

Conclusions: There was an association between parameters of low systemic inflammation (NLR ≤4.46, good LIPI and GPR 0) and survival of this group of patients, but without statistical significance, which could be due to a low number of patients in certain subgroups. Investigations are ongoing on a larger group of our patients, with a hope of defining easy to measure, low cost parameters which could help in predicting response to ICIs.

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.10 Clinicopathologic Features, Genetic Characteristics and Prognostic Analysis of Advanced Non-Small Cell Lung Cancer, Not Otherwise Specified

X. Yu, Y. Fan
Zhejiang cancer hospital, Hangzhou/CN

Introduction: Non-small cell lung cancer, not otherwise specified (NSCLC-NOS) is a type of undifferentiated/poorly differentiated NSCLC. To enhance the understanding of NSCLC-NOS, we systematically summarized and comprehensively analyzed its clinicopathological characteristics, genomic landscapes and prognostic factors.

Methods: From January 2021 to December 2023, we retrospectively screened 2324 undifferentiated/poorly differentiated NSCLC patients. Patients with NSCLC-NOS in stage III/IV diagnosed by morphology and immunohistochemistry (IHC) were included. The primary study endpoint was overall survival (OS). Clinicopathological and molecular features, as well as prognostic factors of survival for NSCLC-NOS were analyzed.

Results: 91 patients diagnosed as NSCLC-NOS were enrolled in this study. Most were male (92.3%), current/former smokers (78.0%), with a median age of 66 years. After a median follow-up of 21.6 months, the median overall survival (mOS) of NSCLC-NOS patients were 12.2 months (95%CI: 7.3-17.1). Among 91 patients, 37 undergoing gene test, the most common gene alterations were TP53 (45.9%) and KRAS (16.2%), and three patients were detected with driver gene mutations, including MET exon 14 skipping mutation (2/37) and KRAS G12C mutation (1/37). Univariate and multivariate regression analysis showed that ECOG PS score (HR: 2.36, 95%CI: 1.30-4.27, p = 0.01) and immunotherapy (HR: 0.16, 95%CI: 0.37-1.00, p = 0.05) were significantly associated with improved survival outcomes. Patients, whose ECOG PS score was 0-1, demonstrated superior mOS than ECOG PS score 2 patients (14.9 vs. 3.1 months, HR: 0.21, p < 0.01). Besides, ICIs (immune checkpoint inhibitors) treatment significantly improved mOS (15.8 vs. 7.3 months, HR: 0.48, p < 0.01) compared to non-ICIs treatment.

Conclusions: NSCLC-NOS is predominantly observed in elderly male smokers, with poor survival prognosis and rare driver gene mutations. The addition of ICIs significantly improved survival for advanced patients with NSCLC-NOS.

Keywords: NSCLC-NOS, Prognosis, Immunotherapy

EP.11.11 Real World Outcomes of First-Line Pembrolizumab With or Without Chemotherapy in Patients With Non-Small Cell Lung Cancer

I. Sullivan[1], K. Laurence[1], A. Kwok[1,2], E. Paul[2], M. Alamgeer[1,2], P. Briggs[1,2], R. Pham[1], S. Arulananda[1,2]
[1]Monash Health, Melbourne/AU ,[2]Monash University, Melbourne/AUrüh[1]

Introduction: Non-small cell lung cancer(NSCLC) remains the leading cause of cancer-related morbidity and mortality worldwide. Despite treatment advancements, prognosis for these patients remains poor. The use of immunotherapies such as pembrolizumab, an anti-PD-1 receptor antibody, in lung cancer treatment has dramatically improved outcomes for patients. Known associations with PDL-1 expression on tumour cells and efficacy of pembrolizumab treatment have been well described in other studies. This analysis aimed to evaluate survival outcomes and their predictors in patients with NSCLC who received either pembrolizumab monotherapy (mono-pembro) or combined pembrolizumab and chemotherapy (chemo-pembro).

Methods: This retrospective analysis included adult patients with NSCLC who received first-line pembrolizumab with or without chemotherapy between January 1, 2015 and March 31, 2024 at a major tertiary hospital network, identified through hospital prescribing records. Medical record data collection included biochemical and genetic testing results, severity of disease at diagnosis, and immunotherapy-related adverse events(irAE). Subgroup analyses were conducted for the mono-pembro and chemo-pembro cohorts. Kaplan-Meier methods were used to estimate survival as a function of time. Cox proportional hazards regression was used to analyse the primary outcomes of overall survival (OS) and progression-free survival (PFS). Variables of potential clinical significance and univariate analyses statistical significance were selected for inclusion in the multivariate analyses.

Results: The mono-pembro cohort included 73 patients with 2-year survival of 42% and the chemo-pembro cohort included 132 patients with 2-year survival of 33%. Univariate analysis revealed ECOG, LDH and albumin were markers of prognosis across both subgroups. The presence of irAE was also found to improve OS and PFS in both mono-pembro (HR 0.40, p=0.002; HR 0.27, p=<0.001 respectively) and chemo-pembro (HR 0.45, p=0.001; HR 0.49, p=0.002 respectively) cohorts. The presence of KRAS non-G12C mutation was associated with worse PFS outcomes in the mono-pembro group (HR 2.30, 95% CI 1.07 - 4.97, p=0.03), but not in the chemo-pembro group (HR 0.98, p=0.96).

Multivariate analysis demonstrated higher ECOG and Neutrophil-Lymphocyte ratio(NLR), and lower albumin were associated with worse OS and PFS in the mono-pembro group. Patients who smoked at higher volumes were associated with increased PFS (HR 0.54, p=0.008) whereas adenocarcinoma histopathology was related with poorer OS (HR 2.38, p=0.024). Statistically significant multivariate outcomes in the chemo-pembro group were ECOG and NLR, which both were associated with worse OS.

Conclusions: Patient characteristics which carried a favourable prognosis included the presence of irAE, favourable biochemical markers(LDH, Albumin, NLR) and functional baseline(ECOG) at the time of initial treatment. Improved PFS was demonstrated with KRAS G12C mutation in the chemo-pembro group but not in the mono-pembro group, which also demonstrated reduced PFS with KRAS non-G12C mutation. This may suggest that pembrolizumab efficacy in NSCLC patients with KRAS mutations is inferior to traditional platinum-based chemotherapy. A proposed mechanism for the association between irAE and improved primary outcomes may be that they are both indicative of a stronger systemic immunological upregulation response to immunotherapy. Alternatively, the increased lysis of malignant cells in treatment response may result in higher rates of systemic adverse events.

EP.11.12 Real-World Impact of Immune Checkpoint Inhibitors in Elderly Patients With Advanced NSCLC: A Retrospective Cohort Study From South Korea

E.Y. Heo[1], I.H. Lee[2], K.H. Kim[1], Y.S. Park[2]
[1]SMG-SNU Boramae medical center, Seoul/KR ,[2]Seoul National University Hospital, Seoul/KR

Introduction: Immune checkpoint inhibitors (ICIs) are a preferred treatment option for advanced non-small cell lung cancer (NSCLC) without targetable oncogenic mutations. While evidence supporting their efficacy is increasing, data on their effectiveness in elderly patients remain inconclusive. In South Korea, PD-L1 inhibitors such as pembrolizumab and nivolumab were approved for second-line treatment of advanced NSCLC in August 2017. This study aimed to assess changes in treatment patterns following ICI approval and to evaluate the real-world effectiveness of ICIs in elderly patients with advanced NSCLC.

Methods: We retrospectively reviewed patients aged ≥75 years who were diagnosed with stage IV NSCLC between August 2015 and December 2021 at Seoul National University Hospital and Boramae Medical Center. We evaluated trends in systemic therapy use before and after ICI reimbursement and analyzed the proportion of patients who received ICI therapy. We compared 1-year survival rates and overall survival (OS) between ICI-treated and non-ICI-treated groups, with stratification by ECOG performance status and PD-L1 expression.

Results: A total of 395 patients were included (median age 79 [range 75-94]; 54% male). ECOG performance status was ≥2 in 184 patients (51.3%) and <2 in 174 (48.7%). Histologically, 29.8% had squamous and 70.4% had non-squamous NSCLC. Among 359 patients with treatment data, 49.3% received first-line chemotherapy and 21.4% received second-line therapy. ICI monotherapy was used in 9.7% of patients as second-line treatment; none received ICI as first-line therapy.Following ICI reimbursement approval, 41.5% (44/106) of patients who received first-line chemotherapy proceeded to second-line treatment, with 24 receiving ICIs. Before reimbursement, 46.5% (33/71) received second-line therapy, suggesting no substantial increase in treatment continuation post-reimbursement.Among patients with ECOG <2, those treated with ICIs had significantly higher 1-year survival (64.5% vs. 26.4%, P<0.001) and longer median OS (518 vs. 189.5 days, P=0.04) compared to those who did not receive ICIs. However, after adjusting for PD-L1 expression, this survival benefit remained statistically significant only in patients with high PD-L1 expression.

Conclusions: While ICI reimbursement approval did not significantly alter treatment patterns among elderly patients with advanced NSCLC, ICIs may confer meaningful survival benefits, particularly in those with preserved performance status. However, the benefit was not consistent across all subgroups and appeared limited to patients with high PD-L1 expression. Careful assessment of performance status and biomarker-driven patient selection is essential when considering immunotherapy in elderly patients with advanced lung cancer.

EP.11.13 ICI Rechallenge in Non Small Cell Lung Cancer: A Retrospective Analysis of Efficacy and Prognostic Factors

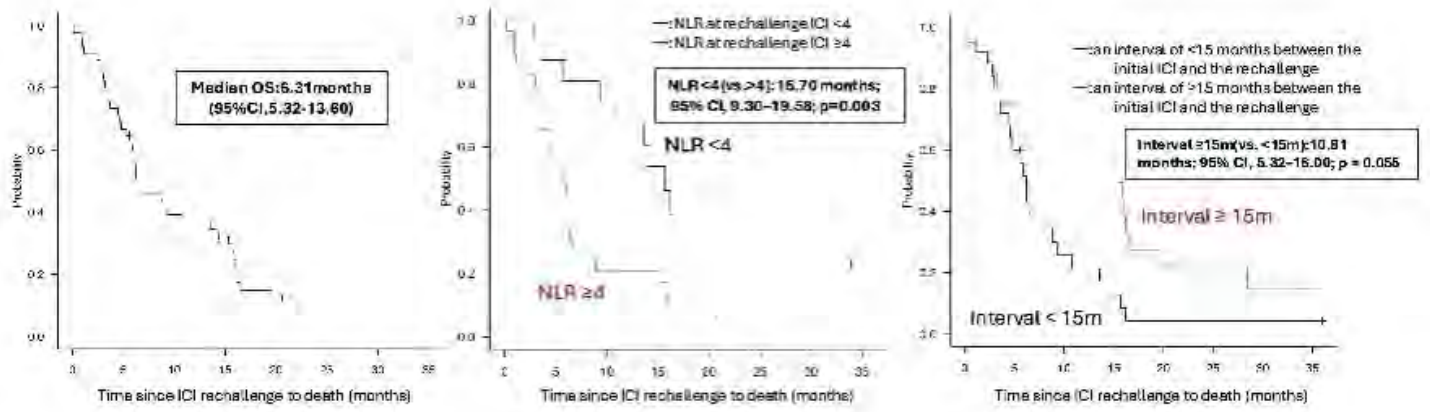
S. Minami, Y. Yamazaki, T. Doman, A. Narumi, Y. Toi, Y. Kimura, S. Sugawara
Sendai Kousei Hospital, Sendai city/JP[1]

Introduction: Immune checkpoint inhibitor (ICI) rechallenge may benefit patients with non-small cell lung cancer (NSCLC) who previously discontinued therapy due to progression or toxicity. However, the therapeutic efficacy and safety of this approach remain uncertain. Predictive factors such as performance status (PS), PD-L1 expression, neutrophil-to-lymphocyte ratio (NLR), and lung immune prognostic index (LIPI) have been recognized for their influence on initial ICI effectiveness, but reliable predictive markers specific to rechallenge therapy are not yet defined. This retrospective study aims to evaluate the clinical efficacy of ICI rechallenge and identify relevant prognostic factors affecting treatment outcomes.

Methods: This single-center retrospective study involved NSCLC patients who underwent ICI rechallenge between August 2017 and November 2024. Clinical data were obtained from electronic medical records, assessing overall survival (OS), progression-free survival (PFS), and the incidence of immune-related adverse events (irAEs). Prognostic factors related to OS were also evaluated.

Results: 47 patients, with a median age of 67, participated. In PD-L1 tumor proportion scores (TPS), 14 patients (29.8%) had TPS <1%, 16 patients (34.0%) had TPS 1-49%, and 14 patients (29.8%) had TPS ≥50%. Initial ICI treatments included atezolizumab in 5 patients (10.6%),durvalumab in 7 patients (14.9%), pembrolizumab in 19 patients (40.4%), and nivolumab in 16 patients (34.0%). Performance status was PS 0 in 5 patients (10.6%), PS 1 and 2 in 42 patients (89.4%). Although the overall prognosis after ICI rechallenge was limited, with a median PFS of 2.17 months (95% CI, 1.87-3.94) and a median OS of 6.31 months (95% CI, 5.32-13.60), significantly prolonged OS was observed in specific subgroups: patients with an interval of ≥15 months between the initial ICI and the rechallenge (10.81 months; 95% CI, 5.32-16.00; p=0.055), those who experienced adverse events during initial ICI treatment (15.31 months; 95% CI, 3.68-16.55; p=0.048), and those with NLR <4 (15.70 months; 95% CI, 9.30-19.58; p=0.003). Multivariate Cox regression indicated that the presence of irAEs (HR: 0.29, 95% CI: 0.13-0.62, p=0.0016) and NLR <4 (HR: 0.34, 95% CI: 0.16-0.76, p=0.0080) were independently linked to enhanced OS. During the rechallenge ICIs, irAEs during ICI rechallenge were observed in 34.0% of patients, with 19.1% experiencing grade ≥3 events.

Conclusions: Patients with longer intervals since their initial ICI, prior irAEs, or a high NLR demonstrated improved survival outcomes with ICI rechallenge. This indicates that clinical and inflammatory markers might help identify suitable candidates for this treatment strategy.



Keywords: ICI rechallenge, NLR, irAE

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.14 Impact of Bone Metastases on the Efficacy of First-Line Immunotherapy in Advanced NSCLC: An Analysis From a Prospective Real-World Study

J. Zheng[1,2], C. Ye[1], J. Zhou[1,2], J. Zhou[1,2]
[1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN ,[2]The Clinical Research Center for Respiratory Diseases of Zhejiang Province, Hangzhou/CN

Introduction: Preclinical studies suggest that bone metastases in non-small cell lung cancer (NSCLC) are associated with an immunologically "cold" tumor microenvironment, potentially impairing the efficacy of immune checkpoint inhibitors. However, clinical evidence remains limited to a few retrospective studies, most of which analyzed patients receiving different lines of therapy without stratification. Prospective clinical data with consistent treatment lines are needed to validate this observation.

Methods: This was a prospective real-world study enrolling patients with advanced NSCLC who had not received prior systemic therapy for advanced disease. Patients received PD-1 inhibitor-based treatment, including monotherapy, or in combination with chemotherapy or antiangiogenic agents. The PD-1 inhibitor was administered at a fixed dose every 21 days per treatment cycle.

Results: A total of 177 patients were analyzed, with a median age of 66 years. The overall median PFS and OS were 10.4 months (95% CI: 7.121-13.746) and 38.4 months (95% CI: 31.710-45.023), respectively. Among them, 63 patients had bone metastases and 114 did not. Patients with bone metastases had significantly shorter median PFS (9.8 vs. 13.7 months, P=0.048). OS was numerically shorter, but the difference was not statistically significant (26.6 vs. 39.5 months, P=0.065). ORR (19.05% vs. 27.19%, P=0.226) and DCR (96.83% vs. 95.61%, P>0.999) were comparable between groups. In patients with bone metastases, denosumab treatment was associated with prolonged PFS (P=0.031), whereas bisphosphonates showed no significant benefit (P=0.964). Patients receiving ≥5 doses of denosumab had significantly longer OS compared to those without bone-targeted therapy (P<0.001).

Conclusions: Bone metastases may negatively impact survival outcomes in advanced NSCLC patients receiving first-line immunotherapy. Denosumab combined with immunotherapy may improve clinical outcomes, and prolonged use may further enhance treatment efficacy.

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.15 Bimodal Onset and Pan-Cancer Uniformity of Immune-Mediated Liver Injury: A Retrospective Cohort Study

Y. Xia[1], J. Song[2], B. Xu[2], L. Yu[3], H. Fu[4], B. Wang[4], M. Zhou[3], Y. Hu[2], X. Chen[5]
[1]Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou City, Zhejiang Province/CN ,[2]The First People's Hospital of Linhai, Taizhou, Zhejiang [317000], China., Taizhou/CN ,[3]Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang [310052], China., Hangzhou/CN ,[4]Taizhou First People's Hospital, Taizhou, Zhejiang [317000], China., Taizhou/CN ,[5]The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN

Introduction: Immune-mediated liver injury (IMLI) is a critical adverse event in patients treated with PD-1/PD-L1 inhibitors. The study aims to characterize the clinical heterogeneity, temporal dynamics, and immunological drivers of PD-1/PD-L1 inhibitor-associated IMLI and optimize surveillance and management strategies.

Methods: We retrospectively recruited 373 IMLI patients. We evaluated clinical data, including liver injury patterns, severity, temporal trends, and immune cell subsets. Statistical analyses identified risk factors for severe IMLI and temporal dynamics.

Results: Among 373 patients (median age: 65 years; male: 74.8%), IMLI severity was graded as G1 (53.9%), G2 (25.2%), G3 (17.9%), and G4 (2.7%), with hepatocellular (17.2%), mixed (42.6%), and cholestatic (40.2%) patterns observed. The median time to onset was 106-115 days across severity groups. In contrast, recovery time was significantly prolonged (G3/4: 23 days vs. G1/2:14 days, $P<0.05$), and recovery-phase $CD8^+$ T cells (524.9 vs. 270.68 cells/μL, P=0.026) were higher in severe cases. Bimodal onset peaks occurred at 1-2 months and 3-4 months, with 88% recovering within 100 days. No tumor-type differences existed in patterns (P=0.427) or severity (P=0.054). Elevated baseline NK cells (OR=1.004, P=0.036) predicted severe IMLI.

Conclusions: IMLI demonstrates bimodal onset and pan-cancer uniformity, driven by systemic immune dysregulation. Baseline NK cells are potential predictors of severity. Risk-adapted monitoring within 4 months post-ICI and standardized protocols are recommended.

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.16 Immunotherapy Rechallenge of Advanced NSCLC Patients Who Progressed on 3rd-Generation of EGFR-TKI and Immunotherapy Sequentially

S. Hu, X. Shi, C. Chen, X. Wang, G. Zhou
The Affiliated Cancer Hospital of Nanjing Medical University, Jiangsu Cancer Hospital, Nanjing,Jiangsu Province/CN

Introduction: Whether patients with advanced NSCLC should choose immunotherapy rechallenge after the sequential treatment of EGFR-TKIs and immunotherapy is currently unclear.

Methods: We evaluated the following treatment (immunotherapy rechallenge or non-Immunotherapy) of 131 patients who progressed on 3nd generation of EGFR-TKIs and immuno-based therapy sequentially. We assessed progression-free survival (PFS) of these patients. We further explored the overall survival (OS) of patients choosing immunotherapy rechallenge and potential benefit group of immunotherapy rechallenge.

Results: The immunotherapy rechallenge group had higher PFS months of non-immunotherapy group with no statistical difference (3.33 (95%CI:2.83-3.90) vs 2.83 (95%CI: 2.47-4.13), P=0.609). The rechallenge of immunotherapy reached higher PFS for patients with a progression pattern of new organ metastases than non-immunotherapy(4.80 (95%CI: 3.31-6.30) vs 2.10 (95%CI:1.54-2.67) months, P=0.01). Those who responded positively to first-time immunotherapy reached better efficacy (PR of longer PFS). Patients achieved PR, SD and PD had median PFS of 5.38(95%CI:3.23-NA), 3.28(95%CI:2.67-3.90) and 2.23 months(95%CI:1.40-NA)(P=0.051)and median OS of 74.47(95%CI: 32.83-NA),59.03(95%CI: 37.87-68.23)and 23.67 months (95%CI:20.67-NA)(P=0.005). We chose the cut-off value of 7.7 months (10 cycles of immunotherapy) in first-time immunotherapy PFS. Patients who were sensitive to first-time immunotherapy (PFS>7.7 months) had longer PFS and OS than others (PFS:3.48 (95%CI:2.17-NA)vs 3.33 (95%CI:2.60-3.90)months(P=0.046), OS: 85.07 (95%CI:61.47 - NA) vs 41.50 (95%CI:31.77 - 52.33) months (P=0.006)).

Conclusions: Patients who progressed on EGFR-TKIs and immunotherapy sequentially with the progression pattern of new organ metastases and great response of first-time immunotherapy may be the optimal group of immunotherapy rechallenge.

EP.11.17 Promising Effect of Nivolumab With Carboplatin, Paclitaxel, and Bevacizumab in EGFR-Mutant NSCLC Following EGFR-TKI Therapy

A. Narumi, Y. Toi, S. Minami, S. Yamanda, Y. Kimura, S. Sugawara
Sendai Kousei Hospital, Sendai-shi/JP

Introduction: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) are the standard first-line treatment for patients with EGFR-mutant non-small cell lung cancer (NSCLC). However, resistance to EGFR-TKIs inevitably develops, making platinum-based chemotherapy the primary subsequent treatment option. Although the ONO-4538-52/TASUKI-52 trial evaluated nivolumab in combination with chemotherapy and bevacizumab (NBCP) as a first-line treatment in patients with non-squamous NSCLC, its findings have raised interest in the potential utility of this combination beyond the first-line setting. This study evaluates the efficacy and safety of NBCP compared with ABCP (a combination of atezolizumab, bevacizumab, carboplatin, and paclitaxel) in patients with EGFR-mutant advanced NSCLC who have progressed after EGFR-TKI therapy.

Methods: A single-center retrospective analysis was conducted on 31 patients with EGFR-mutant NSCLC treated with either ABCP or NBCP between 2019 and 2024. The primary endpoints were progression-free survival (PFS) and overall survival (OS), and the secondary endpoint was the incidence of adverse events (AEs). All patients had received prior EGFR-TKI therapy.

Results: NBCP demonstrated efficacy comparable to ABCP. The median PFS was 8.7 months versus 4.4 months, and the median OS was 23.4 months versus 9.9 months. The hazard ratio for PFS was 0.48 (95% confidence interval [CI]: 0.21-1.06), and for OS was 0.53 (95% CI: 0.20-1.37). The AE profiles were similar, though grade 3-4 neutropenia was more frequent in NBCP, while liver dysfunction was less common.

Conclusions: NBCP showed efficacy comparable to ABCP as a treatment for EGFR-mutant advanced NSCLC after EGFR-TKI therapy, with an acceptable safety profile. NBCP may be a viable alternative to ABCP for patients with EGFR-mutant advanced NSCLC who have experienced disease progression following EGFR-TKI treatment.

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.18 Non-Small Cell Lung Cancer Metastases to Adrenal Glands Are Not Differentially Sensitive to Immune Checkpoint Inhibitors

c. soutif, L. Pirard, F. Duplaquet, T. Vander Borght, N. Mulquin, O. Sebahat
CHU UCL namur, Yvoir/BE

Introduction: Adrenal gland metastases (AGM) are common in advanced-stage non-small cell lung cancer (NSCLC), occurring in up to 20% of patients. Immune checkpoint inhibitors (ICIs) have markedly improved the outcome of patients suffering from NSCLC. However, some case series/retrospective studies have suggested that responses to ICIs in AGM are lower than in other metastatic sites, particularly in melanoma, while a better overall survival (OS) with AGM than bone or cerebral metastases has been reported in NSCLC. The most-accepted hypothesis to explain a lower efficacy of ICIs in adrenal glands is the production of glucocorticoids in this organ, countering the action of ICIs. We aimed to investigate whether having AGM is associated with a poorer outcome and whether ICI responses are lower in adrenal glands as compared with other organs in patients with metastatic NSCLC.

Methods: We retrospectively compared tumor response rates, overall (ORR) and specifically in adrenal glands (AGMRR), central nervous system (CNSMRR), liver (LMRR), and bone (BoMRR), as well as OS in 42 patients with NSCLC and AGM and a control group of 86 patients with metastatic NSCLC but no AGM, who were treated with an ICI (PD-(L)1 inhibitor) in monotherapy in first or second-line at a single institution between January 2017 and January 2023. Tumor responses were evaluated using RECIST 1.1. OS was defined as the time between ICI initiation and death or last date known alive.

Results: In the AGM group vs the no-AGM group, patient main baseline characteristics were similar, with a median age of 65 years vs 67 years (P=0.4), 69% vs 69% males (P>0.9), and 71% vs 67% non-squamous NSCLC (P=0.6). ORR was 23.8% in patients with AGM vs 28% in those without AGM (P=0.8). AGMRR was 29% vs 23% CNSMRR (P=0.6), 44% LMRR (P=0.8), and 14% BMRR (P=0.5). Median OS was 8.9 months in the AGM group and 11.1 months in the no-AGM group (P=0.7).

Conclusions: In this monocentric cohort of patients with metastatic NSCLC treated with an ICI in monotherapy, we did not find any significant difference in ORR or OS between patients with AGM and those without AGM. Moreover, we did not find any significant difference between AGMRR and tumor response rates in the other frequent metastatic sites.

EP.11.19 Efficacy and Safety of Continuing Tislelizumab After Progression of First-Line Tislelizumab in Patients With Advanced NSCLC

B. Qin[1], X. Ge[1], J. Zhai[1], Y. Mao[1], S. Sheng[1], Y. Jia[1], Y. Gao[1], Y. Li[1], L. Lin[1], M. Li[2], H. Zhou[2], J. Wang[1]
[1]the Fifth Medical Center, Chinese PLA General Hospital, Beijing/CN ,[2]Nankai University, Tianjin/CN

Introduction: Immune checkpoint inhibitors (ICIs) have changed the management of non-small cell lung cancer (NSCLC). However, resistance is inevitable and therapeutic options beyond resistance remain challenging. Treatment beyond progression of ICIs was evaluated in NSCLC patients from clinical trials as well as real-world clinical, but changing ICIs potentially introduced confounding factors.

Methods: A retrospective analysis was conducted on NSCLC patients who progressed after first-line treatment with tislelizumab (PD-1 inhibitor) at the Fifth Medical Center of the Chinese PLA General Hospital between January 2020 and December 2023. All enrolled patients had to have histologically or cytologically confirmed stage IIIB/IIIC or newly diagnosed stage IV NSCLC and have received at least two cycles of first-line treatment with tislelizumab. All patients had documented evidence of disease progression after the first line treatment. Eligible patients were divided into two groups: those who received second-line treatment with tislelizumab combined with chemotherapy and those who received chemotherapy alone. Patients received anti-angiogenic agents on the second line were permitted. The primary endpoint was time to treatment failure (TTF) for first-line plus second-line treatment.

Results: Thirty-three patients were included in the study, with 16 patients in the tislelizumab group and 17 in the chemotherapy group. The median age was 65 years, 63.64% of patients were stage IV, and the proportion of squamous versus adenocarcinoma patients was 66.67% and 21.21%, respectively. Baseline characteristics were balanced between the two groups. The median TTF for second-line treatment was longer in the tislelizumab group compared to the chemotherapy group (4.23 vs. 2.76 months, HR 0.55 [0.25-1.20]). The median TTF for first-line and second-line treatments combined was 13.57 months in the tislelizumab group and 9.54 months in the chemotherapy group (Fig. HR 0.59 [0.27-1.23]). No new safety signals were observed in continuing tislelizumab post-PD, only G1-2 irAEs were observed in 2 patients (2/16, 12.5%).

Conclusions: Continuing tislelizumab treatment post-PD is associated with a positive benefit risk in NSCLC patients. Further analysis with larger samples size is needed to identify the patients who gained more survival benefits and the optimal combination.

Introduction: Chemo-immunotherapy is the standard frontline treatment of advanced non-squamous non-small cell lung cancer (nsq-NSCLC). Among oncogenic drivers, KRAS mutation accounts for ~25% of lung adenocarcinomas, with KRAS p.G12C being the most common variant (~40%).This study aimed to explore the clinical characteristics and survival outcomes according to KRAS mutation in a real-life population of nsq-NSCLC patients treated with platinum-pemetrexed-pembrolizumab as first-line therapy.

Methods: This is a retrospective-prospective study including patients with nsq-NSCLC who received first-line platinum-pemetrexed-pembrolizumab from September 4th, 2018 in 33 Italian Centers.

Results: Of 874 patients assessable for KRAS status, 121 (13.8%) had KRAS p.G12C mutation, 201 (23.0%) KRAS non-p.G12C mutation and 443 (50.7%) KRASwt. KRAS-mutated (KRASm) patients were more often smokers compared to KRASwt (90.6% vs 84.1%, p=0.012). Bone metastases were more frequent in KRASm than KRASwt patients (44.1% vs 35.9%; p=0.022).Median real-world progression-free survival (PFS) was shorter in KRASm than KRASwt patients (median PFS 8.8 vs 10.8 months; adjusted Hazard Ratio [HR] 1.29, 95% Confidence Interval [CI] 1.04-1.59, p=0.018). Among KRASm patients, KRAS p.G12C exhibited the same PFS than KRAS non-p.G12C (8.8 months, HR 0.95, 95%CI: 0.70-1.30, p=0.756).No statistically significant difference in overall survival (OS) was found between KRASm and KRASwt patients (median OS 16.7 vs 18.2 months; adjusted HR 1.19, 95% CI 0.95-1.50, p=0.132). Among KRASm patients, no difference in OS was found between KRAS p.G12C and KRAS non-p.G12C (median OS 15.9 vs 17.0 months respectively, HR 0.93, 95%CI: 0.66-1.31, p=0.676). Real-world objective response rate (ORR) and duration of response (DoR) were similar between KRASm and KRASwt patients (ORR KRASm vs KRASwt 41.6% vs 47.6%, p=0.106; DoR KRASm vs KRASwt 13.8 vs 14.8 months, p=0.606).

Conclusions: KRAS mutation had a potential negative predictive role in advanced nsq-NSCLC patients treated with first-line chemo-immunotherapy in a real-life setting. The impact of co-mutations and post-progression outcomes warrant further investigation.

EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.21 Efficacy of Immunotherapy in EGFR-Mutant NSCLC After Tyrosine Kinase Inhibitors: Real World Analysis at a Tertiary Oncology Center in Hong Kong

G.W.G. Kwok, A. Helali, H. Kwok, T. Fung, F. Sun, A. Chan, R. Leung, R. Hui
University of Hong Kong, Hong Kong/HK

Introduction: The efficacy of anti-PD1/PD-L1 immunotherapy (IO) added to platinum-based chemotherapy in EGFR-mutant NSCLC after tyrosine-kinase inhibitors (TKI) is unclear. Here we report real world outcomes in EGFR-mutant NSCLC patients who received anti-PD1/PD-L1 immunotherapy after progression on TKI.

Methods: We retrospectively identified patients with histological diagnosis of EGFR mutation positive advanced lung adenocarcinoma treated at Queen Mary Hospital between 1/1/2017 and 31/12/2022 from the electronic medical record of the Hospital Authority in Hong Kong. Patients with sensitizing mutations must have progressed on 1 or more TKI (gefitinib, erlotinib, afatinib, osimertinib) and subsequently received platinum-doublet chemotherapy with or without concurrent IO +/- bevacizumab. The date of commencement of chemotherapy was considered as index date. We explored the efficacy of any immunotherapy on overall survival (OS), and on real-world progression free survival (rwPFS)/OS with respect to PDL1 expression (<1%, 1-49%, >50% TPS). Survival was analyzed by the Kaplan-Meier method and between groups comparisons by the log-rank test or Fisher exact test.

Results: Of 104 patients with EGFR-mutant NSCLC, median age was 62.3 years (range 32.4-78.0), 65.4% were female and 79.8% non-smokers. All except 3 patients with exon-20 insertions had prior TKI, of which 38.6% received osimertinib (10.9% as 1st line TKI). At data cutoff on 31/12/2024, median OS was 20.0 months (95% CI 13.9 - 24.5). 36 patients who received any IO either in combination with anti-VEGF and chemotherapy (72.2%), with chemotherapy, or as late-line monotherapy, had an OS of 24.0 months (95% CI 16.8 - 33.1) vs 15.7 months (95% CI 10.0 - 24.5) for those without IO (log-rank P=0.83). PD-L1 expression by TPS was available in 75 patients (57.3%, 25.3%, and 17.3% in the <1%, 1-49%, and >50% category respectively), but was not predictive of rwPFS (P=0.37) or OS (P=0.76) in IO users. Patients who received IO in combination with platinum chemotherapy and bevacizumab showed a trend for improved OS (25.8 vs 16.3 months, P = 0.4) compared with those who did not receive the combination. This regimen showed meaningful improvement in rwPFS (9.7 vs 3.2 months, P=0.024) and objective response (34.5% vs 0%, P=0.15) among IO users.

Conclusions: Our real-world analysis highlights the limited therapeutic benefit of anti-PD1/PD-L1 immunotherapy in EGFR-mutant NSCLC after TKI progression. Our data suggests that the optimal efficacy of immunotherapy is in second line when prescribed with platinum chemotherapy and bevacizumab. PDL1 expression as a biomarker was not predictive of immunotherapy outcomes.

EP.11.22 Efficacy and Safety of Atezolizumab Plus Bevacizumab-Based Therapy in Non-Small Cell Lung Cancer: A Meta-Analysis of Clinical Trials

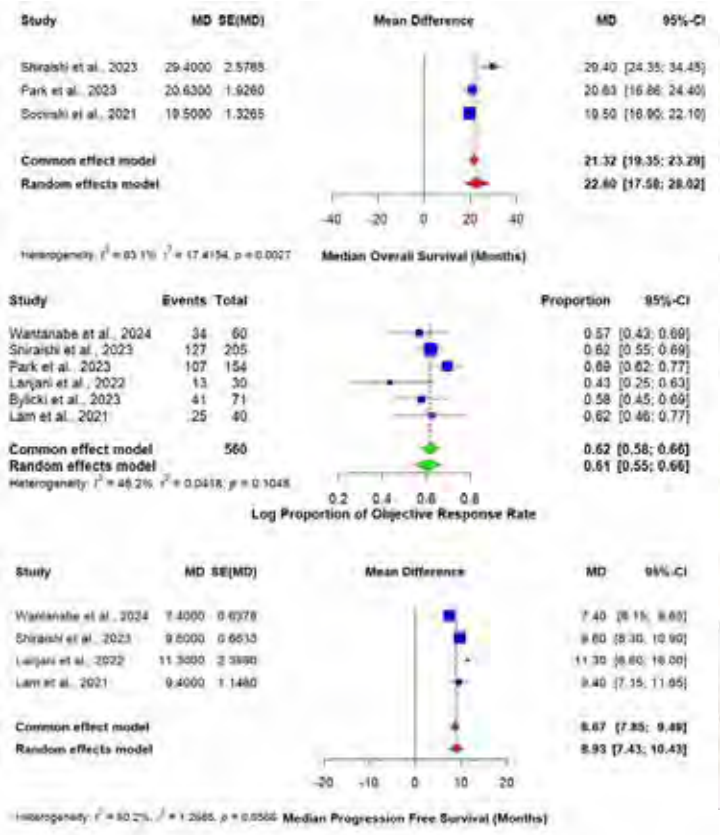
D.K. Rohita[1], A.B. Shrestha[2], A. Cheema[1], A. Usama[1], M.R. Islam[3], F. Chowdhury[4], A. Devkota[5], S.A. Mohamed[6], H. Singh[7], A. Subedi[8], Z. Thet[1]
[1]Wyckoff Heights Medical Center, Brooklyn/NY/USA ,[2]Patan Academy of Health Sciences Hospital, Patan/NP ,[3]Shaheed Suhrawardy Medical College Hospital, Dhaka/BD ,[4]Chittagong Medical College, Chattogram/BD ,[5]Medstar Health, Baltimore/MD/USA ,[6]DMC Sinai Grace, Detroit/MI/USA ,[7]Bronx Healthcare System, Bronx/NY/USA ,[8]University of Maryland Capital Region Health, Baltimore/MD/USA

Introduction: Combination of immunotherapy, particularly anti-programmed cell death 1 protein and anti-programmed cell death 1 ligand 1 (PD-L1) with Antiangiogenic drug are a novel approach to treatment for lung cancer. However, its efficacy and safety remains limited in patients with Non-small Cell Lung Cancers (NSLC).

Methods: A systematic search was conducted on various databases, Pubmed, Embase and Scopus since inception until Jan 2025. Appropriate search strategy was done using MeSh terms for; Atezolizumab, Bevacizumab and Non-small cell lung cancer. Proportional analysis was done for the intervention group using the software R.

Results: A total of seven trials were included with 960 patients in the Atezolizumab and Bevacizumab group with mean age of 63.3 yrs and duration of follow up being 21.4 months. Efficacy outcomes meta-analysis: Median Objective Response; 61%, 95%CI: 55-66%, Median Progression Free Survival; 8.93 months, 95%CI: 743-10.43, Median Overall Survival, 22.8 months, 95%CI: 17.58-28.02 and Median Duration of Response; 7.44 months, 95%CI: 4.8-10.08. Safety outcomes meta-analysis: All Adverse Event; 99%, 95%CI: 97-99%, Any treatment emergent adverse event; 99%, 95%CI: 95-100%, Any Treatment Related Adverse Events (TRAE); 91%, 95%CI: 73-97%, Any Serious Adverse Event: 34%, 95%CI: 14-62%, TRAEs leading to dose interruption or modification; 25%, 95%CI: 2-82%, TRAEs leading to permanent discontinuation; 2%, 95%CI: 1-5%, and TRAEs leading to Death; 2%, 95%CI: 1-5%.

Conclusions: These findings suggest that Atezolizumab and Bevacizumab combination is a potential treatment for NSCLC. However, to validate this result more randomized trials are required.



EP.11 METASTATIC NON-SMALL CELL LUNG CANCER – IMMUNOTHERAPY

EP.11.23 Sex-Based Differences in Immune Toxicity Without Survival Trade-Offinlate-Lineici Therapy for Lung Cancer

B. Resuli[1], J. Walter[1], D. Kauffmann-Guerrero[1], P. Mertsch[1], J. Behr[1], A. Tufman[1]
[1]LMU University Clinic, Munich/DE

Introduction: Sex-based immunological differences may shape both therapeutic efficacy and toxicity profiles of immune checkpoint inhibitors (ICIs). Although several first-line ICI trials have reported sex-specific variations in clinical outcomes, real-world evidence in the late-line setting remains limited. This study aimed to evaluate the impact of gender on treatment efficacy and immune-related toxicity in patients receiving late-line ICI therapy prior to the approval of ICIs in the first-line setting.

Methods: We conducted a retrospective analysis of administrative claims data from lung cancer patients diagnosed between 2015 and 2016 and insured under a major German statutory health fund. Patients who received at least two cycles of immune checkpoint inhibitor (ICI) therapy were included. Sex-based comparisons were performed for the incidence of immune-related adverse events (irAEs), other treatment-related toxicities, ICI treatment duration, and overall survival (OS), utilizing chi-square tests, Student's t-tests, and Kaplan-Meier survival analysis with log-rank testing.

Results: Among 342 patients (244 men, 98 women), female patients were significantly younger at treatment initiation (mean age 63.0 vs. 65.6 years; p=0.01). The median interval from diagnosis to initiation of ICI therapy did not differ significantly between sexes (506.5 days in women vs. 486 days in men; p=0.69). Although the overall incidence of immune-related adverse events (irAEs) was higher in women compared to men (43.9% vs. 34.4%), this difference did not reach statistical significance (p=0.13). However, specific toxicities were more frequent among female patients, including hyperthyroidism (13.3% vs. 6.1%; p=0.05) and nausea or vomiting (35.8% vs. 24.6%; p=0.01). No significant sex-based differences were observed in the number of ICI treatment cycles or overall survival (p=0.27).

Conclusions: This real-world analysis demonstrates that female patients undergoing late-line ICI therapy exhibit a distinct and more pronounced toxicity profile, despite no observable differences in treatment duration or overall survival. These findings challenge generalized assumptions regarding sex-based benefit in immunotherapy and underscore the importance of nuanced, sex-specific toxicity monitoring. As immuno-oncology advances toward increasingly personalized approaches, biological sex should be regarded as a critical variable in both therapeutic decision-making and toxicity management—rather than a simplistic surrogate for clinical benefit.

EP.11.24 A CT Based Tumor Microenvironment Specific Radiomics Signature for Predicting the Efficacy of Checkpoint Inhibitor Therapy in Advanced NSCLC

H. Zhou[1], Q. Huang[1,2]
[1]Department of Thoracic Surgery, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou [510080], China., Guangzhou/CN ,[2]Guangdong Cardiovascular Institute, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, [510080] Guangdong, China., Guangzhou/CN

Introduction: Develop a CT-based tumor microenvironment (TME)-specific radiomics signature model combined with clinical information to construct a nomogram for predicting the efficacy of immune checkpoint inhibitors (ICIs) in advanced non-small cell lung cancer (aNSCLC).

Methods: Data from TCGA, GEO, and TCIA were integrated. WGCNA was used to identify Immunotherapy Related Genes(IRGs) in GEO, which were used to build prognostic models in TCGA. The tumor immune microenvironment were analyzed. Radiomics features were extracted from TCIA's lung_3 cohort using PyRadiomics, with 94 features strongly associated (r > 0.4) with IRGs selected. A retrospective analysis of 210 NSCLC patients from Guangdong Provincial People's Hospital was conducted, with patients divided into training (n=147) and validation (n=63) groups. In the training group, use Least Absolute Shrinkage and Selection Operator (LASSO) to screen radiomic features, then build clinical-radiomic combined model and nomogram for predicting ICIs response via logistic regression. Evaluate model performance using Receiver Operating Characteristic (ROC) curve, calibration curve, and decision curve.

Results: IRGs related to the immune response activation pathway. The TME - based radiomics signature with clinical features effectively predicted ICI efficacy. The combined model outperformed individual models in both training (AUC = 0.725, 95% CI: 0.644 - 0.807) and validation cohorts (AUC = 0.706, 95% CI: 0.577 - 0.836). Calibration curve and decision curve analysis (DCA) of the nomogram confirmed its clinical utility.

Conclusions: The "genomic-radiomic-clinical" multidimensional predictive framework established in this study provides an interpretable biomarker combination and clinical decision-making tool for efficacy evaluation of immunotherapy in aNSCLC.

Introduction: ROS1 rearrangements occur in 1-2% of metastatic NSCLCs (mNSCLC), confer aggressive biology and Concurrent mutations may add to these challenges. We present here mutational profile and therapeutic outcomes of ROS1 fusions from a community oncology practice

Methods: A retrospective analysis was conducted for ROS-1-positive mNSCLCs treated between March 2018 and September 2024. Clinical and molecular data was extracted from electronic medical records, highlighting ROS-1 mutation types, treatment modalities, and clinical outcomes

Results: A total of 2281 patients were diagnosed with mNSCLC out of which 43 patients were ROS-1 positive (1.88%). The median age of the cohort was 60 years (32-83); with M:F ratio being 1.15:1 and 4 patients were diagnosed at less than 40 years of age. ROS1 alteration testing was done by FISH(3/43), IHC(10/33) and NGS(14/43) while no records of testing method were available for 16/43. On NGS testing, the most common rearrangement partners were SDC4 (n=3), SLC34A2 (n=2), CD74 (n=3), and EZR(n=2). ROS rearrangement was associated with co-mutations in 15/43 patients which constitute co-mutations with EGFR (n=9), TP53 (n=5), and EGFR+ALK (n=1). Brain metastasis at baseline were detected in 10/43 patients of which 4/10 underwent upfront Radiation treatment and 2/10 underwent surgical resection. Tyrosine Kinase Inhibitors (TKIs) were used alone in 28/43 (65.1%) and as a combination with chemotherapy in 2/43 (4.6%), only chemotherapy was used in 7/43 (16.2%) patients. Of the TKIs, Crizotinib was used in 20, Enterectinib was used in 6 and Lorlatinib was used in 3 patient. The median overall survival (mOS) of the cohort was 42.3 mo (with 95% CI 31.5-53.2) with a median follow-up of 32.8 mo (with 95% CI of 18.1-47.4) with no significant difference outcomes between males and females. The mOS was 39.1 mo (95% CI NA-NA) for ROS1-positive patients and 42.3mo (95% CI 16.9-67.8) for those with co-mutations (p = 0.33). The mOS was 42.3 mo for ROS1+EGFR co-mutations and 21.9 mo for ROS1+TP53 co-mutations

Conclusions: ROS-1 rearrangements are uncommon, availability of 1st generation TKIs has significantly improved survival however, access to newer-generation TKIs with intracranial penetration is important to further improve outcomes. Comutations have lower survival outcomes emphasizing the molecular profiling in these patients

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.02 Efficacy and Safety of Firmonertinib for EGFR Exon 21 L858R Mutation-Positive NSCLC Patients With Brain Metastases

H. Su, Y. Kang, H. Shi, C. Liao, N. Ma, D. Liu, Y. Shan, Y. Song, L. Liu, j. Min
Tang-Du Hospital, Xi'an/CN

Introduction: The frequency of brain metastases is reported to be 48% to 50% in advanced non-small cell lung cancer (NSCLC) patients with epidermal growth factor receptor (EGFR) mutations. Patients with advanced EGFR exon 21 L858R mutation-positive NSCLC show poor outcomes compared with EGFR exon 19 deletion. Firmonertinib is a pan-EGFR tyrosine kinase inhibitor (TKI) known for its high brain penetration and broad therapeutic window. This study aims to prospectively evaluate the efficacy and safety of firmonertinib in EGFR mutation-positive NSCLC patients with brain metastases. Here we present preliminary data focusing on the EGFR exon 21 L858R mutation -positive NSCLC patients with Brain Metastases.

Methods: EGFR-mutant NSCLC patients with brain metastases who were prescribed Firmonertinib were enrolled. Eligible patients were aged at least 18 years old and had histological or cytological confirmed advanced NSCLC harboring an EGFR mutation. The primary endpoints in this prospective observational study included intracranial progression-free survival (iPFS), intracranial objective response rate (iORR) and intracranial disease control rate (iDCR). Secondary endpoints included PFS, ORR, DCR, and safety.

Results: Ten patients with EGFR exon 21 L858R mutation from Tang-Du Hospital were enrolled, including four (40%) with an ECOG score of ≥2. All patients received firmonertinib as first-line treatment. Six patients (60%) received 80 mg, while four patients (40%) were treated with 160 mg of firmonertinib. The median follow-up time was 16.8 months. The median iPFS was not reached (95%CI:NA-NA). Among 10 patients with measurable brain lesions, the iORR and iDCR were 80% and 100% respectively. Overall, the median PFS was not reached (95%CI:NA-NA), ORR and DCR were 90% and 100%. Specifically, in the 80 mg group, the ORR was 83.33% and DCR was 100%, while in the 160 mg group, both ORR and DCR were 100%. Notably, All four patients with an ECOG PS score ≥2 achieved PR (partial response) in both intracranial and overall assessments. Five patients experienced Grade 1 treatment-related adverse events (TRAEs), with no Grade 2 or higher TRAEs reported.

Conclusions: Firmonertinib showed encouraging anti-tumor efficacy and manageable safety in EGFR exon 21 L858R mutant NSCLC patients with brain metastases, despite a significant proportion of individuals having poor performance status.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.03 Study on the Effects of Anlotinib Combined with PD-1 Antibody in Lung Cancer Rats and Its Impact on the PLGF/Flt-1 and TGF-ß1 Pathways

S. Tang[1], T. Zhang[2], J. Zhang[2]
[1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Guangzhou/CN ,[2]Shenzhen Hospital, Southern Medical University, Shenzhen/CN

Introduction: To investigate the effect of anlotinib combined with PD-1 monoclonal antibody on rats with lung cancer and its effect on placental growth factor (PLGF)/vascular endothelial growth factor receptor (Flt-1) and transforming growth factor-β1 (TGF-β1) pathways.

Methods: Fifty SD rats were selected as the subjects, 10 SD rats were randomly selected as the blank control group, and the remaining 40 SD rats were randomly divided into model control group, anlotinib group, PD-1 monoclonal antibody group, and combined treatment group, with 10 rats in each group. The model control group and the blank control group were intraperitoneally injected with the same amount of normal saline, the anlotinib group was treated with anlotinib by gavage, the PD-1 monoclonal antibody group was treated with PD-1 monoclonal antibody, and the combination group was treated with anlotinib combined with PD-1 monoclonal antibody. The immune cell infiltration, angiogenesis, PLGF/Flt-1 and TGF-β1 pathway levels in each group were compared.

Results: After 2 weeks of intervention, the combined treatment group had significantly higher counts of CD4+T cells, CD8+ red blood cells, and CD68+ macrophages than the model control, anlotinib, and PD-1 monoclonal antibody groups ($P<0.05$). The number of CD206+ macrophages was lower than that of the other three groups ($P<0.05$). The results of immunohistochemistry showed that the angiogenesis of the combined group was relatively less, and the number of yellow particles was less. There was no significant difference in angiogenesis between anlotinib group and PD-1 monoclonal antibody group. The results of real-time fluorescence quantitative PCR and Western Blot showed that the mRNA and protein levels of PLGF, Flt-1, and TGF-β1 in the combined group were lower than those in the model control group, anlotinib group, and PD-1 monoclonal antibody group ($P<0.05$).

Conclusions: Anlotinib combined with PD-1 monoclonal antibody can reduce immune cell infiltration and inhibit angiogenesis in rats with lung cancer, and the mechanism may be related to PLGF/Flt-1 and TGF-β1 pathways.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.04 Efficacy of EGFR TKIs of a Rare but Sensitive Subtype of EGFR L833V/H835L Mutation in Advanced NSCLC

Y-L. Sun
Guangdong Lung Cancer Institute, Guangzhou/CN

Introduction: Epidermal growth factor receptor (EGFR) gene mutations represent the most prevalent genomic aberrations in non-small-cell lung cancer (NSCLC). Among these, exon 19 deletions and exon 21 L858R mutations constitute approximately 90% of all EGFR mutations. Large-scale Phase III clinical trials have consistently demonstrated that NSCLC patients harboring these canonical mutations exhibit favorable responses to EGFR tyrosine kinase inhibitors (TKIs) with prolonged progression-free survival (PFS). However, 10%-15% of EGFR mutations are classified as uncommon variants, including compound mutations involving two rare variants or a combination of common and rare mutations. Due to their exclusion from most clinical trials, evidence regarding TKI efficacy in this subgroup remains limited to small retrospective cohorts. This study investigates the therapeutic activity of EGFR TKIs in advanced NSCLC patients with the rare L833V or H835L mutation.

Methods: We retrospectively analyzed 13 NSCLC patients diagnosed with L833V or H835L compound mutations at Guangdong Lung Cancer Institute between 2016 and 2022. Clinical data, treatment regimens, and survival outcomes were systematically collected. Additionally, a PubMed search identified 13 published cases of L833V/H835L mutations, yielding a pooled cohort of 26 patients for analysis.

Results: The median age of the 26 patients was 66 years (range: 36-89), with a predominance of adenocarcinoma histology (100%). Most patients were non-smokers (n=18) and male (n=11). TKI sensitivity was observed across generations of EGFR inhibitors. Notably, patients with L858R/L833V mutations achieved significantly longer PFS compared to historical data from trials involving common EGFR mutations. One elderly patient with an isolated H835L mutation exhibited sustained response to afatinib (PFS: 12.7 months). Furthermore, other L833V-containing compound mutations demonstrated superior survival benefits relative to classical EGFR variants.

Conclusions: The L833V/H835L compound mutation in advanced NSCLC demonstrates enhanced sensitivity to EGFR TKIs, with survival outcomes potentially surpassing those observed in common EGFR-mutated cohorts. These findings underscore the need for prospective studies to validate the therapeutic implications of rare EGFR variants.

Table 1. Clinical characteristics, treatment regimen and prognosis of NSCLC patients harboring the L833V or H835L mutation.

	Reported /Diagnosis Year	Sex	Age (year)	Pathological type	Smoking status	EGFR Mutations	Treatments	PFS (months)

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.05 The Effect of a Dutch Breakfast on the Exposure of Alectinib Using a Microtracer Approach: A Proof-Of-Concept Study

M.I. Mohmaed Ali
The Netherlands Cancer Institute, Amsterdam/NL

Introduction: Alectinib is advised to be taken with food to enhance bioavailability, based on a food-effect study with a high caloric and high fat breakfast. This breakfast does not reflect a standard breakfast in many countries, including the Netherlands (containing less energy and fat), making extrapolation of the food-effect to Dutch patients challenging. Thus the food-effect should be re-evaluated at a steady state, which requires extended periods of standardized meal intake and prolonged hospital stays, especially for drugs with long half-lives like alectinib. An alternative approach is using microdoses of stable isotopically labeled drugs (microtracers) to study the food-effect. The food-effect is determined on the pharmacokinetics (PK) of the microtracer without affecting therapeutic treatment of the oral anticancer drug. The aim of our study is to investigate the food-effect of a Dutch breakfast on alectinib PK using the microtracer 2H6-alectinib.

Methods: A prospective, single-centre, open-label, cross-over study assessed the food-effect on the microtracer 2H6-alectinib (100µg) in ALK-positive non-small cell lung cancer (NSCLC) patients on 600mg alectinib bidaily. Patients were hospitalised for twelve hours on two occasions, with at least a seven-day washout. On day one (fed state), patients received the microtracer with their regular dose and a standardized Dutch breakfast (320-392 kcal, 7.5-7.8g fat). On day two (fasted state), patients received the microtracer and alectinib without food. During the washout, they continued alectinib without dietary restrictions. PK samples were collected up to eight hours post-dose on both days.

A population PK model was developed to investigate the effect of food on relative bioavailability (F). Simulations (taking into account uncertainty in final model parameters) were performed to assess the area under the plasma concentration-time curve (AUC) and maximum concentration (Cmax) differences between fed and fasted states.

Results: Ten patients were included with a median age of 57 years (range: 40-72 years), and most of them were diagnosed with stage IV NSCLC. In total 140 PK samples of 2H6-alectinib were available for PK analysis, of which 15 samples were below the lower limit of quantification.

The results show that intake with a Dutch breakfast delays absorption with 28% and increases plasma concentration of the microtracer with 35% (F). The geometric mean of the simulation AUC in fed and fasted state was 980.8 pg*h/mL (coefficient of variation (CV): 31.0%) and 643.9 pg*h/mL (CV: 29.9%), respectively with a ratio (fed vs fasted) of 1.52 (90% Confidence Interval (CI): 1.25-1.89). The geometric mean Cmax in fed and fasted state was 78.2 pg/mL (CV: 28.5%) and 54.9 pg/mL (CV: 27.9%), respectively. The ratio (fed vs fasted) for Cmax was 1.42 (90% CI: 1.16-1.76).

Conclusions: These results show that the intake of a Dutch breakfast leads to a delay in absorption of alectinib, and to higher total exposure. Also, this study demonstrated the feasibility of a microtracer food-effect study using a study design with a relatively low patient burden with only two food-controlled drug administrations and a short period of sample collection.

Introduction: The Brilliant study is a non-interventional, ambispective (retrospective + prospective) study of Chinese patients (pts) treated with brigatinib as first-line therapy from 2022 to 2029 (NCT05721950). The aim is to better understand the real-world practice of brigatinib in China. Here, we report the baseline characteristics and safety based on the first analysis.

Methods: Pts with anaplastic lymphoma kinase positive (ALK+) locally advanced or metastatic non-small cell lung cancer (NSCLC) were eligible and will be followed for up to 3 years. The primary endpoint is real-world time-to-treatment discontinuation. Safety assessments included monitoring treatment-related adverse events (TRAEs), dose modification, and treatment interruption or discontinuation. Pts who received ≥1 dose of brigatinib constituted the safety analysis set.

Results: By June 30, 2024, 82 pts were enrolled with a median follow-up of 3.96 months. Baseline characteristics are shown in the table. The median age was 55.5 years (range 28-80). 7.3% (6 pts) were at stage III and 92.7% (76 pts) at stage IV. 92.7% (76 pts) were reported having ≥ 2 metastatic sites. Any grade and ≥ grade 3 TRAEs were reported in 42.7% (35 pts) and 7.3% (6 pts) of pts, respectively. Any grade TRAEs > 5% included increased aspartate aminotransferase (19.5%), increased blood creatine phosphokinase (17.1%), increased alanine aminotransferase (11%), and rash (6.1%). TRAEs leading to dose modification and interruption occurred in 4 (4.9%) and 3 (3.7%) pts, respectively. Grade 5 events occurred in 1 (1.2%) patient.

Conclusions: The real-world baseline characteristics and safety profile of pts with ALK+ locally advanced or metastatic NSCLC treated with brigatinib align with clinical experience. The study observed that pts with locally advanced stage IIIA and IIIC received brigatinib treatment in real-world clinical practice. Real-world effectiveness and post-treatment will continue to be evaluated.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.07 Using Online Continuing Medical Education to Identify Ongoing Gaps in Global Clinicians' Understanding of HER2-Altered NSCLC

M.A. Worst[1], Z. Fiske[1], N. Dorkham[1], A. Carothers[1], S. Dunn[1], M. Cannon[1], T. Abair[1], E.K. Singhi[2]
[1]Medscape LLC, Newark/NJ/USA ,[2]The University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: Non-small cell lung cancer (NSCLC) treatment is evolving rapidly, with HER2 emerging as a critical biomarker for targeted therapy. Clinicians must accurately recognize HER2 alterations, apply appropriate testing methodologies, and interpret clinical trial data to optimize patient care across the globe. The objective was to assess the knowledge and skills of global oncologists and pathologists related to HER2-altered NSCLC and its ongoing management approaches, as well as highlight ongoing educational gaps to guide future educational efforts.

Methods: An online, text-based CME survey instrument comprising 20 multiple-choice knowledge, practice-based, and confidence questions assessed participants' clinical understanding of HER2-altered NSCLC. The activity launched on August 16, 2024, and data were collected through March 2025. Responses from global oncologists and pathologists were analyzed and compared by grouping questions into clinical themes and calculating the percentage of correct responses in each area.

Results: Analysis of participant data revealed several key trends in understanding of HER2-related concepts in NSCLC, with notable differences between US and outside the United States (OUS) clinicians. Generally, OUS oncologists and pathologists had lower remaining gaps compared to their US counterparts. The most persistent gaps across all clinicians were awareness of clinical trial data and ability to tailor care decisions.

Conclusions: This educational initiative yielded important insights into ongoing practice gaps related to the recognition, testing methodologies, clinical data, and management of HER2-altered NSCLC. The particular deficits related to awareness and applicability of data likely stems from the relative novelty of HER2 as a therapeutic target in NSCLC, highlighting the urgent need for targeted, practice-based education. Further studies are planned to assess the effect of ongoing medical education initiatives in closing these global clinical practice gaps.

Learning Theme	OUS Clinician Remaining Gaps		US Clinician Remaining Gaps	
	Oncologists (n=79)	Pathologists (n=16)	Oncologists (n=43)	Pathologists (n=32)
Recognizing characteristics of HER2 alterations	27%	35%	37%	41%
Understanding of testing methodologies	47%	53%	55%	62%
Awareness of clinical trial data	51%	67%	59%	63%
Ability to tailor care decisions	49%	68%	59%	64%

Table: Remaining gaps by clinician type and geographic practice setting

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.08 A Real-World Study of the Efficacy and Safety of Firmonertinib for Patients With Non-Small Cell Lung Cancer With EGFR Uncommon Mutati

Z. Zhang[1], J. Jiang[1], P. Deng[1], J. An[1], H. Yang[1], L. Cao[1], C. Hu[1], M. Zhang[1], L. Zhang[2], M. Li[1]
[1]Xiangya Hospital, Central South University, Changsha/CN ,[2]The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University/Hunan Cancer Hospital, Changsha/CN

Introduction: Firmonertinib is a novel third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI). The FAVOUR study (NCT04858958, a phase I b trial) demonstrated preliminary efficacy in patients with non-small cell lung cancer (NSCLC) harboring EGFR exon 20 insertion mutations (ex20ins). Additionally, the FURTHER study (NCT05364073, a phase Ib trial) showed promising activity in patients with EGFR P-loop and αC-helix compressing (PACC) mutations. Building on these findings, this study aims to evaluate the real-world efficacy and safety of firmonertinib in patients with locally advanced or metastatic NSCLC harboring uncommon EGFR mutations.

Methods: We retrospectively analyzed the clinical data of patients with locally advanced or metastatic EGFR uncommon mutations non-small cell lung cancer (NSCLC) who were treated with firmonertinib at Xiangya Hospital of Central South University and multiple medical centers in Hunan Province from October 28, 2022, to March 1, 2025. The evaluated endpoints included the objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), and Treatment-Emergent Adverse Event (TEAEs).

Results: As of the data cutoff date (March 31, 2025), 53 patients were enrolled. Mutations were classified based on structure-based classification, with ex20ins identified in 41.5% (22/53) and PACC in 47.2% (25/53). The median follow-up time was 289 days. The ORR and DCR were 77.4% (41/53) and 100.0% (53/53), respectively. The median PFS (mPFS) was 17.8 months (95% CI 10.7-24.8). Specifically, patients with brain metastasis (n=24) had a mPFS of 17.8 months (95% CI: 10.2-25.3), whereas those without (n=29) achieved 19.7 months (95% CI: 4.9-34.6). In terms of treatment line, first-line therapy (n=44) demonstrated a significantly longer mPFS of 17.8 months (95% CI: 7.9-27.6) compared to second-line therapy (n=9, mPFS 9.5 months; 95% CI: 4.1-14.9). In first-line patients, the 80 mg cohort (n=23) had a median PFS not reached (NR), while the 160 mg cohort (n=21) achieved 24.4 months (95% CI: 13.3-35.5). The PFS of patients in the PACC group was significant longer (24.4 months) compared to that of patients in the ex20ins group (14.0 months; P = 0.0345) and the Classical-like group (19.7 months; P = 0.0089). However, there was no statistically significant difference in PFS between the ex20ins and Classical-like groups (P = 0.1287). Overall survival (OS) data remain immature. TEAEs of any grade occurred in 30.2% (16/53) of patients, with Grade 3 TEAEs reported in 1.9% (1/53; oral ulceration). No Grade ≥4 TEAEs, treatment discontinuations, dose reductions, or treatment-related deaths were observed. The most common TEAEs included liver dysfunction (15.9%), oral ulceration (7.6%), rash (5.7%), and diarrhea (3.8%).

Conclusions: Firmonertinib has shown encouraging antitumor activity in patients with locally advanced or metastatic NSCLC harboring uncommon EGFR mutations and a manageable safety, supporting further clinical exploration. EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.09 Third-Generation EGFR-TKIs in T790M-Negative NSCLC After First/Second-Generation EGFR-TKI Failure: A Retrospective Study

W. Su, Z. Cheng, X. Huang
Affiliated Hospital of Guangdong Medical University, Zhanjiang/CN

Introduction: In non-small cell lung cancer (NSCLC) patients resistant to first- or second-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKI), only half develop T790M mutation and thus qualify for the treatment using third-generation EGFR-TKIs. For T790M-negative patients, chemotherapy is the recommended second-line treatment. We compared the efficacy between third-generation EGFR-TKIs and chemotherapy with or without first/second-generation EGFR-TKIs in T790M-negative patients.

Methods: This study included T790M-negative patients with EGFR-mutated advanced NSCLC and progressing after first-line treatment with first- or second-generation EGFR-TKIs. Data on clinical characteristics, disease features, and survival were collected, including general conditions, medical history, imaging, histology, and molecular profiling.

Results: Of 82 patients progressing after first- or second-generation EGFR-TKIs without acquiring T790M, 45 received third-generation EGFR-TKIs and 37 received chemotherapy and/or first/second-generation EGFR-TKIs. We found that third-generation EGFR-TKIs led to significantly longer median progression-free survival (mPFS) than other treatments [10.20 months vs. 5.70 months, P = 0.017]. Subgroup analyses indicated that third-generation EGFR-TKIs had similar mPFS to chemotherapy group but was significantly superior to first/second-generation EGFR-TKIs with or without chemotherapy (10.20 months vs. 4.80 months, P < 0.001; 10.20 months vs. 3.30 months, P = 0.004). The median overall survival (mOS) for patients treated with the third-generation EGFR-TKIs and with non-third-generation therapy was 39.80 months (95% CI 23.14 to 56.46) and 32.40 months (95% CI 18.71 to 46.09), P = 0.408, respectively.

Conclusions: Third-generation EGFR-TKIs significantly improved mPFS in T790M-negative patients with EGFR-mutated advanced NSCLC and resistant to first-line treatment with first- or second-generation EGFR-TKIs.

EP.12.10 Clinical Investigators' (CIs) Preferences for First-Line Therapy of ALK-Positive Metastatic Non-Small Cell Lung Cancer

K.H. Pang[1], J.F. Gainor[2], D. Paley[1], K. Miller[1], T. Cruse[1], L. Petelka[1], D. Lyons[1], T. Wallace[1], G. Kelly[1], K.A. Ziel[1], N. Love[1]
[1]Research To Practice, Key Biscayne/FL/USA ,[2]Massachusetts General Hospital, Boston/MA/USA

Introduction: The management of patients with non-small cell lung cancer (NSCLC) harboring an ALK rearrangement (ALK+) is an important targeted therapy success story in cancer research. However, as is currently observed in a number of oncology scenarios, a lack of head-to-head comparisons between multiple agents in the same class mandates that clinicians consider other clinical, biologic and practical factors to guide decision-making. Little information is available with regards to how clinicians are selecting between the six approved ALK inhibitors.

Methods: In March 2025, 20 US-based and international CIs completed a survey evaluating their preferred first-line treatment for ALK+ metastatic NSCLC (mNSCLC). For each case-based question, one or more key variables (eg, age, sites and extent of metastases, comorbidities, prior therapy) were varied. A modest honorarium was provided.

Results: For a 60-year-old asymptomatic patient with ALK+ mNSCLC (PD-L1 tumor proportion score [TPS] 0) and no comorbidities, CIs preferred lorlatinib over alectinib as their first-line treatment of choice (80% vs 20%). For a patient with multiple bilateral brain metastases requiring whole-brain radiation therapy (WBRT), lorlatinib was also favored (90% vs 10%).

Among patients with various comorbidities (hypertension, diabetes, anxiety/depression, bradycardia, chronic kidney disease/dialysis), the choice of ALK inhibitor varied but lorlatinib was chosen by at least 50% of CIs (see Table 1). For an 80-year-old patient with no comorbidities, CIs were evenly divided between alectinib and lorlatinib (50% each).

From a global standpoint, most CIs (18 of 20) believed lorlatinib to have the greatest efficacy among the various ALK inhibitors as first-line treatment, and all felt it had the greatest CNS activity. Conversely, 16 of 20 CIs believed alectinib to be the most tolerable, with none selecting lorlatinib.

Furthermore, the CIs' median projected likelihood of dose interruption or reduction for patients receiving lorlatinib was 50% (range, 10%-100%) compared to 20% (range, 5%-50%) with alectinib. Similarly, the median estimated likelihood of permanent discontinuation with lorlatinib was 10% (range, 0%-20%) compared to 5% (range, 0%-15%) with alectinib.

Conclusions: The majority of CIs prefer lorlatinib as first-line treatment for ALK+ mNSCLC, perhaps due to the unprecedented outcomes reported from the 5-year follow-up of the Phase III CROWN trial. However, older age and specific preexisting conditions and comorbidities may lead to another treatment approach. Future work is needed to explore current decision-making in these situations for general medical oncologists practicing in a community setting.

Table 1: CI's Choice of First-Line Systemic Therapy in Various ALK-Positive mNSCLC Clinical Scenarios

Clinical scenario in ALK+ mNSCLC (PD-L1 TPS 0)	Choice of first-line systemic therapy
60-yo with no comorbidities	Lorlatinib (16/20) = 80% Alectinib (4/20) = 20%
60-yo with multiple bilateral brain metastases requiring WBRT	Lorlatinib (18/20) = 90% Alectinib (2/20) = 10%
60-yo with poorly controlled diabetes mellitus	Lorlatinib (10/20) = 50% Alectinib (10/20) = 50%
60-yo with a history of anxiety or depression	Lorlatinib (11/20) = 55% Alectinib (9/20) = 45%
60-yo with congenital long QT syndrome or preexisting bradycardia	Lorlatinib (13/20) = 65% Alectinib (5/20) = 25% Crizotinib (1/20) = 5% Ensartinib (1/20) = 5%
60-yo with preexisting hypertension	Lorlatinib (16/20) = 80% Alectinib (4/20) = 20%
60-yo with chronic kidney disease and on dialysis	Lorlatinib (13/20) = 65% Alectinib (7/20) = 35%
80-yo with no comorbidities	Lorlatinib (10/20) = 50% Alectinib (10/20) = 50%

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.11 Prognostic Impact of Metastatic Tumor Burden in Patients With Egfr-Mutated Lung Cancer: Real-World Data From a Single Center

O. Valle Carcel[1], J. Marchal Cabrera[1], E.I. Morcillo Calero[1], S. Sequero López[1], E. Mañas Mora[1]
[1]Hospital Universitario Clinico San Cecilio, Granada/ES

Introduction: Non-small cell lung cancer (NSCLC) with EGFR mutation constitutes a well-defined molecular subtype with specific clinical and therapeutic characteristics. In the metastatic setting, tumor burden—defined by the number of metastatic sites—may hold prognostic value. This study evaluates clinical outcomes in a real-world cohort of patients with EGFR-mutated metastatic NSCLC, stratified by baseline metastatic burden.

Methods: We conducted a retrospective observational study of patients with EGFR-mutated metastatic NSCLC treated at our institution between January 2020 and January 2024. Clinical, demographic, and tumor-related variables were collected. Patients were categorized according to tumor burden at diagnosis: low (≤2 metastatic sites) or high (>2 sites). Progression-free survival (PFS) and overall survival (OS) were estimated using Kaplan-Meier curves, and hazard ratios (HR) with 95% confidence intervals (CI) were calculated.

Results: Thirty-eight patients were included. Median age was 62.5 years; 71.1% were female and 44.7% were never smokers. Median PFS and OS for the total cohort were 18.5 and 24.5 months, respectively. At data cutoff, 34.2% remained on first-line therapy.Patients with low tumor burden showed better outcomes: PFS was 23.4 vs. 13.6 months (HR 2.32; 95% CI 1.03-5.23) and OS was 34.6 vs. 20.3 months (HR 1.82; 95% CI 0.75-4.41). While OS differences did not reach statistical significance, a clinically relevant trend was observed.

Conclusions: Lower metastatic tumor burden was associated with significantly longer PFS and a possible OS benefit in patients with EGFR-mutated NSCLC. Its role as a prognostic marker warrants consideration in clinical practice.

Table 1. Baseline characteristics of EGFRm population

Variable	Distribution
Age	Median: 62,5 years (range 37–80)
Stage IV at diagnosis	100%
Histology	Adenocarcinoma (100%)
Sex	Male: 28,9% Female: 71%

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.12 Efficacy of Lazertinib in Treatment-Naive Patients for EGFR Mutated Non-Small Cell Lung Cancer With Brain Metastases

H.S. Kwak, W. Ji, J.C. Lee, S.Y. Song, Y.S. Shin, Y.H. Cho, J.E. Park, C-M. Choi
Asan Medical Center, Seoul/KR

Introduction: Although non-small cell lung cancer (NSCLC) with an epidermal growth factor receptor (EGFR) mutation is associated with brain metastasis, there is currently no guideline regarding local therapies combined with tyrosine kinase inhibitors (TKIs). We investigated the efficacy of the third-generation EGFR TKI, Lazertinib, in patients with EGFR-mutant NSCLC and brain metastases.

Methods: This study was a single-center, open-label, single-arm phase II trial. Patients with both symptomatic and asymptomatic brain metastases were included. All patients received oral Lazertinib 240 mg once daily, combined with local therapies based on multidisciplinary team discussions. The primary outcomes were progression-free survival (PFS), while key secondary outcomes included changes in symptoms based on the European Organization for Research and Treatment of Cancer (EORTC)-Quality of life Questionnaire 30 (QLQ-C30).

Results: A total of 75 patients were enrolled, with a median age of 65.0 years, 69.3% being female, and 25.3% having a history of smoking. Among EGFR mutation types, 53.3% had the E19del mutation, while 46.7% had the L858R mutation. Regarding brain metastasis symptoms, 37 patients were asymptomatic, 20 had mild symptoms, and 18 had moderate to severe symptoms. For the initial treatment modality, 56 patients received Lazertinib monotherapy, while 19 received Lazertinib with local therapy, including 2 with surgery, 8 with focal radiotherapy, and 9 with whole-brain radiotherapy. The median follow-up duration was 13.6 months, and the median PFS was 13.8 months (95% confidence interval [CI]: 12.1-19.1) among all study patients. There was no significant difference in median PFS between patients with initial neurologic symptoms and those without (14.3 vs. 13.6 months; log-rank test, P = 0.647). Among the 43 patients with disease progression, 16 (37.2%) experienced intracranial disease progression, while 27 (62.8%) had only extracranial disease progression. All QLQ-C30 symptom scores, except for diarrhea, improved after treatment initiation. There was no significant difference in symptom score changes between patients with initial neurologic symptoms and those without. The most common adverse event was paresthesia (71%), followed by skin rash (68%). Grade 3 or higher adverse events occurred in 17.3% of patients, and eight (10.7%) discontinued Lazertinib due to adverse events.

Conclusions: In the current trial including patients with symptomatic brain metastases, Lazertinib demonstrated a favorable PFS regardless of the presence of initial neurologic symptoms related to brain metastases. Further large-scale prospective studies involving patients with symptomatic brain metastases are warranted to establish guidelines for TKI treatment in combination with local therapies.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.13 Gradually or Locally Progressed NSCLC Patients Benefit From Aumolertinib in Post-1L Dose-Escalation Treatment

J. Li, Z. Wang, Y. Xia
China-Japan Union Hospital of Jilin University/third Hospital of Jilin University, Changchun/CN

Introduction: Third-generation EGFR-TKIs demonstrate high selectivity for NSCLC with classical EGFR mutations and EGFR T790M mutations. Nevertheless, resistance is inevitable. Continuous EGFR-TKIs are recommended when patients experience localized progression. This study presents the efficacy and safety of using 165mg or 220mg of aumolertinib, a third-generation EGFR-TKI, in post-1L dose escalation treatment for gradual or localized progression NSCLC patients in the real world.

Methods: Patients with histologically confirmed metastatic NSCLC were enrolled and received first-line treatment with standard-dose aumolertinib (110 mg, once daily). When the patients showed gradual progression, a high-dose aumolertinib (165mg qd/220mg qd) was given subsequently until disease progression or intolerable toxicity. Gradual progression meant disease control ≥6 months, compared with the previous assessment, the tumor load was slightly increased by ≤2 points, symptom score ≤1 point or new brain metastasis. PFS1 was defined as the period from the initiation of first-line treatment to the second progression; PFS2 was defined as the period from the dose escalation treatment to the second progression. The primary endpoint was mPFS2. Secondary endpoints included mPFS1, ORR, DCR and safety.

Results: Forty-eight patients were enrolled. The median age was 63.02 years, and 41.7% were male. 21.7% were current/ever smokers. The dosage of aumolertinib was 165 mg in 11 cases and 220 mg in 37 cases depending on the presence or absence of brain metastasis. At the data cut-off (July 12, 2024), thirty patients (30/48) experienced disease progression after dose escalation, with CEA elevation in 12/30 cases and extracranial progression pattern in 24/30 cases. The median PFS2 of high-dose aumolertinib period was 13.2 months (95% CI 8.1-21.3). The ORR was 70.8% (55.9, 83.0), and the DCR was 100% (92.6, 100). Overall, the median PFS1 was 32.4 months (95% CI 26.4-36.5). The median OS was not reached. No new safety signals were identified. All common drug-related toxicities were mild rash and diarrhea. No grade≥3 AE was observed.

Conclusions: High-dose aumolertinib is an optional regimen for patients with advanced NSCLC who develop resistance following initial therapy. It demonstrates promising efficacy and an acceptable safety profile, thus warranting large-scale, multi-center clinical trials to optimize its dosing and patient selection criteria for enhanced clinical utility.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.15 Predictive Value of Gastrin for the Absorption of pH-Dependent Small-Molecule Inhibitors in Patients With NSCLC

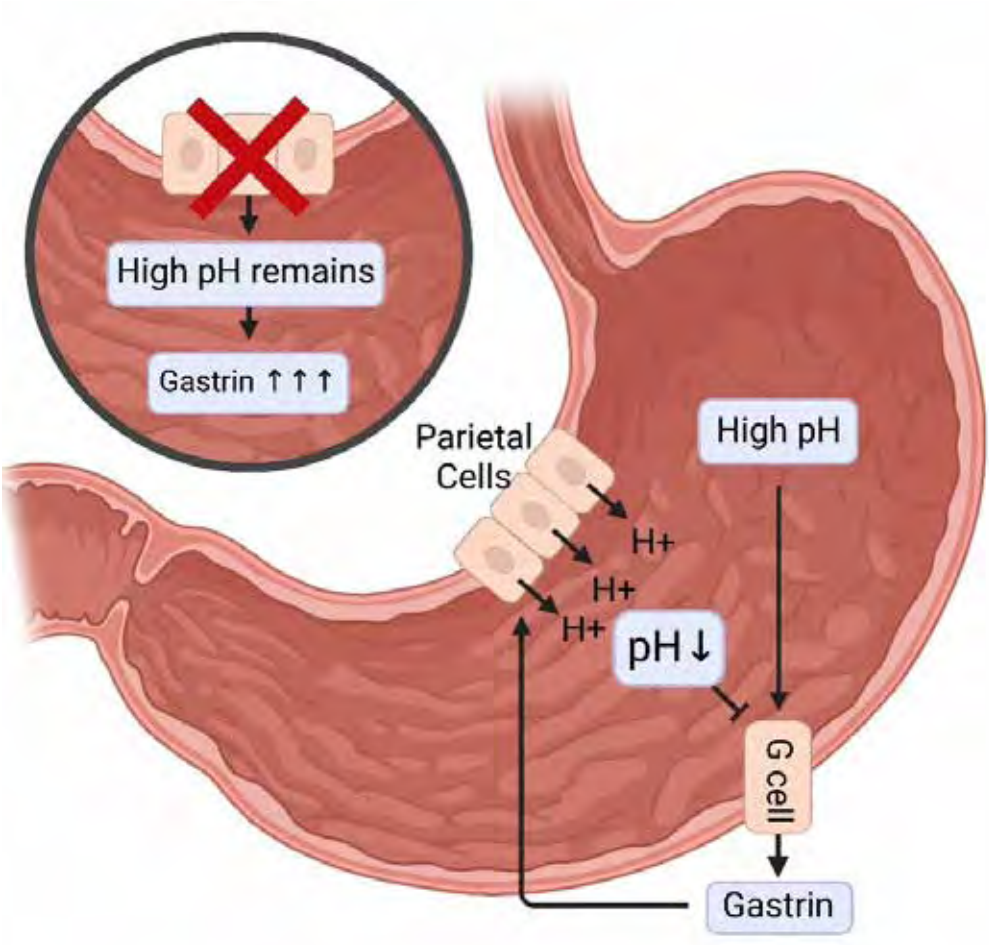
N. Heersche[1], S.M. Ernst[1], K. Kramers[2], A-M.C. Dingemans[1], R.H.N. van Schaik[1], R.H.J. Mathijssen[1], G.D.M. Veerman[1]
[1]Erasmus University Medical Center, Rotterdam/NL ,[2]Radboud University Medical Center, Nijmegen/NL

Introduction: Achlorhydria (AH) is the pathological condition characterized by chronically elevated gastric pH due to the destruction of acid-producing parietal cells. In response to the high gastric pH, gastrin levels are elevated (Figure 1). It is well established that proton pump inhibitors (PPIs), which elevate gastric pH iatrogenically, can significantly reduce the absorption of small-molecule inhibitors (SMIs) in metastatic lung cancer (LC) patients, potentially leading to treatment failure. Since the solubility and absorption of the SMIs erlotinib and sotorasib are pH-dependent, we hypothesize that gastrin, as marker of AH, could predict drug absorption and exposure in patients with LC.

Methods: We measured gastrin levels in prospectively collected samples from two cross-over drug-interaction studies with erlotinib in which dense blood sampling was performed during 24h. Also, consecutive single-day erlotinib and sotorasib samples from a prospective cohort study (NCT05221372) were used to quantify SMI and gastrin levels. For erlotinib, Area Under the Curve (AUC) and maximum (Cmax) and trough concentrations (Cmin 24h) were calculated. For sotorasib, only Cmin 24h was calculable. Spearman's correlation test used gastrin as a continuous variable, where the Mann-Whitney U test used gastrin ≥150 pg/ml to distinguish patients with AH for dichotomous comparison of the data.

Results: In total, SMI and gastrin levels were quantified from 52 patients who used erlotinib and 48 who used sotorasib. Gastrin as continuous variable showed a significant inverse correlation with erlotinib AUC0-12h (R = -0.277; p = 0.047) and Cmax (R = -0.423; p = 0.002). In 11 patients with AH, Cmax was 30% lower compared to 43 patients with physiological levels of gastrin (i.e. <150 pg/mL), c.q. 1169 vs 1672 pg/mL; p = 0.024. AUC0-12h was 26% lower in patients with AH, but this was not statistically significant (10052 vs 13529; p = 0.087) due to limited sample size. For sotorasib Cmin, no correlation was found with gastrin (R = 0.158; p = 0.255) in the total cohort.

Conclusions: Gastrin serves as an effective marker for the absorption and exposure of the pH-dependent SMI erlotinib. This was not the case for sotorasib Cmin. Patients with AH are at heightened risk for reduced erlotinib exposure and subsequent treatment failure. Future studies should focus on the pre-therapeutic assessment of gastrin levels to identify patients with AH, and explore interventions to mitigate treatment failure, such as adjusting the initial erlotinib dose or implementing therapeutic drug monitoring during treatment.



EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.16 Prolonged Survival in Oligometastatic ALK-Positive NSCLC: Impact of Local Ablative Therapy in a Multimodal Treatment Approach

C. Kamali
Karolinska Institute, Stockholm/SE

Introduction: Oligometastatic disease (OMD) in ALK-positive non-small cell lung cancer (NSCLC) presents a unique therapeutic challenge. Current guidelines advocate a multimodal approach, integrating tyrosine kinase inhibitors (TKIs) with local ablative therapy (LAT) to improve disease control and potentially prolong survival. However, long-term outcomes in this subset of patients remain poorly defined due to the rarity of the condition and the limited available data. This study aims to evaluate the prevalence, clinical impact, and survival outcomes of OMD in ALK-positive NSCLC.

Methods: This retrospective study included patients with oligometastatic ALK-positive NSCLC treated at Karolinska University Hospital from 2009 to 2021. Patient demographics, tumor characteristics, and treatment regimens were extracted from medical records. OMD was classified according to the Guckenberger framework as de novo (initial presentation with oligometastases), repeat (recurrence after prior oligometastatic disease), or induced (conversion from polymetastatic to oligometastatic disease following systemic therapy). Initial response to TKIs, median progression-free survival before first progression (PFS1), and sites of progression were recorded. A subset of patients with OMD underwent LAT, including radiotherapy or surgical resection of progressive lesions, while continuing the same TKI. Additionally, some patients were converted to an oligometastatic state but did not receive further LAT. Survival outcomes, including progression-free survival from first progression (PFS2) and overall survival (OS), were estimated using the Kaplan-Meier method.

Results: Among 160 patients with metastatic ALK-positive NSCLC, 64 (40.0%) developed OMD. The median follow-up was 74.0 months (95% confidence interval [CI]: 56.5-91.5), during which 16 patients died. The median OS was 160.0 months (95% CI: 101.4-218.6) for the whole cohort. Nine patients presented with de novo OMD, one experienced a recurrence (repeat OMD), and the majority (54 patients) developed induced OMD following systemic therapy. At the time of OMD diagnosis, 58 patients were receiving an ALK-TKI, four were on chemotherapy, and two had not started systemic therapy. LAT was administered to a total of 45 patients. Among these, 3 received consolidative external beam radiotherapy, 16 underwent stereotactic body radiotherapy (SBRT), 23 received stereotactic radiosurgery (SRS), and 2 underwent surgical procedures. The mPFS1 from the start of systemic therapy was 14.0 months (95% CI: 10.3-17.7), while the mPFS2 from the first progression was 14.0 months (95% CI: 5.6-22.4). Treatment-related toxicities were observed in a subset of patients, with pneumonitis reported in two cases, radiation-induced brain toxicity in seven cases, and radiation esophagitis in one case; all events were classified as CTCAE grade 1 to 3.

Conclusions: This study demonstrates that oligometastatic ALK-positive NSCLC is associated with a prolonged overall survival of over 10 years. LAT is linked to extended progression-free survival after first progression, supporting its inclusion in multimodal treatment strategies. While some patients experienced treatment-related toxicity, adverse events were generally mild to moderate and manageable. These findings underscore the potential role of LAT in carefully selected patients with OMD and highlight the need for prospective studies to refine treatment approaches and optimize patient outcomes.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.17 NNMT as a Therapeutic Target in EMT-Associated Osimertinib Acquired Resistance in EGFR-Mutant Lung Adenocarcinoma

W. Wang
Taizhou Hospital of Zhejiang Province affiliated to Wenzhou Medical University, Linhai/CN

Introduction: EGFR-mutant lung adenocarcinoma demonstrates high initial sensitivity to osimertinib, a third-generation EGFR tyrosine kinase inhibitor. However, the emergence of acquired resistance remains a major clinical challenge, with limited therapeutic options available upon progression. Elucidating the molecular mechanisms driving resistance is essential for the development of more effective and durable treatment strategies.

Methods: Osimertinib-resistant cell lines (HCC827-OR) were established by exposing HCC827 parental cells to gradually increasing concentrations of osimertinib over six months. Cell viability was assessed using MTT assays. EMT marker expression was evaluated by western blotting, and functional changes were assessed using transwell migration and invasion assays, as well as 3D oncosphere formation assays. RNA sequencing (RNA-Seq) was performed to compare transcriptomic profiles between HCC827-OR and parental cells. Differentially expressed genes (DEGs) were identified and visualized through heatmaps and volcano plots. Expression changes were validated using qRT-PCR and western blotting. Functional enrichment analysis, including Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis, was conducted based on DEG-associated protein-protein interaction networks.

Results: HCC827-OR cells exhibited mesenchymal-like morphology, accompanied by decreased E-cadherin and increased Vimentin and N-cadherin expression. Functionally, HCC827-OR cells showed significantly increased migration, invasion, and 3D sphere-forming capacity compared to parental cells. Transcriptomic profiling revealed 2,587 DEGs, including 1,621 upregulated and 966 downregulated genes. KEGG pathway enrichment of the upregulated genes highlighted activation of the PI3K-AKT signaling pathway, focal adhesion, and Rap1 signaling pathways. Among the top 10 upregulated genes, Nicotinamide N-methyltransferase (NNMT) was significantly overexpressed in resistant cells. Importantly, genetic knockdown of NNMT substantially restored osimertinib sensitivity in HCC827-OR cells, indicating its functional role in acquired resistance.

Conclusions: Our findings identify NNMT as a critical mediator of osimertinib resistance in EGFR-mutant lung adenocarcinoma. These findings support NNMT as a promising, actionable target to re-sensitize resistant tumors and improve outcomes in EGFR-mutant NSCLC. Further investigation is warranted to explore clinical translation of NNMT inhibition strategies.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.18 Osimertinib-Associated Asymptomatic Depigmented Skin Macules in a Mexican Cohort

S. Campos-Gomez, A. Gonzalez-Santana, E. Escobedo-Sanchez, D. Aguirre-Quezada, K. Campos-Gomez
Centro Oncológico Estatal ISSEMyM, Toluca/MX

Introduction: First and second-generation EGFR-TKI's most commonly cause papulopustular acneiform rash, pruritus, and nail toxicities. Typically, cutaneous toxicities are low grade (Common Terminology Criteria for Adverse Events Grade 1-2) but reports of severe grades have been recorded and have led to dose modification or interruption of cancer treatment. Currently, less literature exists describing cutaneous toxicities from third-generation EGFR-TKI's, like Osimertinib. These skin reactions are well documented in patients with lighter skin, there is a paucity of literature and images to guide clinicians in their assessment in patients with darker skin tones. We present a series of cases of asymptomatic depigmented skin macules occurring during osimertinib treatment. To our knowledge, this is a pigmentary change secondary to a third-generation EGFR-TKI no reported previously.

Methods: A total of 42 patients with advanced NSCLC receiving Osimertinib in first line treatment were analyzed from January 2022 through May 2024. We summarize to better understand. We review patients with any dAE associated with osirmertinib use. For each case the following data were extracted, age, sex , Osimertinib dose, characterization of dAE, intervention and outcome. Skin toxicities were graded according to CTCAE version 4.03. All data presented are descriptive.

Results: The 42 patients included for this analysis. The average age of the patients was 64 years, and 64 % of patients were female. In the EGFR mutation-positive, (77.3%) were exon 19, 5 (22.7%) were exon 21. The median timing taking Osimertinb was 16.8 months. It develops after around 6 months of therapy and usually are more evident when treatment continues. Patients present progressive skin discoloration on upper arms, forearms, hands, thorax and facxe. This effect is characterized by well-defined depigmented skin macule on the measuring millimeters to centimeter (Figure 1). These were usually asymptomatic grade 2 or below, no dose reduction or discontinuation were necessary.

Conclusions: Pigmentary changes secondary to Osimertinib have been reported rarely and have been attributed to post-inflammatory changes. To our knowledge, this report represents a onset pigmentary changes due to Osimertinib in the published literature. This dAE has a female predominance, mostly in more pigmentated skin types primarily seen in our patient of Latin descent, in patient taking Osimertinib for at least 6 moths to over 2 years. The majority of patient has good and long responses, it will be important to weigh the benefit analysis. Treatment options have no yet been considered, but we hope our report encourages continued efforts in characterize this dAE.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.19 Efficacy of Aumolertinib in Patients With Advanced NSCLC for Uncommon EGFR Exon 19 Deletion Mutations

Y. Yang, S. Kong, Y. Hei, R. Yang, H. Zhang, Y. Chen
Xijing Hospital of Air Force Military Medical University, Xi'an/CN

Introduction: The exon 19del L747_P753>S is associated with inferior progression free survival (PFS) compared with common E746_A750del mutation, with an incidence of only 2.8%. The purpose of this study is to investigate the clinical efficacy for patients (pts) with advanced non-small cell lung cancer (NSCLC) harboring ex19del L747_P753>S who received the third-generation epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) aumolertinib at first-line therapy (1L) or subsequent-line therapy (≥2L), and to provide a valuable therapy regimen with a potential benefit for these pts.

Methods: We collected 10 pts confirmed NSCLC with uncommon ex19del L747_P753 > S mutation in our hospital over the last 5 years. All pts had 1-2 metastasis sites including lung, bone, brain, pleura and lymph nodes. Total 9 pts received 1L therapy, and 1 patient received fourth-line treatment (4L). The mutation was confirmed by NGS assay, of which 7 subjects were detected by tissue,, 2 pts were detected by blood and 1 pts were detected by pleural effusion. All pts were received aumolertinib (110 mg), and 5 of them were received aumolertinib plus platinum-pemetrexed.

Results: Among the 9 pts who received 1L treatment, 3 pts were treated with aumolertinib monotherapy, the PFS were 12 and 16 months respectively, and another patient is still received aumolertinib. For the combination therapy of 6 pts, 4 of them had PFS of 5,8,13,15 months respectively, 2 pts has not progression. In this study, there had 1 patient with 4L treatment and benefited from combination chemotherapy for 5 months so far.The pts were well tolerated during treatment, and there were no grade ≥3 adverse events (AEs) occurred after treatment with aumolertinib monotherapy, only 1 patient developed grade 2 abnormal liver function. The most common AEs of combination therapy were grade 2 gastrointestinal reactions(60%) and grade 3 leukopenia(60%).

Conclusions: This is the first report showed that aumolertinib monotherapy or combined with chemotherapy performed positive efficacy and safety in pts with ex19del L747_P753>S mutation. It is necessary to conduct further exploration for clinical efficacy of aumolertinib in uncommon ex19del mutations in a larger scale.

Keywords: uncommon EGFR mutations, NSCLC, Aumolertinib

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.20 A Realworld Study: Clinical Molecular Characteristics and Prognostic Factors of NSCLC With MET Alteration

X. Fu[1], Y. Yao[2], A. Jiang[2], T. Tian[2], X. Liang[2], Z. Ruan[2]
[1]First Affiliated Hospital of Xi'an Jiaotong University, Xi'an/CN ,[2]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an/CN

Introduction: The MET proto-oncogene, a member of the receptor tyrosine kinase (RTK) family, encodes the hepatocyte growth factor receptor (HGFR). In non-small cell lung cancer (NSCLC), MET dysregulation occurs through protein overexpression, gene amplification, or specific mutations such as MET exon 14 skipping (METex14). While MET tyrosine kinase inhibitors (TKIs) like capmatinib and savolitinib are FDA-approved for METex14-altered NSCLC, their efficacy in primary MET-amplified disease remains under investigation. Notably, combined MET- and EGFR-TKI therapy has shown promising activity in EGFR-TKI-resistant NSCLC with secondary MET amplification. However, real-world data on their clinical impact and optimal management remain limited. This real-world study aims to characterize the clinicopathological and molecular profiles of MET-altered NSCLC and to identify prognostic factors influencing progression-free survival (PFS) and overall survival (OS).

Methods: We retrospectively analyzed 170 NSCLC patients with MET alterations from a cohort of 2,180 cases at the First Affiliated Hospital of Xi'an Jiaotong University. Clinicopathological features, treatment responses, and survival outcomes were assessed. Prognostic factors were evaluated using Kaplan-Meier and Cox regression analyses. Statistical analyses were performed using GraphPad Prism 9.5, IBM SPSS Statistics R26.0.0.0, and R (v4.3.0).

Results: MET alterations were detected in 7.79% of NSCLC patients, predominantly in elderly (median age: 65 years), non-smoking (53%), and adenocarcinoma (83%) populations. Among primary MET alterations (n=112), including MET mutation (40 cases), of which METex14 skipping (36 cases) is the most common mutation, amplification (25 cases), and overexpression (58 cases). Acquired MET alterations were seen in 58 patients. Metastasis frequently involved bone (30%), lung (28%), and brain (22%). Savolitinib demonstrated superior efficacy over crizotinib. Crizotinib: For METex14 skipping vs. MET amplification, objective response rates (ORR) were 60% vs. 33.33%, and disease control rates (DCR) were 80% vs. 58.33%. Savolitinib: ORR was 53.33% vs. 68.75%, and DCR was 86.67% vs. 81.25% for METex14 skipping vs. MET amplification, respectively. First-line MET-TKI mPFS was 8.2 months (95% CI: 2.244-14.156) vs. 5.5 months (95% CI: 4.260-6.740) for later-line therapy. TP53 co-mutations (HR: 2.68, P=0.007) and second-/later-line MET-TKIs (HR: 2.9, P=0.002) independently predicted worse PFS. Median OS (mOS) was 24.8 months (95% CI: 22.08-27.52) overall and 14.5 months (95% CI: 1.71-27.29) for primary MET-altered cases. Independent OS predictors included smoking (HR: 2.21, P=0.043), stage IIIB-IV (HR: 3.58, P=0.036), and treatment with immunotherapy/chemotherapy (HR: 0.16, P=0.021) or targeted therapy (HR: 0.41, P=0.043). Common adverse events included edema (31.30%), liver dysfunction (13.91%), diarrhea (13.04%), fatigue (12.17%), and nausea/vomiting (8.69%).

Conclusions: MET-altered NSCLC exhibits distinct clinicopathological features. Next-generation MET-TKIs (e.g., savolitinib) show improved efficacy over crizotinib, particularly in METex14-mutated cases. TP53 co-mutations and treatment timing critically influence survival, highlighting the need for biomarker-guided therapeutic strategies. These findings underscore the need for optimized therapeutic strategies in MET-driven NSCLC.

EP.12.21 The Impact of Afatinib and Osimertinib Plasma Concentrations on Treatment Toxicities, Quality of Life, and Effectiveness in Patients With NSCLC

S-K. Liang[1], C-L. Hsu[2], Y-F. Wei[3], C-C. Ho[2], C-Y. Yang[2], T-H. Tsai[2], S-G. Wu[1], W-Y. Liao[2], C-K. Huang[2], Y-F. Wen[4], C-Y. Chu[2], G-Y. Chen[2], T-I. Weng[2], Y. Lo[2], J-Y. Shih[2], K-Y. Chen[2]
[1]National Taiwan University Cancer Center, Taipei city/TW ,[2]National Taiwan University Hospital, Taipei city/TW ,[3]E-Da Cancer Hospital, Kaohsiung/TW ,[4]National Taiwan University Hospital Hsinchu branch, Hsinchu/TW

Introduction: Epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) are widely used as first-line treatments for advanced EGFR-mutated non-small cell lung cancer (NSCLC). However, inter-patient variability in drug exposure may influence treatment toxicities, quality of life (QoL), and therapeutic outcomes. This study evaluated the impact of afatinib and osimertinib plasma concentrations on toxicities, QoL, and treatment effectiveness.

Methods: This prospective study enrolled treatment-naïve NSCLC patients receiving afatinib or osimertinib. Plasma concentrations were measured at Week 2 using liquid chromatography-tandem mass spectrometry (LC-MS/MS). Treatment-related toxicities and QoL were assessed at Weeks 2 and 4. Associations between plasma concentrations, toxicities, QoL, and progression-free survival (PFS) were analyzed.

Results: A total of 45 patients (25 afatinib, 20 osimertinib) were included. A trend of negative correlation between plasma concentration and body mass index (BMI) was observed, though not statistically significant (Fig.1). Higher afatinib plasma concentrations were significantly associated with increased dermatology life quality index (DLQI) scores (p=0.001) (Fig.1) and greater anti-diarrhea agent use (p=0.024) (Fig.2), indicating higher toxicity. Elevated osimertinib plasma concentrations were significantly correlated with impaired physical (p=0.017) and social functioning (p=0.003) (Fig.2). Additionally, patients with higher osimertinib plasma concentrations had longer PFS (p=0.022) (Fig.2).

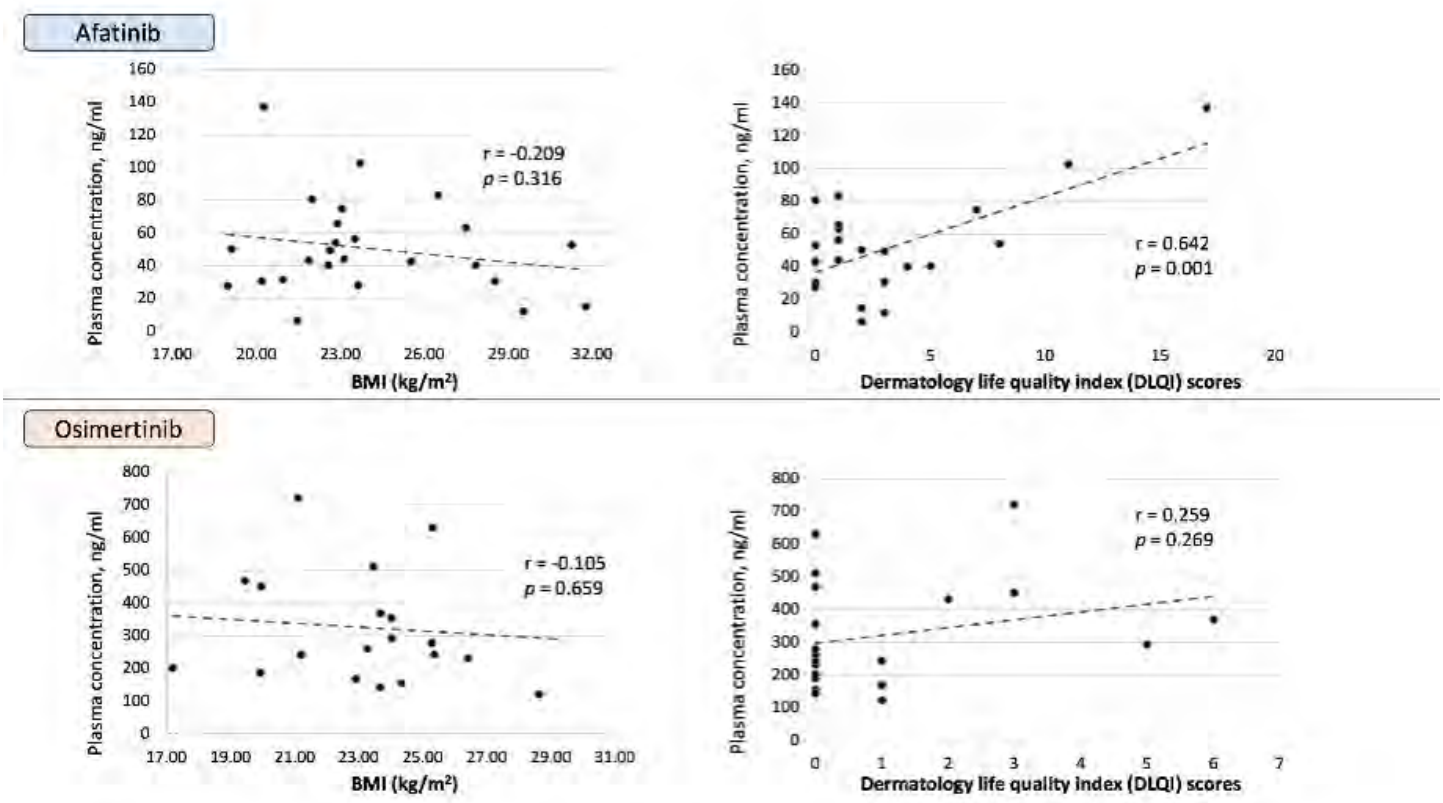

Fig. 1. Correlation analyses of plasma concentrations with BMI and treatment-related toxicities (DLQI) for afatinib and osimertinib.

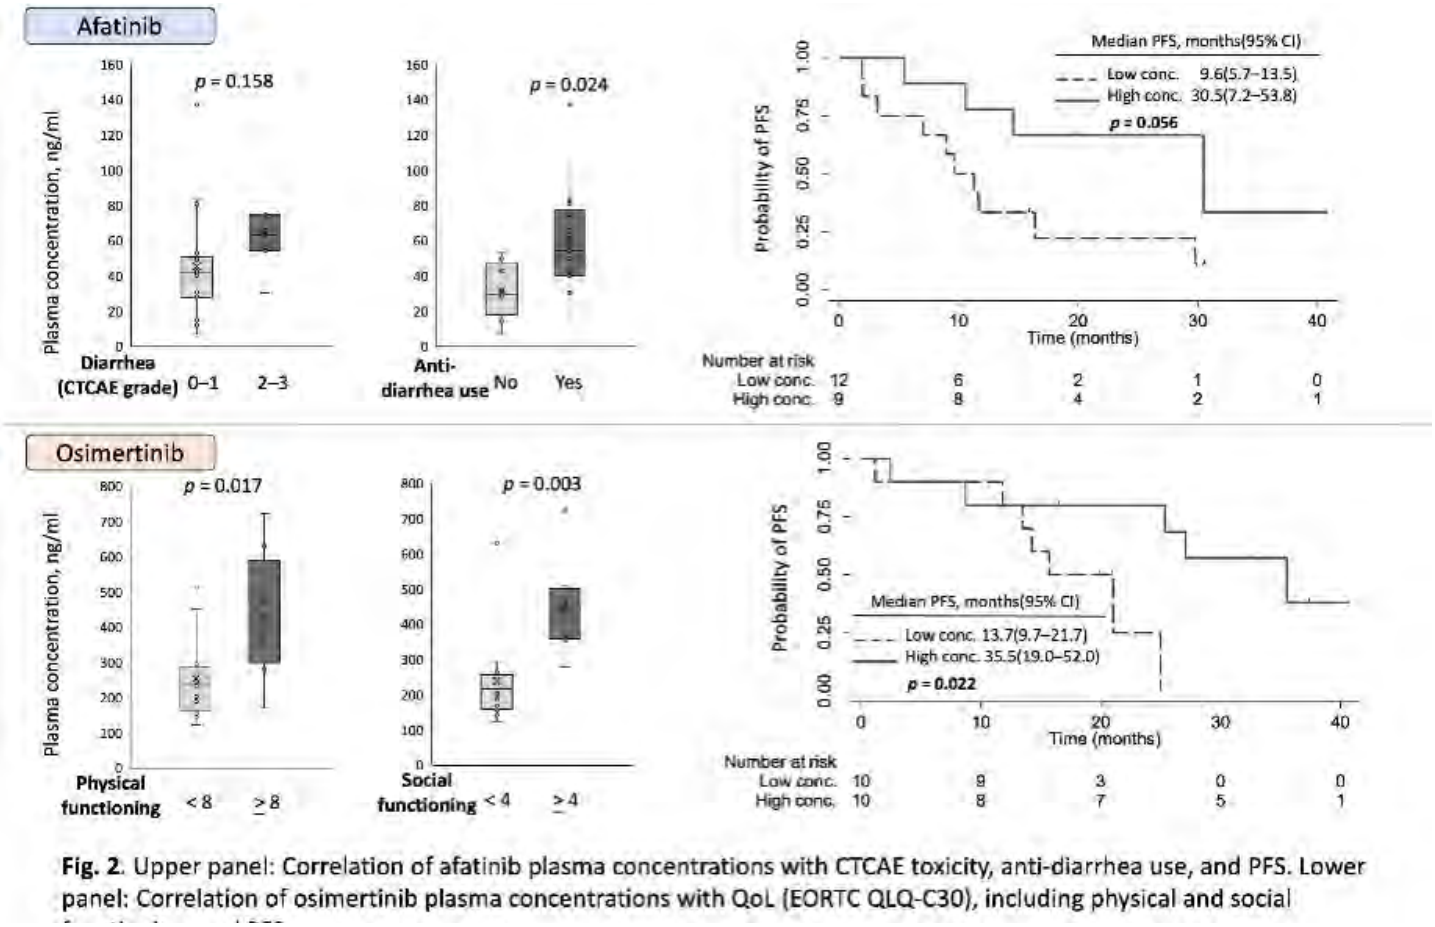

Fig. 2. Upper panel: Correlation of afatinib plasma concentrations with CTCAE toxicity, anti-diarrhea use, and PFS. Lower panel: Correlation of osimertinib plasma concentrations with QoL (EORTC QLQ-C30), including physical and social

Conclusions: Afatinib and osimertinib plasma concentrations are associated with treatment toxicities, QoL, and effectiveness. Therapeutic drug monitoring (TDM) may help optimize dosing strategies to minimize adverse events while maintaining efficacy in NSCLC patients.

Keywords: therapeutic drug monitoring, EGFR-TKI, precision medicine

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.22 Clinical Treatment Outcomes of Erlotinib in Metastatic Non-Small Cell Cancer Harboring Uncommon EGFR Mutations

C. Lagampan
Chonburi Hospital, Chonburi/TH

Introduction: Patients with non-small cell lung cancer (NSCLC) harboring uncommon epidermal growth factor receptor (EGFR) mutations often exhibit variable responses to EGFR tyrosine kinase inhibitors (TKIs). This study evaluates the clinical outcomes of first-line erlotinib in patients with advanced NSCLC harboring uncommon EGFR mutations, compared to those with common mutations.

Methods: We conducted a retrospective analysis of 193 patients with advanced NSCLC and documented EGFR mutations, treated with erlotinib at Chonburi Hospital, Thailand, from January 1, 2020, to December 31, 2023. We collected data on patient demographics, mutation types, treatment regimens, progression-free survival (PFS), overall survival (OS), and physician-assessed objective response rates.

Results: Patients with uncommon EGFR mutations (10.3%) had significantly shorter median OS (7.6 months, 95% CI: 3.2-12.0) and PFS (5.7 months, 95% CI: 0.0-11.4) compared to those with common EGFR mutations (median OS: 19.5 months, 95% CI: 15.8-23.2; median PFS: 11.0 months, 95% CI: 9.2-12.7). The objective response rate to erlotinib was lower in patients with uncommon mutations (33.3% had partial responses) compared to those with common mutations (78.1% for Exon 19 deletion and 82.4% for L858R). Multivariate analysis identified ECOG performance status as a significant prognostic factor for survival in patients with uncommon EGFR mutations.

Conclusions: Patients with advanced NSCLC harboring uncommon EGFR mutations exhibit poorer survival outcomes with first-line erlotinib treatment compared to those with common mutations. Alternative treatment strategies and personalized approaches are warranted for these patients.

EP.12.23 Disease Burden and rwPFS as a Surrogate Endpoint for rwOS in NTRK+ NSCLC and Other Advanced/Metastatic Solid Tumors

C. Flores Avile[1], I-H. Su[2,3], P-C. Huang[4], C. Cho-Phan[1], R. Camidge[5], Y. Yuan[2]
[1]Flatiron Health, New York/NY/USA ,[2]Bristol-Myers Squibb, Princeton/NJ/USA ,[3]University of North Carolina, Chapel Hill/NC/USA ,[4]Flatiron Health, Durham/NC/USA ,[5]University of Colorado Cancer Center, Aurora/CO/USA

Introduction: Neurotrophic tropomyosin receptor kinase rearrangements (NTRK+) are rare oncogenic fusions identified across solid tumors. However, incidence and prevalence remain poorly characterized. Real-world progression-free survival (rwPFS) provides key insights into treatment effectiveness and disease progression as a surrogate endpoint for real-world overall survival (rwOS) when follow-up time is limited. This study aimed to estimate disease burden (prevalence and incidence) and the relationship between rwPFS and rwOS in patients with NTRK+ advanced/metastatic solid tumors.

Methods: Patients were included from the US-based deidentified Flatiron Health (FH)-Foundation Medicine (FMI) solid tumor and pantumor Clinico-Genomic Databases with clinical data from the FH Research Database linked to genomic data derived from FMI comprehensive genomic profiling tests. Patients were diagnosed with advanced/metastatic solid tumors on/after 2011 and received ≥1 line of therapy in the advanced/metastatic setting (data cutoff: March 31, 2024). NTRK+ prevalence was assessed overall and by tumor type. Incidence was reported overall and between 2013-2024. We estimated rwPFS and rwOS from first-line treatment start (Kaplan-Meier); evaluated relationships between rwPFS and rwOS (Spearman's rank correlation coefficient [ρ]; Kendall's tau as a supportive measure); and evaluated rwOS between patients with/without progression at the 12-month landmark (Cox proportional hazard models, unadjusted and adjusted for prognostic factors).

Results: This study included 159 (0.20%) patients with NTRK+ advanced/metastatic solid tumors across 28 tumor types, most commonly non-small cell lung cancer (NSCLC, 23%), colorectal cancer (CRC, 22%), and breast cancer (BC, 16%). NTRK+ prevalence was highest in CRC (0.28%), BC (0.21%), and NSCLC (0.20%). Overall incidence was 201 per 100,000 cases (76-288/100,000 cases/year). Among 88 patients (55.3%) with progression, median rwOS was 21 months (95% CI, 18-47), and median rwPFS was 8.6 months (95% CI, 6.7-11). Correlation between rwPFS and rwOS was moderate (Spearman's ρ, 0.64 [0.44-0.77]; Kendall's tau, 0.46 [95% CI, 0.34-0.57]). Disease progression at 12 months was significantly associated with higher risk of death, in univariate and multivariate analyses (Table).

Conclusions: This is among the largest real-world studies to characterize disease burden of NTRK+ and first to assess rwPFS as a surrogate endpoint for rwOS. NTRK+ were rare and varied by tumor type. A statistically significant mortality risk between rwPFS and rwOS suggests rwPFS as a meaningful surrogate endpoint. Continued research is needed to optimize outcomes for these patients.

Table. Progression Landmark Analysis for Patients With Advanced/Metastatic *NTRK+* Solid Tumors

Landmark time	Landmark status	HR (95% CI) for rwOS	*P* value

EP.12.24 Common vs Uncommon EGFR Mutations in NSCLC and the Potential Prognostic Role of Neutrophil-To-Lymphocyte Ratio

S. Sequero López[1], D. Castillo-Barnes[2], I. Rodriguez-Rodriguez[2], E. Mañas-Mora[1], O. Valle-Carcel[1], M. Provencio[3], J. Baena Espinar[4]
[1]Hospital Universitario San Cecilio, Granada/ES ,[2]University of Malaga, Malaga/ES ,[3]Hospital Universitario Puerta del Hierro, Madrid/ES ,[4]Hospital [12] de Octubre, Madrid/E

Introduction: Patients with advanced unresectable or metastatic Non-Small Cell Lung Cancer (NSCLC) harboring Epidermal Growth Factor Receptor (EGFR) mutations can achieve prolonged remission with targeted therapies. However, clinical outcomes vary considerably due to tumor heterogeneity and interindividual differences. EGFR mutations are traditionally classified as common (exon 19 p.Glu746_Ala750del and exon 21 p.Leu858Arg) or uncommon. The prognostic significance of these EGFR mutation subtypes remains uncertain. This study investigates survival differences based on EGFR mutation subtype in advanced NSCLC, incorporating the neutrophil-to-lymphocyte ratio (NLR) as an additional prognostic marker.

Methods: This single-center, retrospective study included 50 patients diagnosed and treated at the Medical Oncology Department of San Cecilio Hospital, Granada, Spain. All patients had confirmed EGFR-mutated NSCLC. Clinical and analytical data, treatments received, mutation types determined by Next Generation Sequencing (NGS), and survival outcomes were retrospectively reviewed. Survival analyses, including Progression-Free Survival (PFS) and Overall Survival (OS), were performed using Kaplan-Meier curves and log-rank tests. Patients were stratified by mutation subtype (common vs uncommon) and baseline NLR (≤2.8 vs >2.8).

Results: Of 50 patients analyzed, median age was 64 years (range 31-88), 86% presented stage III-IV disease, and 10% had brain metastasis at diagnosis. Common mutations included exon 21 p.Leu858Arg (30%) and exon 19 p.Glu746_Ala750del (20%). Uncommon mutations included exon 19 SNV p.Ala750Pro (8%), exon 19 DELINS p.Leu747_Ala750delinsPro (4%), exon 20 duplication p.Ser768_Asp770dup (4%), and exon 19 INDEL p.Glu746_Ala750del (4%). PD-L1 expression <1% was noted in 28%. Mean NLR at diagnosis was 5.8 ± 7.0, and 9.9 ± 21.0 at last follow-up.

No significant differences in survival were observed between mutation subtypes alone (median OS: common 32.0 months vs uncommon 31.5 months; p=0.895). However, integrating baseline NLR revealed significant prognostic stratification. Patients with common mutations and NLR >2.8 had significantly worse OS (5.2 months) compared to those with NLR ≤2.8 (66.3 months). In patients with uncommon mutations, OS was 26.2 months for NLR >2.8, while median OS was not reached for those with NLR ≤2.8 (p=0.011).

Conclusions: Incorporating neutrophil-to-lymphocyte ratio at diagnosis significantly enhances prognostic accuracy. Patients with high NLR (>2.8) have poorer survival outcomes, especially those harboring common EGFR mutations. NLR may thus represent a valuable biomarker complementing EGFR mutation analysis, potentially guiding therapeutic decisions.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.25 Demographic Influences on Treatment Preferences in Advanced EGFR+ mNSCLC: A Qualitative Analysis of Patient Perspectives on Osimertinibb

R. Seeger[1], D. Stacey[1], E. Bossio[2,3], P. Wheatley-Price[1,4]
[1]University of Ottawa, Ottawa/ON/CA ,[2]Lung Cancer Canada, Toronto/ON/CA ,[3]Advocate living with lung cancer, Calgary/AB/CA ,[4]Ottawa Hospital Research Institute, Ottawa/ON/CA

Introduction: As first-line treatment options for EGFR+ metastatic non-small cell lung cancer (mNSCLC) continue to expand, shared decision-making plays a crucial role in aligning treatment plans with patients' values. Targeted therapies such as Osimertinib offer benefits like convenience and independence. Recent studies, including FLAURA2 and MARIPOSA, investigate therapeutic combinations with intravenous drugs, demonstrating greater efficacy but increased side effects, highlighting the need for patient-centered, unbiased approaches. This study explores how demographic factors influence treatment preferences among patients with EGFR+ metastatic non-small cell lung cancer (mNSCLC) considering first-line therapies.

Methods: With ethics board approval, we carried out an interpretive descriptive qualitative study, guided by the Ottawa Decision Support Framework. Inclusion criteria were: adults aged 18 and older; diagnosis of mEGFR+ NSCLC; current or prior Osimertinib therapy; and proficiency in English. Interviews were held via Microsoft Teams using a standardized interview guide. We used purposeful sampling until we reached thematic saturation and recruited an additional 3 participants to ensure adequate saturation. Data were analyzed through inductive thematic analysis and identified themes were mapped onto the Ottawa Decision Support Framework.

Results: Sixteen participants were interviewed from Sep-Nov 2024: median age 62 years; 11 females; 13 currently taking Osimertinib; 10 diagnosed >1 year before participation. All participants recognized the advantage of Osimertinib in prolonging life and enabling them to continue daily activities. However, they also noted disadvantages, particularly specific side effects that caused physical discomfort. Considering these trade-offs, participants described that Osimertinib provided a sense of hope and stability. Men more commonly reported immediate physical relief, such as pain reduction, while women more frequently emphasized long-term quality of life and the ability to maintain daily activities. Younger participants (under 62) described advantages of survival and long-term treatment effectiveness. Younger participants also noted that taking Osimertinib made it easier to distance themselves from their cancer diagnosis, with some expressing that having just one pill a day felt less intrusive and served as a smaller reminder of their terminal illness. Older participants (over 62 [the median]) described advantages of pain management and sustaining normal routines. When it came to discussing hypothetical combination therapy of Osimertinib plus intravenous treatment, younger patients asked for more information on the evidence of effectiveness and described the importance of preserving access to future therapies, including second-line options. Both older and younger participants described the impact of IV treatment on their quality of life as a disadvantage. Patients who had previously undergone earlier treatments (e.g. afatinib, chemotherapy) had stronger opinions about whether they would be willing to try the combination therapy, influenced by their initial experience with the treatment.

Conclusions: Across different demographics, sex, age, and prior treatment experience, participants vary in how they perceive the drug's benefits and drawbacks. The findings emphasize the need to customize counseling based on personal characteristics and the importance of asking participants what advantages they want to gain and disadvantages they want to avoid to ensure their own preferences inform treatment decisions.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.26 Multi-Omics Decipher the Molecular Landscape of EGFR+ Non-Small Cell Lung Cancer Patients Following Osimertinib Treatment

E-B. Braune[1], E. Langels[1], I.J. Zwicky Eide[2], O. Grundberg[1], L. De Petris[1], O.T. Brustugun[2], S. Ekman[1], P. Hydbring[1]
[1]Karolinska Institutet, Stockholm/SE ,[2]Drammen Hospital, Drammen/NO

Introduction: Targeted therapy with tyrosine kinase inhibitors (TKIs) against Epidermal Growth Factor Receptor (EGFR) is part of clinical routine for around 10-15% of advanced non-small cell lung cancer (NSCLC) patients with tumors harboring activating mutations in the kinase domain of EGFR. Osimertinib is a third-generation EGFR TKI displaying potency to both activating kinase domain EGFR mutations and the T790M gatekeeper mutation. Osimertinib is approved by the FDA and EMA for usage in the first-line setting to NSCLC patients with EGFR activating mutations regardless of presence of T790M. Despite improved clinical response following osimertinib treatment compared to treatment with first-generation EGFR TKIs, resistance is inevitable. Intriguingly, a significant fraction of resistant cases following osimertinib treatment cannot be linked to additional genetic aberrations. Here we analyzed if circulating RNAs as well as circulating proteins could provide clues of molecular factors associated with acquired resistance to osimertinib.

Methods: Plasma was collected at baseline and progression of disease using paired samples from 20 patients enrolled in the multicenter phase II study First-line treatment with osimertinib in EGFR-mutated non-small cell lung cancer (FIOL). Plasma was centrifuged at 16000g followed by exosomal RNA extraction using Qiagen exoRNeasy Midi kit according to manufacturers' instructions. Total RNA was subjected to paired-end 150 Illumina sequencing with ribodepletion (mRNA-seq, lncRNA-seq) or single-end 50 Illumina sequencing (microRNA-seq). For systematic protein analysis, plasma was subjected to the SomaLogic SomaScan 7K Assay Kit, measuring more than 7000 proteins.

Results: Systematic transcriptome profiling revealed hundreds of differentially expressed mRNA transcripts, adjusted p-value <0.05, while 13 microRNAs and 17 proteins displayed differential expression using an identical statistical cutoff. Interestingly, 16 out of 17 differentially expressed proteins were upregulated at disease progression, including proteins associated with VEGF and TGF-beta signaling, while 9 out of 13 differentially expressed microRNAs were downregulated at disease progression. Baseline samples clustered in a distinct manner compared to samples from disease progression when using either mRNAs and lncRNAs as input or proteins as input. We are currently investigating the therapeutic impact of modulating the expression of top-candidate RNAs and proteins in cell lines with acquired resistance to osimertinib. Additional data will be presented at the meeting.

Conclusions: Our study demonstrates the usage of circulating RNAs and proteins from plasma to unveil resistance signatures to the third-generation TKI osimertinib. Furthermore, it highlights the involvement of multiple RNAs and proteins of potential functional impact in osimertinib-refractory NSCLC patients.

EP.12.27 Effect of PD-L1 Expression Level on Clinical Outcomes of Stage IV EGFR Mutant Lung Cancer Patients Treated With Osimertinib

J. Lee, X. Jin, S. Bogdan, J. Bliss, M. Rafizadeh, J.W. Chang, E.C. Kang, C. Garcia, X.K. Zhou, A. Saxena
New York-Presbyterian Weill Cornell, New York/NY/USA

Introduction: Epidermal growth factor receptor (EGFR) and programmed death ligand 1 (PD-L1) are cell surface proteins that interact in the context of immune evasion to promote cancer growth. Mutations in EGFR signaling are linked to upregulation of PD-L1, though the associations between higher PD-L1 expression and clinical characteristics and disease features of EGFR mutant (EGFR-mut) non-small cell lung cancer (NSCLC), as well as response to Osimertinib (Osi), are unclear.

Methods: We retrospectively analyzed clinical outcomes in patients (pts) with EGFR-mut Stage IV NSCLC treated with first line (1L) Osi at three New York City (NYC) hospitals between 2018-2023. Response was defined as radiographic improvement in tumor burden. Progression-free survival (PFS) was defined as time from first Osi dose to radiographic evidence of progression of disease. Overall survival (OS) was defined as time from diagnosis to death. PFS and OS were calculated using log rank test and cox proportional hazard model.

Results: A total of 101 pts were included for final analysis. Median age was 68 and pts were predominately female (68%), Asian (58%), and never smokers (66%). PD-L1 score was divided into <1% (51%), 1-10% (25%), and >10% (24%). Sites of disease metastasis included bone (51%), pleural effusion (42%), adrenal gland (12%), liver (11%), and pericardium (5%). CNS disease was present in 56 pts (55%) and twenty pts (20%) had radiographic evidence of leptomeningeal disease. Forty-eight pts (48%) had only one site of metastatic disease. There were no significant differences in sites of metastatic disease between PD-L1 expression levels. There was a non-statistically significant higher rate of TP53 co-mutations in the PD-L1 > 10% cohort (Table 1). Overall response rate (ORR) to Osi varied based on PD-L1 expression, with higher expression levels associated with lower ORR. There was also a statistically significant decrease in OS and a trend towards worse PFS with higher PD-L1 expression.

Conclusions: PD-L1 expression level was generally low (≤10%) in our diverse population of EGFR-mut NSCLC pts treated across three NYC hospitals. PD-L1 level was not associated with sites of metastases. Higher rates of TP53 co-mutations were seen in the PD-L1 >10% cohort. Inferior ORR and OS were also seen in the PD-L1 >10% cohort, which was statistically significant.

	Total	PD-L1 <1	PD-L1 1-10	PD-L1 >10	p-value
N	101	52	25	24	
RR (%)	86 (85)	48 (92)	21 (84)	17 (71)	0.051[a]
PFS Median (95% CI)	19.0 (16.8, 25.0)	21.0 (18.5, 26.6)	18.1 (12.4, 41.5)	12.5 (7.2,34.7)	0.194[b]
OS Median (95%CI)	64.9 (33.9, not reached)	64.9 (38.8, not reached)	42.9 (28.6, not reached)	31.2 (15.1, not reached)	0.029[b]
TP53+ (%)	49 (49)	22 (42)	11 (44)	16 (67)	0.133[a]

[a] Fisher's exact test; [b] Log rank test

Table 1. Clinical endpoints and TP53 co-mutation rate by PD-L1 level. RR calculation and TP53 mutation rate included 101 pts. PFS and OS calculated in months and included 72 and 24 pts respectively.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.28 Real-World Clinical Outcomes in Chinese Patients With Advanced EGFR-Mutated NSCLC on First-Line Third-Generation EGFR-TKIs Treatment

X. Mu[1], W. Xi[1], Y. Wu[2], R. Li[1], D. Yang[1], D. Zhao[3]
[1]Peking University People's Hospital, Beijing/CN ,[2]Taiyuan People's Hospital, Taiyuan/CN ,[3]Lixin County People's Hospital, Bozhou/CN

Introduction: Aumolertinib and osimertinib are both third-generation (3G), irreversible epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) that were approved for first-line treatment of advanced non-small cell lung cancer (aNSCLC) patients with EGFR mutation (EGFRm). The clinical outcome on first-line 3G EGFR-TKIs in clinical practice remains to be elucidated among Chinese patients. In this study, we present the real-world clinical outcomes of Chinese aNSCLC patients with EGFRm who were treated with first-line 3G EGFR-TKIs.

Methods: A retrospective analysis was conducted on the records of patients diagnosed with EGFRm aNSCLC who received 3G EGFR-TKIs between December 2019 and July 2024. At the data cut-off date of 9 November 2024, 169 eligible patients were included in the data analysis. The clinical outcomes (best response measured from the initiation of first-line treatment and PFS) were presented.

Results: A total of 169 pts were enrolled in this retrospective study, of whom 60 pts received aumolertinib and 109 pts received osimertinib. The median age of the 60 pts receiving aumolertinib was 69 years (range, 35 to 86), 38.3% was male, ECOG performance status (PS) was ≤1 in 32 pts, ≥2 in 28 pts, and 16 pts had brain metastasis or 3 pts had leptomeningeal metastasis. EGFR mutations included 19del (14 pts, 23.3%), L858R (42 pts, 70.0%) and others (4 pts, 6.7%). The median age of the 109 pts receiving osimertinib was 70 years (range, 33 to 87), 35.8% was male, ECOG PS was ≤1 in 44 pts, ≥2 in 65 pts, and 21 pts had brain metastasis or 3 pts had leptomeningeal metastasis. EGFR mutations included 19del (57 pts, 52.3%), L858R (45 pts, 41.3%) and others (7 pts, 6.4%). At data cut-off, the median follow-up for progression-free survival was 17.6 months (range, 5.6 to 31.9) for aumolertinib and 16.6 months (range, 1.3 to 51.3) for osimertinib. 11 and 47 pts progressed after first-line treatment with aumolertinib and osimertinib, respectively. The median progression-free survival was not reached (95% confidence interval [CI], not calculable) with aumolertinib and 26.5 months with osimertinib (95% CI, 22.9 to 30.1). The 18-month PFS rate was 80% with aumolertinib and 70% with osimertinib. The objective response rate was higher with aumolertinib than with osimertinib, 75.0% and 57.8%, respectively. The disease control rates were similar at 96.7% and 94.5%, respectively. Any grade AEs occurred in 31.7% of aumolertinib patients and up to 38.5% of osimertinib patients, with grade 3 or higher (G3+) AEs occurring in 6.7% and 13.8% of patients, respectively.

Conclusions: Unlike the phase 3 trials FLAURA (FLAURA-China) and AENEAS, the real-world baseline characteristics of Chinese patients diagnosed with EGFRm aNSCLC were more complex, yet 3G EGFR-TKIs demonstrated a more favourable clinical outcome. The results of this study have provided further insight into the clinical practice of using 3G EGFR TKIs in Chinese patients diagnosed with EGFRm aNSCLC in a real-world setting.

EP.12.29 Association Between Tepotinib-Induced Edema and Clinical Outcomes in Patients With MET Exon 14 Skipping NSCLC

T. Kobayashi[1], K. Watanabe[1], K. Misawa[2], Y. Kato[3], R. Saito[4], S. Katakura[5], K. Nishiyama[6], K. Shinada[1], N. Furuya[6], T. Okano[3], H. Mizutani[2], Y. Hosomi[1]

[1]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Bunkyo-ku/JP ,[2]Saitama Cancer Center, Ina-machi/JP ,[3]Nippon Medical School Chiba Hokusoh Hospital, Inzai-shi/JP ,[4]Yamanashi Prefectural Central Hospital, Kofu-shi/JP ,[5]Kanagawa Cancer Center, Yokohama-shi/JP ,[6]St. Marianna University School of Medicine, Kawasaki-shi/JP

Introduction: The VISION study demonstrated that tepotinib, a highly selective MET inhibitor, was effective against MET exon 14 (METex14) skipping NSCLC. Edema is a common adverse event associated with this drug, but its relationship with patient characteristics and treatment outcomes remains unclear. The present study investigated the association between tepotinib-induced edema and clinical outcomes in patients with METex14 skipping NSCLC receiving first-line tepotinib therapy.

Methods: We retrospectively analyzed data on patients with METex14 skipping NSCLC, which was diagnosed in any of the six participating, Japanese hospitals between August 2020 and December 2024. Patient demographics, treatment details, and the efficacy and safety outcomes of first-line tepotinib were extracted from electronic medical records.

Results: Of 98 patients with METex14 skipping NSCLC, 62 (63.2%) who received tepotinib as first-line therapy, 38 (61.3%) were male and 24 (38.7%) were female, and 37 (59.7%) patients had a smoking history. Adenocarcinoma was the predominant histology (73.0%). The median patient age was 76 years (range: 56-90), and most patients had advanced-stage cancer (58.1%), with the second largest group comprising those with a recurrence (37.1%). There were 27 patients (43.5%) with PD-L1 ≥ 50%. The ECOG PS was 0 or 1 in 46 (74.2%) patients and 2 or higher in 16 (25.8%) patients. The median observation period was 29.1 months (range: 1.5-51.5). First-line tepotinib achieved an overall response rate (ORR) of 61.4% (95% confidence interval [CI]: 48.8-74.0), median progression-free survival (PFS) of 8.2 months (95% CI: 6.3-10.1), and median overall survival (OS) of 24.4 months (95% CI: 9.5-39.2). Edema occurred in 44 patients (71.0%), with Grade 3 or higher edema occurring in eight patients (12.9%). Diuretics were administered in 26 of 44 patients (59.1%). The ORR was higher in patients with edema (70.4% vs. 30.7%). Patients with edema had significantly longer PFS than those without edema (10.8 months [95% CI: 8.0-13.6] vs. 4.2 months [95% CI: 2.8-5.5]; hazard ratio: 0.31; 95% CI: 0.16-0.60; P < 0.001). While edema led to a dose reduction in 37.1% of patients and dose interruption in 25.8%, only 8.1% discontinued tepotinib therapy due to edema.

Conclusions: The present, real-world analysis found that tepotinib-induced edema was associated with better treatment efficacy in patients with METex14 skipping NSCLC receiving first-line tepotinib therapy. These findings provide valuable insights for optimizing tepotinib therapy management in clinical practice while highlighting the importance of appropriate supportive care for edema.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.30 Real-World Outcomes of Full and Reduced Dose Capmatinib and Tepotinib Treatment for MET Exon 14 Skipping Mutation NSCLC

J. Fuchs[1], N. Patel[1], N. Mohindra[2], J. Patel[2], D. Gupta[2]
[1]McGaw Medical Center of Northwestern University, Chicago/IL/USA ,[2]Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago/IL/USA

Introduction: Non-small cell lung cancer (NSCLC) accounts for 85% of lung cancers. Of these, approximately 3% have MET exon 14 skipping mutations (METex14) and MET amplifications. Capmatinib and tepotinib are FDA approved MET tyrosine kinase inhibitors (TKI) for METex14 advanced NSCLC. As part of our analysis of healthcare delivery at Northwestern Medicine, we investigated outcomes in METex14 NSCLC to evaluate response to MET TKI at full and reduced doses.

Methods: We queried the Northwestern Medicine OncoSET Molecular Database for patients with METex14 NSCLC between January 2013 and November 2024 at Northwestern Memorial Hospital and affiliates. Inclusion criteria included patients with METex14 or MET amplification advanced or metastatic NSCLC. Demographic information, stage, and prior treatment data were collected. Response rate, median Progression Free Survival (PFS) by Kaplan-Meier survival analysis, dose reduction data, and adverse events (AE) were analyzed from the medical record.

Results: 43 patients were treated with MET TKI. 36 (84%) had a METex14 and 7 had MET amplification. Median age was 71 years (range 46-93), 25 (58%) were female, 28 (65%) identified as White, 8 Asian, 4 Black, and 3 Hispanic. 21 (49%) had tobacco use history. ECOG Performance Status (PS) of 0-1: 27 (63%), ECOG PS of 2: 16 (37%). 42 (98%) had stage IV disease and 1 had unresectable advanced disease. 14 (33%) had CNS involvement. 23 (53%) were treatment naive prior to initiation of MET TKI. 41 (95%) patients had not previously received MET targeted therapy, 2 had received crizotinib.

28 (65%) patients were treated with capmatinib, of these, 23 (82%) had stable or partial disease as best response. 12 (52%) patients underwent dose reduction at median 63 days after treatment initiation (range 0-240). Median PFS for patients treated with full dose capmatinib was 11 months, median PFS was 13 months for dose reduced patients. This was not statistically significant by chi-square (p=0.19). 8 patients had dose reduction due to AE (5-edema and 3-liver function abnormalities), 4 were initiated on dose reduction due to advanced age and PS. The median duration of treatment after dose reduction was 11 months.

15 (35%) patients were treated with tepotinib, of these, 12 (80%) had stable or partial disease as best response. 5 (42%) patients underwent dose reduction at median 28 days after treatment initiation (range 0-173). Median PFS for full dose tepotinib treated patients was 9 months and 11 months for the reduced dose group, this was not statistically significant by chi-square (p=0.74). Of dose reduced patients, 3 had dose reduction due to AE (2-nausea and 1-edema), 2 were initiated on dose reduction due to advanced age and PS. The median duration of treatment after dose reduction was 9 months.

Conclusions: This single-institution analysis suggests patients on full and reduced dose capmatinib and tepotinib have similar median PFS despite dose reductions. Median PFS is similar to previous real-world analysis (Correia et al, JCO 2024). These data suggest that in older patients, often with comorbidities, or patients with AE necessitating dose reduction, patients have similar benefit to MET TKI.

EP.12.31 Dual Target Drug Discovery for EGFR and PIK3CA in Lung Adenocarcinoma Using Machine Learning and Molecular Simulation Techniques

S. Lu[1,2], C. Lei[3,4], K. LI[1], Y. HAN[1], Y. Zhu[1], Q. Shi[5], X. Leng[1]
[1]Department of Thoracic Surgery , Sichuan Clinical Research Center for Cancer , Sichuan Cancer Hospital & Institute , Sichuan Cancer Center , Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu/CN ,[2]Chongqing Medical University, Chongqing/CN ,[3]Department of Oncology , Sichuan Provincial People's Hospital , Sichuan Chengdu, Chengdu/CN ,[4]University of Electronic Science and Technology of China, Chengdu/CN ,[5]Medical University, Chongqing/CN

Introduction: With the advancement of personalized medicine, multi-target drug development has gained significant attention, particularly for complex diseases such as lung adenocarcinoma. This study identifies potential dual-target inhibitors for the epidermal growth factor receptor (EGFR) and phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha (PIK3CA), both of which are critically involved in lung adenocarcinoma progression. EGFR mutations are known to drive tumor growth and metastasis, while PIK3CA mutations contribute to resistance against EGFR-targeted therapies.

Methods: IC50 values of active compounds targeting EGFR and PIK3CA were obtained from the BindingDB database, standardized using RDKit software, and converted to PIC50 values. A total of 2048 extended connectivity fingerprints (ECFPs) were computed as molecular descriptors. Machine learning models, including support vector machine, decision tree, random forest, gradient boosting, k-nearest neighbors, and LightGBM, were utilized. Optimal parameters were determined through ten-fold cross-validation and grid search. Model performance was evaluated using mean absolute error, mean squared error, and R^2.

Results: The support vector machine model exhibited superior performance and was selected for predicting EGFR and PIK3CA activity in lung adenocarcinoma. A screening of 479 inhibitors from the Coconut natural product database was conducted, followed by molecular docking using AutoDock Vina. Ten natural product compounds were chosen for molecular dynamics simulations, revealing stable binding with EGFR and PIK3CA through hydrogen bonds and hydrophobic interactions.

Conclusions: Natural product compounds CNP0456830 and CNP0467494, which showed the lowest binding free energies with EGFR and PIK3CA, were identified as the most promising dual-target inhibitors for lung adenocarcinoma. These findings offer valuable insights into developing personalized therapeutic strategies that target both EGFR and PIK3CA to overcome resistance in lung adenocarcinoma treatment.

EP.12.32 Targeted Therapy Utilization in Patients With Stage IV Non-Small Cell Lung Cancer Harboring Actionable Mutations

T. Patel, MD[1], S.". Divers, MD[2], D.P. Petro, MD[3], B. Mulherin, MD[4], E. S. Santos, MD[5], R. Choksi, MD[3], M. Gart, MBA[6], P. Dave, MHA[6], B. Wang, MBA[6], P. Varughese, PharmD, MBA[6], R. Geller, MD[6], J. Scott, MD[6]
[1]Zangmeister Cancer Center, Columbus/OH/USA ,[2]Genesis Cancer and Blood Institute/AON, Hot Springs/AZ/USA ,[3]University of Pittsburgh Medical Center (UPMC), Pittsburgh/PA/USA ,[4]Hematology Oncology of Indiana, Indianapolis/IN/USA ,[5]The Oncology Institute of Hope and Innovation, Fort Lauderdale/FL/USA ,[6]Integra Connect, West Palm Beach/FL/USA

Introduction: The NCCN guidelines recommend non-small cell lung cancer (NSCLC) patients (pts) who are stage IV that harbor actionable mutations such as EGFR Exon 19 Del or L858R, ALK, ROS1, BRAF V600E, MET Exon 14 Skipping, RET, NTRK1/2/3, KRAS G12C, ERBB2, and now recently NRG1, receive targeted therapy. We aim to show treatment practices among stage IV NSCLC pts who harbor such mutations receiving care at oncology practices in the U.S.

Methods: Among Integra Connect PrecisionQ's de-identified database the analysis included pts >= 18 years of age, who were confirmed via manual chart abstraction with newly diagnosed stage IV NSCLC and found positive for either of the following EGFR Exon 19 Del or L858R, ALK, ROS1, BRAF V600E, MET Exon 14 Skipping, RET, NTRK1/2/3, KRAS G12C, and ERBB2. Pts positive for EGFR Exon 19 Del or L858R, ALK, ROS1, BRAF V600E, MET Exon 14 Skipping, RET, and NTRK1/2/3 must have started first-line treatment on or after January 1, 2022. Pts positive for KRAS G12C must have started second-line treatment on or after January 1, 2022. Pts positive for ERBB2 must have started second-line treatment on or after September 1, 2022. Descriptive analyses were performed to analyze the data.

Results: The use of targeted therapy was as follows based on each of the first-line pts with actionable mutations so long as the pt did not harbor another first-line actionable mutation: 94% among EGFR Exon 19 Del or L858R pts (N = 144), 73% among ALK positive pts (N = 52), 60% among ROS1 positive pts (N = 45), 41% among BRAF V600E positive pts (N = 27), 52% among MET Exon 14 Skipping pts (N = 25), 61% among RET positive pts (N = 18), and 5% among NTRK1/2/3 positive pts (N = 19). The use of targeted therapy was as follows based on each of the second-line pts with actionable mutations so long as they did not harbor another second-line actionable mutation: 67% among KRAS G12C positive pts (N = 94) and 39% among ERBB2 positive pts (N = 31). Across all pts with actionable mutations in either first or second-line who did not harbor another actionable mutation for treatment in that respective line of therapy, the use of targeted therapy was 68% -- those with adenocarcinoma (N = 377) received targeted therapy at a rate of 71% compared to 36% for pts with squamous cell carcinoma (N = 28).

Conclusions: The real world shows that pts who harbor actionable mutations are not all equally treated with targeted therapy -- rates are highest in EGFR exon 19 and L858R at 94%, followed by ALK at 73%, ROS1 and RET at 60% with continued decline in use for other actionable mutations such as BRAF, MET and NTRK with rates of <60%. The pts with a histology of squamous cell carcinoma were less likely to receive targeted therapy.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.33 Retrospective Analysis of Adenocarcinoma of Lungs From Medical Oncology Clinic in Eastern India

K. YIDAGUR GANGADHARAIAH LOKESH, S. KUMAR MISHRA
ALL INDIA INSTITUTE OF MEDICAL SCIENCE, BHUBANESWAR, BHUBANESWAR/IN

Introduction: Lung cancer (LC) is the most common cancer in the world and poses a significant health burden globally. The study aims to analyze the demographic, clinicopathological features and treatment outcomes of Adenocarcinoma of Lungs in patients presented to our medical oncology clinic at Aiims Bhubanesar.

Methods: The study is a retrospective descriptive study. A total of 145 patients with Adenocarcinoma of the lung were registered in the medical oncology clinic. Their demographic, clinical pathological, mutation profiles, and treatment outcomes were analyzed.

Results: Out of 145 Adenocarcinoma lung patients analyzed, 11 patients belonged to stage III (7.5%), and 134 (92%) were stage IV. The male-to-female ratio was 1.6:1, with males comprising 90 cases. The median age of patients was 58 years, with a range of (26 years to 84 years). ECOG performance status was > 2 in 38 (26%) patients. Among the data available, 24 patients had a prior history of smoking. Thoracic metastases alone were seen in 30(20%). Among the extra-thoracic metastases 102(70%) patients, bone metastases 80 (55%) were the commonest, followed by brain metastases 39(27%), and adrenal metastases 20(14%).

EGFR mutation was seen in 50/145(34%), ALK rearrangement was seen in 18/145(12%) and ROS in 2(1%). Among EGFR mutations, exon 19 was commonest (30/50) , followed by exon 21 (15/50), exon 20 insertion (4/50) and exon 18 deletion (1/50) mutation. Among patients who underwent NGS(85); EGFR was seen in 24 cases (28%), TP53 mutation was seen in 20, (24%), ALK in 8(5.5%), KRas in 4(5%) , ERBB2 in 4(5%), MET in 3(3%), BRAF in 3(3%), PTEN in 2(2%). PDL1-TPS score > 1% was present in 30 cases. Median PFS of the entire cohort for the first line of therapy received was 13 months (range 2 to 33), and the median OS for the entire cohort was 20 months (range 3 to 36). The median OS with ECOG-PS 0-1 was 21 months (range 9 to 6) and with PS ≥2 was 15 months (range 2 to 36 months) Among mutations (EGFR/ALK/ROS1), median PFS was 17 months in the positive subset versus 5 months in the negative subset. The median OS was 22 months in the positive versus 9 months in the negative subset. Among the EGFR positive subset, mPFS was 12 months in the TP53 positive subset versus 15 months in the TP53 negative. The median OS was 22 months in the TP53 positive subset versus 24 months in the negative patients.

Conclusions: Our study revealed that EGFR mutation was the most common in our patients, and ALK was seen in 12% of cases. NGS identifies 10-15% additional actionable mutations, and in patients with EGFR/ALK/ROS- WT, NGS can be considered. Patients with good ECOG-PS had a better mOS; EGFR, ALK, and ROS1 positive had better mPFS and mOS; patients with TP53 mutation positive had inferior outcomes

Keywords: Mutation analysis, Survival analysis, NGS requirement

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.34 Long-Term Control of Leptomeningeal Disease in NSCLC With EGFR Mutations: A Case Series

H.A. Bravo Thompson[1], C.T. Jani[2], A. Fernandez[2], G. Lopes[2], E. Rodriguez[2]
[1]University of Miami Miller School of Medicine, Miami/FL/USA ,[2]Sylvester Comprehensive Cancer Center, Miami/FL/USA

Introduction: Leptomeningeal disease (LMD) is a rare and historically devastating complication of advanced non-small cell lung cancer (NSCLC). With an incidence of about 3-5%, LMD is associated with a poor prognosis, with median survival from 3-11 months.

Methods: A retrospective review was conducted on three patients diagnosed with metastatic EGFR+ NSCLC who developed LMD. Data on clinical presentation, diagnostic techniques, treatment strategies, and outcomes were collected from medical records. Patient follow-up was conducted to evaluate survival, neurological function, and disease progression.

Results: Case 1: A 48-year-old male with EGFR+ L858R NSCLC on frontline Osimertinib developed LMD after five months, presenting with cervical neck pain, dizziness, and hand paresthesia. Brain MRI revealed leptomeningeal enhancement, confirmed by CSF cytology. Double-dose Osimertinib led to temporary neurological improvement, but two months later, MRI showed progressive LMD. cfDNA testing identified EGFR V834L, associated with Osimertinib resistance. The patient received whole-brain radiotherapy and three cycles of carboplatin/ pemetrexed, followed by five cycles of intrathecal pemetrexed, achieving a significant reduction in CSF tumor cell capture by a thousandfold from baseline. Despite this, LMD progressed after six months, and weekly intrathecal pemetrexed (7 cycles) with double-dose osimertinib failed to control the disease. Overall survival 17 mos. Case 2: A 63-year-old female with EGFR+ L858R NSCLC and brain metastases presented with altered mental status. She underwent left parieto-occipital and suboccipital craniotomies, SBRT, and frontline osimertinib. She remained neurologically stable for six months until imaging showed progressive brain metastases, leading to salvage SRS. Two months later, lumbar spine MRI suggested early LMD, prompting osimertinib dose escalation, though limited by dermatologic toxicity. After six months of stable disease, new brain metastases were detected, but CSF cytology remained negative. She received multiple rounds of brain radiotherapy while continuing osimertinib for eight months until progression of LMD. She underwent craniospinal proton therapy and four cycles of carboplatin/ pemetrexed/ bevacizumab with osimertinib. Despite complications from a subdural hematoma post-fall, imaging five months later showed partial response. She resumed pemetrexed/ bevacizumab with osimertinib and remains stable. Alive 39 months from diagnosis. Case 3: A 63-year-old female with EGFR exon 19 deletion, TP53 P278R, and CHEK2 loss NSCLC presented with persistent cough, headaches, nausea, and vomiting. MRI showed marked cerebellar and occipital leptomeningeal enhancement. Frontline double-dose osimertinib led to a significant neurological and imaging response within six weeks. Stable disease lasted three months before new pleural/pericardial effusions revealed small-cell transformation (new RB1/MAP2K4 loss). She received four cycles of carboplatin/etoposide plus osimertinib, maintaining stable CNS disease. Three months later, worsening dysarthria prompted lumbar puncture, confirming persistent LMD. Craniospinal proton therapy was followed by progressive disease, with cfDNA revealing new EGFR C797S. She was referred for a clinical trial with T-cell engager targeting delta-like ligand 3 (DLL3). Overall survival 15 months.

Conclusions: These cases illustrate that NSCLC patients with LMD and actionable mutations can achieve prolonged responses to targeted therapies, challenging the historically grim prognosis of LMD. Early detection and initiation of targeted agents, in conjunction with close radiation oncology support, may be crucial in extending survival.

Keywords: Leptomeningeal disease, EGFR Lung Cancer, Targeted Therapy

EP.12.35 Insights on Treatment Experience From Patients With ALK+ NSCLC Treated With 1St-Line Brigatinib, Lorlatinib and Alectinib

D. Cherepanov[1], S. Farmen[2], K.W. Culver[2], C.G. Danes[3], A. Ashaye[1], S. Kakked[4], J-H. Tsai[4], K. McCarrier[4]
[1]Takeda Development Center Americas, Inc., Cambridge/MA/USA ,[2]ALK Positive, Atlanta/GA/USA ,[3]Takeda Oncology, Cambridge/MA/USA ,[4]OPEN Health, Bethesda/MD/USA

Introduction: Patients with non-small cell lung cancer (NSCLC) often present with respiratory and systemic symptoms. In anaplastic lymphoma kinase-positive (ALK+) NSCLC, next-generation ALK tyrosine kinase inhibitors (TKIs), brigatinib, alectinib, and lorlatinib, are typical first-line therapies. Each TKI has a unique efficacy/tolerability profile, yet little is known about how these treatments impact daily life from the patient perspective. This study explores patient-reported experiences regarding symptoms, functioning, and impacts on health-related quality of life (HRQoL) among ALK+ NSCLC patients treated with first-line ALK-TKIs.

Methods: A cross-sectional qualitative interview study was conducted in US adults with ALK+ NSCLC that received first-line TKIs for ≥4 weeks within the past 12 months. Participants were recruited via purposive sampling through the ALK-Positive patient advocacy group. One-time, virtual, semi-structured qualitative interviews (~60 minutes) captured patients' self-reported sociodemographic information, symptom and treatment burden, and impact on function and overall HRQoL. Interviews were transcribed and analyzed using ATLAS.ti; codebook was developed using deductive and inductive methods. After concept saturation was achieved, data were summarized descriptively and qualitatively.

Results: Forty-six patients (15, brigatinib; 15, alectinib; 16, lorlatinib) were interviewed (median age: 49 years; female: 67.4%; full/part-time employed: 60.9%); 13 reported brain metastases prior to their first use of a TKI. Some patients (n=21) spontaneously reported being misdiagnosed with conditions such as pneumonia, GERD, asthma, or allergies. The symptoms frequently expressed by participants as their most troublesome during first TKI treatment were weight gain among patients on lorlatinib (31.3%) and alectinib (20.0%), fatigue/tiredness in patients on alectinib (33.3%) and brigatinib (13.3%), GI symptoms in patients on brigatinib (20.0%), and neuropathy or cognitive issues in patients with lorlatinib (18.8%, each; Table). Patients provided ratings on a scale of 0 (least) to 10 (most troublesome/difficult) on their experience with daily pill intake (mean rating: 0.2, brigatinib; 1.3, lorlatinib; 2.1, alectinib) and taking medications as prescribed (mean rating: 0.1, brigatinib; 1.4, lorlatinib; 2.1, alectinib; Table). Treatment satisfaction ratings were reported on a scale of 0 (extremely dissatisfied) to 10 (extremely satisfied), with a mean rating of 9.3 in brigatinib patients, 7.9 in lorlatinib patients, and 7.7 in alectinib patients (Table).

Conclusions: Unique experiences were reported by patients with ALK+ NSCLC treated with different first-line ALK-TKIs. These data illustrate the multifaceted impact of ALK-TKI treatment on daily life, highlighting the importance of addressing both physical and psychosocial dimensions of patient care. These findings emphasize the importance of patient experience considerations in treatment decisions for ALK+ NSCLC.

Table. Patients' Self-Reported Perceptions of Treatment and Treatment Experiences by ALK-TKI

	Brigatinib (n=15)		Alectinib (n=15)		Lorlatinib (n=16)	
Patient rating: troublesome taking the tablet(s) daily,[1] mean (SD), [median, range]	0.2 (0.6) [0, 0-2]		2.1 (2.1) [1, 0-8]		1.3 (1.6) [1, 0-6]	
Patient rating: difficulty in taking medication as prescribed,[2] mean (SD), [median, range]	0.1 (0.3) [0, 0-1]		2.1 (1.9) [2, 0-8]		1.4 (1.0) [1, 0-3]	
Patient rating: treatment satisfaction,[3] mean (SD), [median, range]	9.3 (1.3) [10, 6-10]		7.7 (2.5) [8, 1-10]		7.9 (1.6) [8, 5-10]	
Most troublesome symptoms experienced by the patient **before** treatment[4]	**Symptom**	**n (%)**	**Symptom**	**n (%)**	**Symptom**	**n (%)**

	Physical limitations; Relationship concerns; Limitations to work productivity	1 (6.7%), each impact	Weight gain/ poor body image	2 (13.3%)		

ALK: anaplastic lymphoma kinase; SD: standard deviation; TKI: tyrosine kinase inhibitors
[1]Defined as the extent to which participants perceived daily tablet intake as inconvenient or bothersome, rated on a scale from 0 (not at all troublesome) to 10 (extremely troublesome).
Question asked to the participant to elicit this rating was: "How troublesome did you find taking your tablet/s every day on a scale of 0-10, where 0 is not at all and 10 is extremely troublesome?"
[2]Defined as the degree of difficulty experienced by participants in adhering strictly to prescribed medication instructions, including missing or forgetting doses, rated on a scale from 0 (not at all difficult) to 10 (extremely difficult).
Question asked to the participant to elicit this rating was: "How difficult was it for you to take [first TKI therapy] as prescribed on a scale of 0-10, where 0 is not at all difficult and 10 is extremely difficult?"
[3]Defined as participants' subjective evaluation of their overall satisfaction with the medication, reflecting their perceived effectiveness and acceptability of the therapy, rated on a scale from 0 (extremely dissatisfied) to 10 (extremely satisfied).
Question asked to the participant to elicit this rating was: "On a scale of 0-10, where 0 is extremely dissatisfied and 10 is extremely satisfied, how satisfied are you with [first TKI therapy]?"
[4]Questions asked to the participant to elicit most troublesome symptoms before and during treatment were as follows:
Before: "Of all the symptoms you have mentioned, which of these symptoms was the most troublesome to you during the time BEFORE you started [first TKI therapy]? What made this symptom the most troublesome for you?"
During: "Of all the symptoms and/or side effect you have mentioned, which of these symptoms and/or side effects was the most troublesome to you when taking [first TKI therapy]? What made this symptom and/or side effect the most troublesome for you?"
[5]Questions asked to the participant to elicit most troublesome impacts during treatment were as follows:
During: "Of all the impacts you have mentioned, which of these impacts was the most troublesome to you when taking [first TKI therapy]? What made this impact the most troublesome for you?"

Introduction: BRAF mutations are found in 1-8% of non-small cell lung cancer (NSCLC) patients (pts), primarily in lung adenocarcinomas. Of these, BRAFV600E is the most common variant. Due to its rarity, clinical characteristics and real-world treatment practices for patients with BRAFV600E mutant (BRAF MT) metastatic NSCLC (mNSCLC) are often not well described. Data visualization enables faster interpretation of data and identification of trends and relationships. The aim of this exploratory analysis is to visualize real-world data of treatment patterns in adult patients with BRAFV600E mNSCLC.

Methods: OCTOPUS (NCT05546905) is a multicenter, observational, descriptive, ambispective European study in adult patients who initiated a first systemic treatment for mNSCLC from 1st December 2017, and either before (retrospective cohort) or after (prospective cohort) study entry. Data on patient and clinical characteristics, BRAF mutation testing practices, treatment patterns, safety and effectiveness were collected. Results from the interim analysis of the retrospective cohort have been previously presented. Based on this interim analysis machine learning, time sequence analysis through K clustering (TAK), was used to identify and visualize patients with similar treatment sequences. Other advanced visualization techniques were used and will be displayed.

Results: A total of 152 pts were included, with a median follow-up (FU) time of 16.7 (0.2-71.6) months and median age at metastatic disease of 70.0 (44.0; 90.0) years. Visualization with Sankey diagram provided an overview of the diversity of treatment sequences observed from line 1 (L1) to line 3 and further. Among patients who received a 1st line of treatment (LoT), 45.3% (N=69) received a 2nd LoT, 37 pts (24,3%) were still under 1st LoT, and 15.1% (N=23) received a 3rd LoT during the FU period. At the end of the FU, 42,1% (N=64) of the pts were ongoing. Pts were gathered in groups depending on the type of 1st LoT received. “Targeted Therapy” (TT) group comprised 74 pts, “Chemotherapy + Immunotherapy” (Chemo-IO) 26 pts, “Chemotherapy” (Chemo) 24 pts, “Immunotherapy” (IO) 15 pts.15 pts were not classified in any of the previous groups and were grouped in “Other”. Pts who received TT in L1 had an average age (+/-sd) of 70.3 (+/- 10.3) years, while patients who received another type of L1 (N=78) had an average (+/-sd) of 66.9 (+/- 9.1) years. Chemo-IO group had the lowest rate of patients with comorbidities at 57.7% (N=15), while the TT group had the highest rate at 78.4% (N=58). Duration of 1st LoT was the longest in the TT group with 16.0 (+/- 14.8) months in average while IO, Chemo, Chemo-IO and “Other” (N=13) had shorter durations of 2.9 (+/- 3.6), 3.3 (+/- 3.0), 6.6 (+/- 6.4) and 10.5 (+/- 12.3) months, respectively.

Conclusions: Advanced visualization techniques reveal insights into clinical practices, pathways, and how patient differ by type of treatment. These findings highlight the varied treatment management patterns in real-world settings and the lack of clear treatment sequences despite the availability of recommendations in international guidelines. This is an exploratory analysis based on an interim analysis; data should be interpreted with caution.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.37 Targeted Treatment of NSCLC With? BRAF Fusions: A Systematic Review

S. Verma[1], J. Samuel[2], E. Winquist[1], S.A. Climans[1], C. Cacciotti[2], G. Boldt[1], D. Breadner[1], J. Raphael[1]
[1]Verspeeten Family Cancer Centre, London Health Sciences Centre; Schulich School of Medicine and Dentistry, Western University, London/ON/CA ,[2]London Health Sciences Centre; Schulich School of Medicine and Dentistry, Western University

Introduction: BRAF fusions are rare oncogenic drivers (<1%) in non-small cell lung cancer (NSCLC). While the BRAF V600E mutation is an established therapeutic target, the role of BRAF fusions in guiding targeted treatment remains unclear due to limited clinical data. This systematic review was done to summarize the available literature on the targeted treatment of BRAF fusion-positive solid cancers. Here, we report on the available evidence on the efficacy of targeted therapies, including BRAF and MEK inhibitors, in patients with advanced BRAF fusion-positive NSCLC.

Methods: A systematic review was conducted to evaluate the reported efficacy, response rates and survival outcomes of targeted treatment in patients with BRAF fusion-positive solid tumors. PubMed, EMBASE, and Cochrane CENTRAL were searched for relevant studies between 2014 and 2024.

Results: A total of 8 studies, including 9 patients with BRAF fusion-positive advanced NSCLC treated with targeted therapy, were identified. Seven were case reports, and one was a phase I/II clinical trial that included two patients with BRAF fusion-positive NSCLC. Table 1 depicts BRAF fusion partner, targeted therapy, outcomes and toxicity. The targeted therapies used included MEK inhibitors (trametinib) or BRAF inhibitors (dabrafenib or vemurafenib) alone or in combination with other targeted agents. The BRAF fusion partners were heterogenous. The objective response rate (ORR) in NSCLC was 89%, the highest among all analyzed tumor types (including sarcoma, melanoma and CNS tumors with ORR of 57%, 52% and 41% respectively). However, survival and safety data remain limited due to the rarity of these fusions.

Conclusions: Targeted therapies, particularly BRAF and MEK inhibitors, show promising efficacy in BRAF fusion-positive NSCLC, with a high response rate in available reports. However, the current evidence is largely based on very limited case reports and clinical trial data. Given the rarity of these fusions, international collaboration and novel trial designs, such as basket and platform trials, are crucial to better define optimal therapeutic strategies and improve patient outcomes.

Table 1. Details on *BRAF* fusion partner, targeted therapy and outcomes

	Study (year)	Type of study	Number of patients	*BRAF* fusion partner	Treatment	Best radiological response	Toxicity
1	Chou et al 2022	Case Report	1	KIAA1549	Dabrafenib with trametinib, and capmatinib	SD	Grade 3 peripheral edema, Grade 2 fatigue, Grade 1 fever, rash and nausea
2	Kian et al 2023	Case Report	1	MKRN1	Osimertinib with trametinib and dabrafenib	PR	NA

Introduction: This study aimed to evaluate the efficacy and safety of Firmonertinib (160 mg) combined with pemetrexed and platinum-based chemotherapy as a first-line treatment for non-small cell lung cancer (NSCLC) patients with EGFR mutations and central nervous system (CNS) metastases.

Methods: This prospective, single-arm, phase II clinical study enrolled 12 NSCLC patients with EGFR classic mutations and CNS metastases from multiple medical centers in Anhui Province between January 17, 2024, and March 16, 2025,moreover, the study is still ongoing with continuous enrollment. All patients received a combination therapy of Firmonertinib(160mg), pemetrexed plus platinum-based chemotherapy. Clinical baseline characteristics, efficacy outcomes, and safety data were systematically collected and analyzed.

Results: Among the 12 patients, 50% had EGFR exon 19 deletions, and 50% had L858R mutations, with 33% also presenting TP53 co-mutations. The objective response rate (ORR) and CNS ORR were 75% and 83.3%, while the disease control rate (DCR) and CNS DCR were 100% and 91.7%, respectively. With a median follow-up of 4.95 months, only 1 patient had experienced disease progression, with the remaining 11 patients continuing treatment. Progression-free survival (PFS) and CNS PFS data were not yet mature. The safety profile of the combination therapy was manageable, with 33.3% of patients requiring dose reductions due to treatment-related adverse events (TRAEs),the most common adverse events were anemia and leukopenia, which were more strongly associated with chemotherapy. However, no treatment interruptions, discontinuations, grade 4 adverse events, or treatment-related deaths were reported.

Conclusions: Firmonertinib (160mg)combined with pemetrexed and platinum-based chemotherapy demonstrated promising clinical efficacy and manageable toxicity in EGFR-mutated NSCLC patients with CNS metastases. These findings support its potential as a viable first-line treatment option for this patient population.

Introduction: Resistance to tyrosine kinase inhibitor (TKI) has become a major therapeutic challenge in ALK-positive non-small cell lung cancer (NSCLC). The exact roles of genomic factors and tumor microenvironment characteristics in ALK-TKI resistance remain unclear and warrant thorough investigation, especially at the dynamic level.

Methods: To explore these mechanisms, we collected baseline and post-TKI treatment specimens from 16 patients with ALK-positive NSCLC, along with baseline samples from 28 ALK-negative NSCLC patients, for RNA and whole-exome sequencing. The comprehensive mutational landscape and mutation signatures analysis were conducted to explore genomic resistance mechanisms. Additionally, CIBERSORT, MCP-counter, xCELL, and quanTIseq were applied to evaluate immune infiltration.

Results: Notably, ALK-positive tumors displayed distinct TME features compared to ALK-negative NSCLC, characterized by enhanced antigen presentation and high expression of immunosuppressive components. Genomic analysis revealed novel mutation sites potentially linked to ALK-TKI resistance. From the microenvironment perspective, a “cold” tumor microenvironment with lower abundance of CD8+ T cells, memory B cells, and dendritic cells was observed in TKI-resistant samples, indicating that immunosuppressive transformation tumor microenvironment may promote ALK-TKI resistance. Furthermore, estrogen pathways were enriched in TKI-resistant samples, and a quantitative method of ER scores derived from estrogen pathways was associated with a poor prognosis under ALK-TKI therapy.

Conclusions: The study profiled the evolving mutational landscape and tumor microenvironment features of ALK-positive NSCLC across treatment stages, characterized the potential resistance mechanisms to ALK-TKI, and may provide insights for optimizing therapeutic strategies.

Keywords: ALK rearrangement, Tumor microenvironment, Tyrosine kinase inhibitors

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.40 Clinical Efficacy and Safety Analysis of Osimertinib Versus Aumolertinib in Real-World Treatment of EGFRm Advanced NSCLC

H. Qiao[1], N. Wang[2], C. Fu[3], S. Li[4], X. Hou[1]
[1]The First Hospital of Lanzhou University, Lanzhou City/CN ,[2]Lanzhou University Second Hospital, Lanzhou/CN ,[3]Gansu Provincial Cancer Hospital, Lanzhou/CN ,[4]Gansu Provincial Hospital, Lanzhou/CN

Introduction: China leads globally in the universality and availability of third-generation epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs), with intense competition among these agents. Despite various treatment options, there remains lack of direct comparative studies to guide patients (pts) in making informed decisions regarding third-generation EGFR-TKIs. Aumolertinib, a highly potent and irreversible third-generation EGFR-TKI, has been developed independently in China.

Methods: This study retrospectively analyzed the clinical data of 168 EGFR-mutated non-small-cell lung cancer (NSCLC) pts who received osimertinib (85 pts) and aumolertinib (83 pts) at four medical centers from January 2015 to January 2024. Pts with stage IIIB-IV were divided into two cohorts and were given either 80mg osimertinib (56 pts) or 110mg aumolertinib (53 pts) as first-line treatment recommended by guidelines.

Results: At data cut-off (November 25, 2024), the median follow-up for the osimertinib and aumolertinib groups was 26.92 months and 24.44 months, respectively. The median PFS was significantly longer in aumolertinib group than osimertinib group at 34.4months (95% CI, 30.9-not reached) versus 26.9 months (95% CI, 22.2 to 40 ;HR, 0.52; 95% CI, 0.29 to 0.92; P = 0.031). Subgroup analyses(age, baseline brain metastasis, baseline liver metastasis, EGFR mutation types, and co-mutations)using a univariate Cox model indicated that the HR between two groups were all less than 1, suggesting that all subgroup pts benefit from aumolertinib. Adverse events of grade ≥ 3 severity (any cause) were observed in 3.57% and 3.77% of pts in two groups, respectively.

Conclusions: Presently, aumolertinib is undergoing global development studies to maximize benefits of pts worldwide. This study provides guidance for the future selection of third-generation EGFR-TKIs in countries beyond China.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.41 FUTURE Trial:First-Stage Data of Initial Firmonertinib 160mg in EGFR+/PD-L1+ Locally Advanced or Metastatic NSCLC (Simon's Two-Stage Design)

H. Yu, J. Wang, X. Wu, H. Wang, Y. Zhang, Y. Lin, Z. Wu
Fudan University Shanghai Cancer Center, Shanghai/CN

Introduction: Firmonertinib, a novel third-generation epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI), demonstrates superior brain penetration, a broad therapeutic window, and a favorable toxicity profile. While third-generation EGFR-TKIs have become the established first-line standard for advanced EGFR-mutant non-small cell lung cancer (NSCLC), emerging evidence suggests that strong PD-L1 expression (TPS≥50%) may drive primary resistance to third-generation EGFR-TKIs, adversely impacting patient prognosis. Dose escalation of third-generation TKIs may represent a potential therapeutic strategy.

Methods: The FUTURE study is a prospective multicenter phase II trial evaluating firmonertinib (160 mg once daily) in patients with locally advanced or metastatic EGFR-sensitive mutations and PD-L1 positive status. Utilizing a Simon's two-stage design, the study plans to enroll 30 subjects in the first stage, requiring a 1-year progression-free survival (PFS) rate >60% to proceed to the second stage. An additional 32 subjects will be subsequently enrolled, totaling 62 patients. This trial will be deemed successful if the pooled 1-year PFS rate exceeds 70%. The primary endpoint is 1-year PFS rate, with secondary endpoints including objective response rate (ORR), PFS, and safety assessments. This report presents the data analysis of 30 subjects enrolled in Stage 1 of the study.

Results: As of March 1, 2025, the first stage of this study had successfully enrolled 30 subjects. The cohort comprised patients with a median age of 59 years (range: 45-76), predominantly never-smokers (80.0%) with stage IV lung adenocarcinoma (83.3%). Key characteristics included L858R mutation (56.7%) and brain metastases (26.7%), while 50.0% of patients exhibited high PD-L1 expression. Median follow-up was 27·1 months. Investigator-assessed outcomes demonstrated a confirmed objective response rate (cORR) of 86.7% (1 CR, 25 PR) and a disease control rate (DCR) of 96.7%, with a median tumor regression depth of 56.0%. The 1-year PFS rate reached 73.3%. Treatment-related adverse events (TRAEs) of grade ≥3 were observed in 6.7% of patients, primarily manifesting as elevated transaminases, rash, and diarrhea. The study has now progressed to Simon's second stage.

Conclusions: The FUTURE study has preliminarily demonstrated the excellent efficacy and manageable safety profile of firmonertinib as first-line treatment in patients with EGFR-sensitive mutations and PD-L1 positive status.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.42 Durable Response to ROS1-Tkis in Metastatic Squamous NSCLC With EZR-ROS1 Fusion

E.M. Urbanska[1], E.S. Petersson[2], M.H. Suppli[1], M. Grauslund[2], J.B. Sørensen[1], E. Santoni-Rugiu[2,3]
[1]Copenhagen University Hospital, Copenhagen/DK ,[2]Copenhagen University Hospital, Rigshospitalet, Copenhagen/DK ,[3]University of Copenhagen, Copenhag

Introduction: Molecular testing in patients with metastatic pulmonary squamous cell carcinoma is currently not standard of care (SOC) as the chances of finding a therapeutic target are generally very limited. However, it may be performed upon request from the oncologist for exploring further potential therapeutic options.

Methods: We present an 82-year-old man in PS 1, current light smoker, with hyperthyroidism as only comorbidity. The patient was diagnosed by EBUS-FNA from mediastinal lymph nodal station 4R, 7, 4L, and 11L in Maj 2020 with T4N3M0 pulmonary squamous cell carcinoma. The cell block from the EBUS-FNA contained keratinizing metastatic tumour cells, which immunohistochemically were positive for CK5 and p40, while reactions for CK7, TTF1, and synaptophysin were negative. The PD-L1 Tumour Proportion Score was > 50%. The patient initially received SOC curative-intended concomitant chemo-radiotherapy followed by Durvalumab. However, after five months, adjuvant treatment was stopped due to symptomatic failure with-in the radiotherapy field corresponding to the primary lung tumour in the left lower lobe with compression of the left bronchial tree. Relief from obstruction and hemoptysis due to intrabronchial tumour growth was obtained by argon beam therapy, but the patient had further progression of mediastinal lymph nodal metastases and malignant pleural effusion. Thus, extended molecular testing of the diagnostic EBUS-FNA was requested, while considering second-line Docetaxel

Results: DNA-NGS (Oncomine Comprehensive Assay v.3, ThermoFisher Scientific) showed a pathogenic mutation of the cell proliferation-inducing TERT promoter (c.-124C>T(C228T)), whereas RNA-NGS (Archer Fusionplex Lung panel, IDT V1) revealed the EZR (exon 9)-ROS1 (exon 34) fusion. In July 2021, the patient initiated second-line treatment with the ROS1-tyrosine kinase inhibitor (TKI), Crizotinib, with good clinical effect and radiographic partial response. Treatment continued until July 2022, at which time grade 3 peripheral edema occurred and was resolved during a 2-week treatment break. No radiographic progression was observed at this point, and in August 2022 the patient started treatment with the new-generation ROS1-TKI, Entrectinib, at a reduced dose. The patient is currently continuing Entrectinib treatment with maintained remission of the disease and good quality of life.

Conclusions: This case demonstrates the relevance of extended molecular testing by DNA- and RNA-NGS also in selected patients with pulmonary squamous cell carcinoma. Indeed, to our knowledge, this is the first case demonstrating objective and prolonged response to sequential ROS1-targeted treatment of metastatic pulmonary squamous cell carcinoma with EZR-ROS1 fusion. The patient's current progression-free survival on ROS1-TKIs is 45 months.

Keywords: ROS1 fusion, pulmonary squamous cell carcinoma, RNA-NGS

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.43 Long Progression-Free Survival With Sunvozertinib in EGFRm NSCLC Patients After Third-Generation EGFR TKI Failure: Case Series

M. You
National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Sunvozertinib is an oral, potent, irreversible EGFR TKI with strong efficacy against various EGFR mutations, including exon 20 insertions. In EGFRm patients, resistance to third-generation EGFR TKI often leads to poor outcomes with continued therapy. This real-world case series highlights sunvozertinib's potential in advanced NSCLC harboring with EGFR sensitizing mutations after third-generation EGFR TKI treatment failure.

Methods: We retrospectively collected data from EGFRm NSCLC patients who experienced treatment failure with third-generation EGFR TKI and subsequently received sunvozertinib. PFS was analyzed.

Results: At the data cutoff (Dec 11, 2024), three patients were reviewed: A 72-year-old male was diagnosed with stage IIIB lung adenocarcinoma (EGFR L858R) underwent lobectomy and adjuvant chemotherapy in Aug 2006. After relapsing in Jun 2010, he received various chemotherapy regimens until Aug 2012, followed by icotinib, then osimertinib (found T790M mutation) was administered as fifth-line therapy (Dec 2017-May 2023) combined with anlotinib from 2020, and nab-paclitaxel plus sugemalimab as sixth-line (May-Oct 2023). For seventh-line treatment, sunvozertinib 150 mg QD with vinorelbine maintained for over 12 months. The second patient, a 70-year-old male with stage IV lung adenocarcinoma (EGFR 19del, T790M) diagnosed in Nov 2018, received osimertinib until Jul 2023, along with radiotherapy. Second-line sunvozertinib 300 mg QD treatment for over 13 months. The third patient, a 61-year-old female with stage IIIB lung adenocarcinoma, underwent lobectomy and adjuvant chemotherapy in Jun 2011. After relapsing in 2016, she received gefitinib. In Sep 2018, genetic testing revealed EGFR R776H, T790M, and L858R mutations, leading to osimertinib until Oct 2020. After third-line anlotinib and fourth-line anlotinib combined with S1, she began sunvozertinib 225 mg QD as fifth-line therapy, resulting in reduced lung nodules and continuing treatment for 12 months.

Conclusions: This case series demonstrates that sunvozertinib offers promising clinical benefits for EGFRm NSCLC patients after third-generation EGFR TKI treatment failure, highlighting its potential as an optional subsequent treatment strategy.

Table 1. Case summary (Data cutoff: Dec 11, 2024)

Cases	Sex	Age	EGFR mutation subtype	Treatment line of sunvozertinib	Previous third-generation TKI treatment	Previous chemotherapy treatment	Adverse events	Progressive disease	PFS (months)
1	Male	72	EGFR L858R, T790M	7	Yes	Yes	Diarrhea	None	12
2	Male	70	EGFR 19del, T790M	2	Yes	No	Paronychia	None	13
3	Female	61	EGFR R776H, T790M and L858R mutations	5	Yes	Yes	Fatigue, poor appetite	None	12

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.44 The Efficacy of Capmatinib in Treating NSCLC Patients With MET Amplification in a Multi-Center Real-World Setting

N.n. Yan[1], Z. He[2], J. Li[3], X. Wang[4], Z. Zhang[5], X. Li[1]
[1]zhengzhou university first affiliated hospital, zhengzhou/CN ,[2]Henan Cancer Hospital, Zhengzhou/CN ,[3]Qilu Hospital of Shandong University, Jinan/CN ,[4]Shanxi Traditional Chinese Medical Hospital, Taiyuan/CN ,[5]The Second Affiliated Hospital of Zhengzhou University, Zhengzhou/CN

Introduction: In non-small cell lung cancer (NSCLC), MET amplification is recognized as an independent oncogenic driver. Capmatinib is an oral, ATP-competitive, highly potent, and selective type Ib inhibitor of the MET receptor tyrosine kinase. It was approved for use in NSCLC patients with MET exon 14 skipping mutations. However, no agents have been approved for patients with MET amplification. This study aims to investigate the efficacy of capmatinib in patients with either de novo or acquired MET amplification through a multi-center retrospective analysis.

Methods: This study was a multi-center retrospective investigation. Patients with de novo and acquired MET amplification treated with capmatinib between January 2020 and June 2024 were recruited. Patient-related disease information and treatment regimens were gathered from the hospital medical records system. Kaplan-Meier analysis was utilized to evaluate the real-world progression-free survival (rwPFS) of patients who received at least one dose of capmatinib. The objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety profile were also analyzed.

Results: A total of 14 patients from 5 centers in China were enrolled in the study. The median number of treatment lines using capmatinib was 3 (ranging from 1 to 6). Regarding the MET status, there were 2 patients with de novo MET amplification, 8 patients with acquired MET amplification. 4 patients were detected to have a MET gene copy number (GCN) ≤5, and 6 patients had a MET GCN >5. The median observation period was 38.6 months (95% CI: 30.47-NA]). The median rwPFS for patients with both de novo and acquired MET amplification was 8.08 (95%CI: 4.3-NA), and the median rwOS was14.6 (95% CI: 1.13-NA). When stratified by GCN, no significant difference was observed in the median rwPFS (8.08 months vs 8.68 months for GCN>5 and GCN≤ 5 respectively, p = 0.84). Although the median rwOS for patients with GCN>5 was numerically longer than that for patients with GCN≤ 5 (40 months vs 14.60, p = 0.78), due to the limited sample size, no statistically significant difference was found.The ORR for patients with de novo and acquired MET amplification was 40% (4/10) (95%CI: 12.16-73.76). The DCR was 90%(95%CI: 55.5-99.75). When stratified by MET copy number, the ORR for patients with a gene copy number (GCN)>5 was 66.7% (4/6), while the ORR for patients with GCN ≤ 5 was 0%. The most commonly reported adverse event was peripheral edema, which was consistent with previous reports.

Conclusions: In a real-world context, capmatinib emerges as a promising treatment alternative for patients with either de novo or acquired MET amplification. The MET GCN holds potential as a biomarker for predicting the efficacy of capmatinib in treating patients with MET amplification. Moreover, the fact that adverse events are manageable further validates its application in clinical practice.

Keywords: Capmatinib, MET amplification, NSCLC

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.45 Concurrent ROS1-Rearrangements of Brain Metastasis in EGFR-Mutation Lung Adenocarcinoma

C.M. Tseng
Cheng Hsin General Hospital, Taipei/TW

Introduction: A 51-year-old female, who smoked over 20 pack-year suffered from productive cough and left chest pain for 2 weeks. Chest computer tomography (CT) showed perivascular consolidation at RUL (3.2x 0.9x 1.5cm), an ill-defined nodule (2.1x 1.9x 1.4cm) at RML with enlarged nodes including subcarinal region. Brain MRI found at least 7 intracranial small nodular metastases. Pathologic report from RLL tumor showed adenocarcinoma. The AJCC 8th TNM staging is cT4N2M1c, stage IVB. Gene mutation showed 1. EGFR Del19 under Real-time PCR/ cobas EGFR mutation 2. PD-L1 TC<1% under SP263 3. ROS-1 IHC 2+ under SP384, ROS-1 FISH negative under Abbott Vysis ROS1 Break Apart FISH Probe Kit 4. ALK equivocal under D5F3 with Ventana. She received afatinib.

Methods: However, RUL tumor progression and severe headache occurred after 2 months of afatinib use. She received palliative whole brain radiotherapy, but in vain. Due to lung tumor progression, she received CT guide biopsy from RML consolidation. Neurosurgery suggested and she also received separated supratentorial and infratentorial craniotomy for tumor removal.

Results: Molecular mutation examination from RML lung tissue showed adenocarcinoma without EGFR mutation. Pathologic result from brain tumor showed metastatic adenocarcinoma, and NGS report by Roche foundation medicine found ROS1 EZR-ROS1 fusion. Therefore entrectinib 200mg 3 tabs per day was given. She tolerated it well and it showed partial response in the primary lung tumor in RML and no occurrence in brain metastasis.

Conclusions: We suggest the patient may have concurrent EGFR mutation and ROS-1 rearrangement in different part of lung tumor

Keywords: cocurrent ROS-1 rearragement and EGFR mutation, target therapyt

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.46 Efficacy of Sunvozertinib in Advanced NSCLC With HER2 Exon 20 Insertion After Prior Treatment Failure: A Real-World Case Serie

D. Liu, L. Liu
Tianjin Medical University Cancer Institute & Hospital, Tianjin/CN

Introduction: Non-small cell lung cancer (NSCLC) with HER2 exon 20 insertion mutations represents an aggressive disease subset with limited treatment options and poor prognosis. Sunvozertinib, a novel tyrosine kinase inhibitor (TKI) designed for EGFR exon 20 insertions, has shown potential activity against HER2 exon 20 insertions. This case series assesses the efficacy and safety of sunvozertinib as ≥second-line therapy in patients with HER2 exon 20 insertion mutations after prior treatment failure.

Methods: We retrospectively reviewed data from patients with advanced NSCLC harboring confirmed HER2 exon 20 insertion mutations who received sunvozertinib following progression on prior therapies. Data encompassed patient demographics, disease stage, previous treatments, sunvozertinib dosage, treatment response (per RECIST 1.1 where applicable), adverse events (AEs), and clinical outcomes.

Results: At data cutoff (Nov 20, 2024), three patients were retrospectively reviewed: 1): A 59-year-old female who was diagnosed with stage IIIA lung adenocarcinoma (HER2 p.G776delinsLC) in 2022, received sunvozertinib 300 mg once daily (QD) as third-line therapy in December 2023. Prior treatments included first-line chemotherapy plus immunotherapy (PFS 3 months) and second-line dacomitinib (PFS 4 months). She achieved a partial response (PR) with 40% tumor shrinkage with sunvozertinib monotherapy, which sustained for 9 months until September 2024. Subsequent sunvozertinib plus vinorelbine yielded stable disease (SD) for 1 month, followed by progression after 2 months. AEs (rash, diarrhea, mucositis, and appetite loss) were managed without discontinuation. 2): A 58-year-old female with stage IIIB lung adenocarcinoma (HER2 p.Y772-A775dup), who was diagnosed in 2023, started sunvozertinib 300 mg QD as second-line therapy in May 2024 after progression on first-line immunotherapy plus chemotherapy (PFS 8 months). She achieved PR with 40% tumor shrinkage, with AEs including diarrhea, rash, oral mucositis, and decreased appetite, which were all tolerable. 3): A 48-year-old female with advanced NSCLC (HER2 p.Y772-A775dup), who was diagnosed in 2022, received sunvozertinib 300 mg QD as sixth-line therapy starting from April 2024. She was heavily pretreated with chemotherapy, immunotherapy, radiotherapy, and targeted agents across five prior lines. Sunvozertinib resulted in stable disease (SD) with 10% tumor shrinkage observed after one month, which sustained for 6 months until progression. AEs comprised diarrhea, rash, oral mucositis, decreased appetite, and leg cramps, which were managed conservatively.

Conclusions: Sunvozertinib exhibited clinical efficacy in advanced NSCLC with HER2 exon 20 insertions across second to sixth-line settings with tumor obvious shrinkage post-prior treatment failures. The AE profile (rash, diarrhea, mucositis) was tolerable and manageable. These real-world data suggest sunvozertinib as a promising option for this population, meriting further prospective research.

Keywords: NSCLC, HER2 Exon 20 Insertion, Sunvozertinib

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.47 Persistent Response of Sunvozertinib in Lung Adenocarcinoma Patient With EGFR Exon 20 Insertion Mutation

H. Han, J. Zhou
Liaocheng People's Hospital, Liaocheng/CN

Introduction: Sunvozertinib is an oral, potent, highly selective epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) approved in China for the treatment of advanced non-small cell lung cancer (NSCLC) with EGFR exon 20 insertion (exon20ins) mutation. The clinical trial of sunvozertinib in first-line setting is under exploration. Here, we firstly report the encouraging efficacy and safety of sunvozertinib as first-line maintenance therapy in a lung adenocarcinoma patient with EGFR exon20ins mutation after receiving immunotherapy and chemotherapy.

Methods: Medical records were reviewed retrospectively. The data analyzed by investigators included response assessment by RECIST1.1 and safety outcomes.

Results: A 67-year-old male patient underwent CT scan in February 2022 which showed left lung malignancy with bilateral hilar and mediastinal lymph node metastasis, bilateral rib and thoracic vertebrae metastasis. The longest diameter of the tumor was 7.4 cm. A lymph node biopsy of left neck was performed, and immunohistochemistry confirmed lung adenocarcinoma with PD-L1 expression of 80%. Next-generation sequencing (NGS) showed EGFR exon20ins mutation (p.P772delinsPH). The TNM stage was cT4N3M1c, IVB (AJCC 8th edition). From March 2022, the treatment of tislelizumab, pemetrexed and carboplatin was given every 3 weeks for 6 cycles. The tumor size shrank from 7.4 cm to 4.9 cm. Maintenance treatment with tislelizumab and pemetrexed and then pemetrexed alone was started from July 2022, and the tumor lesion remained stable. However, the patient refused to continue using tislelizumab or pemetrexed due to tolerance issues. The patient started sunvozertinib 300mg QD monotherapy from Dec 2023 based on the accessibility and efficacy. After the drug change, the tumor continuously shrank under the treatment of sunvozertinib with good safety and tolerability. Only grade 1 diarrhea and paronychia occurred, which were improved by symptomatic treatment. The most recent follow-up CT scan showed the tumor size shrank to 3.8 cm. By March 2025, the patient's progression-free survival reached 36 months.

Conclusions: For lung adenocarcinoma patient with EGFR exon20ins mutation, sunvozertinib showed sustained efficacy and safety benefits as first-line maintenance treatment after the patient developing intolerance to immunotherapy and chemotherapy.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.48 Identifying Optimal First-Line Treatment Strategy for Advanced-Stage EGFR Mutant NSCLC: A Network Meta-Analysis

D. Feng[1,2], J. Tang[2,3], C. Zhou[3]
[1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]Guangzhou Medical University, Guangzhou/CN ,[3]First Affiliated Hospital of Guangzhou Medical University National Key Laboratory of Respiratory Diseases Clinical Experiment Department, Guangzhou/CN

Introduction: Epidermal growth factor receptor (EGFR) mutations drive 50-60% of unresectable non-small cell lung cancer (NSCLC) in Asian populations, positioning EGFR tyrosine kinase inhibitors (TKIs) as first-line therapy. Although numerous head-to-head randomized controlled trials (RCTs) have emerged comparing novel agents and combination therapeutic strategies, the comparative efficacy among these regimens remains to be systematically evaluated. The meta-analysis was conducted to assess the individual and comparative clinical outcomes of various first-line EGFR-TKI-based treatment strategies.

Methods: This PROSPERO-registered (CRD42024572724) network meta-analysis followed PRISMA guidelines, systematically searching PubMed, Embase, Cochrane Library, Web of Science, and major conferences as of January 2025 for II/III RCTs comparing EGFR-TKI regimens. Outcomes included survival metrics (PFS/OS), response rates (ORR/DCR), and adverse events (AEs).

Results: A total of 54 RCTs, involving 12,344 patients and 35 first-line EGFR-TKI-based treatment strategies were included. Osimertinib combined with chemotherapy demonstrated superior PFS (SUCRA=0.8235) and OS (SUCRA=0.8932). Osimertinib and savolitinib achieved the highest ORR (SUCRA=0.9238), while first-generation TKI plus chemotherapy ranked first for disease control rate (SUCRA=0.8226). The safety analysis revealed that second-generation TKI-antibody combination therapy (afatinib plus cetuximab) was associated with the highest incidence of adverse events, evidenced by the maximum SUCRA values for both any-grade AEs (SUCRA=0.8207) and grade 3 or higher AEs (SUCRA=0.8252), while osimertinib plus chemotherapy also showed high incidence of grade 3 or higher AEs (SUCRA=0.7472).

Conclusions: For patients with advanced EGFR-mutated NSCLC, osimertinib plus chemotherapy is considered the optimal choice due to its superior efficacy in improving PFS and OS compared with other EGFR-TKI-based treatment strategies. However, the toxicity of third-generation EGFR-TKI plus chemotherapy requires careful attention.

EP.12.49 Osimertinib Distribution in Brain Metastases From Patients Withmetastatic Non-Small Cell Lung Cancer

D.A.C. Lanser, N. Heersche, E.M. Bos, P. de Bruijn, J.L.M. Jongen, M.S. Paats, A-M.C. Dingemans, R.H.J. Mathijssen, G.D.M. Veerman
Erasmus MC, Rotterdam/NL

Introduction: Osimertinib is a small-molecule kinase inhibitor used for EGFR+ non-small cell lung cancer (NSCLC) with relative good penetration into the cerebrospinal fluid (CSF) compared to other EGFR-inhibitors. CSF concentrations from lumbar punctures range from 0.77 to 18.1 ng/ml, which represents 0.2% to 5% of the systemic osimertinib exposure1-4. It is however unknown how much osimertinib actually reaches brain tissue and central nervous system (CNS) metastases.

Methods: Patients with EGFR+ metastatic NSCLC were included in a prospective biomarker cohort study (NCT05221372). For this sub-study, patients who used osimertinib and underwent metastatectomy of a CNS metastasis were selected for collection of blood, CSF, and CNS tumour tissue. Also, other (peritumoral brain) tissue which became available during the procedure was collected, e.g. the entry cortex. Samples were quantified using validated LC-MS/MS assays.5,6

Results: Three patients underwent CNS metastatectomy because of progression of a single CNS metastasis during osimertinib treatment of 80mg QD. Patient 1 received osimertinib after 10 months of erlotinib treatment, because she developed new CNS metastases. Regardless of the highest concentration in the tumour, osimertinib did not result in CNS response. Molecular diagnostics showed new MET and EGFR amplifications as resistance mechanisms. Patients 2 and 3 received osimertinib as first-line treatment. Patient 2 was pre-treated with cranial stereotactic radiotherapy, including the later progressive metastasis. She had CNS response to osimertinib for 12 months, despite low concentrations in plasma, tumour, and peritumoral brain tissue. Ultimately, no resistance mutations were found. Patient 3 did only have extracranial response on osimertinib, with progressive CNS disease. He also had low osimertinib plasma and CSF concentrations, but higher tumour-to-brain tissue ratio than patient 2. Less vascularised areas, such as necrotic tumour centres and CSF, had lower osimertinib concentrations relative to other tissue. All osimertinib concentrations are shown in table 1.

Conclusions: This is the first analysis describing the distribution of osimertinib in various CNS compartments in patients with CNS progression. The results could further help guiding studies that focus on optimising osimertinib penetration in this difficult-to-understand body compartment. Osimertinib accumulates into the tumour tissue, which could explain its clinically relevant effectivity against CNS metastases. However, no comparison could be made with osimertinib concentrations in patients with stable CNS disease. The large interpatient variability could indicate a subset of patients with progression due to low osimertinib CNS penetration. This data underlines the importance for future studies to focus on the individual differences in osimertinib's CNS distribution.

Table 1. Osimertinib concentrations in blood, CSF, peritumoral brain tissue and CNS metastases

Patients	***Patient 1***	***Patient 2***	***Patient 3***
Osimertinib concentrations			
Plasma (ng/mL)	*234*	*84.6*	*92.1*

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.50 Tepotinib Plus an EGFR Tyrosine Kinase Inhibitor as an Effective Subsequent Line: A Case Series From Kuwait

A. AlJassim, T. AlSaleh, F. AlEnizi, M. AlNassar
Kuwait Cancer Control Center, Kuwait/KW

Introduction: Epidermal Growth factor receptor Tyrosine Kinase inhibitors (EGFR-TKIs) are the primary therapy for EGFR mutant NSCLC. Inevitable resistance develops with acquired resistance often driven by MET alterations and MET amplification being the most common of about 5-50% post osimertinib. Selective MET-TKIs (like tepotinib) plus third generation EGFR-TKIs show promise with trials like INSIGHT reporting improve survival outcomes in MET amplification patients

Methods: We conducted a retrospective case series of 4 patients with EGFR mutant NSCLC and MET mediated resistance treated in Kuwait Cancer Control Center (KCCC). Patients received tepotinib plus osimertinib after progressing on first line EGFR TKI. Data on treatment response, PFS and OS were collected from our medical records and analyzed.

Results: This case series of 4 patients with EGFR mutant NSCLC and MET amplification resistance to osimertinib, treated in Kuwait highlights tepotinib efficacy. Tepotinib effectively controlled extracranial disease but CNS penetration remains limited, underscoring the need for further research to optimize combination therapy in this population with poor prognosis

Conclusions: Our case series highlights the critical unmet need for patients with advanced EGFR mutant, MET-altered NSCLC in clinical practice demonstrating the clinical utility of tepotinib plus EGFR TKI in overcoming resistance, aligning with prior trials data. Compassionate use programs may play a critical role in facilitating access to novel therapies and generating real world evidence of treatment efficacy.

Keywords: EGFR-TKI resistance, MET amplification, Tepotinib

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.51 Clinical Landscape and Future Perspectives of Targeted Protein Degradation Therapies in Lung Cance

M. Sun, D. Zang, J. Chen
The Second Hospital of Dalian Medical University, Dalian/CN

Introduction: As the leading cause of cancer-related mortality worldwide, lung cancer presents three major challenges: acquired resistance, treatment-related toxicity, and limited efficacy. Some patients respond poorly to standard therapies, prompting the exploration of novel approaches. Due to the lack of druggable binding sites in certain intracellular proteins, conventional drugs often fail, rendering these targets "undruggable". Targeted protein degradation (TPD), an emerging strategy, recruits pathogenic proteins to E3 ligases, inducing their degradation via proteasomal, lysosomal, or autophagic pathways, thereby overcoming the limitations of conventional therapies.

Methods: This study analyzed the global profile of clinical trials of TPD drugs in lung cancer using the Trialtrove database system. Search criteria included "mechanism of action as a protein degrader" and lung cancer subtype (non-small cell lung cancer and small cell lung cancer), and a total of 108 trials were identified, of which 100 were confirmed after manual screening. Data were extracted and statistically analyzed for trial phase, treatment combination, funding source, and target protein.

Results: From 2000 to 2025, the number of clinical trials involving TPD drugs increased significantly, peaking in 2024. Geographically, trials cover nine regions, with the United States and China leading. Molecular glues dominate the clinical pipeline (55%), followed by SERDs (28%) and PROTACs (17%). Most trials are in early stages (Phase I and II: 85%), with few advancing to Phase III (8%) or IV (7%). Trial statuses include completed (46%), planned (12%), ongoing (21%), terminated (17%), and concluded (4%), reflecting the ongoing evaluation of TPD safety and efficacy. Funding mainly comes from academic institutions (43%) and biotech companies (29%). Notably, TPD drugs are primarily used as first-line (19%) and second-line (35%) therapies. Target protein analysis shows a shift from conventional targets (ERα, IKZF1/3) to emerging "undruggable" proteins like KRAS and SMARCA2. Increasingly, combination therapies are explored, especially with chemotherapy (29%) and targeted therapy (28%), aiming to improve efficacy.

Conclusions: TPD drugs, by targeting "undruggable" proteins, are advancing precision therapy for lung cancer to a new stage. As clinical trials progress, the integration of TPD therapies with existing treatment modalities holds the potential to effectively overcome resistance and improve patient outcomes.

EP.12.52 A High-Fat Meal Optimizes the Pharmacokinetic Profile of DO-2, a Novel MET-Kinase Inhibitor for NSCLC

D.A.C. Lanser[1], P. De Bruijn[1], E. Oomen-de Hoop[1], V. Van de Walle[2], F. Wastelin[3], C. Ahlin[3], D. Kanters[3], P. De Waele[3], M.H. Lam[1], J. Verweij[3], T.P.S. Perera[3], R.H.J. Mathijssen[1]
[1]Erasmus University Medical Center, Rotterdam/NL ,[2]PreCare Trial & Recruitment, Born/NL ,[3]DeuterOncology, Liège/BE

Introduction: DO-2 is a selective MET-kinase inhibitor with potential in non-small cell lung cancer (NSCLC) for MET-exon 14 skipping and MET-amplification. DO-2 is a deuterated version of JNJ-38877605, redesigned to reduce toxic metabolite (M5) formation via AOX-1. Currently, in a phase 1 study in patients with solid tumours, DO-2 is being evaluated for safety and pharmacokinetics. Preclinical data suggest that a Time over Threshold (ToT) of 8-10 hours for DO-2 is necessary and sufficient for anti-tumor efficacy but avoids continuous wild-type MET-inhibition causing edema. In the current study, the effects of food and green tea extract (EGCG; an AOX-1-inhibitor) were studied in healthy volunteers.

Methods: This randomized crossover study compared a single 40mg DO-2 dose in fasted state versus after a high-fat meal in humans. Participants were randomized 1:1 to start with either condition, followed by the alternate condition. Each period included 24-hour pharmacokinetic sampling of DO-2 and metabolites. Additionally, half of the patients received EGCG, while the other half did not, to explore its potential AOX-1 inhibition and the formation of M3 and M5.

Results: The ToT of DO-2 was prolonged from 7.6 hours in the fasted state compared to 11.6 hours with food (p=0.003), while the Tmax was extended from 1.52 hours (IQR: 1.44-1.97) in the fasted state compared to 4.49 hours (IQR: 3.95-4.97) in the fed state (p=0.002). The Cmax of DO-2 was reduced by 16.2% (90%CI: -3.1% to -31.0%, p=0.047) while the total exposure (AUC0-24h) of DO-2 was comparable to fasted state (+3.9%; 90%CI: -2.8% to +10.1%, p=0.308). EGCG showed a trend for lower formation of M3, with a difference in AUC0-24h of -23.3% (p=0.128) and Cmax of -13.7% (p=0.291) with EGCG compared to no EGCG, see table 1. The ratio of DO-2:M3 in AUC0-24h was higher (+13.2%; p=0.590) as well for Cmax (+12.4%; p=0.977) with EGCG.

Conclusions: This study shows that food significantly prolongs ToT and reduces Cmax for DO-2 in a clinically relevant way, likely due to an increase in pH following food intake, as DO-2 solubility and hence absorption is known to be pH-dependent. Total exposures (AUC0-24h) to DO-2, DO-5 and M3 are similar with and without food. Since an 8-10 hour ToT is ideal for efficacy and toxicity, food optimizes the pharmacokinetic profile of DO-2, which is further evaluated in the extension phase of the phase 1 study in patients (NCT05752552). Possibly, EGCG could reduce M3 formation and should be studied further.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.53 Case Report Response to Treatment With Erdafitinib in a Patient With FGFR2 Mutation in Adenocarcinoma Lung Cancer

G.R. Siancas, G. Oblitas, L. Gonzalez
Unidad Oncologica Molecular Peruana, Lima/PE

Introduction: Erdafitinib is a pan-fibroblast growth factor receptor (FGFR) inhibitor approved in the US for the treatment of locally advanced or metastatic urothelial carcinoma in adults with susceptible FGFR3 alterations; however, mutations in FGFR are found in various solid tumors, including lung cancer. Multiple studies are demonstrating the efficacy of anti-FGFR therapies in patients with solid tumors with FGFR alterations. The etiology of non-small-cell lung cancer (NSCLC) and the distribution of associated molecular aberrations vary according to the patient's profile and origin, with the most frequent mutations being KRAS, EGFR, ALK, ROS1, and TP53. However, FGFR aberrations, including mutations, fusions, and gene amplifications, were detected in 1.9% of the population. FGFR abnormalities were more frequently observed in lung squamous cell carcinomas (6.8%) than in lung adenocarcinomas (1.3%). Due to the low prevalence of this mutation, the response to novel therapies in patients with lung adenocarcinoma is limited.

Methods: Collect the information through the patient's medical history

Results: We present a 65-year-old female patient from Lima, Peru, with an ECOG score of 1, diagnosed with INVASIVE MUCINOUS LUNG ADENOCARCINOMA Stage IV, multi-treated and with poor response to chemotherapy and radiotherapy. After failing a third line with Docetaxel, next-generation sequencing (NGS) studies were conducted, revealing: FGFR2 rearrangement intron 17, FGFR2-MYH16 rearrangement. Based on these findings, targeted treatment with Erdafitinib was initiated, resulting in Grade 2 dermatological toxicity and a progression-free survival (PFS) of seven months, with PET-CT imaging showing a partial response in the lungs but disease progression in the liver.

Conclusions: This report presents the case of a patient with advanced lung adenocarcinoma who underwent multiple lines of treatment and responded to anti-FGFR targeted therapy (Erdafitinib), achieving a progression-free survival of seven months without altering quality of life. The adverse effects related to the therapy were not the reason for discontinuation; however, treatment had to be stopped due to disease progression. This report aims to provide greater insight into the response to novel treatments in patients with FGFR mutations in non-small cell lung cancer.

Keywords: Lung cancer, FGFR, Erdafitinib

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.54 Real-World Use of Targeted Therapy Combinations to Manage Secondary Oncogenic Addiction in Non-Small Cell Cancer

C. MORIN, M-C. PAJIEP CHAPDA, J. MILIA, J. MAZIERES
CHU Larrey Toulouse, TOULOUSE/FR

Introduction: The identification of oncogenic addictions has significantly improved the prognosis of Non-Small-Cell Lung Cancer (NSCLC), paving the way for targeted therapy development including tyrosine kinase inhibitors (TKIs) or antibody drug-conjugate (ADC) . However, the duration of therapeutic response is often limited by the emergence of acquired resistance. In case of disease progression during targeted therapy, rebiopsy (or liquid biopsy if tissular biopsy is not possible) is recommended to identify the underlying resistance mechanisms. Activations of bypass pathways can potentially be addressed through combination therapies, a strategy currently under investigation in clinical trials. In clinical practice, molecular tumor boards are increasingly proposing off-label combinations for selected patients, based on their individual resistance profiles, to optimize therapeutic outcomes.

Methods: This French monocenter ambispective cohort study collected real-world outcomes of targeted therapy combinations in patients with advanced Oncogene-Addicted Non-Small-Cell Lung Cancer who harbored other oncogenic driver(s) as resistance mechanisms. Patients from the University Hospital of Toulouse who received a combination of targeted therapy since 2015, were included in the analysis. Key endpoints analyzed include clinical characteristics, progression-free survival (PFS), overall survival (OS), and treatment-related adverse events.

Results: Eighteen patients were included (66,7% women, median age : 59 years, history of smoking : 27,8%). At diagnosis, sixteen patients (88.9%) exhibited EGFR oncogenic alteration, while two patients (11.1%) had an ALK fusion. Fifty-five percent of the patients (n=10) received a combination of targeted therapies as a second-line treatment. Six out of the eighteen patients (33.3%) had previously been treated with chemotherapy before initiating combination of targeted therapy.We identified MET amplification as the major resistance mechanism which required targeted therapy combinations, detected in 14 out of 16 EGFR-positive patients and in 50% of ALK-positive patients. Crizotinib was the most frequently used agent in combination therapy. Overall, median real-world PFS was 5,8 months and the Duration of Treatment (DoT) was 9,9 months. While efficacy and safety data are still immature, preliminary findings show that 31.6% of patients experienced toxicities of grade 3 or higher according to the CTCAE. Dose reductions were required for 38.9% of patients, and 22.2% discontinued treatment due to toxicity. Furthermore, one patient death has been attributed to toxicity associated with the targeted therapy combination.

Conclusions: Combination targeted therapy were predominantly utilized for addressing MET amplification in our cohort. Combination strategies could provide clinical benefit with real-world progression-free survival (rwPFS) data aligning with efficacy findings from clinical trials. Such combinations represent an alternative to chemotherapy, which is still the standard of care, potentially delaying its use. However, the risk of overlapping toxicities and resulting dose adjustments may impair effectiveness of these combinations, necessitating careful patient monitoring. Further investigations are needed and the ongoing KOMBILUNG study, an international multicenter ambispective cohort study, aims to provide comprehensive data on the outcomes of patients receiving combination targeted therapies.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.55 Aumolertinib Combined With Metronomic Oral Vinorelbine in Advanced EGFR-Mutant NSCLC

Z. Liu, J.Y. Zhou, T.T. Qiu, W. Yan, H.Q. Liu, L.J. Wan
Jiangxi Cancer Hospital, Nanchang/CN

Introduction: The monotherapy of 3rd generation EGFR-TKIs has been the standard first-line treatment for advanced NSCLC patients harboring EGFR mutation. However, the PFS monotherapy is around 20months, which seems to be insufficient and how to further prolong patients' survival time remains a clinical issue that is required to attach great importance. FLAURA2 study showed the combination of EGFR-TKI and chemotherapy significantly improved PFS, whereas intravenous chemotherapy has its distinct drawbacks, including inconveniency of administration, relatively severe adverse reactions and repeated hospitalizations. EGFR-TKI plus metronomic oral chemotherapy is a promising approach to address above clinical concerns, particularly, both aumolertinib and oral vinorelbine have been identified efficacious in treating advanced NSCLC patients. Hence, a single-arm, prospective study was conducted.

Methods: An estimated 165 untreated EGFR-mutant advanced NSCLC patients will be enrolled in the study and all participants will be given aumolertinib (110mg once daily) and metronomic oral vinorelbine (40mg once, three times a week for continuous 3 weeks of a four-week cycle). The primary endpoint is PFS and secondary endpoints conclude ORR, DCR, DoR and safety.

Results: 11 patients were recruited and analyzed with a median age of 61 years old. All patients were pathologically diagnosed with adenocarcinoma harboring EGFR mutations. Among all the subjects, 72.7% were evaluated as ECOG 1 or greater. At data-cutoff (March 2025), 10 patients were evaluated as PR and 1 patient maintained SD. The ORR of the combination therapy is 90.9% and the DCR is 100%. During the treatment process, no grade≥3 AE was observed.

Conclusions: Aumolertinib plus metronomic oral vinorelbine has preliminarily shown superior efficacy and the combination therapy is well-tolerated. Enrollment will continue for further analyses.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.56 Ipd Meta-Analysis of Intracranial Efficacy: Can CNS Data Refine First-Line Choices in EGFR-Mutant NSCLC?

B. Resuli, D. Kauffmann-Guerrero, P. Mertsch, P. Arnold, T. Bolt, J. Götschke, J. Behr, A. Tufman
LMU University Clinic, Munich/DE

Introduction: Central nervous system (CNS) progression remains a major unmet need in EGFR-mutant non-small cell lung cancer (NSCLC). Although osimertinib has demonstrated intracranial activity, the CNS efficacy of emerging EGFR-targeted combinations may offer enhanced CNS control.

Methods: To clarify the relative intracranial efficacy of EGFR-targeted regimens, an individual patient data (IPD) meta-analysis of the MARIPOSA (amivantamab plus lazertinib [AMI+LAZ]) and FLAURA2 (osimertinib plus chemotherapy [OSI+CT]) trials was conducted. Intracranial endpoints included intracranial progression-free survival (iPFS), intracranial objective response rate (iORR), CNS complete response (CR) rate, and time to CNS progression. A one-stage mixed-effects IPD model was used. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox regression; odds ratios (ORs) were derived from logistic models adjusted for trial and baseline CNS involvement. Cumulative incidence of new CNS metastases was evaluated using competing risks methodology.

Results: A total of 705 patients (n=429 AMI+LAZ, n=276 OSI+CT) were included, of whom 188 (26.7%) had brain metastases at baseline. In this subgroup, median iPFS was 17.6 months for AMI+LAZ and 18.2 months for OSI+CT, with 12-month iPFS rates of 71.3% and 74.0%, respectively (HR 0.92; 95% CI 0.66-1.28; p=0.61). iORR was similar (60.2% vs 58.7%), while CNS CR occurred in 31.0% (AMI+LAZ) vs 43.1% (OSI+CT) of patients (OR 0.60; 95% CI 0.32-1.12; p=0.11).

Among patients without baseline CNS involvement (n=517), the 18-month cumulative incidence of new brain metastases was numerically lower with AMI+LAZ (10.2%) compared to OSI+CT (14.6%), although the difference was not statistically significant.

Conclusions: AMI+LAZ demonstrated comparable intracranial efficacy to OSI+CT in patients with baseline brain metastases and showed a trend toward lower CNS progression in those without. These findings support AMI+LAZ as a CNS-active first-line option in EGFR-mutant NSCLC and highlight the need for dedicated CNS-specific endpoints in future EGFR-targeted trials.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.57 Ensartinib Exhibits Potential Synergistic Effects With Radiotherapy in ALK-Positive Non-Small Cell Lung Cancer

B. Wang[1], J. Chen[1], X. Wang[2], Y. Shu[2], Y. Wang[3], K. Liu[3], P. Pan[3]
[1]Northern Jiangsu People's Hospital Affiliated to Yangzhou University, Yangzhou/CN ,[2]Northern Jiangsu People's HospitalAffiliated to Yangzhou University, Yangzhou/CN ,[3]Betta Pharmaceuticals Co.,Ltd., Hangzhou/CN

Introduction: Ensartinib, an ALK inhibitor, has been shown to significantly improve outcomes in ALK-positive non-small cell lung cancer (NSCLC) patients. Radiotherapy serves as a critical local therapeutic modality for lung cancer. In multiple treatment strategies, systemic therapy often requires combination with local therapies. However, the efficacy of combining ensartinib with radiotherapy remains unknown.

Methods: A re-analysis of clinical trial data for ensartinib was conducted. A total of 97 NSCLC patients with baseline brain metastases who were ALK-positive and crizotinib-resistant received ensartinib treatment. Among them, 37 (38%) had previously received brain radiotherapy. Efficacy analyses compared outcomes between patients with and without prior brain radiotherapy to explore the potential synergistic interaction between ensartinib and radiotherapy. The H3122 human cell line (EML4(13)-ALK(20) variant 1 fusion) was used as the model. Ensartinib monotherapy, radiotherapy alone (doses of 0, 2, 4, 6, and 8 Gy) and combination were administered to evaluate the antitumor activity in vitro.

Results: Clinical data analysis revealed that among patients with baseline measurable intracranial lesions, those who had received prior brain radiotherapy achieved an intracranial objective response rate (ORR) of 88% (95% CI: 47-100) and disease control rate (DCR) of 100% (95% CI: 63-100). In contrast, patients without prior brain radiotherapy showed an intracranial ORR of 66% (95% CI: 47-81) and DCR of 97% (95% CI: 84-100). The median progression-free survival (PFS) was 13.9 (95% CI: 11.8, NE) months and 7.7 (95% CI: 5.4-11.8) months, respectively. The incidence of neurological treatment-emergent adverse events (TEAEs) was 29.7% (11/37) and 28.3% (17/60), respectively. There was no difference in the incidence of neurological adverse events between the two cohorts, patients with prior brain radiotherapy did not exhibit an increased risk of neurological adverse events, suggesting that the combination of radiotherapy and ensartinib exhibits a synergistic interaction in enhancing antitumor efficacy with good toleration and safety. Furthermore, in-vitro experiments demonstrated that ensartinib combined with radiotherapy at various doses exhibited significantly enhanced inhibition of cell proliferation ($P < 0.0001$).

Conclusions: Both in-vitro experiment and clinical study data demonstrate that the combination of ensartinib and radiotherapy exhibits a potential synergistic effect.

Keywords: NSCLC, ALK, Ensartinib

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.58 Feasibility of Aumolertinib Followed by SRT in EGFR+ NSCLC Patients With Intracranial Oligo-Progression: A Phase II, Prospective Study

J. Chen[1], M. Fan[1], B. Wang[1], J. Wen[1], H. Li[1], X. Xu[2], Y. Zhao[3], S. Wang[1], H. Yu[1], C. Zhou[1]
[1]Fudan University Shanghai Cancer Center, Shanghai/CN ,[2]MD. Anderson Cancer Center, Houston/TX/USA ,[3]Tulane University School of Medicine, New Orleans/LA/USA

Introduction: Third-generation EGFR tyrosine kinase inhibitors (EGFR-TKIs), such as aumolertinib, have demonstrated significant efficacy in EGFR-mutant non-small cell lung cancer (NSCLC)with brain metastases. The timing of SRT and optimal treatment strategy for patients with intracranial oligo-progression during EGFR-TKI therapy remains unclear. This phase II, prospective study evaluates the efficacy and toxicity of aumolertinib followed by stereotactic radiotherapy (SRT) for intracranial oligo-progression in EGFR-mutant NSCLC patients.

Methods: This prospective, single-arm phase II trial enrolled EGFR-mutant NSCLC patients with brain metastases (≤10 brain lesions). All patients were initially treated with aumolertinib (110 mg orally once daily), upon intracranial oligo-progression, patients received stereotactic radiotherapy (SRT) to the progressive brain lesions while continuing aumolertinib thereafter if extracranial disease is stable. The primary endpoint was intracranial progression-free survival (iPFS). Secondary endpoints included overall survival (OS), progression-free survival (PFS), intracranial objective response rate (iORR), and safety. Intracranial responses were evaluated using RECIST v1.1 criteria, and adverse events were graded according to CTCAE v5.0.

Results: From August 2021 to July 2024,a total of 41 patients were enrolled, with a median age of 65 years (50% female). The majority of patients had EGFR exon 19 deletions (56%). The median follow-up duration was 23.2m(17.8-28.6). The median intracranial progression-free survival (m-iPFS) has not yet been reached, 1-year iPFS rate: 80.5%(95% CI:68.4%-94.6%) ,2-year iPFS rate: 65.6 %(95% CI:50.6%-85.0%).2-year OS: 94.7%(95% CI: 88.1%-100%),3-year OS: 82.9%(95% CI: 68.3%-100%). Intracranial objective response rate (iORR): 78%, including 14.6% (N=6)complete responses (CR) and 63.4% (N=26) partial responses (PR).A total of 11 patients experienced intracranial progression, 3 patients developed leptomeningeal progression, and 11 patients had extracranial progression, including 6 cases of pulmonary progression (2 of which also had simultaneous intracranial progression), 3 cases of bone lesion progression, 1 case of mediastinal lymph node progression, and 1 case of liver lesion progression. 18 patients remained free of disease progression. Among the 11 patients with intracranial progression, 7 underwent the planned intracranial stereotactic radiotherapy (SRT), 3 received whole-brain radiotherapy (WBRT) due to extensive intracranial lesions, and 1 patient refused radiotherapy. Grade 1-2 adverse events, such as headache (20%) and fatigue (45%), were common. Grade 3 adverse events occurred in 12% of patients, with no Grade 4 or 5 events reported.

Conclusions: The combination of SRT and Aumolertinib therapy is an effective and well-tolerated treatment strategy for EGFR-mutant NSCLC patients with intracranial oligo-progression. We are currently conducting a phase III randomized trial (ALMORA STUDY,NCT05800223) based on this phase II clinical study to investigate the optimal timing of intracranial stereotactic radiotherapy (SRT) in the treatment of brain metastases in patients with EGFR-mutant NSCLC during third-generation EGFR-TKI therapy.

Keywords: EGFR-mutant NSCLC, aumolertinib, SRT

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.59 Calcium Channel Blockers and Irreversible EGFR TKIS. Opportunities Missed?

J. Monsen
N/A, Oslo/NO

Introduction: EGFR TKIs are standard of care (SOC) for EGFR+NSCLC. Recent real-life data shows a median overall survival (OS) of 17 months in patients with Stage IV - L858R EGFR+ NSCLC treated with first-line Osimertinib in the Netherlands. Patients with EGFR+ Del19 NSCLC have longer but limited OS due to resistance to EGFR TKIs. A recent study suggests that these patients (especially those with L858R) could benefit from upfront chemotherapy. The potential improvement in OS is modest, still this could improve the SOC for L858R patients. Could SOC be improved by addition of calcium channel blockers (CCB)? Two recent retrospective studies support this.

Methods: Literature review.

Results: Two seminal studies were published in 2021 and in 2023, spanning several years. Total patients included: 63 + 345 (n 408). Both studies reported longer OS (6 months longer OS), largest study reported a 2-year PFS rate of 44.4% for the patients that used CCB and EGFR TKI vs. only 8.4% for EGFR TKI alone. This should spur further investigations and clinical trials. Most likely these patients were treated with first generation EGFR TKIs and the combination of CCB and second generation or third generation (both irreversible) EGFR TKIs might be even better. This should be tested in a clinical trial. Study in cell lines concluded that β-Catenin could become a novel therapeutic target in combination with irreversible EGFR-TKIs, such as Afatinib, but not with reversible EGFR TKIs such as Erlotinib. It has been reported that Wnt/β-catenin, EGFR, clathrin pathway and endocytosis are connected. There are several possible mechanisms that could explain how CCB could promote an OS advantage in EGFR+ NSCLC: Inhibition of β-Catenin and the Wnt/Ca2+ PLC/NFAT signaling pathway. Verapamil could do this through the FRZB (Frizzled/LRP5/6) complex. An ongoing (2024) study of Osimertinib and Tegavivint, a novel ß-catenin / Wnt inhibitor indicate that β-catenin could be a relevant target with Osimertinib, an irreversible EGFR TKI. Another study showed that irreversible EGFR TKI Afatinib and Ethacrynic Acid, a diuretic agent, have strong antitumor effects in vitro and in mice models of EGFR/T790M NSCLC by inhibiting WNT/ß-catenin pathway. Intriguingly one study did report that EGFRs internalized via Clathrin-mediated endocytosis (CME) will be recycled to the cell surface. Clathrin-independent internalization will degrade the EGF receptors. Verapamil might attenuate the clathrin-independent pathway and stimulate clathrin-mediated endocytosis. Amlodepine or Verapamil are candidates for clinical trials with Afatinib or Osimertinib. Verapamil inhibits pancreatic cancer tumor growth in vivo potentially by targeting stem-like cells. Verapamil inhibits P-GP/MDR1/ABCB1 transport and was successful in clinical trials with chemotherapy. Deletions of the P-GP/MDR1/ABCB1 genes in mice result in higher levels of Erlotinib.

Conclusions: EGFR is part of the Wnt9a-Fzd9b complex. Targeting ß-catenin / Wnt with inhibitors and the therapeutic potential of understanding and optimizing EGFR endocytosis are rapidly developing. Repurposing of existing medications can save patients' time and provide safe, affordable and effective treatments that improve SOC. Industry sponsorship of repurposed drugs and clinical trials are not readily achievable and other mechanisms for financial incentives and sponsorship should be considered.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.60 Multiple Primary Lung Cancer With Driver Gene Mutations: Is Targeted Therapy Always the Optimal Choice?

Z-R. Ren[1], L. Wu[2], C. Lu[2], F. Wang[3], Y-L. Peng[4], D-X. Cai[2], L-B. Tang[4], J-T. Li[5], Z. Guo[2], Z-H. Chen[2], Y. Deng[2], L. Sun[6], X-W. Wei[2], Q-L. Huang[2], C-R. Xu[2], Q. Zhou[2]

Introduction: With the widespread adoption of CT screening, the detection rate of multiple primary lung cancer (MPLC) has significantly increased. While targeted therapy remains the standard treatment for driver-positive lung cancer, most MPLC patients exhibit inter-lesional molecular heterogeneity, leading to suboptimal outcomes with single-agent targeted therapy. This study reports a classic case of synchronous MPLC to explore clinical treatment challenges and strategies.

Methods: .Tissue specimens were obtained via CT-guided percutaneous biopsy, bronchoscopic biopsy, and surgical resection. Collaborative diagnosis was performed using immunohistochemistry (IHC) and next-generation sequencing (NGS). EGFR+ osimertinib targeted therapy was administered, and a multidisciplinary team (MDT) formulated a combination regimen of nab-paclitaxel, carboplatin, and nivolumab.

Results: Initial CT revealed 34 pulmonary nodules highly suspicious for MPLC. Pathological confirmation of the larger right upper lobe lesion identified lung adenocarcinoma, with NGS detecting an EGFR L858R mutation. After 12 weeks of osimertinib treatment, a "mixed response" was observed: the larger right upper lobe lesion shrank, but smaller right upper lobe and left upper lobe lesions enlarged, with mediastinal lymph node progression, precluding surgical eligibility. Following MDT discussion, chemotherapy-immunotherapy combination therapy was initiated for 2 cycles, resulting in significant shrinkage of all visible lesions and enabling successful right upper lobectomy. The smaller lesion in the right lung was adenocarcinoma without detectable driver mutations, confirming the diagnosis of MPLC.Seven months postoperatively, a recurrence developed in the surgical bed; lymph node biopsy revealed poorly differentiated NSCLC-NOS (non-small cell lung cancer-not otherwise specified), with NGS showing no driver mutations, indicating aggressive tumor progression.

Conclusions: This case highlights marked therapeutic heterogeneity in MPLC, where single-agent targeted therapy may not be optimal. Regardless of whether MPLC lesions present as multi-driver-positive or driver-positive plus driver-negative, chemotherapy-based combination regimens are recommended. Early multi-site biopsies are advised to clarify molecular profiling of individual lesions.

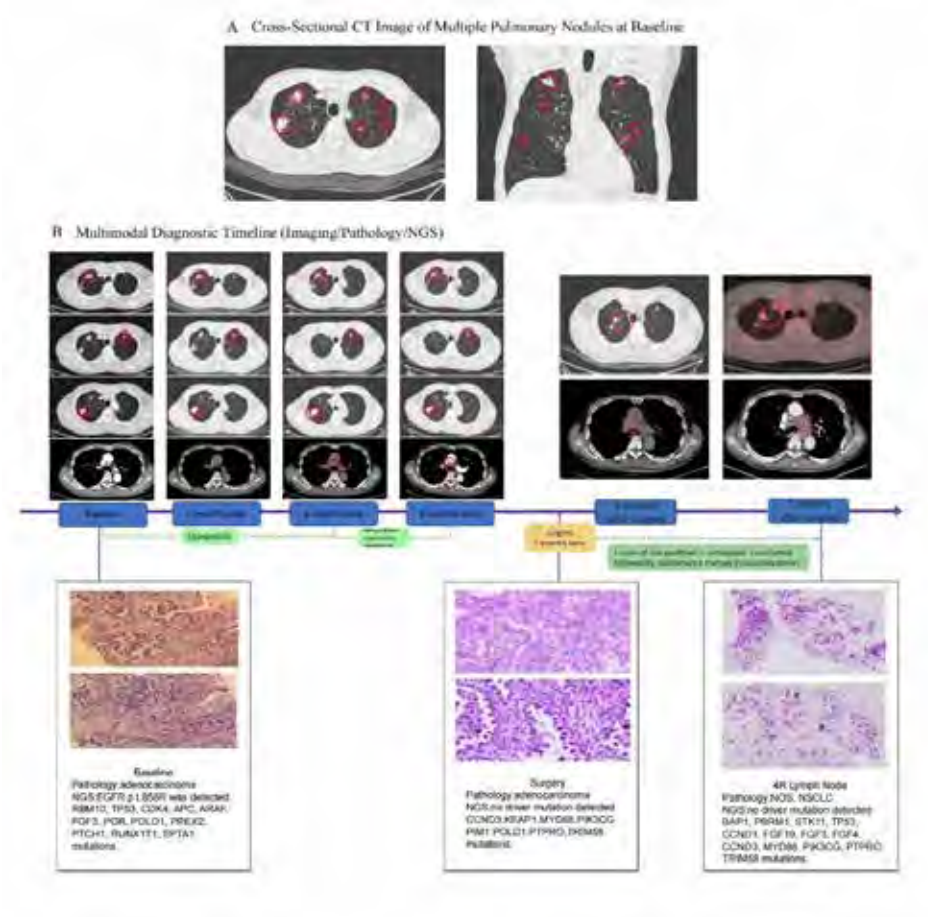

Table 1 Summary of Multiple Pulmonary Nodules at Baseline

	location	characterization	size
nodule 1	RUL apical segment	Mass	30*21mm
nodule 2	RUL apical segment	Solid nodule	25*19mm
nodule 3	RUL anterior segment	Solid nodule	20*18mm

EP.12.61 Prognostic-Predictive Modeling in Advanced Non-Small Cell Lung Cancer: A Review of Biomarkers Using AI, ML and DL

S.R. Khan[1,2], A. Khan[3], A. Tareen[3], T. Dawood[4], S. Mestiri[5], A. Raza[6]
[1]Verspeeten Family Cancer Centre, London Health Sciences Centre, London/ON/CA ,[2]Schulich School of Medicine & Dentistry, Western University, London/ON/CA ,[3]Ziauddin Medical College, Karachi/PK ,[4]Cross Cancer Institute, University of Alberta, Edmonton/AB/CA ,[5]Qatar Biomedical Research Institute (QBRI), Hamad Bin Khalifa University – Qatar Foundation, Doha/QA ,[6]Department of Biomedical Sciences, College of Health Sciences, Abu Dhabi University, Abu Dhabi/AE

Introduction: Lung cancer remains the most prevalent cancer globally and the leading cause of cancer-related mortality. With the majority of cases diagnosed at a later stage, prognosis remains poor. Advanced non-small cell lung cancer (NSCLC) presents a particularly formidable challenge, with the absence of a practical prognostic-predictive model to guide treatment decisions. However, the advent of artificial intelligence (AI) has emerged as a promising avenue for advancing such models in lung cancer. Machine learning (ML) plays a pivotal role, enabling systems to enhance their performance over time through experience and data-driven adaptation. The components of AI, particularly ML and Deep Learning (DL), have witnessed extensive research applications in lung cancer, ranging from staging and diagnosis to treatment and surveillance. This review explores AI-driven analytics in shaping clinical, inflammatory, genomic, and radiomic data to develop a superior prognostic-predictive model for advanced NSCLC, promoting global, equitable cancer care.

Methods: A systematic exploration of peer-reviewed literature was conducted, focusing on studies employing AI, ML, and DL to enhance prognostic modeling in advanced NSCLC. A diverse array of biomarkers were examined, including neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte ratio (PLR), lymphocyte to monocyte ratio (LMR), advanced lung cancer inflammation index (ALI), eastern cooperative oncology group (ECOG) performance status, lactate dehydrogenase (LDH), albumin, PD-L1 Combined Positive Score (CPS), tumor mutational burden (TMB), circulating tumor DNA (ctDNA), long non-coding RNAs (lncRNAs), histone modifications, chromatin remodeling, and radiomic signatures. The assessment focused on AI-driven methodologies for integrating biomarkers into a reliable prognostic-predictive mode. Inclusion criteria focused on AI techniques, particularly ML and DL, in developing prognostic models for advanced NSCLC, with study limitations critically addressed for a comprehensive perspective.

Results: AI-driven analytics significantly outperformed conventional prognostic models, enhancing risk stratification and outcome prediction with unparalleled precision. ML algorithms effectively identified high-risk patient subgroups and those poised to benefit from targeted therapies, offering a refined approach to treatment personalization. Notably, radiomics and ctDNA-based biomarkers emerged as key players in prognostic modeling, bridging the gap between imaging, liquid biopsy, and molecular profiling.

Conclusions: The integration of parameters and AI algorithms presents a transformative approach in the management of advanced NSCLC patients. By utilizing AI driven prognostic markers, clinicians can tailor treatment strategies, enhance decision-making, and improve patient outcomes. However, challenges persist, including dataset variability, algorithmic transparency, and clinical interpretability, underscoring the need for further standardization and validation.

Major parameter	Primary task	AI tool
PDL1, ECOG, LDH, NLR, ANC, TNM staging	IO efficacy	CB, LR, NN, RF, SVM

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.62 Identification of Optimal Candidates for the FLAURA2 Regimen in EGFR-Mutated NSCLC Based on PFS2 Analysis

Y. Murase[1], T. Ueda[2], H. Koba[2], S. Nanjo[2], Y. Tambo[2], S. Yano[2]
[1]Kanazawa University, Kanazawa/JP ,[2]Kanazawa University Hospital, Kanazawa/JP

Introduction: The FLAURA2 trial demonstrated the efficacy of osimertinib in combination with platinum-pemetrexed chemotherapy for previously untreated EGFR-mutated non-small cell lung cancer (NSCLC). However, optimal patient selection for this regimen remains unclear. The aim of this study is to investigate clinical characteristics associated with shortened second progression-free survival (PFS2) to identify appropriate candidates for the FLAURA2 regimen.

Methods: We retrospectively analyzed 87 patients diagnosed with EGFR-mutated NSCLC at Kanazawa University Hospital between 2008 and 2022. PFS1, PFS2, and overall survival (OS) were evaluated. PFS2 was defined as the time from the start of first-line treatment to second disease progression or death. Univariate and multivariate analyses were performed to identify factors associated with shorter PFS2.

Results: Patient characteristics: median age was 69 (range: 34-91) years. male/female: 31/56. Peformance status 0/1/2: 53/29/5. EGFR mutations del19/L858R/others: 41/39/7. First-line EGFR-TKI usage included first/second/third-generation: 23/17/47 cases.Median PFS1, PFS2, and OS were 13.9, 24.3, and 34.3 months, respectively. Multivariate analysis revealed that the presence of central nervous system (CNS) metastases at diagnosis (HR 2.90, p = 0.00049) and EGFR mutation subtype (19del vs L858R, HR 1.88, p = 0.020) were significant predictors of shorter PFS2. Subgroup analysis revealed that patients with CNS metastases had significantly worse outcomes, even when treated with second-line chemotherapy after EGFR-TKI failure.

Conclusions: Patients with L858R mutations and CNS metastases at diagnosis have a significantly shorter PFS2 with standard sequential therapy and may derive greater benefit from the FLAURA2 regimen. These results suggest that such patients are an appropriate subset for upfront combination therapy with osimertinib and chemotherapy.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP.12.63 Combining Chemotherapy With Osimertinib Beyond Progression in EGFR-Mutant NSCLC: A Case-Based Experiencecombining Chemotherapy and Osimertinib Beyond Progression in EGFR-Mutant NSCLC: A Case-Based Experience

A. Cardeña-Gutiérrez, I. Castellano Carneiro, P. Rodríguez Hernáez, A. Herrero Márquez, L. Herrera Gorrín, K. Medina Sánchez
Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife/ES

Introduction: Osimertinib is the standard first-line therapy for advanced non-small cell lung cancer (NSCLC) harboring EGFR-sensitizing mutations. However, most patients eventually develop resistance, and platinum-based chemotherapy remains the recommended second-line option when no targetable alterations are identified and local ablative strategies are not feasible. While the addition of immunotherapy to chemotherapy has failed to show clear benefit in this setting, the strategy of continuing osimertinib beyond progression in combination with chemotherapy has gained interest, particularly in light of the FLAURA2 trial, which demonstrated a significant progression-free survival (PFS) benefit for the combination in the first-line setting. Retrospective studies also suggest that maintaining osimertinib with platinum-pemetrexed in second line may prolong disease control and delay central nervous system (CNS) progression.

Methods: We reviewed the clinical history of three patients with EGFR-mutated NSCLC treated at our institution who received platinum-based chemotherapy combined with osimertinib beyond radiological progression. Clinical characteristics, timing of progression, treatment response, and tolerability were analyzed. All patients were treated in accordance with standard clinical practice, and the decision to continue osimertinib beyond progression was based on multidisciplinary evaluation.

Results: Case 1: A 51-year-old male with stage IV EGFR L858R-mutated NSCLC received first-line osimertinib in July 2023 with an initial systemic and CNS complete response. In April 2024, he started platinum-pemetrexed chemotherapy combined with ongoing osimertinib due to new pulmonary lesions not suitable for radical treatment. A partial response was documented in May 2024, with disease control ongoing as of March 2025, over 11 months after starting combination therapy.

Case 2: A 72-year-old female with EGFR exon 19-mutated NSCLC progressed in August 2023 under first-line osimertinib, with pleural carcinomatosis and bone involvement. She began second-line treatment with carboplatin, pemetrexed, and osimertinib in March 2024. Initial disease stabilization was achieved and maintained until January 2025, when bone progression led to functional decline due to severe pain, unresponsive to palliative radiotherapy. Due to poor performance status, she was not considered a candidate for further systemic therapy and was referred to supportive care.

Case 3: A 79-year-old never-smoker female initially enrolled in the ADAURA trial received adjuvant osimertinib for 3 years. In late 2022, systemic relapse was treated with osimertinib reintroduction and focal radiotherapy. Due to oligoprogression with pleural and vertebral involvement in March 2024, combination therapy with platinum-pemetrexed and osimertinib was started. The patient achieved disease stabilization and continued on maintenance pemetrexed plus osimertinib from June 2024 onward, with good tolerance.

Conclusions: In selected patients with EGFR-mutant NSCLC and non-curable progression to first-line osimertinib, continuation of osimertinib combined with platinum-pemetrexed chemotherapy may represent a valid therapeutic strategy, particularly when access to novel agents such as amivantamab is limited or contraindicated. This approach appears to be safe and may contribute to extended disease control, especially in preventing early CNS relapse. While prospective validation is awaited from ongoing trials like COMPEL, our case series supports this combination as a feasible and clinically relevant option in real-world practice, offering a potential bridge in the evolving treatment landscape of EGFR-mutated lung cancer.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP12.64 Real-World Effectiveness of First-Line Osimertinib in EGFR-Mutated NSCLC: Interim Results From the French POSITHES Study

J-B. Aulia[1], A. Bizieux[2], O. Bylicki[3], F. Guisier[4], P-A. Hauss[5], N. Goyard[6], A. Hedoux[6], A. Lahouegue[6], F. Marlin[6], S. Musilli[6], R. Corre[7]
[1]Centre Hospitalier Intercommunal de Créteil, CRETEIL/FR ,[2]Centre Hospitalier Départemental Vendée, LA-ROCHE-SUR-YON/FR ,[3]Hôpital d'Instruction des Armées Sainte-Anne, TOULON/FR ,[4]CHU de Rouen, ROUEN/FR ,[5]CHI Elbeuf Louviers Val de Reuil, SAINT-AUBIN-LES-ELBEUF/FR ,[6]AstraZeneca, COURBEVOIE/FR ,[7]CH de Cornouaille, QUIMPER/FR

Introduction: Osimertinib is a tyrosine kinase inhibitor (TKI) indicated in first-line (1L) treatment for patients with locally advanced or metastatic non-small cell lung cancer (NSCLC) with activating common mutations (Ex19del and L858R) of the epidermal growth factor receptor (EGFR). POSITHES study aimed to complement the evidence of osimertinib monotherapy efficacy observed in clinical trial by describing its effectiveness in real-world (RW).

Methods: POSITHES (NCT05103605) is a French observational multicenter ambispective study combining a descriptive cross-sectional survey and a prospective cohort. NSCLC patients with an activating common EGFR mutation newly treated with 1L osimertinib were recruited in 47 sites in France. Patients were enrolled from May 2021 to November 2022 and interim data are now available with a 24-month overall follow-up.

Results: A total of 233 patients were included. The majority of patients were women (n=154, 66.1%), never-smokers (n=138, 59.5%) and had an ECOG status ≤1 (n=189, 82.2%). One third (31.7%) of patients presented brain metastases (BM) at initial diagnosis (ID). The median age [IC95%] was 73 years [64;83] with a proportion of 59.6% aged ≥70y. Regarding the best overall response, 19 (9.1%) patients presented a complete response, 130 (62.5%) a partial response, 47 (22.6%) a stable disease, 5 (2.4%) a progressive disease. The median [IC95%] progression-free survival (mPFS) after osimertinib initiation was 16.6 months [14.3;18.8] in the overall population, while patients with BM at ID had a lower mPFS (12,9m) compared to those without BM (18,8m). No difference was observed in patients ≥70y vs <70y (mPFS 16,8m [13.0;23.8] vs 16,6m [13.2;19.2] respectively). More than half of patients (52.8%) were still treated by osimertinib at data cut-off. The safety profile was consistent with the expected safety profile of osimertinib.

Conclusions: POSITHES is the first ambispective study in France to investigate the effectiveness of osimertinib in a RW setting. POSITHES shows very similar efficacy outcomes to those observed for osimertinib monotherapy in the FLAURA and FLAURA2 trials, despite the broader eligibility criteria, confirming its clinical utility as a 1L treatment for EGFRm NSCLC.

EP.12 METASTATIC NON-SMALL CELL LUNG CANCER – TARGETED THERAPY

EP12.65 Factors Impacting Targeted Therapy Use in Stage Iv Non-Small Cell Lung Cancer Patients With Infrequent Actionable Mutations

B. Mulherin, MD[1], D.P. Petro, MD[2], T. Patel, MD[3], S.". Divers, MD[4], E. S. Santos, MD[5], R. Choksi, MD[2], M. Gart, MBA[6], A. Rui, MPH[6], D. Parris, PhD, MPH[6], A. Shrivastava, B. Tech[6], B. Wang, MBA[6], P. Varughese, PharmD, MBA[6], R. Geller, MD[6], J. Scott, MD[6]
[1]Hematology Oncology of Indiana, Indianapolis/IN/USA ,[2]University of Pittsburgh Medical Center (UPMC), Pittsburgh/PA/USA ,[3]Zangmeister Cancer Center, Columbus/OH/USA ,[4]Genesis Cancer & Blood Institute/AON, Hot Springs/AZ/USA ,[5]The Oncology Institute of Hope and Innovation, Fort Lauderdale/FL/USA ,[6]Integra Connect, West Palm Beach/FL/USA

Introduction: The NCCN guidelines recommend non-small cell lung cancer (NSCLC) patients (pts) who are stage IV that harbor actionable mutations receive targeted therapy for first-line treatment. We aim to show among pts with infrequent actionable mutations, defined by less than 10% positivity, who receive care at oncology practices in the U.S. what clinical or demographic factors impact whether such pts receive targeted therapy or not.

Methods: Among Integra Connect PrecisionQ's de-identified database the analysis included pts >=18 years of age, who were confirmed via manual chart abstraction as newly diagnosed stage IV NSCLC and found positive for either of the following ALK, ROS1, BRAF V600E, MET Exon 14 Skipping, RET, or NTRK1/2/3 and started first-line treatment between 1/1/2022 to 12/31/2024. Pts were assessed as to whether age, gender, race, Eastern Cooperative Oncology Group (ECOG) performance status, histology, stage, site of metastatic (mets) disease, and test turnaround time (TAT) impacted receiving targeted therapy. Descriptive analyses were performed, and chi-squared analysis were used for comparisons.

Results: Targeted therapy utilization (TTU) occurred in 101/185 pts (55%) with less common actionable mutations. The mean age of pts receiving targeted therapy was 65.2 compared to 70.2 for those who did not receive targeted therapy. Comparing pts by gender, TTU was 55/95 (58%) among females and 45/89 (51%) among males. Comparing pts by race, TTU was 71/137 (52%) among White pts, 11/21 (52%) among Black/African American pts, 6/7 (86%) among Asian pts, and 13/20 (65%) among other pts. Comparing pts by ECOG, TTU was 47/94 (50%) among 0-1 pts, 9/22 (41%) among 2+ pts, and 45/69 (65%) among pts with an unknown ECOG. The TTU by histology was 75/129 (58%) among pts with adenocarcinoma, 3/18 (17%) among pts with squamous cell carcinoma, and 23/37 (62%) among pts all others subtypes or unknown histology ($p < 0.01$). TTU among stage IVA was 35/72 (49%) compared to stage IVB at 34/60 (57%), and unspecified stage IV at 32/53 (60%). Comparing pts by site of metastatic disease, TTU was 37/56 (66%) among pts with bone mets, 21/37 (57%) among pts with brain/central nervous system mets, and 12/31 (39%) among pts with liver mets ($p < 0.05$). Based on test TAT, the TTU was 23/42 (55%) for TAT of <7 days, 43/88 (49%) for TAT of 7-to-14 days, and 9/21 (43%) for TAT of >14 days.

Conclusions: The real-world data shows stage IV NSCLC pts who harbor less common actionable mutations tend to receive targeted therapy if they had a histology of adenocarcinoma compared to squamous cell carcinoma or had bone mets compared to liver or brain/CNS mets. Factors such as age, sub-stage, ECOG, gender, race, and test TAT showed a difference in use of targeted therapy not to be statistically significant.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.01 Survival Analysis of Malignant Pleural Effusion in Small Cell Lung Cancer: A Single-Center Retrospective Analysis

P. Zhan, W. Lu
nanjing university, Nanjing/CN

Introduction: Malignant pleural effusion (MPE) is a negative prognostic factor for non-small cell lung cancer (NSCLC). However, the occurrence rate of MPE varies in small cell lung cancer (SCLC), and the prognostic implications and associated factors in SCLC patients with MPE have been underreported

Methods: Patients diagnosed with SCLC at Jinling Hospital were enrolled from 2008 to 2024. Cox regression analyses were used to identify risk factors affecting the survival of patients with indwelling pleural catheters (IPCs). Logistic regression analyses were employed to explore independent risk factors for MPE occurrence. The primary survival outcome measured was overall survival (OS)

Results: Among the 1026 patients, 363 (36.4%) presented with pleural effusion (PE). 284 (27.6%) patients had at the diagnosis, with 129 undergoing pleural fluid analysis via IPCs, of which 80 showed positive cytology. An ECOG performance status (PS) ≥2 (P=0.035), elevated serum neuron-specific enolase (s-NSE) levels (P=0.05), and positive cytology (P=0.07) were perceived as risk factors for poorer survival in patients with IPCs. Patients with maximal PE had the shortest median OS of 5.2 months, while those with minimal effusion had a median OS of 13.8 months (P<0.001), comparable to patients without effusion, whose median OS was 14.8 months. Longer OS was observed in MPE patients who received immunotherapy, had low sNSE levels, and had negative cytology

Conclusions: Approximately one-third of SCLC patients present with PE, with an MPE incidence of 12.6%. SCLC patients with MPE exhibit the poorest survival outcomes. However, the difference in OS between patients with minimal PE and those without PE is unobvious

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.02 Incidence and Characteristics of Small Cell Lung Cancer at the National Respiratory Center of Persahabatan Hospital, Indonesia in 2023-2024

K. Widyastuti, E. Syahrudin, A. Radiyah, F. Iranita Liza, M. magdalena, M. Masdi, E. Hermansyah, P. Suardi
Persahabatan Hospital, Jakarta/ID

Introduction: Globally, lung cancer is the leading cause of death from all types of cancer. In Indonesia, lung cancer accounted for 8.6% of all cancer incidence and 12.6% of all cancer deaths, making it the leading cause of cancer-related death. Small cell lung cancer (SCLC) comprises only 15-25% of lung cancer cases, but it is known as one of the most aggressive malignancies, characterized by rapid growth and high metastatic ability. Therapy modalities for Non-Small Cell Lung Cancer (NSCLC) have evolved, the use of chemotherapy, targeted therapy and checkpoint inhibitors has been standardized. Meanwhile, management for SCLC has not changed much, perhaps because the number of cases is small, especially in Indonesia. The aim of this study to evaluate characteristic, risk factor and outcome treatment of patient with SCLC in Indonesia.

Methods: A retrospectives observational study conducted at Persahabatan Hospital for 2 years in 2023 and 2024. This study includes patients with confirmed results of small cell lung carcinoma pathology. Demographic, risk factor, and treatment of patient were analyzed. The Indonesian Association for the Study of Thoracic Oncology (IASTO)-Indonesian Society of Respirology (ISR) 2023 Risk Factor score was used to examine the risk factor level.

Results: In this study, based on anatomical pathology data, 1,677 cases of lung cancer were obtained in the period 2023-2024. There were 1,583 (94.39%), NSCLC (diagnoses adenocarcinoma, squamous cell carcinoma, large cell carcinoma and rarer cases such as neuroendocrine/carcinoid tumors) and only 94 (5.61%) SCLC. The characteristics of the SCLC patients based on age: there was median 61 (30 -80) years old. Gender: male was 82 (87.23%) and female were 16 (19.51%). Using a scoring system to determine the level of risk factors obtained low risk was 1 (3.13%), medium risk was 43 (44,79%) and high risk was 50 (52.08%). We used the chemotherapy carboplatin/cisplatin and etoposide regimen but for various reasons only 31 people received chemotherapy at Persahabatan Hospital.

Conclusions: Until today, the reason why the SCLC incident is low in Indonesia has not been found when compared to the percentage of global data which reaches 15-25%. On the other hand, based on the results of multi-center observations in Indonesia, Persahabatan Hospital has a higher incidence than other centers in Indonesia. Perhaps because most of them are referral cases, especially for difficult cases. After a definite diagnosis is obtained, a back referral is made for therapy.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.03 A Single-Center Experience With Tarlatamab in Relapsed/Refractory Advanced Small Cell Lung Cancer and Neuroendocrine Carcinomas

Y. Nie[1], X. Wang[1], D. Luon[2], A. Chiang[1]
[1]Yale Cancer Center, Yale School of Medicine, New Haven/CT/USA ,[2]Yale New Haven Hospital, New Haven/CT/USA

Introduction: High-grade neuroendocrine carcinomas, including extensive-stage small cell lung cancer (ES-SCLC), are aggressive malignancies with poor prognoses, with most patients developing resistance to first-line chemoimmunotherapy within 6 months. Tarlatamab, a DLL3-CD3 Bispecific T-Cell Engager, is now commercially available as a promising second line or later option for patients with ES-SCLC. The safety and efficacy of tarlatamab in a real-world setting in patients with ES-SCLC and other neuroendocrine tumors remains to be fully characterized.

Methods: We conducted a single-center retrospective analysis of clinicopathologic data, safety, and outcomes in patients receiving tarlatamab from September 2023 to March 2025, with a focus on cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Data cut off was April 2, 2025.

Results: 22 patients with advanced neuroendocrine carcinoma (77.3% ES-SCLC) received at least 1 dose of tarlatamab (Table 1). 4 patients had baseline interstitial lung disease and 1 patient had CHF. All patients had prior exposure to an immune checkpoint inhibitor (ICI) with a median 3.5 months (range 1.1 - 65.3) between last dose of ICI and tarlatamab. 10 patients had brain metastases, with 8 patients fully treated, 1 partially treated (16/25 lesions), and 1 untreated pre-tarlatamab. 14 (63.6%) patients developed any grade CRS (two Gr. 3, one Gr. 4) and 9 (40.9%) developed any grade ICANS (three Gr. 3), with all Gr. 3 toxicities occurring at the C1D1 1mg dose and one Gr. 4 CRS at the C1D8 10mg dose. At data cutoff, 16 patients are alive and 11 remain on treatment. Of 14 evaluable patients, initial responses were 6 partial responses (PR) including in a patient with prostate small cell carcinoma, 1 stable disease, 5 mixed responses, and 2 progressive disease. Objective response rate and disease control rate were 42.9% and 50% respectively. 9 patients progressed, with a median PFS of 2.9 months (0.5-5.5), of which 4 had CNS-only progression.

Conclusions: Tarlatamab was well tolerated in a real-world setting, including in patients with ILD and CHF. The rates of Grade 3 or higher CRS or ICANS were comparable to that reported in the clinical trial. Importantly, patients with primary extra-pulmonary small cell carcinoma and large cell neuroendocrine histologies did respond to tarlatamab. CNS progression remained common, including CNS-only events. Further studies such as DLL3 expression characterization and molecular analyses of patient samples will be essential to determine predictors of response and risk factors for severe adverse events to tarlatamab.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.04 Patients With Limited Stage Small Cell Lung Cancer Detected Through Lung Cancer Screening May Have Improved Survival

J. Gor, T. Hill, M. Pasquinelli, R. Nguyen, F. Weinberg
University of Illinois Chicago, Chicago/IL/USA

Introduction: Small cell lung cancer (SCLC) is an aggressive malignancy with poor prognosis. Our study aims to evaluate patients diagnosed with limited stage (LS) SCLC through the lung cancer screening (LCS) program at UI Health to determine if there is a survival difference when compared to patients diagnosed outside of the screening program.

Methods: A retrospective chart review was conducted on a database of 1743 patients diagnosed with lung cancer between 2015 and 2024 in a single center analysis at UI Health. Of these, a total of 164 patients were diagnosed with SCLC and 45 of these patients were determined to be LS (stage I, II, or III). Of the 45 patients diagnosed with LS SCLC, 6 were identified through the LCS program. We collected data on baseline demographics, date of initial diagnosis, disease characteristics, and outcomes. Survival was analyzed using the Kaplan-Meier method and two-sided Fisher's exact testing.

Results: Of the 39 patients diagnosed with LS SCLC outside of the LCS program, 46% were Black and 51% were White. Five (5%) percent identified as "other" race. Of the 6 patients diagnosed through the screening program 50% were Black, 33% were White, and 17% were identified as "other" (p-value 0.66). Patients who smoke made up 70% of the non-screened group and 50% of the screening group, whereas patients with a smoking history made up 30% of the non-screened group and 50% of the screening group (p-value 0.37). When comparing overall survival (OS), the patients diagnosed outside of the screening group have an OS of 1.6 years versus 4.2 years for patients in the screening program (p-value 0.13).

Conclusions: While this study was limited by the sample size, the large numerical increase in OS observed in the individuals diagnosed with LS SCLC through the LCS program warrants further investigation. Traditionally, SCLC is thought to evolve rapidly and progress quickly to extensive stage disease. Our data suggests that when caught early through the lung cancer screening program, SCLC outcomes are potentially greatly improved.

EP.13.05 Twice Daily Hyperfractionated vs Once Daily Normofractionated Chemo-Radiotherapy in LS-SCLC: A Monocentric Experience

A. Cappelli[1], A. Benini[2], S. Scicolone[2], R. Leporati[3], G. Guaitoli[3], L. Trudu[3], J. Imbrescia[2], F. Incalcaterra[1], P. Giacobazzi[2], F. Bertolini[3], M. Dominici[1,3], A. Bruni[1,2]
[1]Department of Medical and Surgical Sciences for Mother, Child and Adult, University of Modena and Reggio Emilia, Modena/IT ,[2]Radiotherapy Unit, Department of Oncology and Hematology, Modena University Hospital, Modena/IT ,[3]Division of Oncology, Department of Oncology and Hematology, Modena University Hospital, Modena/IT

Introduction: The appropriate thoracic radiotherapy (TRT) schedule in limited-stage Small-Cell Lung Cancer (LS-SCLC) is still a matter of debate. Three randomized phase III trials compared twice daily (BID) schedule and once daily (OD), so that BID 45 Gy/30 fractions with concurrent cisplatin-etoposide (CDDP/VP16) chemotherapy represents the standard of care. These results were then confirmed by two clinical trials, where higher doses in the OD group were used. Nevertheless, in clinical practice not all patients (pts) are suitable for concurrent chemo-radiotherapy (cCRT), nor fit for CDDP. The aim of this study is to compare clinical outcomes in pts treated with BID or OD TRT given concurrently or sequentially (sCRT) to platinum-based chemotherapy in a real-world cohort.

Methods: A retrospective analysis was conducted on 68 pts affected by LS-SCLC treated with OD (60 Gy/30 fr) or BID CRT (45 Gy/30 fr) at Modena University Hospital from 2013 to 2024. Kaplan-Meier methods estimated Overall Survival (OS), progression-free survival (PFS) and metastasis-free survival (MFS). Treatment-related toxicities and patterns of failure were additionally analyzed.

Results: Pts features are summarized in Table 1. Mean follow-up was 15.8 months (3-148). 27 pts (39.7%) were treated with BID schedule while 41 (60.3%) underwent OD schedule. 54.4% of pts received cCRT, 45.6% received sCRT. 35 pts (51.5%) underwent prophylactic cranial irradiation (PCI). The most frequent sites of first metastatic progression were brain (51.3%) and liver (33.4%). 51.5% pts had a loco-regional recurrence. Acute grade≥3 toxicities were reported in 38 pts (55.9%), mostly hematological (35 pts, 92.1%) followed by esophagitis (3 pts, 4.3%), pneumonitis (2 pts, 2.9%) and cardiac events (1 pt, grade 3 heart failure). Of note, 2 grade 5 neutropenia were described. Five pts experienced grade≥3 late toxicities, 4 pulmonary-related and 1 renal failure. No grade 5 late toxicity were reported. Toxicity was comparable between the BID and OD schedules. 3- and 5-year OS, MFS and PFS were 38.8%(SE±6.5%) and 25.5%(SE±6.6%), 41.1%(SE±6.6%) and 41.1%(SE±6.6), 30.5%(SE±5.8%) and 26.1%(SE±6.4%), respectively. In terms of OS and MFS, there was a trend favoring pts who underwent PCI ($p<0.07$ for both), while the difference was statistically significant for PFS ($p < 0.02$). No significant differences in clinical outcomes were observed according to BID or OD schedule.

Conclusions: Both BID and OD schedules showed to be safe and effective when modern RT-techniques are used in LS-SCLC. Furthermore, PCI PCI appears to influence key clinical outcomes and should be considered for the majority of patients.

Median Age	67.5 years

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.06 Immunotherapy for ES-SCLC Comorbid With COPD: A Real-World Retrospective Study

Y. Jiang, P. Zhan
Jinling Hosipital, School of medicine, Southeast university, Nanjing/CN

Introduction: The prognosis and reliable survival predictors for small cell lung cancer (SCLC) patients with comorbid chronic obstructive pulmonary disease (COPD) remain unclear. We aimed to discuss the effect of COPD on SCLC in the settings of immunotherapy and explore the candidate pulmonary function or serum parameters, which might help the selection of the COPD population benefiting from immunotherapy.

Methods: We retrospectively recruited histologically confirmed ES-SCLC patients receiving first-line chemoimmunotherapy and pulmonary function tests in Nanjing Jinling Hospital. Baseline information was extracted, including pulmonary function parameters such as vital capacity (VC) (% of predicted), forced expiratory volume in one second (FEV1) (% of predicted), forced expiratory volume in one second/ forced vital capacity (FEV1/FVC) and peak expiratory flow (PEF) (% of predicted), serum parameters such as lactate dehydrogenase, albumin, counts for neutrophil, lymphocyte, monocyte and eosinophil, and clinical parameters such as age, gender and treatment regimens. The primary outcome was overall survival (OS). Step-wise multivariate Cox regression was used to identify candidate variables. Cox regression analysis, Log-rank tests, and landmark analysis were applied to determine candidate survival predictors.

Results: During the median follow-up period of 19 (13.9-27.7) months, a total of 100 ES-SCLC patients undergoing first-line chemoimmunotherapy with additional pulmonary function tests were retrospectively enrolled, among whom 59 patients were diagnosed with COPD. According to the global initiative for chronic obstructive lung disease (GOLD) criteria, most patients were categorized into stages I-II [46 (78.0%)], while 13 (22%) patients were grouped into Level 3-4. Within 9 months' follow-up, patients with COPD exhibited superior OS compared to those without COPD (P=0.041), while thereafter, COPD patients were prone to unfavorable survival (P=0.011). However, there existed no distinct disparities for PFS between the two subgroups (P=0.76). Multivariate Cox regression analysis suggested that three variables were suggestive of the prognosis, including maximum VC%>68.8 [hazard ratio (HR)= 0.23, 95% confidence interval (CI): 0.08-0.72, P=0.01], PEF%>65 (HR=0.37, 95% CI: 0.10-1.34, P=0.13) and neutrophil>3.80 (HR=0.20, 95% CI: 0.07-0.59, P=0.004).

Conclusions: For ES-SCLC patients, comorbid COPD is a protective factor for immunotherapy in the short term but a risk factor in the long term. Elevated levels of neutrophils and VCMAX% are indicative of favorable prognosis in ES-SCLC patients with comorbid COPD. Our findings convince the positive effect of COPD on the survival of SCLC patients in the settings of immunotherapy and might guide the selection of appropriate COPD patients benefiting from immunotherapy.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.07 Association of Gut Microbiota and Metabolites With Thalidomide-Induced Antiemetic Efficacy in Small Cell Lung Cancer Patients

Q-G. Sun, Y. Xin, D. Zang, J. Chen
The Second Hospital of Dalian Medical University, Dalian/CN

Introduction: Small cell lung cancer (SCLC) is highly aggressive and has a poor prognosis. Platinum-based chemotherapy often reduces the tolerance of treatment due to chemotherapy-induced nausea and vomiting (CINV). A previous study (CLOG1302 study, NCT02203253) confirmed that thalidomide (THD) combined with palonosetron and dexamethasone could significantly improve the complete response rate of delayed CINV after hyperemetogenic chemotherapy with good safety. Recent studies have found that intestinal flora and its metabolites are involved in the occurrence and development of CINV through multi-dimensional mechanisms. The aim of this study is to explore whether gut microbiota and metabolites synergistically enhance the antiemetic efficacy of THD in SCLC patients.

Methods: Baseline fecal samples were collected from 38 SCLC patients, stratified into two groups: the THD (E) group (n=18), comprising patients receiving THD for antiemetic intervention, and the control (C) group (n=20), comprising those without THD intervention. Metagenomic and metabolomic sequencing were performed to compare differences in gut microbiota composition and metabolite profiles between two groups.

Results: Significant disparities in gut microbiota and metabolites were observed between two groups. Metagenomic analysis revealed higher α diversity in the E group, as evidenced by an elevated Shannon index (P=0.037), suggesting THD enhanced gut microbial diversity. Gut microbiota with increased relative abundance in the E group included c_Clostridia (P<0.05), o_Eubacteriales (P<0.05), p_ Firmicutes (P<0.05), o_Bacteroidales (P<0.05), and c_Bacteroidia (P<0.05). Metabolomic profiling identified higher levels of Hydrogenated MDI (P<0.05), Carteolol (P<0.05), Becocalcidiol (P<0.05), B-Octylglucoside (P<0.05), and Azelaic acid (P<0.05) in the C group. KEGG pathway analysis highlighted significant differences in Neomycin, kanamycin, and gentamicin biosynthesis and Tryptophan metabolism.

Conclusions: These findings suggest that THD may alleviate CINV in SCLC patients by modulating gut microbiota and associated metabolites. Gut microbiota composition and metabolite profiles may correlate with THD antiemetic efficacy, positioning them as potential predictive biomarkers and therapeutic targets for optimizing CINV management in SCLC patients treated with THD.

EP.13.08 Early Hospitalization During Chemoradiation for Limited-Stage Small Cell Lung Cancer Is Associated With Inferior Survival

D.L. Billing[1], C.B. Simone II[2], D.Y. Gelblum[1], P. Iyengar[1], A.J. Wu[1], J.Y. Shin[1], T. Chaunzwa[1], J. Ma[1], M. Thor[1], C.M. Rudin[1], D.R. Gomez[1], N. Shaverdian[1], A.J. Cooper[1]
[1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]New York Proton Center, New York/NY/USA

Introduction: Consolidative durvalumab significantly improves survival outcomes and is a new standard of care in limited-stage small cell lung cancer (LS-SCLC); however, not all eligible patients will receive this therapy. Approximately 30% of patients with locally advanced non-small cell lung cancer treated with chemoradiation (CRT) do not receive consolidative durvalumab as intended, primarily due to ongoing toxicity from CRT. We, therefore, aimed to analyze early hospitalization rates and the association of hospitalizations with toxicity and outcomes in a cohort of LS-SCLC patients treated with definitive intent in order to establish a benchmark prior to the consolidative immunotherapy era.

Methods: We conducted a retrospective, single-institution review of consecutive patients with LS-SCLC who were treated with definitive concurrent chemoradiation (cCRT) between 2017 and 2024. cCRT was defined as initiation of radiation within the first two cycles of first line chemotherapy. Baseline characteristics, toxicity, and outcome data were collected. Early hospitalization was defined as occurring during or within 30 days of cCRT end. Overall survival and progression free survival were analyzed using the log-rank test (significance: $p<0.05$). Toxicity outcomes were analyzed using Fischer's exact test (significance: $P<0.05$)

Results: A total of 211 patients who met inclusion criteria were identified. Of these, 70 (33.0%) were hospitalized during or within 30 days of radiation therapy. The most common reasons for hospitalization were due to infectious (51.4%), hematologic (37.1%), pulmonary (20%), esophagitis (18.6%), and failure to thrive (17.1%). The baseline characteristics of hospitalized vs non hospitalized patients were well balanced with respect to smoking history, history of cardiac disease, and history of pulmonary disease. Baseline performance status was worse in patients who were hospitalized (median ECOG 1 vs 0, $p = 0.04$). Patients had early hospitalization had shorter median overall survival (30.3 months vs 52.21 months, $p = 0.02$), although progression free survival was not significantly different between cohorts (median 12.2 months vs 15.9 months, $p = 0.57$). Hospitalized and non-hospitalized patients received similar treatment courses including median number of chemotherapy cycles (3 vs 3), receipt of twice daily radiation (62.9% vs 63.8%,and receipt of prophylactic cranial radiation (31.4% vs 40.4. Despite this, hospitalized patients were more likely to discontinue radiation therapy early (14.3% vs 1.4%, $p = 0.003$), experience grade 2+ esophagitis midway through radiation treatment (17.1% vs 6.4%, $p = 0.03$), and develop grade 2+ radiation pneumonitis (28.6% vs 15.6%, $p=0.03$).

Conclusions: Early hospitalization is associated with inferior survival and early chemoradiation toxicities in this pre-immunotherapy cohort. Patients who are hospitalized earlier may be less likely to receive consolidative durvalumab as intended, and this survival disparity may be amplified further. Predictive models are needed to personalize treatment strategies to mitigate toxicity risk and increase the number of patients eligible to receive durvalumab consolidation.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.09 Neoadjuvant Chemoimmunotherapy Versus Chemotherapy for LS-SCLC

L. yang[1], x. wang[1]
[1]The Forth Hospital of Hebei Medical University, Shijiazhaung/CN

Introduction: This study aimed to analyze the safety and effectiveness of neoadjuvant immunotherapy combined with chemotherapy for people with limited-stage small cell lung cancer (LS-SCLC) and to explore new treatment ideas.

Methods: This study was a retrospective analysis of clinical data from participants with LS-SCLC who underwent neoadjuvant therapy followed by surgical resection at the Fourth Hospital of Hebei Medical University between April 2018 and February 2024. The participants were divided into the neoadjuvant immunotherapy combined with chemotherapy group (NICT, 13 cases) and the neoadjuvant chemotherapy group (NCT, 25 cases) to compare the pathological complete response (pCR) rate, major pathological response (MPR) rate, overall survival (OS), and disease-free survival (DFS).

Results: The NICT group demonstrated significantly higher rates of pCR (46.2% vs. 12.0%) and MPR (53.8% vs. 16.0%) compared to the NCT group ($P < 0.05$). Additionally, the lymph node pCR rate was markedly elevated in the NICT group (76.9% vs. 40.0%, $P < 0.05$). However, no statistically significant differences were observed between the two groups in OS, DFS, R0 resection rate, intraoperative parameters, or postoperative complication rates.

Conclusions: Neoadjuvant immunotherapy combined with chemotherapy improved pathological responses and lymph node downstaging in people with LS-SCLC. Long-term survival outcomes require further follow-up. The regimen demonstrated comparable safety to chemotherapy alone. Prophylactic cranial irradiation is recommended for people with clinical TNM stage III LS-SCLC after neoadjuvant therapy.

Introduction: Superior Vena Cava Syndrome (SVCS), arising from obstruction of the superior vena cava, often due to external tumor compression or thrombosis, It is most commonly associated with malignancies—particularly small cell lung cancer (SCLC)—given the disease's aggressive biology and frequent central tumor location, may lead to an oncologic emergency and compromise prognosis. This study explores the relationship between SVCS and survival outcomes in patients with ES-SCLC, focusing on clinical and prognostic implications.

Methods: We analyzed data from the Mayo Clinic's Epidemiology and Genetics of Lung Cancer (EGLC) database, a prospective lung cancer cohort, to identify patients with ES-SCLC. Clinical variables included demographics, comorbidities, tumor characteristics, treatments, and outcomes. "Excellent survival" was defined as the top 10th percentile of ES-SCLC patients, while "Ordinary survival" was defined as the median ± 2 standard errors. A 1:4 matching was performed based on age at diagnosis, sex, smoking history, ECOG performance status, and year of diagnosis. Statistical analyses included t-tests, chi-square tests, and logistic regression.

Results: Of 20170 lung cancer cases diagnosed between 1997 and 2016 and followed through 2024, 2309 (11.4%) were SCLC, of which 1340 (58%) had ES-SCLC. Among the 1259/1340 (94%) ES-SCLC patients with known smoking history, 96.6% were current or former smokers. Disease progression was noted in 80.3% of patients, with local recurrence in 84.3%. Treatment modalities included chemotherapy (74.1%) and chemoradiotherapy (25.9%). The median overall survival was 0.80 years (95% CI: 0.73-0.86), and median progression-free survival was 0.52 years (95% CI: 0.49-0.58). ECOG performance status was 1 in the majority of cases (77.2%). After matching, 509 patients (118 Excellent survival and 391 Ordinary survival) were analyzed. Excellent survivors showed higher rates of several comorbidities diagnosed before ES-SCLC treatment, including mental illness (p=0.04), depression (p=0.02), peripheral vascular disease (p=0.0005), GERD (p<0.0001), paraneoplastic syndromes (p=0.0038), and coronary artery disease/myocardial infarction (p=0.0137). The presence of liver metastases was significantly associated with worse survival (p<0.0001), while bone (p=0.0059) and brain metastases (p=0.0170) were more frequent in Ordinary survivors. Interestingly, SVCS was notably more common among Excellent survivors (12.7%) than among Ordinary survivors (3.6%, p=0.0002).

Conclusions: Contrary to its traditional association with poor prognosis, SVCS may be linked to prolonged survival in certain patients with ES-SCLC. These findings suggest that SVCS could represent a distinct clinical subset with potential prognostic value. Further investigation is warranted to validate these observations and better understand the underlying mechanisms.

EP.13.11 Real-World Survival Data Over 25 Years in Extensive-Stage Small-Cell Lung Cancer: The Impact of Immune Checkpoint Inhibitors

R. Ariyasu, H. Iso, M. Ito, K. Nibuya, S. Fujishima, M. Sugai, R. Tsugitomi, Y. Amino, K. Uchibori, N. Yanagitani, M. Nishio
The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo/JPM. Früh[1]

Introduction: Unlike in non-small-cell lung cancer (NSCLC), therapeutic advancements for extensive-stage small-cell lung cancer (ES-SCLC) have been relatively scarce. Although immune checkpoint inhibitors (ICIs) have been approved for the treatment of ES-SCLC since 2019, their impact on patient survival in real-world settings remains uncertain. This study aimed to evaluate the survival trends in patients with ES-SCLC over the past 25 years.

Methods: This single-center retrospective study analyzed survival data from 452 patients diagnosed with ES-SCLC between 1999 and 2023. The patients were divided into five groups according to their diagnosis year: Period A (1999-2003), Period B (2004-2008), Period C (2009-2013), Period D (2014-2018), and Period E (2019-2023). Overall survival (OS) was estimated using the Kaplan-Meier method, and survival differences were assessed with the log-rank test. Additionally, a multivariate Cox proportional hazards model was applied to identify the independent prognostic factors affecting OS.

Results: The patient characteristics are summarized in Table. The median follow-up period was 11.6 months, during which 394 out of 452 patients experienced an OS event. The median OS (mOS) was 9.8, 12.5, 13.4, 11.8, and 13.6 months for Periods A through E, respectively. The corresponding 2-year OS rate was 6.2%, 18.2%, 18.6%, 17.3%, and 29.3% (Figure). The proportion of patients who received ICIs was 14.1% in Period D and 73.1% in Period E. Patients treated with ICIs had a significantly longer mOS compared with those who were not (15.2 vs. 11.8 months, $p < 0.005$) (Figure). Multivariate analysis identified performance status, history of chemotherapy, and history of ICI treatment as independent prognostic factors influencing OS.

Conclusions: Survival outcomes for patients with ES-SCLC improved over time. Our results indicate that ICIs are associated with improved OS in real-world clinical settings.

Characteristics	Period A (1999-2003)	Period B (2004-2008)	Period C (2009-2013)	Period D (2014-2018)	Period E (2019-2023)

Introduction: In recent years, combination therapy with immune checkpoint inhibitors has been approved for extensive-stage small cell lung cancer (ES-SCLC) and becoming the standard treatment. However, there are little is known about regarding the safety and effectiveness of this treatment in the elderly. Therefore, we tried to compare and examine the effects of treatment using the age of 75 years old, which is generally considered an elderly person in a medical sense in Japan.

Methods: We retrospectively collected pure ES-SCLC patients who received primary treatment with Carboplatin + Etoposide + Atezolizumab or Durvalumab at four institutions from August 22, 2019 to December 31, 2023. Safety and efficacy were then analyzed separately for the elderly group (over 75 years old) and the non-elderly group (under 74 years old).

Results: The number of cases was 77, of which 40 were in the elderly group (median age 78 years [range: 75-86 years]) and 37 were in the non-elderly group (median age 68.5 years [range: 51-74 years]). There were 33 (82.5%) and 29 (78.4%) males in each group. The response rate was 70.0%/78.4%, disease control rate was 92.5%/83.8%, PFS was 148/161 days and OS was 305/294 days in each group. The hazard ratio for PFS in the elderly group versus the non-elderly group was 1.4119 (95% CI, 0.8233 to 2.421; p=0.210), and OS was 1.3788 (95% CI, 0.8051 to 2.361: p=0.242). Only one patient in the non-elderly group had over Grade 3 immune-related adverse events (irAE).

Conclusions: The effectiveness of the treatment was also demonstrated in the elderly group, and there was no obvious increase in the frequency of serious irAE compared to the non-elderly group. Combination therapy with immune checkpoint inhibitors is considered to be an effective option for patients with ES-SCLC in elderly patients.

EP.13.13 Treatment Outcome in Limited Stage Small Cell Lung Cancer: National Retrospective Study

M. Vrankar, K. Stanic, S. Jelercic, E. Ciric, D. Casar, M. Peternel, N. Dobnikar, U. Elbl, M. Sojar, J. But Hadzic
Institute of Oncology Ljubljana, Ljubljana/SI

Introduction: Small cell lung cancer (SCLC) accounts for approximately 15% of lung tumours and only 30% of these have limited disease that can be cured with combined chemotherapy (CT) and radiotherapy (RT) followed by prophylactic cranial irradiation (PCI). After several decades without significant therapeutic progress, adjuvant treatment with durvalumab after CT-RT in a group of these patients showed significantly longer overall survival (OS) and progression-free survival than placebo.

Methods: We performed a retrospective analysis of patients with limited SCLC treated at the Institute of Oncology Ljubljana from January 2013 to December 2022. We evaluated the outcome of patients according to demographic factors and treatment characteristics. The survival outcomes were calculated using Kaplan - Meier actuarial survival methods.

Results: We included 284 patients with limited SCLC (152 men and 132 women) with a median follow-up of 83 months and a median age of 64 years. The majority of patients (97.5%) completed 1-6 cycles of platinum-based CT combined with etoposide, of whom 69.3% completed 5-6 cycles. Majority of patients (64.8%) were treated with at least one concurrent CT during RT, the others were treated with sequential CT. Median OS was 26 months, 2-year survival was 50.7% and 5-year survival was 28.3%. There were no differences in survival according to sex, age, performance status, TNM stage, number of CT cycles (3 or less, 4 or more), radiotherapy technique (3D or IMRT). In patients who had diagnostic PET CT compared to those without it, we observed a significantly longer mOS, 31 months (CI 23.4-38.5) vs 22 months (CI 18.4-25.6), p<0.048. Patients with concomitant CT had a significantly longer mOS compared to patients with sequential CT, 28 months (CI 22.8-33.2) vs 22 months (CI 17.9-26.1), p<0.014, and 5-year survival (32.3% vs 19.6%). The RT doses were heterogeneous, but patients with BED10 greater than 70 Gy had significantly longer mOS, 28 months (CI 22.7-33.3) vs 21 months (CI 17.3-24.7), p<0.016, and 5-year survival (33.4% vs 16.6%) compared to BED 69 Gy or less. In our group, only 28.9% of the patients completed PCI without any impact on survival. Disease progression was observed in 65.1% of patients, 58.4% of them had metastases in the brain only or in combination with metastases in other organs.

Conclusions: Our findings on treatment outcomes in patients with limited SCLC are consistent with other published real-world data before adjuvant durvalumab era.

EP.13.14 Real-World Data Analysis of Treatment Pattern and Prognosis of Patients With Limited-Stage Small Cell Lung Cancer in Japan

S. Niho[1], T. Kozuka[2], S. Uematsu[3], D. Kawai[3], T. Iwane[3], C. Iwao[3], H. Kitagawa[3], H. Kenmotsu[4]
[1]Dokkyo Medical University, Tochigi/JP ,[2]Toranomon Hospital, Tokyo/JP ,[3]AstraZeneca K.K., Osaka/JP ,[4]Shizuoka Cancer Center, Shizuoka/JP

Introduction: Over the decades, first-line (1L) treatment for inoperable limited-stage small cell lung cancer (LS-SCLC) has not changed from concurrent chemoradiotherapy (cCRT). Sequential chemoradiotherapy (sCRT) and chemotherapy (CT) alone are also 1L treatment options, when cCRT is unfeasible. Treatment selection and prognosis for LS-SCLC patients (pts) in real-world practice is unknown, and there are no data on large-scale treatment patterns and their rationale. Here, we investigated treatment patterns, effectiveness and safety of 1L options in Japanese clinical practice.

Methods: This multicenter, retrospective, observational cohort study collected clinical data of LS-SCLC pts diagnosed between Jan 2014-Dec 2020 (data cut-off Mar 31, 2024) and who underwent cCRT, sCRT, or CT alone as 1L treatment. The primary outcome was median overall survival (OS) in each cohort (cCRT, sCRT, CT alone). Secondary outcomes were median real-world progression-free survival (rwPFS) in each cohort, median OS/rwPFS by platinum choice (cisplatin [CDDP] or carboplatin [CBDCA]) in cCRT, reasons for choosing 1L treatment other than cCRT, and adverse events (AEs) associated with cCRT.

Results: In total, 504 pts (median [range] age: 70.0 [40-88] years [yrs]) were analyzed. Type of 1L treatment was cCRT in 301 pts (59.7%), sCRT in 106 pts (21.0%), CT alone in 97 pts (19.2%). Table 1 shows the reasons for choosing 1L treatment other than cCRT. The most common reason for selection was older age (61.3%) for sCRT and interstitial lung disease (54.6%) for CT alone. Median OS/rwPFS was 4.3 yrs/1.2 yrs, 2.3 yrs/1.0 yr and 1.5 yrs/0.5 yrs for cCRT, sCRT, and CT alone, respectively. Median OS/rwPFS by chemotherapy regimen in cCRT was 4.6 yrs/1.2 yrs and 4.1 yrs/1.1 yrs for CDDP + etoposide (ETP) and CBDCA + ETP, respectively. AE incidences associated with cCRT were radiation esophagitis (any grade) in 176 pts (58.5%), radiation pneumonitis (any grade) in 213 pts (70.8%). Other AEs leading to cCRT discontinuation were observed in 7 pts (2.3%).

Conclusions: Concurrent thoracic radiotherapy was used in approximately 60% of LS-SCLC pts who received chemotherapy. Our study demonstrated that appropriate treatment choices were made according to characteristics of pts (e.g., age, comorbidities) in clinical practice. As the treatment options for LS-SCLC increase in the near future, it is desirable that treatment decisions will be made more appropriately based on the differences in survival outcomes and potential adverse events associated with the specific treatment choices presented in this study.

Table 1. Reasons* for choosing 1L treatment other than cCRT

	sCRT	CT alone
Patients who received 1L treatment, n	106	97
Reason for choosing 1L treatment other than cCRT*, n (%)		
Older age	65 (61.3)	33 (34.0)
Poor PS	4 (3.8)	3 (3.1)

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.15 Outcome and Safety of Lurbinectedin as Compassionate Use in SCLC: A Retrospective Multicentric International Study

D. Scattolin[1,2,3], A-M.C. Dingemans[3], A. Dal Maso[1], V. Guarneri[1,2], J.G.J.V. Aerts[3], G. Pasello[1,2], D.W. Dumoulin[3]
[1]Veneto Institute of Oncology, Padua/IT ,[2]University of Padua, Padua/IT ,[3]Erasmus MC Cancer Institute, University Medical Centre, Rotterdam/NL

Introduction: Lurbinectedin has recently emerged in the treatment landscape of small cell lung cancer (SCLC). We report the real-world outcomes and safety of lurbinectedin within a named patient program.

Methods: Clinical data of patients with SCLC treated with lurbinectedin at the Erasmus Medical Center (EMC, Rotterdam-The Netherlands) and the Veneto Institute of Oncology (IOV, Padua-Italy) were retrospectively collected in this multicentric, international study. The primary endpoints were the effectiveness and safety of lurbinectedin; the effectiveness according to the chemotherapy-free interval (CFI) was secondarily assessed.

Results: At data cutoff (30th September 2024), 238 patients (204 from EMC and 34 from IOV) receiving lurbinectedin as second- (37%), third- (45%) or further-line (18%) were included. Median age was 65 (39-87) years, 51% were females. At lurbinectedin start, patients had metastasis in brain, bone and liver in 22%, 32% and 46% of cases, respectively; the performance status ECOG was ≥ 2 in 24% of cases, the CFI < 90 days in 201 (84%) patients. Primary prophylaxis with granulocyte colony stimulating factor (G-CSF) was administered in 33 (14%) patients, exclusively from the Italian cohort. A central venous catheter (CVC) was applied in 29 (85%) Italian and in 22 (11%) Dutch patients. The objective response rate was 24% (26% at EMC and 15% at IOV). The disease control rate was 47%, 50% in the Dutch, and 29% in the Italian patients. The median duration of response (mDOR) was 2.8 months (95%CI 2.0-3.5), the median progression free survival (mPFS) 2.2 months (95%CI 1.6-2.8) and the median overall survival (mOS) 5.4 months (95%CI 4.5-6.3). The 6-months PFS and OS rates were respectively 12.2% (95%CI 8.3-17.0) and 42.4% (95%CI 36.1-49.0). Considering the Dutch cohort, the mDOR, mPFS and mOS were respectively 2.8 (95%CI 2.1-3.4), 1.8 (95%CI 1.0-2.7) and 5.6 (95%CI 4.7-6.4) months, with a 6-months PFS rate of 11.2% (95%CI 7.3-16.4) and 6-months OS rate of 43.6% (95%CI 36.7-50.7). Among the Italian cohort, the mDOR was 4.6 months (95%CI 3.7-5.5), the mPFS 2.3 months (95%CI 2.0-2.7) and mOS 3.6 months (95%CI 1.8-5.3). The 6-months PFS and OS rates were 17.6% (95%CI 6.7-34.5) and 35.3% (95%CI 19.8-53.5), respectively. Patients with a CFI ≥ 90 days showed a longer mPFS (3.1 vs 1.8 months, HR 0.46, 0.30-0.71, p<0.001) and mOS (6.8 vs 4.5 months, HR 0.56, 0.37-0.85, p=0.006). Adverse events were recorded in 218 (92%) patients, with grade 3-4 in 70 (29%) cases and dose reduction in 47 (20%) patients. A higher rate of venous thrombosis and phlebitis was observed in patients without a CVC. The rate of neutropenia was higher in the Dutch than in the Italian cohort (39% vs 12%), however the febrile neutropenia rate was 2%.

Conclusions: Considering its manageable safety profile and modest but consistent effectiveness, lurbinectedin represents a therapeutic option as compassionate use in patients with SCLC. Heterogeneous outcomes of the two cohorts may be explained by differences in the diagnostic-therapeutic management. The role of G-CSF should be carefully evaluated and the use of central venous catheters may be beneficial in preventing thromboembolic events and phlebitis.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.16 Safety and Efficacy of Chemoimmunotherapy in Stage IV Small Cell Lung Cancer: A Single-Center Retrospective Analysis

A. Peeters, E. Wauters, K. Vanhove, I. Wauters, J. Vansteenkiste, C. Dooms
University Hospitals KU Leuven, Leuven/BE

Introduction: Since IMPOWER-133 and CASPIAN chemoimmunotherapy has become a first-line systemic treatment option for extensive disease SCLC. We conducted a retrospective study on safety and efficacy of a single-center patient cohort.

Methods: A retrospective cohort study was performed on stage IV SCLC patients started on carboplatin-etoposide-atezolizumab between January 2018 till December 2022 at the University Hospitals Leuven. Follow-up data were collected till February 2025. The Kaplan Meier method was used for estimating survival outcomes, and Cox regression models were used to assess the association between baseline clinical characteristics (age, ECOG PS, metastatic sites, s-albumin, s-LDH, s-CRP, s-NSE, Neutrophil-Lymphocyte Ratio (NLR), modified Glasgow Prognostic Score (mGPS) and LIPI score) and survival outcomes.

Results: A total of 74 patients were included, of whom 47% current and 51% former smokers. Median number of induction and maintenance cycles was 4 (range 1-4) and 3 (range 0-84), respectively. The objective response rate was 80%. The median progression-free survival (PFS) was 4.8 months (95%CI 4.5-5.0) and median overall survival (OS) was 11.5 months (95%CI 8.9-14.6). The 1-year, 2-year and 3-year PFS and OS rates (Figure 1) were 16.2% (95%CI 8.9-25.5), 9.5% (95%CI 4.2-17.4), and 8.1% (95%CI 3.3-15.7), and 47.3% (95%CI 35.6-58.1), 18.9% (95%CI 11.0-28.5) and 11.9% (95%CI 5.7-20,5), respectively. In multivariable analysis, bone metastasis (HR 2.21; 95%CI 1.26-3.87), age (+1yr, HR 1.03; 95%CI 1.00-1.07), s-NSE >250 µg/L (HR 4.55; 95%CI 2.13-9.72), and s-albumin ≥35g/dl (HR 0.49; 95%CI 0.25-0.99) were significantly associated with OS. Treatment related adverse events (TRAEs) occurred in 95% of patients: during induction (n=74) 89% experienced TRAEs, of whom 55 patients (74%) TRAEs G≥3; and during maintenance immunotherapy (n=58) 36% experienced immune-related adverse events (irAEs). During induction phase, chemotherapy dose reduction and discontinuation occurred in 31% and 8%, respectively. Overall, irAEs occurred in 21 patients (28%) leading to discontinuation of atezolizumab in 7 patients (9.5%).

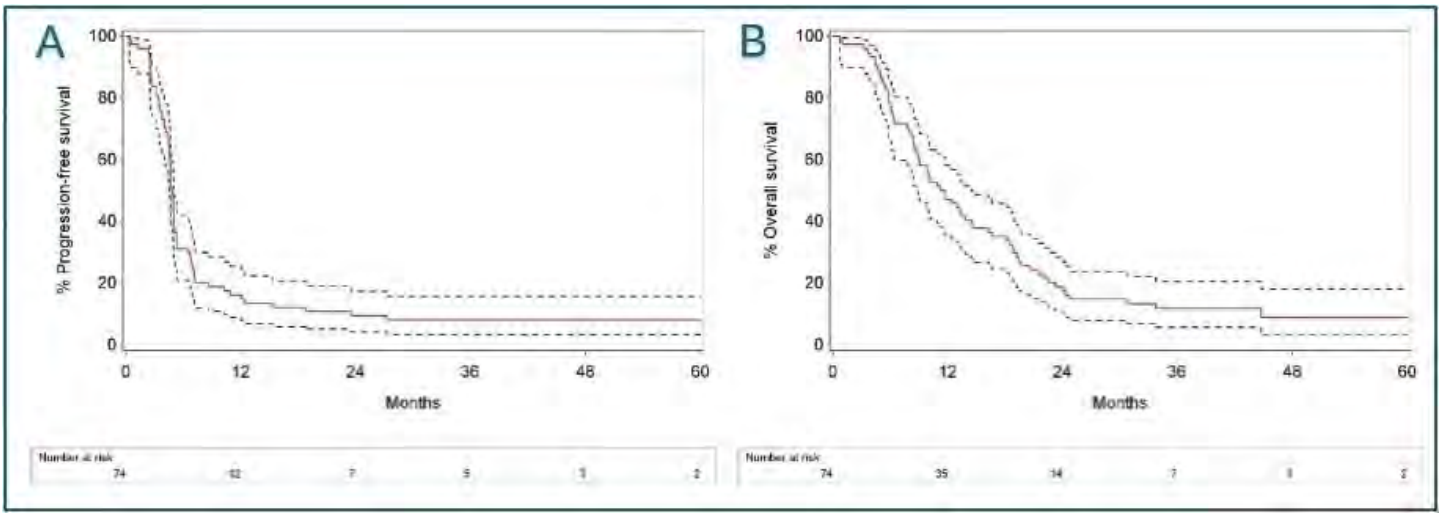

Figure 1: Kaplan-Meier curve of (A) progression free survival and (B) overall survival. The dashed lines indicate the 95% confidence intervals.

Conclusions: Our study provides long-term safety and efficacy outcomes of first-line chemoimmunotherapy in a real world cohort of stage IV SCLC, similar to the IMPOWER-133 registrational study. In multivariable analysis, we found that baseline conventional biomarkers (age, bone metastasis, s-albumin, and s-NSE) did significantly predict overall survival, while systemic inflammation scores (NLR, mGPS and LIPI) did not.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.17 Efficacy of First-Line Chemoimmunotherapy With Durvalumab or Atezolizumab in SCLC - Experiences From Practice of Two Polish Oncology Centers

A. Lomza-Laba[1], M. Knetki-Wróblewska[2], P. Krawczyk[1], I. Chmielewska[1], K. Winiarczyk[2], T. Jankowski[1], M. Szczyrek[1], R. Kieszko[1], N. Galant[1], A. Grenda[1], J. Milanowski[1], M. Krzakowski[2]
[1]Medical University of Lublin, Lublin/PL ,[2]The Maria Sklodowska-Curie National Research Institute of Oncology – National Research Institute, Warsaw/PL

Introduction: Small-cell lung cancer (SCLC) is characterised by an aggressive course with the early development of distant metastases. First-line chemotherapy was recommended treatment for extensive stage of SCLC (ES-SCLC), however the addition of immune checkpoint inhibitors significantly improved the systemic therapy in clinical trials. The aim of the study is to compare the effectiveness of two immunochemotherapy regimens in patients with ES-SCLC with different clinical characteristic in daily practice.

Methods: Here we presented retrospective analysis of patients qualified to immunochemotherapy in two independent oncology centers in 2021-2023. All patients were smokers with good or very good performance status. Clinical data were extracted from electronic database. Overall response rate (ORR), progression-free survival (PFS), and overall survival (OS) were compared according to treatment methods and clinical data. Statistical calculations were performed in MedCalc software version 18.11.6 using the chi-square test and the Kaplan-Meier survival analysis.

Results: 152 patients were diagnosed with ES-SCLC treated in first-line with chemotherapy in combination with atezolizumab (98 patients) or durvalumab (54 patients). 48 women and 104 men with an average age of 61.5 years were enrolled. Disease control rate was similar in the patients treated with atezolizumab and durwalumab (84.7% vs. 85.2%). Partial response (PR), stable disease (SD) and progressive disease (PD) occurred with similar prevalence in the patients treated with durvalumab and atezolizumab. Median of PFS in whole group of patients was 6 months (95% CI: 5.7-6.5), and median OS was 11.5 months (95% CI: 9.7-16). Method of treatment, as well as, the presence of metastases to the bones had no effect on the risk of progression and death. The risk of progression (HR=1.5406, 95% CI: 1.0024-2.3677, p=0.0487) and risk of death (HR=1.7808, 95% CI: 1.1096-2.8581, p=0.0168) were significantly higher in the patients with central nervous system (CNS) metastases. The presence of liver metastases significantly increased the risk of death (HR=1.9727, 95% CI: 1.707-3.3241, p=0.0107), while the risk of progression was insignificantly higher (HR=1.4976, 95% CI: 0.9552-2.3481, p=0.0784) in this group of patients.

Conclusions: Immunochemotherapy can be effective treatment in patients diagnosed with advanced small-cell lung cancer in daily practice. The presence of CNS and liver metastases are the main clinical factors shortening OS and PFS in ES-SCLC patients treated with chemioimmunotherapy. It seems, that the type of chemoimmunotherapy does not influence on treatment efficacy.

EP.13.18 Retrospective Evaluation of the Prognostic Impact of Anti-PD-L1 Antibodies in ECOG-PS 2-3 Patients With Extensive-Stage SCLC

K. Sakai, K. Shiraishi, I. Matsumoto-Ono, S. Ishii, S. Yokosuka, Y. Kawano, T. Takahashi, H. Nishimura, Y. Kuwabara, M. Sasaki-Toda, Y. Ogawa-Kobayashi, S. Kikuchi, Y. Hirata, H. Kyoyama, G. Moriyama, N. Koyama, K. Uematsu
Saitama Medical Center, Saitama Medical University, Kawagoe-shi, Saitama pref/JP

Introduction: The IMpower133 and CASPIAN clinical trials demonstrated the efficacy of adding immune-checkpoint inhibitors to platinum-doublet standard chemotherapy. This evidence led to the approval of atezolizumab and durvalumab for the treatment of patients with extensive-stage small cell lung cancer (SCLC) in Japan. In both studies, enrollment was restricted to patients with Eastern Cooperative Oncology Group-performance status (ECOG-PS) 0-1. Therefore, the clinical significance of combining these anti-programmed death-ligand 1 (anti-PD-L1) antibodies with chemotherapy in patients with ECOG-PS 2-3 remains unvalidated. The objective of this study was to evaluate the efficacy and tolerability of the concomitant use of anti-PD-L1 antibodies in ECOG-PS 2-3 patients with extensive-stage SCLC. This study refined the results presented at the 64th Annual Meeting of the Japan Lung Cancer Society.

Methods: Patients who visited Saitama Medical Center, Saitama Medical University (Kawagoe, Japan) (September 1, 2019-December 31, 2022) and received treatment for pathologically confirmed extensive-stage SCLC were enrolled in this study. Patients with other types of cancer were excluded. Enrolled patients were followed up until February 29, 2024. The objective response rate (ORR) to the first-line chemotherapy and overall survival (OS) were evaluated. These outcomes were stratified based on ECOG-PS and compared between patients treated with chemotherapy plus anti-PD-L1 antibodies and those treated with chemotherapy alone. This study was approved by the ethics board of Saitama Medical Center, Saitama Medical University (approval number: 2023-056).

Results: A total of 74 patients were included in this study (median age: 72 years [range: 43-84 years]). Of those, 32 patients (median age: 70 years [range: 49-82 years]) received anti-PD-L1 antibodies (atezolizumab: n=22; durvalumab: n=10) as first-line chemotherapy, while 42 patients (median age: 75 years [range: 43-84 years]) were treated with chemotherapy alone. Patients in the chemotherapy+PD-L1-antibody group were significantly younger (p=0.0065) than those in the chemotherapy alone group. In all patients (ECOG-PS: 0, n=3; 1, n=37; 2, n=15; 3, n=16; and 4, n=3), the ORR and median OS was 67.6% and 327 days, respectively. Among patients with ECOG-PS 0-1 (n=40), the ORR in the chemotherapy+PD-L1-antibody group (n=17) and the chemotherapy alone group (n=23) was 76.5% and 56.5%, respectively, with no significant difference. The median OS was also not significantly different between these groups (406 vs. 379 days, respectively). Among patients with ECOG-PS 2-3 (n=31), the ORR in the chemotherapy+PD-L1-antibody group (n=15) and the chemotherapy alone group (n=16) was 93.3% and 56.3%, respectively (p=0.0226). The median OS was significantly longer in the chemotherapy+PD-L1-antibody group compared to the chemotherapy alone group (448 vs. 169 days, respectively; p=0.00661). Only one patient underwent chemotherapy at a reduced dose due to poor PS. In five patients with ECOG-PS 2-3, the administration of anti-PD-L1 antibodies was discontinued due to immune-related adverse events.

Conclusions: In patients with extensive-stage SCLC and ECOG-PS 2-3, the addition of anti-PD-L1 antibodies was feasible and improved the ORR, leading to better prognosis.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.19 30-Year Review of Real-World Outcomes in Small Cell Lung Cancer at Hospital Clinic of Barcelona

L. Delgado, M.G. Antelo, C. Clavell, S. Santillan, G. Oses, M. Mollà, F. Casas
Hospital Clinic de Barcelona, Barcelona/ES

Introduction: Limited-Small cell lung cancer (LS-SCLC) is a highly aggressive malignancy with high metastatic potential. Landmark phase III trials have established concurrent Chemotherapy and Radiotherapy (cCh+RT) as the standard of care for SCLC. This study reviews survival and toxicity from our clinical practice at Hospital Clinic of Barcelona over the past 30 years, comparing it with results of pivotal clinical trials.

Methods: This retrospective and unicentric study, analyzed intention to treat outcomes from 218 patients diagnosed with LS-SCLC between 1994-2020, compared to phase III trial data. Radiological responses were evaluated using RECIST criteria. Progression-free survival (PFS) and overall survival (OS) were calculated using Kaplan-Meier and Cox regression models. Toxicity was also documented using CTCAE v5.0.

Results: Among 218 patients, 79% (170) received chemotherapy and radiotherapy (Ch+RT) (69.3% (151) of them cCh+RT and 9,6% (21) sequential RT), 8,3% (18) surgery + Ch, 10,1% (22) received Ch, 1 (0.5%) received only RT and 4 (1,8%) best supportive care. The median radiation dose was 45Gy (12-70Gy) administered over 21 days (7-43 days). Esophagitis (Grade 2-3) was the most frequent radiotherapy toxicity 40.4% (88 patients) and grade 3-4 neutropenia was the most common chemotherapy-related toxicity 75.3% (164). While median OS of all patients was 19.56 months, patients treated with Ch+RT had a median OS of 22.29months (95% CI 1.379-2.33) (cCh+RT 26 months (95% CI 1.602-2.732), compared to 14.6 months (95% CI 1.10-1.338) with sequential RT (p= 0.006)), surgery and chemotherapy 106.18months (95% CI 6.527-11.17) and Ch alone 4.3months (95% CI 0.38-0.68). We selectively analyzed patients who received protocol treatment (n:199) showing median OS of 28 months, OS at one year was 77.4%, 47.2% at 2 years, at 3 years 37.2% and 28.6% at 5y. Compared to landmark trials, including all 218 patients, our median OS is lower. However, analyzing selected patients that received protocol treatment, the 5 years survival in our cohort is comparable to the studies by Jeremic and Takada, superior to Turrisi and only slightly inferior to the results of the Favre-Finn study, despite our higher proportion of negative prognostic factors (Men, PS 3-4) (Table 1).

	Jeremic (1977) (n= 52)	Turrisi (1999) (n= 206)	Takada (2002) (n= 231)	Favre Finn (2017) (n= 274)	Casas (2025) (n= 218)
Age	59 (40-67)	61 (63-80) <65/>65% 60%/40%	65 (39-74)	62 (29-84)	64 (38-89) <65/>65 50.9%/49.1%

Median OS	36 months	23 months	31.3 months	29 months	19.56 months (n: 199) 28mo*
Survival					
1 year					77.4%
3 years		30%	24%		37.2%
5 years	30%			34%	28.6%

Table 1. PS: Performance status; KPS: Karnofsky performance status; Ch: Chemotherapy; RT: Radiotherapy; BSC: Best supportive care; OS: Overall survival.
**Median overall survival of our patients that received treatment protocol.*

Conclusions: Our real-world data shows a lower survival rate compared to pivotal clinical trials. However, when selecting patients who received protocol treatment, survival rates are comparable. These findings suggest that adhering to protocol treatments significantly improves survival with acceptable toxicities.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.20 Stereotactic Body Radiotherapy for Limited-Stage Small Cell Lung Cancer: Outcomes From a Single-Institution Retrospective Study

J. Basílio, I. Rodrigues, T. Figueiredo, S. Costa, J. Lima, J. Cardia
Portuguese Oncology Institute of Porto, Porto/PT

Introduction: Small cell lung cancer (SCLC) is an aggressive malignancy that represents approximately 13-15% of all lung cancers and is typically associated with poor prognosis and early metastatic spread. Traditionally, early-stage SCLC is treated with surgery followed by chemotherapy or chemoradiation, but many patients are not surgical candidates due to comorbidities or poor performance status. In such cases, stereotactic body radiotherapy (SBRT) offers a high-precision, high-dose alternative. Trials in early-stage NSCLC have demonstrated excellent local control and safety, prompting interest in its use for SCLC. Although evidence remains limited, retrospective studies suggest SBRT may yield outcomes comparable to surgery, including a multi-institutional series reporting favourable survival in Stage I SCLC. This study aims to evaluate outcomes of limited-stage SCLC patients treated with SBRT at a single institution.

Methods: We conducted a retrospective review including patients with histologically confirmed SCLC treated with curative-intent SBRT at a single cancer center between 2018 and 2023. Tumours were considered inoperable due to comorbidities or patient refusal. SBRT was delivered using the TrueBeam® system with the following regimens: 30 Gy in 1 fraction, 54 Gy in 3 fractions, 50 Gy in 4 fractions, and 45 Gy in 5 fractions. Endpoints were Time to Local Recurrence (TTLR), Time to Progression (TTP), and Overall Survival (OS). Toxicity was assessed using CTCAE v5.0. Statistical analysis was primarily descriptive. Time-to-event outcomes were estimated using the Kaplan-Meier method.

Results: Twelve patients with 12 lesions were included. Median age was 78 years (range 59-87), 75% were male, and 83.4% had a history of smoking. Most tumours (75%) were peripheral and staged as T1a-T2a. Chemotherapy (carboplatin-etoposide) was given to 58.3%, and one patient received prophylactic cranial irradiation. The most used SBRT regimen was 30 Gy in a single fraction (n=6), followed by 54 Gy in 3 fractions (n=3), 50 Gy in 4 fractions (n=2), and 45 Gy in 5 fractions (n=1). Median SUVmax was 14.2, and mean volume of the planning target volume was 34.7 cm^3. At a mean follow-up of 31.5 months, 8 patients (66.7%) had died, 7 (58.3%) experienced any type of disease progression. Local recurrence occurred in 25%, and distant metastases in 58.3%. Kaplan-Meier analysis estimated median OS at 48.2 months (95% CI: 6.0-90.5; IQR: 40.5), TTP at 24.2 months (95% CI: 1.5-46.8) and TTLR at 52.7 months (95% CI: 36.0-69.4; standard error: 8.5); the median TTLR time was not reached. No grade ≥2 toxicities were observed; pneumonitis grade 1 occurred in 18.2%, with no esophagitis or hemoptysis.

Conclusions: SBRT appears to be a feasible and well-tolerated treatment option for selected patients with SCLC who are unfit for or refuse surgery. In this single-institution retrospective analysis, SBRT provided encouraging outcomes in terms of TTLR, TTP, and OS, with minimal toxicity. Despite the exploratory nature of this study, the results support the role of SBRT as a potentially effective alternative for patients with limited-stage SCLC ineligible for standard treatment. Larger prospective studies are warranted to validate these findings and define optimal patient selection criteria.

Introduction: We previously reported the short-term real-world effectiveness and safety of first-line atezolizumab combined with chemotherapy in patients with extensive-stage small cell lung cancer (ES-SCLC). This study provides an updated analysis on the long-term effectiveness, prognostic factors, and subsequent treatment patterns of first-line immuno-chemotherapy.

Methods: This prospective multicenter observational study enrolled patients with ES-SCLC diagnosed at seven university hospitals throughout Korea between June 2021 and August 2022. Primary outcomes were 1-year overall survival (OS) and progression-free survival (PFS), whereas secondary outcomes included OS, objective response rate, disease control rate, second progression-free survival, and safety, evaluated based on established clinical guidelines.

Results: A total of 100 ES-SCLC patients (median age, 69 years) were enrolled, with a median follow-up duration of 26.0 months. (Table) The median PFS and OS was 6.2 and 17.1 months, respectively, with a 1-year OS rate of 62.5%. (Figure) Favorable prognostic factors for OS included partial response (PR) and stable disease (SD) as the best responses (SD, hazard ratio [HR] 0.79, p=0.003; PR, HR 0.38, p=0.053) and a longer platinum-free interval (HR 0.84, p<0.001). Brain radiotherapy significantly improved OS in patients with brain metastases (p=0.001), whereas thoracic radiotherapy during first-line treatment tended to prolong survival in patients who responded to systemic treatment (p=0.050). Patients receiving second-line treatment after progression had significantly longer OS than did those receiving only best supportive care (p=0.017)

Conclusions: This study outlined the long-term real-world effectiveness and safety of first-line atezolizumab immuno-chemotherapy for ES-SCLC, with our findings showing that implementation of local treatments and subsequent therapies after progression improved survival.

Variable	Total patients (n = 100)	IMpower-133 (n = 201)

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.22 Survival and Treatment Patterns in Limited Disease-SCLC: Real World Data From the Swedish National Lung Cancer Registry

J. Isaksson[1,2], L. Willén[2], A. Berglund[3], H. Vikman[3], S. Conte[4], A. Juhlin[4], K. Lamberg-Lundström[5], J. Botling[6], G. Wagenius[7]
[1]Region Gävleborg, Gävle/SE ,[2]Centre for Research and Development, Region Gävleborg/Uppsala University, Gävle/SE ,[3]Epistat AB, Uppsala/SE ,[4]AstraZeneca, Stockholm/SE ,[5]Uppsala Akademic Hospital, Uppsala/SE ,[6]Institute of Biomedicine, Sahlgrenska Academy, Gothenburg University, Gothenburg/SE ,[7]Department of Oncology-Pathology, Karolinska Institute, Stockholm/SE

Introduction: Small cell lung cancer (SCLC) is an aggressive malignancy with overall poor prognosis. Treatment options in limited and extensive disease have remained largely unchanged for decades until the addition of immunotherapy to standard chemotherapy in first line (1L) extensive disease SCLC. Recently, results from the ADRIATIC trial (NCT03703297) showed significant survival improvements when adjuvant immunotherapy (IO) was added following chemoradiotherapy (CRT) with curative intent in patients primarily diagnosed with limited disease. The aim of this study was to provide real world survival data in the limited disease (LD) setting as well as to describe treatment strategies and outcomes in patients experiencing relapse prior to the approval of IO.

Methods: Data of patients diagnosed with SCLC between 2014-2023 was extracted from the Swedish National Lung Cancer Registry. LD was defined as TNM stage I-III. CRT was defined as a minimum of 45 Gy thoracic radiotherapy administered in conjunction with chemotherapy (CT). If radiotherapy started within 42 days of the start of chemotherapy, it was classified as concomitant CRT (cCRT); if it commenced after 42 days, it was considered sequential CRT (sCRT).

Results: The LD SCLC cohort included 1046 patients, primarily with stage III (n=836, 80%). Median age at diagnosis was 71 years, 60.9% were female and 98.2% had current or previous smoking history. ECOG PS distribution was PS 0 22.3%, PS 1 43.5%, PS 2 22.2%, PS 3 8.9% and PS 4 1.8%. CRT (n=380) and systemic therapies (n=365), [including CT (n=344) and CT+IO (n=21)] were the most common treatments in 1L. cCRT (n=310) was used more frequently than sCRT (n=70). In the CRT group, the median overall survival (mOS) was 27.9 months with 2-year survival 55.2% and 5-year survival 29.1%. In patients receiving systemic therapies, mOS was 10.5 months with 2- and 5-year survival at 20% and 8.3%, respectively. In the CRT group, the median progression-free survival (mPFS) was 16.5 months versus 7.4 months for the systemic therapies group, with CRT patients being younger (70 vs 73 years), having better PS (80% vs 51.5% for PS 0-1) and a lower proportion of stage IIIB-C patients (52.1% vs 61.6%). In patients receiving prophylactic cranial irradiation (PCI) after CRT (n=158), mPFS was 16.5 months and mOS 33.3 months compared to mPFS 7.1 months and mOS 18.9 months for those without PCI. The PCI group had better PS (85.4% vs 76.6% for PS 0-1) and a higher proportion of stage III patients (86.7% vs 77%). Relapse was reported in 238 CRT patients receiving CT as a subsequent treatment (n=203, 85%) resulting in a mPFS of 6.5 months in second line.

Conclusions: Patients who received CRT had more favorable outcomes and better prognostic baseline characteristics than those who received systemic therapy (i.e., CT or CT+IO). Overall results in this nationwide real-world, unselected cohort were similar to recent phase 3 trial of CRT data in terms of mOS and mPFS for the CRT group. The addition of PCI to CRT improved survival results reinforcing the role for this treatment modality in this setting.

EP.13.23 Tislelizumab Plus Sitravatinib or Anlotinib as Maintenance Therapy in Extensive-Stage Small-Cell Lung Cancer (ES-SCLC)

Y. Fan, K. Chen, S. Yu, H. Lu, H. Li, Y. Xu, L. Gong, F. Xie, J. Qin, X. Yu, J. Zhao, G. Lou, W. Wang, C. Gu, N. Han, X. Xu, L. Shao, Z. Huang
Zhejiang Cancer Hospital, Hangzhou/CN

Introduction: First-line induction chemo-immunotherapy, followed by maintenance immune-monotherapy, significantly improved survival for ES-SCLC. However, rapid disease progression frequently occurs (mPFS: 4.5-5.8 months from induction therapy). We assessed an enhanced treatment strategy by adding an anti-angiogenic agent to immune-monotherapy during maintenance to delay recurrence. This report presents the efficacy and safety of two phase II trials evaluating maintenance tislelizumab (TIS, a PD-1 inhibitor) plus sitravatinib (Sitra, Trial 1) or anlotinib (Anlo, Trial 2) in ES-SCLC patients following induction TIS + chemo.

Methods: Untreated ES-SCLC patients received TIS + platinum-based chemo Q3W for 4 cycles (induction), followed by maintenance TIS (200 mg) and Sitra (70 mg QD; Trial 1) or Anlo (12 mg QD on D1-14; Trial 2) in a 21-day cycle for up to 2 years (including both the induction and maintenance phases). The primary endpoint was 1-year PFS rate in maintenance analysis set (MAS). MAS included patients receiving ≥1 dose maintenance therapy. Efficacy and safety in MAS were calculated from the start of maintenance therapy.

Results: 21 patients were enrolled separately in trial 1 and trial 2, with most patients had an ECOG PS of 1 (95.2% in each trial), and had more than 3 metastatic sites (90.5% in Trial 1 and 85.7% in Trial 2). 18 patients entered maintenance phase in each trial. From the start of maintenance therapy, median follow-up was 17.0 mo and 9.5 mo, respectively. Median PFS was 6.4 mo and 7.8 mo; median OS was 18.3 mo and not reached, with corresponding 1-year OS rates of 61.1% and 87.8%. In MAS, 4 patients in Trial 1 and 3 in Trial 2 achieved further partial responses, resulting in a confirmed ORR of 22.2% and 16.7%, respectively (Table). In MAS, the most common grade ≥3 TRAEs included hypertension (22.2%) in Trial 1 and fatigue (5.6%) in Trial 2. No patients died from TRAEs.

Conclusions: TIS plus Sitra or Anlo yielded promising efficacy with manageable toxicities as maintenance therapy in ES-SCLC patients after induction TIS + chemo. This enhanced maintenance strategy warrants further exploration in larger-scale trials.

Table

	Trial 1		Trial 2	
	MAS, N=18	IAS*, N=21	MAS, N=18	IAS*, N=21

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.24 ES-SCLC Outcomes Following SBRT And/Or Thoracic Consolidation After Induction Systemic Therapy

H. Gandler, P. Adavelly, P. Desai
Temple University Hospital, Philadelphia/PA/U

Introduction: Small cell lung cancer (SCLC) is an aggressive malignancy strongly linked to tobacco use and comprises 10-15% of all lung cancers. At diagnosis, approximately 70% of patients present with extensive-stage disease (ES-SCLC). While platinum-doublet chemotherapy (CTX) has long been the standard of care, the addition of immunotherapy (IO) has modestly improved outcomes. The role of radiation therapy (RT), including stereotactic body radiation therapy (SBRT) to oligometastatic sites or thoracic consolidation (TC), particularly following chemo-immunotherapy, remains poorly defined. We conducted a retrospective analysis to evaluate outcomes in ES-SCLC patients who received RT after induction systemic therapy.

Methods: We reviewed single-institution registry data from January 2013 to December 2023, identifying 29 ES-SCLC patients who received RT following CTX or CTX/IO induction. Patient demographics, clinical characteristics, treatment details, and outcomes were extracted through detailed chart review. RT included SBRT to extracranial metastases (SBRT-ECM), SBRT to cranial metastases (SBRT-CM), and TC.

Results: Of 29 patients receiving RT, 18 underwent CTX alone and 11 received CTX/IO. SBRT-ECM doses ranged from 800-3000 cGy (median 2000), SBRT-CM from 1800-3300 cGy (median 2000), and TC from 2000-12000 cGy (median 4500). Compared to 114 ES-SCLC patients treated with CTX or CTX/IO without RT (median OS 8.9 months), SBRT-ECM (n=12) conferred no OS benefit (median OS 6.5 months, p=0.5222) (Fig. 1). However, SBRT-CM (n=6) and TC (n=18) were associated with improved OS (median OS 24.4 months, p=0.0594 and 18.9 months, p=0.0189, respectively) (Fig. 1). Among patients treated with CTX/IO alone (n=70; median OS 9.5 months), neither SBRT-ECM (n=6) nor SBRT-CM (n=2) significantly improved OS (median OS 8.3 months, p=0.7102 and 18.2 months, p=0.7145). TC following CTX/IO (n=6) showed a trend toward improved OS (median OS 20.7 months, p=0.1388), though limited by sample size.

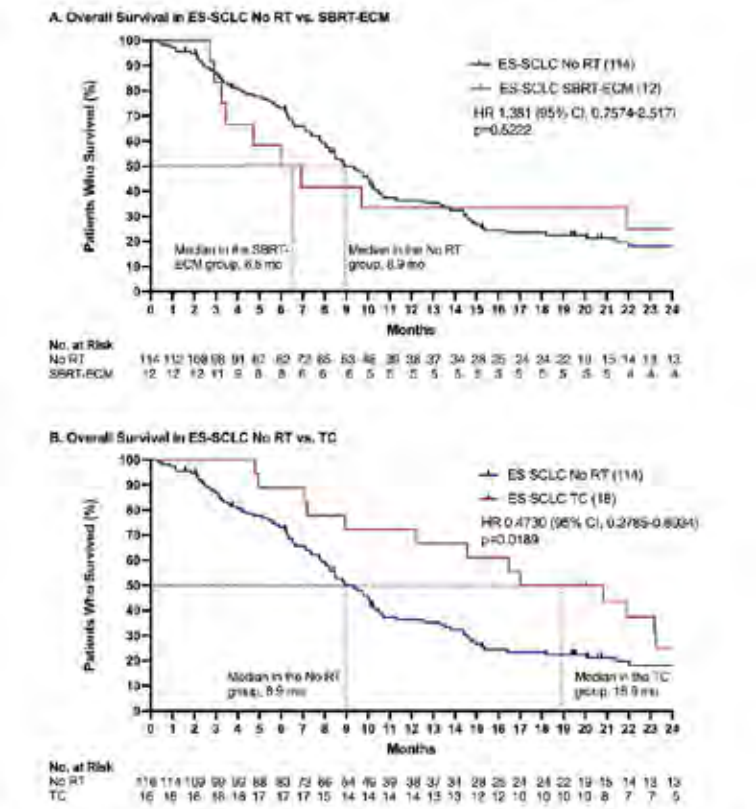

Figure 1. Overall survival of extensive stage small cell lung cancer (ES-SCLC) treated with no radiation therapy (RT) versus (A) stereotactic body radiation therapy to extracranial metastases (SBRT-ECM) (p=0.5222) or (B) thoracic consolidation (TC) (p=0.0189).

Conclusions: Our retrospective study suggests that thoracic consolidation and SBRT to cranial metastases may be associated with improved overall survival in patients with ES-SCLC following induction therapy with this trend maintained after addition of IO. In contrast, SBRT to extracranial metastases did not yield a survival benefit. While limited by small sample size and potential selection bias, these findings support further prospective investigation into the role of RT, particularly TC, in the management of ES-SCLC in the era of chemo-immunotherapy.

EP.13.25 Real-World Treatment Patterns in ES-SCLC Highlight Continued Unmet Medical Need in the Era of New Therapies: ESSENCE Study

B. Halmos[1], S. Anand[2], P. Juneau[3], W. Gouldin[4], H-H. Chen[5], P-C.(. Huang[5], S. Reiss[6], A. Ameri[7], S. Payne[8], T.A.C. Boyle[3], H. Ross[9]
[1]Montefiore Einstein Cancer Center, Bronx/NY/USA ,[2]GSK, Neuhofstrasse/CH ,[3]GSK, Collegeville/PA/USA ,[4]GSK, Philadelphia/PA/USA ,[5]Flatiron Health, Durham/NC/USA ,[6]Flatiron Health, New York/NY/USA ,[7]GSK, Waltham/MA/USA ,[8]GSK, London/GB ,[9]Rush University, Chicago/IL/USA

Introduction: Most patients with small cell lung cancer (SCLC) have extensive-stage (ES) disease at diagnosis and, despite advances in therapy, usually relapse within 6 months of initial treatment. Real-world (RW) evidence detailing contemporary treatment of relapsed SCLC is limited. This longitudinal, retrospective study assessed treatment utilisation and sequencing in a RW cohort of patients with ES-SCLC.

Methods: Dataextracted from the US-based, de-identified, longitudinal Flatiron HealthResearch Database included all adults diagnosed with ES-SCLC from 1 January2019 to 3 months prior to data cutoff (31 December 2024). Treatments forES-SCLC were described by line of therapy. Treatment utilisation in second-line(2L) and third-line (3L) was described in a subpopulation of patients with denovo ES-SCLC, stratified by platinum sensitivity status.

Results: Overall,13,105 patients with ES-SCLC were included; median age was 68 years (interquartilerange [IQR] 62, 75); 48.1% were male; 98.1% had a history of smoking; 81.0% werediagnosed with de novo ES-SCLC; 28.6% had brain metastases at diagnosis. Medianfollow-up was 6.5 months (IQR 2.5, 11.9). There were 10,548 patients with a known disease stage at initial SCLCdiagnosis who received at least first-line (1L) therapy for ES-SCLC. Nearly half (48.8%) of patients in theoverall cohort received only 1L therapy, and 20.2% only 1L and 2L therapyfollowing ES-SCLC diagnosis. Most patients received 1L platinum-basedchemo-immunotherapy with a variety of regimens in subsequent lines (Table 1). 2Land 3L treatment in the de novo cohort varied by platinum sensitivity (Table2).

Conclusions: ThisRW study underscores the heterogeneity of treatment of ES-SCLC in the 2L+ setting,highlighting a high unmet need for effective treatments. Novel therapies,including B7-H3-targeted antibody-drug conjugates and DLL3 bispecifics, maychange treatment options. RW clinical outcome results are forthcoming.

Table 1. Treatment utilisation by line of therapy among patients with ES-SCLC in the US

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.26 Gut Microbiota and Metabolites as Potential Biomarkers for Immunotherapy Efficacy in Patients With Extensive-Stage Small Cell Lung Cancer

M. Lin, C-g. Liu, D. Zang, J. Chen
The Second Hospital of Dalian Medical University, Dalian/CN

Introduction: Extensive-stage small cell lung cancer (ES-SCLC), an aggressive form of lung cancer with poor prognosis, continues to yield less clinical benefit compared to non-small cell lung cancer (NSCLC). While immune checkpoint inhibitors (ICIs) have shown some efficacy in treating ES-SCLC, their response rates and duration of remission remain suboptimal. It is necessary to identify effective biomarkers for predicting the response to immunotherapy in patients with ES-SCLC.

Methods: Patients diagnosed with primary ES-SCLC who were treated with at least one of the ICIs were enrolled from Dalian Medical University Affiliated Second Hospital between May 1, 2021, and September 30, 2023. Baseline fecal samples were collected from the patients before receiving the first treatment, and were tested through metagenomics and untargeted metabolomics. Treatment efficacy was evaluated using the Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1.

Results: A total of 41 patients with ES-SCLC were included in the study. The median progression-free survival (PFS) time was 3.57 ± 5.73 months (ranging from 0.23 to 26.13 months). Patients were categorized into non-responsive (N group) and responsive (R group) based on the median PFS time. No significant differences were observed between the two groups in terms of demographic characteristics, including age, gender, smoking, and alcohol history. The baseline gut microbiota composition and species diversity were similar between the two groups. However, the most enriched microbiota in the R group were Phascolarctobacterium, Acidaminococcales, and Clostridium, while the N group was enriched with Subdoligranulum, Lactobacillales, and Bacilli. Significant differences were observed in the baseline gut microbiota metabolites and their enriched metabolic pathways between the two groups. A total of 34 metabolites were significantly different, with 13 upregulated and 21 downregulated in the R group. L-Norvaline and 20-Hydroxyecdysone were enriched in the R group, while Chenodeoxycholic acid sulfate and N-Acetylneuraminate were enriched in the N group, potentially serving as predictive biomarkers for immunotherapy efficacy in ES-SCLC. Upregulated metabolites in the R group were enriched in sphingolipid metabolism, while downregulated metabolites were enriched in amino sugar and nucleotide sugar metabolism pathways and diterpenoid biosynthesis pathways (Figure 1).

Conclusions: Baseline gut microbiota composition, metabolites, and metabolic pathways differ significantly between ES-SCLC patients responsive and non-responsive to immunotherapy. These findings suggest that gut microbiota and its metabolites may serve as potential biomarkers for predicting the efficacy of immunotherapy in patients with ES-SCLC.

EP.13.27 Co-Targeting SFKs and DNA Damaging Chemotherapy Drugs as a Novel Therapeutic Strategy in SCLC

N. Otegui[1,2,3], M. Redrado[1,2,4], S. León[1,2,3], E. Guruceaga[1], M.J. Guillén-Navarro[5], P. Avilés[5], L. Montuenga[1,2,3,4], A. Calvo[1,2,3,4]
[1]Center for Applied Medical Research (CIMA), Pamplona/ES ,[2]School of Medicine, University of Navarra, Pamplona/ES ,[3]CIBERONC, ISCIII, Madrid/ES ,[4]IDISNA, Pamplona/ES ,[5]Pharmamar SA, Madrid/ES

Introduction: Small cell lung cancer (SCLC) is an aggressive and often fatal tumor for which effective therapeutic options remain limited. For decades, the standard first-line treatment has been etoposide-based chemotherapy combined with a platinum derivative (E/P), but this regimen has not led to significant improvements in survival outcomes. Despite initial responses to treatment, nearly all patients experience disease progression and require second-line therapies. However, second-line treatments are typically palliative, with patients surviving less than a year. Available second-line options include topotecan, lurbinectedin, and maintenance chemoimmunotherapy. We have previously demonstrated the role of Src family kinases (SFKs) in SCLC. These kinases can be targeted with Dasatinib, an FDA approved drug for hematological malignancies. Our goal was to identify new drug vulnerability by co-targeting SFKs with drugs that cause DNA damage.

Methods: Human SCLC H209 and DMS53 and murine SCLC RP cell lines were used for the study of these novel vulnerabilities in SCLC. We selected drugs either currently used in SCLC patients (in first- or second-line treatments) or that might target the DNA damage repair (DDR) in combination with Dasatinib: lurbinectedin, topotecan, etoposide, cisplatin and VE-821. Single drug toxicity and combinatory drugs were assessed by MTS or Cell Titer Glo 2.0. Synergy combination was calculated with CompuSyn software. DNA damage markers were studied by Western Blotting and immunofluorescence staining. Effect of combinatory drugs was studied by apoptosis assay. Two therapeutic combinatory strategies were tested in vivo in athymic nude mice. The effect of these therapies is being tested in immunocompetent mice.

Results: Chemotherapeutics drugs (cisplatin, etoposide and topotecan) inhibited cell proliferation with low IC50 doses of approximately less than 1 µM in a variety of human and murine SCLC cell lines, except for RP that exhibited an IC50 for cisplatin of 2 µM. Moreover, lurbinectedin had a higher cytotoxic effect, with IC50 dose less than 0,1 ng/mL in vitro. Additional combination of Dasatinib exerted a synergistic anti-proliferative and pro-apoptotic effect than that of chemotherapeutics alone. Increasing concentrations of chemotherapeutics alone showed higher amount of pH2Ax, which was increased when combining with different doses of Dasatinib in both H209 and DMS53 cell lines. Other DNA damage markers such as pCHK1 and cleaved PARP were also increased when combined with Dasatinib. These results were in concordance with the increasing intensity of pH2Ax found by immunofluorescence. The combinatorial strategies of Lurbinectedin or Topotecan with Dasatinib exerted a strong anti-tumor activity in DMS53- and H209-bearing nude mice treated with the corresponding combination. Besides, no signs of toxicity, weight loss or changes in hemogram were detected.

Conclusions: Combination of Dasatinib with the DNA damaging chemotherapeutic drugs Lurbinectedin and Topotecan showed synergistic pro-apoptotic and anti-proliferative effect in vitro. Tumor volumes were significantly reduced compared to single drugs when mice were treated in vivo. Thus, combining Dasatinib with Lurbinectedin or Topotecan represent two novel therapeutic strategies for SCLC treatment.

Introduction: Extensive-stage small cell lung cancer (ES-SCLC) presents significant treatment challenges with limited survival outcomes. Immunotherapy, including durvalumab, has become front-line standard-of-care in these patients. This study aimed to evaluate the demographic characteristics, efficacy, and safety profile of durvalumab-based regimens in a real-world Brazilian cohort of ES-SCLC patients.

Methods: EDUR-BRA (LACOG 0322) is a real-world, single-arm, multi-center observational analysis across seven private healthcare facilities in Brazil. Eligible participants were adult patients with histologically or cytologically confirmed ES-SCLC receiving durvalumab-based regimens in first-line. Data were collected retrospectively and prospectively from patients' medical records with a maximum follow-up of 24 months post-treatment initiation. The primary outcome was the assessment of demographic and clinical characteristics, while secondary outcomes included real-world progression-free survival (rwPFS) and overall survival (OS). Safety was assessed by the incidence of adverse events. NCT06008353

Results: A total of 59 patients were enrolled from January to November 2024, with a median age of 69 years; 66% of patients were 65 years or older. Patients were predominantly males (51%). At durvalumab initiation, 44 (75%) patients had a WHO status of 0-1 and 6 (10%) had WHO ≥2. Regarding smoking history, 7 (12%) patients were never smokers, 35 (59%) were former smokers, and 14 (24%) were current smokers. Baseline assessments revealed that a total of 8 (14%) patients had locally advanced disease not amenable to locoregional treatment and most patients (N=51, 86%) had metastatic disease: 10 (20%) patients had brain metastases and 11 (22%) had liver metastases. Most patients (N=56, 95%) received carboplatin-etoposide with a median number of 4 cycles. As per inclusion criteria, all patients were treated with durvalumab. The duration of durvalumab treatment was 23 (0-93) weeks and the median number of durvalumab cycles received was 8 (IQR 5-11). The main reason for treatment discontinuation was disease progression (N=20, 59%); only 2 patients discontinued durvalumab due to adverse event. At the median follow-up of 24.8 months (95% CI: 13.9 - 26.7), the median OS was 13.4 (9.9-15.4) months and the median rwPFS of 6.9 (95% CI: 5.1-7.9 months). Adverse events of any grade and grade ≥3 were observed in 33 (56%) and 16 (25%) patients, respectively. The most frequently observed adverse events included fatigue and nausea. Serious adverse events occurred in 14 (23%) patients.

Conclusions: The present study assessed the clinical characteristics, efficacy and safety of durvalumab-based regimens in a real-world ES-SCLC cohort in Brazil. Overall, the patients from this cohort were older, had a worst performance status and had more brain metastasis compared to the CASPIAN study. Nevertheless, efficacy and safety results were consistent with those observed in the phase III clinical trial.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.29 Safety and Efficacy of DLL3 CAR-T Cells Armored With dnTGFBR2 in a Patient With Recurrent Small-Cell Lung Cancer

Z. Hao[1], A. Qasrawi[1], H. Heath[1], S. Arnold[1], J. Villano[1], C. Brainson[1], L. Anthony[1], S. Parasramka[1], M. Koneru[2], S. Vahora[2], C. Davis[2], D. Geng[2], C. Wang[2], L. Xin[2], P. Schwarzenberger[2], R. Munker[1]
[1]Markey Comprehensive Cancer Center, Lexington/KY/USA ,[2]Legend Biotech Inc, Somerset/NJ/USA

Introduction: LB2102 comprises autologous DLL3-targeted CAR-T cells armored with dominant-negative TGBFR2 to overcome tumor-mediated immunosuppression. One-time infusion is being tested in a phase 1 trial of patients with recurrent high-grade neuroendocrine carcinoma or SCLC. We report the case of a patient with recurrent SCLC who received 1 infusion of LB2102 under a single-patient investigational new drug (IND) application after becoming ineligible from the trial.

Methods: The patient (51 years old, female) had SCLC progression, symptomatic brain metastases, and a lung lesion approximately 8 months after starting platinum-based combination chemotherapy and 3 months after starting atezolizumab maintenance therapy. After whole-brain radiation (WBRT) in February 2024, she was enrolled the study (phase 1, 3+3 design) and planned to receive 2.0×106 CAR+ T cells/kg (LB2102 dose level 3). She received 2 cycles of irinotecan, given weekly as bridging therapy. The patient had recurrent altered mental status (AMS) (delirium). After 1 day of lymphodepletion (fludarabine 30 mg/m2 and cyclophosphamide 300 mg/m2), she was excluded from the trial due to safety concerns from AMS (prior to LB2102 infusion). AMS was ultimately found to result from overuse of opioids for pain control. The investigator obtained single-patient IND permission for administration of LB2102 at 2.3x106/kg after another 3 days of lymphodepletion.

Results: At baseline, the patient had 98% DLL3 expression in tumor specimens, based on immunohistochemical analysis, with 88% ≥2+ in staining density. She tolerated the infusion well, without dose-limiting toxicity, cytokine-release syndrome, or neurotoxicity. Four weeks after LB2102 infusion, Grade 2 (G2) anemia and G4 neutropenia improved to G1 and G2, respectively; her G1 thrombocytopenia resolved by Day 11. After 21 days, contrast computed tomography of the chest showed marked central necrosis within the 7.6 cm target lesion. By 12 weeks, the lesion had decreased by 45%, meeting partial response (PR) criteria for RECIST1.1 and with no new metastases. At 6 months, the central lesion was reduced 76% from baseline (to 1.8 cm); pharmacokinetic data indicated persistence of CAR-T cells (at 2710/mL) and 0.86% CD3+ CAR+ cells (of total CD3+ T cells). Peripheral blood samples contained 0 circulating tumor cells (CTC) (from 27/mL at baseline), 0 DLL3+ CTC (from 6/mL at baseline), and 160 CD4+ T cells/mL. Markers that peaked at Day 11 after CAR-T-cell infusion (C-reactive protein [160 mg/L], ferritin [829 ng/mL], and lactate dehydrogenase [307 U/L], had returned to normal by 6 months; levels of GGT were reduced from peak of 141 to 40 U/L. One year after the first WBRT, MRI showed stabilization of the brain metastases with no new lesions. The patient is pain- and treatment-free with ECOG-1, without additional anti-cancer therapy.

Conclusions: In a case study of a patient with relapsed and refractory SCLC, a single infusion of LB2102 led to a sustained PR (> 6 months) and improvement of disease-related symptoms. No serious LB2102-related adverse events were observed other than those expected with lymphodepletion. The CAR-T cells expanded and persisted for more than 6 months. These findings warrant further research of DLL3-targeted autologous cell therapies for cancer.

EP.13.30 Real-World Analysis of Treatment Patterns in Limited-Stage Small Cell Lung Cancer: Implications for Clinical Practice

S. Yu, X. Feng, S. Li, X. Liu, X. Gao, M. Chen, J. Zhao, W. Zhong, M. Wang, Y. Xu
Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Unresolved issues complicate treating limited-stage small-cell lung cancer (LS-SCLC). We conducted a real-world study analyzing LS-SCLC treatment patterns to address clinical needs.

Methods: We retrospectively enrolled patients with LS-SCLC treated at Peking Union Medical College Hospital between May 2008 and December 2023. Information was collected on clinicopathological features, cancer-related treatments, laboratory test results, and clinical and prognostic data. Kaplan-Meier survival analysis was performed to evaluate progression-free (PFS) and overall survival (OS). Cox regression models were used to assess the factors influencing survival.

Results: Among the 203 patients with LS-SCLC, the median OS (mOS) was 28.8 months. A log-rank test indicated significant differences in mOS across radiotherapy-timing groups (P = 0.031): 30.1 months for concurrent chemoradiotherapy (cCRT), 27.5 months for sequential therapy, and 21.7 months for no radiotherapy. Notably, early cCRT was associated with a longer mOS trend (38.3 months) compared to late cCRT (29.5 months), though the difference was not statistically significant (P = 0.058). mOS was comparable in the prophylactic cranial irradiation (PCI) group or in the non-PCI group (PCI 36.9 vs. non-PCI 29.6 months; P=0.27). Peripheral blood biomarkers were unreliable as prognostic indicators. In multivariate analysis, poor survival was predicted by Eastern Cooperative Oncology Group performance status >1 (hazard ratio [HR] 3.652, 95% confidence interval [CI] 1.579-8.448; P=0.002), and N2 (HR 2.872; 95%CI 1.312-6.286; P=0.008) and N3 (HR 2.645; 95%CI 1.195-5.856; P=0.016) lymph node metastasis. Compared with the early cCRT group, the sequential radiotherapy group had an increased risk of death (HR 1.701, 95% CI 1.125-2.573; P=0.012).

Conclusions: Performance status and lymph node metastasis are prognostic factors for patients with LS-SCLC. cCRT improve the prognosis of LS-SCLC, with early cCRT providing a significant survival benefit and late cCRT being an acceptable option.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.32 Multi-Institutional Real-World Experience of Early Tarlatamab-Related Toxicities for Extensive Stage Small Cell Lung Cancer

N.M. Zuniga[1], H. Qadri[2], D. Rosas[2], D. Morgenstern-Kaplan[1], D.K. Jayram[1], L. Negret[1], R. Dawar[1], D.C. Watson[1], C. Olazagasti[1], L. Raez[2], G. Lopes[1], A. Chauhan[1], E. Rodriguez[1]
[1]Sylvester Comprehensive Cancer Center, Miami/FL/USA ,[2]Memorial Health System, Miami/FL/USA

Introduction: Tarlatamab, a novel bispecific T-cell engager (BiTE) targeting delta-like ligand 3 (DLL3) and CD3, has shown promising efficacy in treating small cell lung cancer (SCLC) and other neuroendocrine malignancies beyond 1st line treatment. However, real-world data on its safety profile remains limited. Clinical trials have reported notable toxicities, including cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), and hospitalization rates, however, the applicability of these observations to broader, uncontrolled clinical contexts remains uncertain. This study presents a multi-institutional real-world experience analyzing toxicity patterns in 25 patients treated with tarlatamab, with a focus on CRS, ICANS, and readmission rates.

Methods: A retrospective cohort study was conducted across two academic cancer centers, evaluating 25 patients who received tarlatamab for relapsed/refractory SCLC between October 2024 through March 2025. Data were extracted from electronic medical records, including patient demographics, prior therapies, treatment duration, and adverse events. Toxicity profiles were assessed and graded in accordance with the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. The severity CRS was further classified using the American Society for Transplantation and Cellular Therapy (ASTCT) consensus grading criteria. Primary endpoints included the incidence and severity of CRS, the incidence of immune effector cell-associated neurotoxicity syndrome (ICANS), early mortality rates, and hospitalization events directly attributable to treatment-related toxicities.

Results: Among the 25 patients, the median age was 68.2 years (range: 50-84), with 48% (12/25) male and 52% (13/25) female. There were 44% (11/25) patients identifying as Hispanic/Latinx. The majority (72%, 18/25) received tarlatamab as a second line therapy. 7/25 had received at least 2 lines of therapy. CRS occurred in 48% (12/25) of patients, with 100% (n=12) experiencing Grade 1-2. There were no Grade ≥3 CRS reported. CRS onset typically occurred within 12 hours post-infusion and was resolved with antipyretics for fever and intravenous fluids for hydration. Corticosteroids were required in 75% of cases (9/12). No tocilizumab was required. ICANS occurred in 16% (4/25) of patients, 1 case required ICU admission (grade 3 event). Regarding readmissions, 20% (5/25) of patients required readmissions due to treatment-related toxicities, with a median length of stay of 2.2 days. The most common reason for hospitalization was CRS (60%, 3/5). Treatment discontinuation was required in 32% (8/25) of patients due to toxicity (8%, 2/25), progression (12%, 3/25), and death (12%, 3/25). Among the deaths, 3 patients expired due to disease progression within 2 cycles of treatment.

Conclusions: This multi-institutional analysis highlights the toxicity profile associated with real-world use of tarlatamab, particularly CRS and ICANS. In general, CRS and ICANS were low grade and mostly manageable with standard interventions. Readmissions due to treatment related toxicities were uncommon. However, there were 3 early deaths due to disease progression within 2 cycles of treatment. These findings underscore the need for patient selection, vigilant monitoring, early intervention, and potential optimization of preemptive management strategies. This is the largest case series of Hispanic patients treated with tarlatamab. Future studies should refine toxicity mitigation protocols to enhance the safety and tolerability of tarlatamab in broader patient populations.

Introduction: Rapid diagnosis and treatment initiation are widely viewed as key principles in the management of extensive-stage small cell lung cancer (ES-SCLC). The Australian Optimal Care Pathway (OCP) for lung cancer recommends confirmation of diagnosis within 2 weeks of initial specialist review and initiation of treatment within 6 weeks of specialist referral. The impact of adhering to these timeliness recommendations in the real-world setting is unknown.

Methods: The Victorian Lung Cancer Registry, a multicentre lung cancer clinical quality registry, was analysed to identify patients with newly-diagnosed ES-SCLC. The referral-to-diagnosis interval (RDI), referral-to-treatment interval (RTI) and diagnosis-to-treatment interval (DTI) were calculated and, in line with OCP guidelines, defined as timely if they were less than 28 days, 42 days and 14 days, respectively. The impact of timeliness on overall survival was determined using univariate and multivariable Cox proportional hazards regression and propensity score matching.

Results: From January 2012 to April 2023, there were 995 evaluable patients with ES-SCLC who were treated with chemotherapy, with a median age was 68 years (interquartile range (IQR) 61-74 years). 59.8% were male. The median RDI, RTI and DTI were 8 days (IQR 4-17 days), 18 days (IQR 10-31 days) and 7 days (IQR 4-13 days), respectively. Overall survival was worse when the DTI was <14 days compared to ≥14 days, with hazard ratios (HR) of 1.31 (95% confidence interval (CI) 1.12-1.54, p=0.001) in the univariate analysis, a 1.32 (95% CI 1.13-1.56, p=0.001) in the multivariable analysis and 1.30 (95% CI 1.07-1.58, p=0.008) in the propensity score-adjusted analysis. Shorter RDI and RTI were also associated with poorer survival. Using multivariable regression, the HR for RDI <28 days relative to RDI ≥28 days was 1.37 (95% CI 1.10-1.71, p=0.005), while the HR for RTI <42 days relative to RTI ≥42 days was 1.58 (95% CI 1.28-1.95, p<0.0001).

Conclusions: The majority of patients received care that met defined timeliness targets, but earlier diagnosis and treatment were associated with poorer survival. This may be explained by unmeasured confounders. Delivery of timely care may also have benefits on symptom burden and quality of life, but these factors were not prospectively captured in our registry data.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.34 Meta-Analysis of First-Line Immunochemotherapy in ES-SCLC: Does ECOG PS =2 Affect Survival Outcomes

X. Yu, X. Shi, Q. He, J. Wu, B. Long
Zhejiang Cancer Hospital, Hangzhou/CN

Introduction: Multiple randomized controlled trials (RCTs) have demonstrated that adding immunotherapy significantly improves the prognosis of patients with extensive-stage small cell lung cancer (ES-SCLC), establishing it as a global standard of care. However, stringent eligibility criteria in RCTs limit the generalizability of these findings to real-world clinical settings. Most trials predominantly included patients with an Eastern Cooperative Oncology Group Performance Status (ECOG PS) of 0 or 1, leaving the efficacy of immunochemotherapy in ECOG PS ≥2 patients uncertain. This meta-analysis evaluates the survival benefits of first-line immunochemotherapy in ES-SCLC patients with ECOG PS ≥2.

Methods: A systematic review was conducted across PubMed, Embase, Cochrane Library, Web of Science, and Scopus using keywords related to "ES-SCLC," "first-line," "immunochemotherapy," and "clinical trials." Inclusion criteria were: (1) adult patients (≥18 years) diagnosed with ES-SCLC; (2) explicit reporting of ECOG PS, including a subgroup of ECOG PS ≥2; (3) treatment with immunochemotherapy; (4) reported progression-free survival (PFS) and/or overall survival (OS); and (5) stratified data comparing ECOG PS ≥2 vs. PS <2 or data allowing derivation of hazard ratios (HRs) with 95% confidence intervals (CIs). Exclusion criteria were: (1) non-first-line studies; (2) lack of ECOG PS data or HRs; (3) studies focusing on pediatric, adolescent, or atypical SCLC populations; (4) chemotherapy-only or immune checkpoint inhibitors (ICIs) monotherapy studies; and (5) incomplete or unavailable studies. The pooled HRs for OS and PFS were calculated based on treatment type (chemotherapy vs. immunochemotherapy) and ECOG PS subgroups (PS <2 vs. PS ≥2).

Results: Of 1,529 screened studies, 17 met inclusion criteria, comprising 3,022 ES-SCLC patients. The pooled analysis estimated that 20.02% (95% CI 14.39-26.29) of newly diagnosed ES-SCLC patients had ECOG PS ≥2. Meta-analysis results demonstrated that ECOG PS did not significantly impact survival outcomes following first-line treatment. Compared to patients with ECOG PS <2, those with ECOG PS ≥2 exhibited no significant difference in OS (HR = 1.14, 95% CI: 0.80-1.63) or PFS (HR = 1.19, 95% CI: 0.88-1.62). Subgroup analysis further revealed that among patients receiving first-line immunochemotherapy, OS (HR = 1.25, 95% CI: 0.77-2.03) and PFS (HR = 1.10, 95% CI: 0.78-1.54) did not differ significantly between ECOG PS ≥2 and PS <2 subgroups. Notably, in the ECOG PS ≥2 subgroup, immunochemotherapy conferred a significant survival advantage compared to chemotherapy alone, with an OS HR of 0.64 (95% CI: 0.47-0.87) and a PFS HR of 0.44 (95% CI: 0.28-0.68), indicating both short- and long-term survival benefits.

Conclusions: Our findings suggest that baseline ECOG PS at diagnosis does not significantly impact long-term prognosis in ES-SCLC patients, and those with ECOG PS ≥2 can also derive substantial survival benefits from first-line immunochemotherapy. However, most of the included studies were retrospective real-world studies, necessitating cautious interpretation of the results. Further large-scale prospective trials incorporating patients with poor ECOG PS are warranted to comprehensively assess the efficacy and safety of first-line immunochemotherapy in this population.

Introduction: Immunotherapy combined with chemotherapy followed by immunotherapy maintenance has demonstrated clinical activity in extensive-stage small cell lung cancer (ES-SCLC). The addition of anti-vascular therapy to immunochemotherapy may further improve survival but could also increase the incidence of adverse events. It remains unclear whether incorporating anti-vascular therapy during the maintenance phase rather than the induction phase could provide additional benefits for treatment-naive ES-SCLC patients.

Methods: This multicenter, prospective, single-arm, open-label, real-world trial evaluated the efficacy and safety of atezolizumab plus chemotherapy (induction phase) followed by atezolizumab plus anlotinib (maintenance phase) as first-line therapy in patients with ES-SCLC. Patients received four to six cycles of atezolizumab plus etoposide and carboplatin (EC), followed by atezolizumab plus anlotinib for up to 2 years. The primary endpoint was progression-free survival (PFS). Safety was assessed in all patients who completed at least four cycles of treatment.

Results: Between July 1, 2020, and December 30, 2024, 69 patients were enrolled. At the data cutoff date (April 1, 2025), the last enrolled patient had been followed up for approximately four months. Among 69 evaluable patients, one (1.4%) achieved a complete response (CR), 49 (71.0%) achieved a partial response (PR), and 16 (23.2%) achieved stable disease (SD), resulting in an objective response rate (ORR) of 72.4% and a disease control rate (DCR) of 95.6%. The median PFS was 9 months (95% CI, 7-12 months). Grade 3 or higher treatment-related adverse events occurred in 17.4% of patients, including neutropenia, anemia, nausea, pneumonia, myocarditis, and liver/kidney damage. Treatment-related deaths occurred in four patients (5.8%), due to pneumonia (n=2), kidney damage (n=1), and myocarditis (n=1).

Conclusions: Atezolizumab plus chemotherapy followed by atezolizumab plus anlotinib as first-line therapy provided a clinically meaningful PFS benefit in patients with ES-SCLC. With the prophylactic use of recombinant human granulocyte colony-stimulating factor (rhG-CSF) in real-world practice, the grade 3 or higher safety profile was favorable compared to previously reported regimens.

EP.13.36 Induction Immunochemotherapy Followed by Concurrent Chemoradiotherapy for Limited-Stage Small Cell Lung Cancer

L. Yang, D. Liu, S. Ren, J. Ni, Y. Xu
Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Immunotherapy, chemotherapy, and radiotherapy all play significant roles in the management of small cell lung cancer (SCLC). Combining radiotherapy with chemotherapy followed by immunotherapy shows promise for limited-stage SCLC (LS-SCLC), offering good tolerability and survival benefits. However, there is limited data on whether immunotherapy combined with chemotherapy for LS-SCLC can be performed before chemoradiotherapy. Therefore, we investigated the safety and effectiveness of induction immunochemotherapy followed by concurrent chemoradiotherapy (CCRT) in patients with LS-SCLC, aiming to contribute new insights to the treatment of SCLC.

Methods: A retrospective analysis was conducted on 138 patients with LS-SCLC who received chemoradiotherapy between January 2019 and January 2025. This study included 34 patients receiving induction immunochemotherapy and 104 patients receiving induction chemotherapy. All patients underwent 2-4 cycles of induction therapy before CCRT. Clinical outcomes, including survival and toxicity, were compared between the two groups. Imaging assessments were performed before and 1 month after radiotherapy. The evaluations included the tumor response to induction therapy, treatment-related adverse events, complications during and after CCRT, tumor response after CCRT, progression-free survival (PFS), and overall survival (OS). Follow-up data were collected through regular check-ups or inpatient records. If unavailable, patients were contacted by phone.

Results: Compared to the induction chemotherapy group, the objective response rate (ORR) of tumors after induction treatment in the induction immunochemotherapy group was 67.6% (23/34) versus 45.2% (47/104) (P = 0.023). After CCRT, the ORR in two groups was 79.4% (27/34) versus 60.6% (63/104) (P = 0.045). The median follow-up time was 27.9 months for the induction immunochemotherapy group and 30.3 months for the induction chemotherapy group. The median progression-free survival (PFS) for two groups was 21.3 months versus 13.1 months (P = 0.007), and the median overall survival (OS) was not reached versus 41.7 months (P = 0.031). Treatment-related toxicities of grade 1-2 were 64.7% versus 54.8% (P = 0.311), and grade 3-4 toxicities were 41.2% versus 41.3% (P = 0.986). No grade 5 treatment-related toxicities were observed in either group.

Conclusions: Induction immunochemotherapy followed by CCRT for patients with LS-SCLC is effective and safe with a high ORR, PFS and OS rate, as well as a tolerable toxicity profile. Larger, randomized controlled trials are required to confirm our findings.

Characteristics	Induction immunochemotherapy (n=34)	Induction chemotherapy (n=104)
Best response to induction therapy–n(%)		
CR/PR	23 (67.6)	47 (45.2)
SD	10 (29.4)	53 (51.0)
PD	1 (2.9)	4 (3.8)
Best response to CCRT–n(%)		
CR/PR	27 (79.4)	63 (60.6)
SD	6 (17.6)	34 (32.7)
PD	1 (2.9)	7 (6.7)
The median progression–free survival–months	21.3	13.1
The median overall survival–months	NR	41.7

EP.13.37 Immunotherapy Plus Chemoradiotherapy for Limited-Stage Small Cell Lung Cancer: A Systematic Review and Meta-Analysis of Randomized Trials

C.C. Lee[1], C.K. Lee[2], C. Hu[3], Y.Y. Soon[1,2], F. Hegi-Johnson[4], K. Higgins[5]
[1]National University Cancer Institute Singapore; National University Health System, Singapore/SG ,[2]National Health and Medical Research Council (NHMRC) Clinical Trials Centre, University of Sydney, Sydney/AU ,[3]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore/MD/USA ,[4]Peter MacCallum Cancer Centre, Melbourne/AU ,[5]City of Hope Cancer Center Atlanta, Newnan/GA/USA

Introduction: For patients with limited-stage small cell lung cancer (LS-SCLC) planned for definitive chemoradiotherapy (CRT), the optimal approach of integrating immune checkpoint inhibitors (ICIs) remains uncertain. This study aimed to clarify the overall effect of adding ICIs to CRT in patients with LS-SCLC and evaluate whether this effect varied according to prespecified treatment characteristics.

Methods: Various medical databases were searched to identify randomized controlled trials (RCTs) evaluating the addition of ICIs to CRT in patients with LS-SCLC. Primary outcome was overall survival (OS). The overall pooled effect was estimated using a two-stage, fixed-effect meta-analysis approach. Differences in overall effect based on treatment characteristics were analysed using either between-trial or within-trial interactions, depending on the availability of data. Prespecified treatment characteristics included (1) ICI timing (concurrent with CRT plus consolidation versus consolidation alone), (2) platinum agent (carboplatin versus cisplatin), (3) thoracic radiation schedule (twice daily versus once daily) and (4) use of prophylactic cranial irradiation (PCI). The risk of bias for individual studies was assessed using the Cochrane Risk of Bias 2 tool. This study is registered with PROSPERO (CRD420251020544).

Results: Four eligible RCTs (n = 1,291 participants) were identified. Three RCTs used consolidation ICI alone, while one RCT employed concurrent ICI with CRT followed by consolidation ICI. The overall risk of bias was assessed as low in two published RCTs, and unclear in two others as the evaluation was limited to the conference abstracts. Overall, the meta-analysis showed no significant OS benefit with the addition of ICIs to CRT (hazard ratio (HR) 0.89, 95% confidence interval (CI) 0.76-1.05, P = 0.16, I2 = 43%). However, prespecified subgroup analyses revealed significant effect modification. The relative effect of incorporating ICIs to CRT on OS was more favorable when used as consolidation alone (HR, 0.78, 95% CI 0.63-0.96) compared to concurrent plus consolidation therapy (HR 1.11, 95% CI 0.85-1.45; interaction P = 0.04). Furthermore, carboplatin-based regimen showed a greater OS benefit (HR, 0.68; 95% CI, 0.51-0.90) compared to cisplatin-based regimen (HR, 1.04; 95% CI, 0.82-1.30; interaction P = 0.02). Thoracic radiation dose schedule (twice daily: HR 0.80, 95% CI 0.59-1.07 versus one daily: HR 0.91, 95% CI 0.74-1.10; interaction P = 0.49) and PCI use (PCI: HR 0.90, 95% CI 0.69-1.17 versus no PCI: HR 0.86, 95% CI 0.68-1.09; interaction P = 0.82) did not significantly modify the overall effect.

Conclusions: For patients with LS-SCLC intended for definitive CRT, the optimal integration of ICIs might be most beneficial when two criteria are met: (1) ICIs are administered exclusively as consolidation therapy following completion of CRT, and (2) carboplatin serves as the platinum backbone in CRT. The effect of ICIs was not influenced by the thoracic radiation dose fractionation schedule or the use of PCI. These findings raise hypotheses for optimising treatment strategies in LS-SCLC.

EP.13.38 Real-World Comparison of Carboplatin-Etoposide vs Cisplatin-Etoposide in ES-SCLC

D. Chowdhury[1], L. Zhan[1], J. Gill[1], D. Patel[1], J. Reibel[1], K. Balaratnam[1], K. Khan[1], F. Al-Agha[1], S. Raptis[1], R. Rittberg[2], G. Kasymjanova[3], B. Lok[1], S. Snow[4], S. Kuruvilla[5], J. Agulnik[3], S. Moore[6], C. Ho[7], P. Wheatley-Price[6], G. Liu[1], D. Dawe[2]
[1]Princess Margaret Cancer Centre, Toronto/ON/CA ,[2]Cancer Care Manitoba, Winnipeg/MB/CA ,[3]Jewish General Hospital, Montreal/ON/CA ,[4]Queen Elizabeth II Health Sciences Centre, Halifax/NS/CA ,[5]London Health Sciences Centre, London/ON/CA ,[6]The Ottawa Hospital Cancer Centre, Ottawa/ON/CA ,[7]Vancouver Cancer Centre, Vancouver/BC/CA

Introduction: Combination chemoimmunotherapy with either a cisplatin-etoposide (CisE) or carboplatin-etoposide (CarboE) backbone is the established first-line (1L) treatment for extensive stage small cell lung cancer (ES-SCLC). A 2012 meta-analysis of four RCTs showed equivalence in terms of PFS, OS, and ORR with either doublet. A real-world analysis which included patients with both limited and ES-SCLC showed similar findings. A real-world comparison of CisE to CarboE in ES-SCLC has not been done and has treatment implications given the importance of chemotherapy in 1L treatment.

Methods: Patient data was obtained from the Canadian Small Cell Lung Cancer Database (CASCaDe), a Canadian database of patient-level clinicopathologic and treatment data from cancer centres throughout the country. Eligible patients were diagnosed between 2000 - 2022; had ES-SCLC at diagnosis; and received either CisE or CarboE as 1L treatment. Primary outcomes were overall survival (OS) and real-world progression-free survival (rwPFS). Secondary outcomes included: rates of treatment completion and discontinuation due to toxicity; receipt of consolidative radiation therapy (RT); and receipt of second-line (2L) therapy. Survival outcomes were evaluated via Kaplan-Meier (KM) curves, multivariable and inverse propensity score weighted Cox proportional hazards models. Weighting utilized the ATE scheme. Covariates included age, sex, and ECOG at diagnosis.

Results: Of 1339 eligible patients, 553 (41%) were treated with CisE and 786 (59%) with CarboE. Compared to those who received CarboE, patients treated with CisE: were younger (median 64.0 (58.0 to 69.0) years versus 69.0 (63.0 to 74.0) years, p<0.01); had better performance status (ECOG 0-1: 65% CisE versus 51% CarboE, p<0.01); and were less likely to have liver metastases at diagnosis (38% CisE versus 47% CarboE, p<0.01). Median OS was slightly longer with CisE compared to CarboE (8.9 (95% CI: 8.2 - 9.5) versus 7.8 months (95% CI: 7.4 - 8.3), p = 0.004). However, in the multivariate Cox proportional hazards model, type of first-line systemic therapy was not significantly associated with OS (HR=1.06; 95% CI: 0.94-1.20, p = 0.31) after adjustment. Median rwPFS was comparable between the two regimens (5.8 (95% CI: 5.5 - 6.2) months CisE versus 5.1 (95% CI: 4.9 - 5.5) months CarboE, p = 0.04), adjusted HR=1.07; 95% CI: 0.95-1.21, p=0.23. The weight-adjusted model yielded consistent results. Patients who received CisE received more cycles of treatment than those who received CarboE (% receiving > 3 cycles of treatment: 71% CisE versus 61% CarboE, p <0.01) but rates of discontinuation due to progression or toxicity were similar (10% CisE versus 11% CarboE, p=0.05). Rates of consolidative thoracic RT were similar between the two groups (39% CisE versus 45% CarboE, p = 0.21), but patients receiving 1L CisE were more likely to receive 2L therapy (30% CisE versus 22% CarboE, p <0.01).

Conclusions: In this large retrospective study, choice of 1L platinum agent in the treatment of de novo ES-SCLC did not significantly impact OS or rwPFS when controlling for confounders such as age and baseline performance status. Choice of CisE or CarboE should be individualized based on patient and disease characteristics.

EP.13.39 Factors Associated With Refusal of Chemoradiotherapy in Stage I-III Small Cell Lung Cancer and Their Effect on Survival

Y.N. Patel, M. Moumne, G. Capo, L. Guy, J. Palmer, C. Quinn, S. Sengupta, G. Raval, D. Yakoub
Medical College of GA, Augusta/GA/USA

ntroduction: While treatment for small-cell lung cancer (SCLC) is highly dependent on its stage, chemoradiotherapy in stage I-III small-cell lung cancer (SCLC) has been associated with improved survival. Yet, some patients refuse chemoradiotherapy. We examined the factors associated with chemoradiotherapy refusal and its effect on median overall survival (OS).

Methods: The NCDB (National Cancer Database) (2004-2019) was queried for patients in the United States with stage I-III SCLC who were recommended chemoradiotherapy. Patients who underwent chemoradiotherapy were compared to those who refused it. Logistic regression was used to identify predictors of chemoradiotherapy refusal. Propensity scored matching (PSM) was implemented to produce comparable groups in terms of demographics, disease characteristics, and treatment. Kaplan-Meir and Log-Rank analysis were used to determine the effect of chemoradiotherapy refusal on OS. A Cox-Proportional Hazard Model was implemented to investigate factors influencing OS.

Results: Out of 68,764 patients with stage I-III SCLC recommended for chemoradiotherapy, 1,493(2.2%) patients refused it. Factors associated with an increased probability of chemoradiotherapy refusal from the multivariate logistic regression were age 50+ (OR=2.43), female sex (OR=1.19), Charleson Deyo comorbidity score (CDCS) of 1 (OR=1.38) and 2+ (OR=1.89), Medicare insurance (OR=1.81), facility location in the West (OR=1.47), tumor size 2-4cm (OR=1.28) and 4cm+ (OR=1.40), patients agreeing to palliative care (OR=1.41), and surgery refusal (OR=93.84). Factors associated with a decreased probability of chemoradiotherapy refusal was having private insurance (OR=0.52). Kaplan-Meir and Log-Rank analysis of PSM groups showed a decrease in median overall survival in those who refused chemoradiotherapy across all stages (Figure-1): Stage-1 [36.72 vs 11.69 mos. HR=3.67, P<0.01], Stage-2 [22.89 vs 6.89 mos. HR=2.89, P<0.01], and Stage-3 [17.07 vs 3.37 mos. HR=5.65, P<0.01]. On multivariate analysis of survival in patients who refused chemoradiotherapy, factors that were associated with decreased survival were CDCS 1 (HR=1.18) and CDCS2+ (HR=1.49), facility location in Southern (HR=1.20) and Midwestern states (HR=1.31), treatment in non-academic centers (HR=1.01), stage 3 disease (HR=1.94), tumor size 4cm+ (HR=1.60), and surgery refusal (HR=2.73). Factors associated with increased survival were Non-Hispanic Black race (HR=0.57) and median income $50,354-$63,332 (HR=0.84). All variables met statistical significance (P<0.01).

Conclusions: Chemoradiotherapy is associated with improved survival in stage I-III SCLC. Targeted counseling and interventions can help mitigate the identified factors associated with chemoradiotherapy refusal to improve outcomes.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.40 Trial of Chemotherapy in Patients With Relapsed Small Cell Lung Cancer Combined With Allopurinol and Mycophenolate (CLAMP)

B.J. Knapp[1], S. Waqar[1], J.P. Ward[1], B. Herzog[1], G. Vellequette[1], A. Cotton[1], D. Turlington[1], M. Plonsky[1], N. Wu[1], A. Rohatgi[1], R. Govindan[1], S. Devarakonda[2], D. Morgensztern[1]
[1]Washington University School of Medicine, St. Louis/MO/USA ,[2]Swedish Cancer Institute, Seattle/WA/USA

Introduction: The prognosis for patients with extensive stage small cell lung cancer (ES-SCLC) who progress on front-line chemoimmunotherapy is poor. Relapsed SCLC frequently upregulates MYC expression and guanosine biosynthesis through the inosine monophosphate dehydrogenase enzymes (IMPDH1 and 2). Pre-clinical data suggests a potential synergistic effect of IMPDH inhibition when combined with chemotherapy. Mycophenolate mofetil (MMF) directly inhibits purine synthesis via IMPDH inhibition and allopurinol limits purine salvage via inhibition of xanthine oxidase. In this phase I trial, we evaluated the safety and efficacy of irinotecan in combination with MMF and allopurinol in relapsed SCLC.

Methods: In this single-center phase I study, patients with previously treated ES-SCLC who had progressed on prior chemoimmunotherapy were enrolled. A 3 + 3 dose de-escalation design was used. Irinotecan was administered on days 1 and 8 of a 21-day cycle while MMF and allopurinol were given daily. The doses of irinotecan, MMF, and allopurinol respectively at various dose levels (DL) were as follows: DL1 (100 mg/m2, 1 g TID and 300 mg/day), DL0 (80 mg/m2, 0.5 g TID, and 200 mg/day), and DL-1 (60 mg/m2, 0.5 g BID, and 100 mg/day). Key objectives were to determine the dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), safety, and antitumor activity using RECIST 1.1.

Results: From 3/1/2023 to 8/6/24, 28 patients were screened for eligibility, and 17 patients were enrolled. Twelve of 17 patients (71%) were female, 7 (41%) had brain metastases at baseline, 13 (76%) had a platinum-free interval of <180 days prior to progression, and the median number of prior therapies was 1 (range 1 - 5). All patients had an adverse event (AE) at least possibly related to treatment (TRAE), most commonly anemia and diarrhea occurring in 12 patients (70%). Grade 3 or higher TRAEs occurred in 12 (70%) patients, including 3 (18%) patients with G3+ lymphopenia and 2 (12%) patients each with G3+ diarrhea, neutropenia, and hypokalemia. There were no G5 TRAEs; 5 (29%) of patients discontinued treatment due to TRAE or intolerance, most commonly diarrhea. A protocol amendment was created after the first 6 patients were enrolled (due to 4 patients requiring dose reduction and 1 discontinuation) to lower the irinotecan dose to 90 mg/m2 (DL1a). Six patients were enrolled at DL1, 5 at DL1a, 3 at DL0, and 3 at DL-1. Two DLTs occurred at DL0 (G3 hypokalemia and G3 diarrhea), and the study was subsequently discontinued due to overall poor tolerance at DL-1, without identification of the MTD. One (6%) patient had a complete response, and 6 (35%) patients had a partial response, with an overall response rate of 41%. The disease control rate was 71%, and the median progression free survival of 2.7 months (95% CI 1.3 - 4.4 mo).

Conclusions: Despite the preliminary evidence of encouraging activity, the combination of irinotecan, MMF, and allopurinol in patients with relapsed ES-SCLC was associated with increased toxicity, most commonly diarrhea. Future studies should explore a more tolerable cytotoxic drug to synergize with inhibitors of purine metabolism.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.41 Expression of PD-L1 and Alternative Immune Checkpoints (ICs) and Their Impact on Outcomes in Small Cell Lung Cancer (SCLC)

M. Lalla[1], S. Nazari[2], H. Jeon[1], J. Song[3], A. Elliott[2], A. Vanderwalde[2], N. Kulkarni[2], H. Borghaei[4], S. Liu[5], X. Zang[6], B. Halmos[1], H. Cheng[1]
[1]Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA ,[2]Caris Life Sciences, Phoenix/AZ/USA ,[3]Memorial Sloan Kettering Cancer Center, Jacobi Medical Center, Albert Einstein College of Medicine, New York/NY/USA ,[4]Fox Chase Cancer Center, Temple Health System, Philadelphia/PA/USA ,[5]Georgetown Lombardi Comprehensive Cancer Center, Washington D.C./DC/USA ,[6]Albert Einstein College of Medicine, Bronx/NY/USA

Introduction: SCLC is an aggressive malignancy with rapid growth and poor prognosis. Recent molecular profiling has highlighted the potential role of IC genes (PD-L1, B7-H3, B7x, and HHLA2) in the treatment of lung cancer, although the relationship between their expression and patient outcomes in aggressive SCLC remains unclear. This study aims to evaluate the expression of these ICs across various SCLC subtypes and their link to clinical outcomes.

Methods: NextGen sequencing of DNA (592-gene/whole exome) and RNA [(whole transcriptome sequencing (WTS)) were performed for 2,187 SCLC samples at Caris Life Sciences. PD-L1 expression was assessed by IHC (22C3 assay, +: TPS ≥1%). RNA expression of IC genes was evaluated across SCLC molecular subtypes (ASCL1, A; POU2F3, P; NEUROD1, N; and inflamed, I) and specimen sites. Insurance claims data were to calculate overall survival (OS) and time on treatment (TOT, from initiation of immunotherapy (IO) to cessation). Cox models and log rank test were used to calculate HR and statistical significance, respectively.

Results: PD-L1 IHC positive tumors had a median PD-L1 gene expression of 6.9 transcript per million (TPM), compared to 4.6 TPM in PD-L1 negative cases (p<0.05). Immune cell fractions positively correlated with the expression of PD-L1 and alternative IC genes. Table 1 summarizes gene expression across the molecular subtypes of SCLC. SCLC-P subtype had the lowest frequency of PD-L1 positivity, while the highest was observed in SCLC-I (26.5% vs 52.1%, p=0.07). Compared to lung-derived samples, lymph node metastases had lower B7-H3 (16.5 vs. 20.8 TPM, p<0.05) and reduced PD-L1 positivity (32.2% vs. 43.3%, p<0.05). Higher PD-L1 expression was associated with improved OS from time of biopsy until last contact/death, at both RNA (HR 1.59, 95% CI: 1.337-1.894, p<0.001) and IHC protein levels (HR 1.49, p<0.001). Similarly, patients with higher PD-L1 expression had better OS from the start of IO, at both RNA (HR 1.52, p<0.001) and IHC (HR 1.38; p=0.003). No significant survival differences were associated with B7x, HHLA2, or B7-H3 expression.

Conclusions: These data suggest a potential impact of PD-L1 expression in SCLC, particularly its association with improved OS following immunotherapy. Gene expression by WTS has clinical utility independent of IHC. These findings provide valuable insights into the molecular landscape of SCLC and the differential expression of ICs across different subtypes. Further studies are needed to explore the broader implications of ICs expression in the management of SCLC.

Table 1: Expression of ICs Across Molecular Subtypes of SCLC and their association with OS and TOT.

	PD-L1		B7-H3		B7x		HHLA2		Statistically significant results **vs other subtypes** (*P<0.05)
	% Positive by IHC	TPM by WTS	TPM by WTS		TPM by WTS		TPM by WTS

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP.13.42 Self-Oxygenating PROTAC Microneedles for Spatiotemporally-Tunable Protein Degradation and Enhanced Small Cell Lung Cancer Therapy

M. HOU
Tongji University, Shanghai/CN

Introduction: Small cell lung cancer (SCLC) characterized by its invasive and infiltrative growth, presents significant challenges for clinical therapy. Proteolysis Targeting Chimera (PROTAC) shows promise in SCLC therapy by diminishing targeted proteins traditionally resistant to small molecular inhibitors. Yet, their effectiveness is limited by the tumor resistance and lack of tumor specificity.

Methods: We innovatively engineered a double-layered microneedle (MN) patch by integrating acid and ROS dual-activatable PROTAC nanoparticles and self-oxygenating BSA-MnO2 nanoparticles into one nanoplatform to overcome the tumor resistance. The microneedle patch were administrated locally at the tumor site to penetrate the tumor and enhance photodynamic therapy (PDT), thus precisely induced bromodomain and extraterminal protein 4 (BRD4) degradation for effective tumor eradication.

Results: Upon administration, the outer layer of the microneedle swiftly releases the PROTAC nanoparticles quickly, which can be specifically activated in the intracellular acidic environment of tumor cells for performing PDT and restored PROTAC prodrug for precise BRD4 degradation. Simultaneously, the BSA-MnO2 nanoparticles loaded inside the inner layer of the MNs acted as an oxygen supply station to counteract tumor hypoxia, and thus promoted PDT and PROTAC activation. This PROTAC-delivered MNs significantly inhibited tumor growth in both subcutaneous and orthotopic SCLC tumor models.

Conclusions: Self-oxygenating PROTAC MNs successfully circumvented the tumor tissue, inducing enhanced BRD4 degradation and PDT for SCLC treatment. This multifunctional MNs might provide a robust nanoplatform for precise protein degradation and highly efficient SCLC therapy.

Introduction: We aimed to assess prognostic factors and the effect of initial location of distant metastases on overall survival (OS) in extensive-stage small cell lung cancer and to compare the results of results with the predictions from Wu et al.'s nomogram based on SEER data.

Methods: A multicenter retrospective analysis comprised 579 patients with metastatic ES-SCLC identified between 2001 and 2023. The data of 9 centers are evaluated. Survival rates were assessed using the Kaplan-Meier method, and prognostic factors were analyzed using Cox regression and Mann-Whitney U tests. Estimated OS rates were calculated utilizing the nomogram developed by Wu et al.

Results: All of the patients had 4-6 courses of chemotherapy, 20 had maintenance atezolizumab. Thoracic radiotherapy (TRT) was administered to 416 (71,8%) patients, while prophilactic cranial radiotherapy (PCI) was performed on 241 (41,6%) patients. Among 579 patients at diagnosis: 302 had bone, 171 had liver, 134 had adrenal, 102 had pleural, 66 had contralateral lung, 164 had brain and 125 had other metastasis. The median OS was 11 months (0-103). 6 months, 1 year, and 2 years OS were 48%, 24%, and 2%, respectively. While patients with brain metastases (p=0.036) has improved survival, liver metastases (p=0.003), bone metastases (p=0.001), pleural metastases (p=0.002), and ECOG performance level (p=0.001) were all significantly related to lower survival in univariate analysis. Additionally, the number of metastases, TRT (p=0.000), PCI (p=0.003), atezolizumab treatment(p=0.038), smoking, marriage, gender, and T and N stages all had an effect on OS. Multivariate studies revealed that pleural metastases (HR:1,41(1,13-1,76)p:0,002), liver metastases (HR:1,41 (1,16-1,7) p:0,001), and ECOG performance status (HR:1,92 (1,12-3,28) p:0,016) were all detrimental prognostic factors. Furhtermore the risk of death is 1,79 (p:0,001) times higher in patients who do not recieve TRT , while the risk of death increases 1,97(p:0,001) times higher in patients who do not recieve PCI. When we compare the predictions of Wu et al.'s nomogram; the results of our data were similar for the patients with liver, bone and brain metastases .

Conclusions: Liver, bone, pleural metastases negatively affected OS in patients with ES-SCLC. TRT and the administration of more than 30 Gy doses demonstrated a positive impact on OS. Moreover, TRT, Atezolizumab treatment, and PCI have survival advantages of 7, 7, and 9 months, respectively. Survival rates of our cohort with liver, bone and brain is correlated with the nomogram of Wu et al..

EP.13.44 Real-World Treatment Patterns and Clinical Outcomes in Patients With Metastatic Neuroendocrine Neoplasms of the Lung (NEN-L)

K. Zu[1], R. Vaidya[2], C. Cho-Phan[2], H. Hu[1]
[1]Merck & Co., Inc., Rahway/NJ/USA ,[2]Flatiron Health, New York/NY/USA

Introduction: NEN-L is a type of lung cancer originating from pulmonary neuroendocrine cells. One subtype of NEN-L is large-cell neuroendocrine carcinoma of the lung (LCNEC), a rare, aggressive disease with a poor prognosis. Due to disease rarity and heterogeneity, there is no consensus on standard of care for metastatic LCNEC. This study aims to evaluate real-world treatment patterns and clinical outcomes in a sample of patients with metastatic NEN-L in which most patients were expected to have LCNEC with some typical and atypical carcinoid cases.

Methods: This retrospective cohort study used the US-based, electronic health record-derived deidentified Flatiron Health Research Database. Included patients had a chart-confirmed diagnosis of metastatic NEN-L (excluding small-cell lung cancer, a subtype of NEN-L) between October 1, 2018, and April 1, 2023, and initiated systemic anticancer treatment. The index event was the initiation of first-line (1L) treatment. Summary statistics were generated for demographics, baseline clinical characteristics, and treatment patterns. Real-world time to next treatment (rwTTNT) by line of therapy (LOT) was estimated by the Kaplan-Meier method. Analyses were conducted in the overall study population and stratified by LOT (1L, 2L, and 3L), treatment class, and disease stage at initial diagnosis.

Results: At database cutoff (March 31, 2024), 154 patients with metastatic NEN-L were included in the analysis. Patients had a median age of 68 years at 1L treatment initiation, 53.9% were female, and 65.6% had an ECOG PS of 0/1. Median follow-up duration was 8.4 (interquartile range, 3.1-17.1) months. Regardless of disease stage at initial diagnosis, platinum-based chemotherapy (either alone or with an immune checkpoint inhibitor [ICI]) was the most common 1L treatment, while "other" treatment options including mostly nonplatinum chemotherapy drugs were most common for subsequent LOTs (Table). Following 1L treatment, 49.4% and 22.7% of patients initiated 2L and 3L treatment, respectively. Median rwTTNT (95% CI) was 5.3 (4.1-6.4) months for 1L treatment, 5.0 (3.5-7.1) months for 2L treatment, and 4.0 (3.3-10.0) months for 3L treatment.

Conclusions: Patients with metastatic NEN-L were primarily treated with platinum-based chemotherapy with or without ICIs as the frontline treatment. In 2L and beyond, diverse treatment options were used, most of which included nonplatinum chemotherapy drugs. The heterogeneity in treatment strategies is accompanied by suboptimal clinical outcomes across LOTs. These results suggest there is a high unmet need among patients with metastatic NEN-L, including LCNEC.

	Overall
1L treatment patterns, n	154
Median time from metastatic diagnosis to 1L treatment initiation (interquartile range), mo	1.3 (0.7–2.5)
Treatment ongoing at database cutoff, n (%)	9 (5.8)

EP.13.45 Efficacy and Prognostic Significance of Immunotherapy in Postoperative Recurrent and Advanced Large Cell Neuroendocrine Carcinoma

H. Zhong
Shanghai Chest Hospital, Shanghai/CN

Introduction: Large cell neuroendocrine carcinoma (LCNEC), representing 2-3% of primary lung cancers, is characterized by aggressive behavior and dismal prognosis. While immune checkpoint inhibitors have transformed outcomes in advanced non-small cell lung cancer (NSCLC), therapeutic standards for LCNEC remain undefined, with limited evidence supporting immunotherapy in this rare histologic subtype.

Methods: This retrospective analysis included 47 patients with postoperative recurrent or advanced LCNEC diagnosed between 2018-2024 from a cohort of 526 lung cancer cases. Clinical parameters including treatment line, PD-L1 expression, RB1/TP53 mutational status, and histologic combinations were analyzed for associations with progression-free survival (PFS) and overall survival (OS). Immunotherapy regimens encompassed PD-1/PD-L1 inhibitors as monotherapy or combined with chemotherapy.

Results: Among 38 immunotherapy-treated patients, the objective response rate (ORR) was 89.5% with median progression-free survival (mPFS) of 8.0 months, and median overall survival (mOS) of 17.5 months. First-line immunotherapy demonstrated superior efficacy compared to later-line therapy, significantly prolonging mPFS (15.0 vs. 5.0 months, p=0.038). PD-L1-positive tumors (≥1% tumor proportion score) exhibited markedly improved mPFS compared to PD-L1-negative counterparts (not reached vs. 3.0 months, p=0.013). Patients with combined LCNEC-NSCLC histology derived substantial survival benefits from immunotherapy, showing significantly extended mOS versus non-combined subtypes (19.0 vs. 8.0 months, p=0.0004). While not statistically significant, wild-type RB1/TP53 tumors trended toward improved survival outcomes compared to mutant variants (mPFS: 11.0 vs. 8.0 vs. 3.0 months, p=0.150; mOS: 18.0 vs. 16.0 vs. 10.5 months, p=0.515).

Conclusions: First-line immunotherapy demonstrates clinically meaningful efficacy in advanced LCNEC, particularly in PD-L1-positive tumors and combined histology subtypes. While RB1/TP53 wild-type status showed favorable trends, larger cohorts are needed to validate genetic predictors. These findings support prioritization of PD-1/PD-L1 inhibitors in the frontline setting for this aggressive malignancy.

EP.13.46 Novel Prognostic Markers in Pulmonary Neuroendocrine Tumors (Carcinoid Tumors)

S. Sushmitha, S. Satapathy, s. kumar, P.S. Malick, A. Nambirajan, D. Jain
All India Institute of medical sciences, New Delhi, New Delhi/IN

Introduction: Pulmonary neuroendocrine tumors include Typical (TC) and Atypical(AC) carcinoids, classified based on mitotic count and presence/absence of necrosis. However, this classification remains subjective and often fails to accurately predict recurrence risk or guide surveillance. Unlike gastrointestinal and pancreatic NETs, Ki-67 labeling index is not part of pulmonary carcinoid grading due to lack of consensus on cut-offs. Recent molecular studies (Laddha et al., 2019; Alcala et al., 2019) have identified transcriptomic subgroups with distinct prognostic outcomes. These are defined by expression of markers like OTP, S100, CD1a, CD44, and ASCL1. We hypothesize that immunohistochemistry (IHC)-based stratification using selected markers may correlate with proliferation indices and histologic grade, thereby providing additional prognostic value.

Methods: An ambispective study(2013-2024) was conducted using the tissue microarray. Formalin-fixed paraffin-embedded pulmonary carcinoid samples were used for IHC using primary antibodies against OTP, S100, CD1a, CD44 and ASCL1. Each case was classified per the 2021 WHO criteria into TC or AC. Ki-67 labeling index and mitotic counts were recorded. Correlation analyses (Spearman's rho, Mann-Whitney U tests) were performed between IHC expression, Ki-67, mitotic index, and histological subtype.

Results: Among TC(n=42), OTP is positive in 88.1% cases, S100 is positive in 9.5%,CD44 is strongly positive in 88.1%, CD1a is strongly positive in 7.1% and ASCL1 is negative in all cases. S100 and CD44 showed negative correlation with ki-67, with spearman's rho -0.089 and -0.116 respectively. OTP and CD1a showed weak positive correlation and ASCL1 is unanalyzable due to no variation in data. With mitotic index, S100 and CD1a showed very weak positive correlation and OTP, ASCL1 being unanalyzable due to no variation in data.Among AC(n=11), OTP is positive in 100% cases, S100 is positive in 18%, CD44 is strongly positive in 82%, CD1a is strongly positive in 9% and ASCL1 is negative in all cases. There is moderate positive correlation between mitotic figures and the ki-67 index with S100 but statistically insignificant. No other correlations found due to no variability of data pertaining to other biomarkers.OTP is diffusely expressed in NETs, irrespective of grade showing a good diagnostic value. Although CD44 and S100 correlated with a lower proliferation index, they are not statistically significant from this study limited by sample size.

Conclusions: Our study tried to depict the utility of using IHC biomarkers- OTP, S100,CD44, CD1a and ASCL1 for effective subgrouping of carcinoids. S100 and CD44 showed negative correlation with ki-67 in TC, although statistically not significant, limited by small sample size. OTP and ASCL1 have come out to be independent prognostic markers irrespective of WHO classification. Future evaluations with a larger sample size and detailed survival analysis may aid in better subclassifying carcinoids in cases with ambiguous mitotic counts and assessing prognostic values improving management strategies.

EP.13.47 The Subtle Signals of Diffuse Idiopathic Pulmonary Neuroendocrine Cell Hyperplasia (DIPNECH): A Clinical Characterization

E. Harris[1], J. Liang[2], A. Esposito[3], N. Choudhury[3], S. Murgu[4], S. Podder[4], C. Bestvina[3], C. Meador[2]
[1]University of Chicago, Chicago/IL/USA ,[2]Massachusetts General Hospital Cancer Center and Department of Medicine, Boston/MA/USA ,[3]University of Chicago Medicine, Section of Hematology Oncology, Department of Medicine, Chicago/IL/USA ,[4]University of Chicago Medicine, Section of Pulmonary Medicine, Department of Medicine, Chicago/IL/USA

Introduction: Diffuse Idiopathic Pulmonary Neuroendocrine Cell Hyperplasia (DIPNECH) is an underdiagnosed, indolent, pre-malignant pulmonary disease that presents as dyspnea and non-productive cough. Mosaicism and bilateral pulmonary nodules are seen on imaging, and pulmonary function tests (PFTs) show obstructive lung disease. Data guiding clinical management is limited, but treatment typically includes inhalers plus somatostatin analogues or everolimus. Symptom progression can result in a decline of quality of life; thus, better understanding of its pathogenesis and prognosis is needed.

Methods: This IRB-approved retrospective cohort study identified 34 patients with DIPNECH at two institutions (MGH, UCMC). DIPNECH diagnoses were confirmed by histologic or radiologic evidence plus clinician evaluation. Baseline characteristics and clinical outcomes were collected; symptom grading was per CTCAE v5.0 guidelines.

Results: Most patients were elderly (median age 69), white (82%), and never smokers (65%) (Table 1). Baseline symptoms included dyspnea (56%) and cough (56%) in most patients. Most patients had normal or restrictive (32%) PFTs at baseline and did not participate in pulmonary rehabilitation. On imaging, the majority had bilateral pulmonary nodules (97%) and mosaic attenuation (65%). Half of patients had biopsy-proven DIPNECH versus clinical diagnosis. Twenty-one patients (62%) had concurrent carcinoid tumors.

[1] patient had an atypical and NOS carcinoid tumor

While 23 patients were observed without intervention, 10 were treated with octreotide alone and one with octreotide and everolimus (Table 2). Among those treated, 9 patients (82%) reported symptomatic improvement. Common side effects from octreotide were gastrointestinal-related; one patient developed stomatitis from everolimus. Four patients stopped treatment. Co-management with pulmonology occurred for 23 patients. Additional supportive care included opioids (n=2) and supplemental oxygen (n=5).

[1]1 received treatment with sequential octreotide and everolimus, respectively.

Conclusions: DIPNECH is a rare, underdiagnosed and likely undertreated condition for which consensus guidelines and highly effective treatment options are lacking. Patients with DIPNECH benefit from comprehensive evaluation and multi-disciplinary management, and future standardization of diagnostic and therapeutic approach to this disease is needed.

Keywords: DIPNECH, Neuroendocrine Tumor

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP13.48 Natural Killer (NK) Cell Heterogeneity in Small Cell Lung Cancer: Implications for Chemo-Immunotherapy Response

Chemo-Immunotherapy Response

C. De Rosa[1], L. Amato[1], F. Somma[2], S. Capaldo[1], C. Tuccillo[1], M. Gilli[3], F. Vitiello[3], A. Servetto[4], G. Viscardi[3], G. Ercolano[2], C.M. Della Corte[1]

Introduction: Small cell lung cancer (SCLC) is an aggressive cancer treated with chemo-immunotherapy, but responses vary. Recent data indicate an "inflamed" SCLC subtype shows improved immunotherapy outcomes, suggesting a role for innate immunity, particularly NK cells. Recently, Rebuffet et al. (Nature Immunology, 2024) identified three prominent NK cell subsets in human blood: NK1, NK2 and NK3, further differentiated into six distinct subgroups. This study investigates differential transcriptional profiles of NK cells from SCLC patients undergoing chemo-immunotherapy, classified as Best Responders (BR) or Non-responders (NR), based on progression-free survival (PFS). It further explores the impact of sequential treatment with cisplatin and a DNA damage repair inhibitor (DNA-PKi) on NK cells, aiming to understand NK cell function in mediating therapeutic efficacy.

Methods: Blood samples were collected from SCLC patients (n=20) at baseline and after chemo-immunotherapy. NK cells were isolated using a Miltenyi NK cell Isolation kit and FACS sorting. Total RNA was extracted for bulk RNA-seq analysis. FACS was used to characterize NK cells subsets. In vitro experiments involved treating NK cells with cisplatin, followed by DNA-PKi for 24 hours. Quantitative RT-PCR was performed to measure the expression of innate immune signaling molecules, and cytotoxicity assays using the SCLC cell lines were conducted using an LDH assay.

Results: Transcriptomic profiling revealed 1,621 downregulated genes in NR NK cells and 1,836 upregulated genes in BR NK cells. Gene Set Enrichment Analysis (GSEA) showed significant upregulation of IFN-related pathways and enrichment in lung proliferating NK cells and DNA repair pathways in BR NK cells. BR patients exhibited increased expression of genes associated with the NK3 phenotype and upregulation of NK1B subtype-related genes. ISMARA analysis demonstrated a higher presence of the IRF3-binding motif in BR NK cells. Treatment with cisplatin alone did not alter the transcriptomic landscape of NR NK cells but induced significant changes in BR NK cells. Sequential treatment with cisplatin and DNA-PKi led to an increase in NK3 and NK1B subtypes in BR patients, while NR patients showed a predominance of the NK intermediate (NKint) subtype. Quantitative RT-PCR revealed upregulation of innate immune signaling molecules (STING, MAVS, CCL5, CXCL10) in BR NK cells following sequential treatment. LDH assay results showed that BR NK cells exhibited higher baseline cytotoxicity against SCLC cells. Sequential treatment enhanced cytotoxicity in both NR and BR NK cells, with BR cells showing superior performance.

Conclusions: The study highlights the importance of understanding NK cells heterogeneity in SCLC, showing a differential response of NK cells from BR and NR SCLC patients to chemo-immunotherapy and sequential cisplatin/DNA-PKi treatment. BR patients' NK cells demonstrated a shift towards more cytotoxic subtypes (NK3 and NK1B) and enhanced immune functionality, contributing to improved treatment outcomes. Finally, the activation of innate immune signaling pathways in BR patients' NK cells suggests potential mechanisms for enhanced therapeutic efficacy.

EP.13 SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS

EP13.49 Prognosis of Perioperative Therapy in Primary Limited-Stage Small-Cell Lung Cancer

G. Chang[1], J. Yan[2], X. Yan[1], X. Li[1]
[1]Peking University People's Hospital, Beijing/CN ,[2]Thoracic Oncology Institute, Peking University People's Hospital, beijing/CN

Introduction: For limited-stage SCLC (LS-SCLC), synchronous chemoradiotherapy is the recommended treatment options,as surgical resection was only recommended for I-IIA SCLC. However, the majority of these patients experience tumor recurrence or metastasis rapidly. Immunotherapy has achieved good efficacy in extensive-stage SCLC and improved survival in resected non-SCLC. Simultaneously, the use of neoadjuvant immunotherapy in limited- stage SCLC is still unknown but promising.

Methods: Patients diagnosed with LS-SCLC spanning stage I to IIIB who underwent surgical resection at our center were included from May 2015 to July 2025. Survival outcomes were identified in patients received neoadjuvant treatment and adjuvant treatment. Meanwhile, Comprehensive analyses encompassed pathological response [major pathological response (MPR) and pathological complete remission (pCR)], downstaging rate, event free survival (EFS) and treatment-related adverse events (trAEs) were compared in neoadjuvant immunotherapy and chemotherapy patients.

Results: A total of 204 surgical resected SCLC with stage I-IIIB were included in the study, 175(85.8%) patients treated with adjuvant therapy and 29(14.2%) received neoadjuvant therapy. Compared to patients underwent adjuvant therapy, neoadjuvant was associated with longer median overall survival (mOS) (42 months vs Not reach(NR), HR=2.03, P=0.02). Among the 29 neoadjuvant patients, 51.7%(N=15) received immunotherapy and 48.3%(N=14) received chemotherapy. The pCR and MPR of the immunochemotherapy group both were significantly higher than those in chemotherapy group (57.1% vs 0%, P<0.001 and 71.4% vs 20% , P=0.009). 22(75.8%) neoadjuvant patients with lymph node metastasis (N+) at baseline. Downstaging of T and N occurred in 14 (100%) and 9(81.8%) patients in the immunochemotherapy group, respectively, which were also higher than ones in chemotherapy group (66.6%, P=0.042 and 18.2%, P=0.009). Meanwhile, the median EFS of the immunochemotherapy group was not reach, which was 19.1months (P=0.302, HR=2.03). There was no significant difference in the incidence of trAEs between the immunochemotherapy group and the chemotherapy group.

Conclusions: For patients with LC-SCLC, neoadjuvant therapy was associated with improved survival than adjuvant therapy, especially for those with neoadjuvant immunochemotherapy. Compared to neoadjuvant chemotherapy, neoadjuvant immunochemotherapy was related to significantly higher pathological response and can produce significant downstaging to increase the possibility of surgery with similar safety. Therefore, neoadjuvant immunotherapy might be a promising treatment modality for resectable SCLC.

EP.14 MESOTHELIOMA, THYMOMA, AND OTHER THORACIC TUMORS

EP.14.01 Chemotherapy Plus Bevacizumab and Immunotherapy Prolonged the Survival of Unresectable Malignant Mesothelioma Patients in First-Line

Y. He, L. Kong, X. Ji, L. Ding, Y. Wang
Peking University Cancer Hospital and institute, Beijing/CN

Introduction: Malignant pleural mesothelioma (MPM) is a kind of rare malignant thoracic tumor with poor prognosis. Pemetrexed-platinum regimen with or without bevacizumab regimen and immunotherapy with nivolumab and ipilimumab are currently standard first-line therapies for MPM patients who are medically inoperable. Recently, a phase III study revealed that pemetrexed-platinum-bevacizumab plus atezolizumab prolonged the progression-free survival (PFS), while it did not translate into overall survival (OS) benefit. So far there are few studies explored the efficacy of chemotherapy combined with bevacizumab and immune checkpoint inhibitors in the real-world cohort.

Methods: We retrospectively analyzed unresectable MPM patients who were administered with standard pemetrexed-platinum chemotherapy with or without angiogenesis inhibitors and immunotherapy in first-line treatment. Patients' baseline demographic characteristics, survival time and adverse events (AEs) during treatment were collected. We then divided the enrolled patients into three groups: group A was defined as patients received first-line chemotherapy alone; group B, chemotherapy plus bevacizumab; group C, chemotherapy plus angiogenesis inhibitors and immunotherapy. Kaplan-Meier methodology was used to compare survival difference among three groups.

Results: 128 patients were enrolled between January 2010 and September 2024 with a median age of 59.5 years. The cohort was predominantly male (78 out of 128, 60.9%) and the median follow-up was 37.3 months. 95.3% had ECOG performance status 0-1. Epithelioid histology was the most frequently reported histological subtype (55 of 128; 43.0%), 7.8% had sarcomatoid histology, 4.7% had biphasic histology, the other 44.5% were unknown. 46 out of 128 had distant metastasis, while 35.9% patients were confined to the thoracic cavity. Both group B and group C showed a better PFS compared with group A (median PFS, group A 8.6 months [5.7-11.7], group B 9.7 months [7.4-12.0], group C 16.4 months [7.0-25.7]; p=0.101). There were no significant differences in OS among the 3 groups (median OS, group A 24.9 months [16.3-33.5], group B 26.4 months [14.9-37.5], group C not reached; p=0.326). After adjusting confounding factors include gender, age, clinical stage, pathological type and ECOG performance status in COX multivariate regression analysis, we found that the four drug-regimen which combined chemotherapy, anti-angiogenic therapy and immunotherapy significantly prolonged PFS and OS compared to chemotherapy alone (PFS: HR 0.29, 95% CI 0.12-0.72, p=0.007, OS: HR 0.27, 95% CI 0.08-0.88, p=0.029). However, there was no statistically significant difference in PFS and OS when compared to the three-drug chemotherapy plus bevacizumab group (PFS: HR 0.47, 95% CI 0.19-1.18, p=0.11, OS: HR 0.31, 95% CI 0.09-1.12, p=0.074). No significant difference in the incidence of grade≥3 AEs were observed among the three groups (group A: 7.6%, 9.8%, 18.2%, respectively, p=0.68).

Conclusions: In our real-world cohort, we found that unresectable MPM patients benefited from the combination of chemotherapy, anti-angiogenic therapy and immunotherapy with tolerable toxicity. Both PFS and OS was significantly longer than chemotherapy alone group. And there was a trend that four-drug therapy prolonged survival than chemotherapy plus anti-angiogenic agent group which was consistent with the latest published ETOP 13-18 trial data and more data is needed to confirm.

EP.14.02 Overall Survival and PD-L1 Expression Analysis of Patients With Pulmonary Mesothelioma

Y. Yonemori
Japan Organization of Occupational Health and Safety Chiba Rosai Hospital, Chiba/JP

Introduction: Immunotherapy has become an important treatment option in patients with mesothelioma.The binding of programmed death ligand-1 (PD-L1) to its receptor PD-1, on the surface of activated T cells, inhibits cytotoxic T cell responses. Immune checkpoint inhibitors target this mechanism, improving outcomes for patients with mesothelioma. Stratifying patients based on their PD-L1 IHC (immunohistochemistry) expression score informs response rates. We investigated the prevalence of PD-L1 IHC expression in a Japanese single center setting, retrospectively collecting patient clinical and pathological data.

Methods: On 38 cases of mesothelioma diagnosed between 2004 and 2024 at our institution, immunohistochemistry was performed to detect PD-L1 expression using clone 22C3. Slides were reviewed for pathological analysis, and clinical data was obtained from medical records. The Kaplan-Meier model was adopted for calculating OS was applied to assess the results.

Results: The cohort included 35 males and 3 females, with a median age of 72 years (range 58-82) . Twenty-three 23 cases were epithelioid mesothelioma (approximately 60%), with the remaining cases being biphasic mesothelioma and sarcomatoid mesothelioma. As for treatment, one case underwent surgery, and all cases received drug therapy (chemotherapy and immune checkpoint inhibitors). Chemotherapy was administered in 25 cases (65.8%). Two immune checkpoint inhibitors (Nivolumab + Ipilimumab) were administered in 11 cases (28.9%), one case was administered a single immune checkpoint inhibitor in 11 cases (28.9%), and 16 cases were not administered any immune checkpoint inhibitors at all. Twenty-three cases (approximately 60%) had a PD-L1 CPS of less than 1, followed by 6 cases of 1 to less than 10. 6 cases of 10 to less than 50, and 3 cases of 50 or more.The median survival time for all 34 patients included in the survival analysis was 17.5 months (95% confidence interval: 9.63-35.5 months).In the histological type study, sarcomatoid was statistically significant for the poorest prognosis, followed by biphasic and epithelioid. Patients with a history of combined immune checkpoint inhibitor treatment or monotherapy showed a significantly longer survival time than those without a history of immune checkpoint inhibitor treatment, but in this exploratory study, the presence or absence of CPS was not statistically related to prognosis. The degree of CPS expression was not statistically related to prognosis.

Conclusions: Although this study only examined a small number of cases, there was no association between anticancer drug treatment and the relationship between treatment and prognosis, but patients with a history of immune checkpoint inhibitor treatment had a better outcome than those without a history of treatment.

EP.14.03 Glutamine Dependency of Pleural Mesothelioma

S. Plans Marin[1], S. Hijazo-Pechero[2], I. Sreeram[1], A. Alay[1,3], D. Palau-Gallinat[1], J. Aramburu[4], C. Muñoz-Pinedo[1], E. Nadal[1,5]
[1]Institut d'Investigació Biomèdica de Bellvitge (IDIBELL), L'Hospitalet de Llobregat/ES ,[2]Instituto de investigación biomédica (IRB), Barcelona/ES ,[3]Catalan Institute of Oncology (ICO, L'Hospitalet de Llobregat/ES ,[4]Barcelona Biomedical Research Park (PRBB), Barcelona/ES ,[5]Catalan Institute of Oncology (ICO), L'Hospitalet de Llobrega

Introduction: Pleural Mesothelioma (PM) is an insidious and very aggressive neoplasm of the mesothelial surface involving the pleura, which is associated with occupational or environmental exposure to asbestos. Metabolism in tumors differs from that in parental tissues to favor maximal use of resources with an adequate energy balance to allow cancer cells to survive and proliferate in a competitive tumor microenvironment. This metabolic rewiring can result in metabolic dependencies and a subsequent change in the cell's energetic profile that has the potential to be exploited therapeutically.

Methods: Publicly available transcriptome data were analyzed from different PM studies to determine the prognostic value of genes involved in glutamine metabolism. Cell viability and cell death were examined in distinct preclinical in vitro models of PM, including commercial cell lines and in-house patient-derived cell lines. Cells were treated with 2-deoxy-D-glucose (2-DG) at 0-5 mM and the glutaminase 1 (GLS1) inhibitor CB-839 at 0-1 µM, which target glucose and glutamine metabolism, respectively. Cell viability was determined by cell counting, while apoptotic death and cell cycle analyses were measured using propidium iodide by flow cytometry. We assessed the adaptive energetic response upon metabolic inhibitor treatment by assessing Oxygen Consumption Rate (OCR) by Seahorse and evaluating mTORC1 pathway dysregulation by Western blot.

Results: Using publicly available transcriptome data, we observed that overexpression of a glutamine metabolism signature, SLC2A1 and GLS1 are significantly associated with shorter overall survival, after adjusting for other clinical covariates (HR = 1.42 [1.11-1.8]). Viability and cell death analysis showed that cell numbers were reduced in several PM lines when treated with 2-DG. Strikingly, PM cells that showed less sensitivity for 2-DG were the most sensitive to CB-839, which reduced proliferation both in 2D and 3D cultures. CB-839 treatment did not arrest cells in any particular phase of the cell cycle. However, in the two most sensitive cell lines, CB-839 treatment resulted in apoptosis at 72h. Supplementation with dimethyl α-ketoglutarate (α-KG) rescued the effect in cell growth and apoptosis seen in 2D mesothelioma cell cultures upon CB-839 treatment. In addition, α-KG supplementation rescued 3D spheroid size in a patient-derived PM cell line. OCR and mTORC1 are significantly reduced upon glutaminase inhibition treatment.

Conclusions: CB-839 reduces cell viability in nine PM cell lines. For the two most sensitive cell lines, CB-839 treatment reduces OCR, mTORC1 and induces cell death, which are rescued by α-KG. These results suggest that glutamine is necessary for PM cell lines to sustain the TCA cycle and maintain energy requirements. Therefore, GLS1 might be a potential new therapeutic target in mesothelioma.

EP.14.04 Mapping the Pleural Mesothelioma: Incidence, Treatment Patterns and Outcomes From Endemic Pocket in Southern Rajasthan, India

A. Jakhetiya, N.K. Deora, A.k. Yadav, R. Purohit, A. Agarwal, R.K. Vyas
Geetanjali Medical College and Hospital, Udaipur/IN

Introduction: The malignant pleural mesothelioma (MPM) is a rare and aggressive cancer with epidemiological linkage to asbestos. While many countries banned the asbestos still China and India are estimated to consume about 50% of global asbestos. Low literacy, ignorance and poor data collection leads to underreporting in India. In last five years we have seen significant cases coming from one area of Rajasthan state in India. Here we analyzed the data of this rare malignancy treated at our center situated in this endemic zone.

Methods: A retrospective analysis of prospectively maintained database of pleural mesothelioma in department of surgical oncology was performed. All the cases treated between May 2018 to December 2024 were identified. A total of 88 cases were treated and as per Pin code districts and villages were mapped to identify the hot spot. Apart from demography, treatment protocols, relapse patterns were also identified.

Results: Out of 88, total 64 cases were localized within a radius of 150 km and three major districts identified as hotspot (image 1). Age range varied from 26 -88 years with male: female ratio of 1.8:1. Majority (56%) were treated with empirical antitubercular treatment (ATT) at peripheral centers. Median duration of symptoms was six months, dyspnea was most common symptom (66%). Tissue diagnosis was done by thoracoscopy in 63 patients followed by CT guided biopsy in 25. Among histological variants Epithelioid was most common (62%) variant followed by sarcomatoid (17%) and Biphasic (10%). Majority received neoadjuvant chemo/immunotherapy (73%), however only 23 patients underwent surgery and in remaining treatment intent was converted to palliative. Out of 23 patients, 12 underwent Extended pleurectomy (EP) and seven underwent extrapleural pneumonectomy, remaining four underwent partial pleurectomy (palliative) in view of extensive disease. After median follow up of 22 months 55 died (62%), 22 were alive and disease free (25%) and 11 were alive with disease (13%).

Conclusions: MPM remains rare and aggressive cancer with poor outcomes despite Tri modality treatment. Due to endemicity of tuberculosis most of the patients are still treated with empirical ATT leading to delay in starting the treatment for this deadly disease. This newly identified hotspot in southern Rajasthan needs more attention to identify the causative factors to further take preventive and curative measures.

EP.14.05 Predictive Factors of Postoperative Long-Term Survival in Patient With Pleural Mesothelioma

M. Hashimoto[1], S. Nakamura[2], A. Kuroda[1], K. Takegahara[1], A. Fukuda[1], T. Kato[2], S. Matsumoto[1], N. Kondo[1], S. Hasegawa[1], T.F. Chen-Yoshikawa[2], S. Funaki[1]

[1]Hyogo Medical University, Nishinomiya/JP ,[2]Nagoya University Graduate School of Medicine, Nagoya/JP

Introduction: To investigate the predictive factors of long-term survival (more than 5 years) in patients with pleural mesothelioma (PM) undergoing curative-intent surgery.

Methods: A total of 255 patients who underwent curative-intent surgery for MPM between January 2006 and December 2019 in two high-volume centers were enrolled in this retrospective cohort study. Long-term survivor was defined as a patient surviving more than 5 years from the date of diagnosis. We analyzed the predictive factor of long-term survival using regression analyses. The data cut-off date was December 31, 2024.

Results: Of 255 patients, 77 (30.2%) survived more than 5 years from the date of diagnosis. Of 77 long-term survivors, the median age was 63-year old, the male was 64(83.1%), the epithelioid type was 75 (97.4%), c-T1(ver.8) and c-T1(ver.9) were 46(59.7%) and 52(67.5%), respectively. Undergoing pleurectomy/decortication was 57 (74.0%) and severe postoperative complication (Clavien-Dindo classification grade 3 or more) was observed in 5 (6.5%).Univariate analysis revealed that PS0, age less than 70 years, blood loss less than 1465g, c-T1(ver.9) and Clavien-Dindo classification adverse effect grade < 3 were significantly associated with long-term survival. Multivariate analysis with regression analyses revealed that age < 70 years (p < .01, 95% CI 1.51-9.38, OR 3.76), Clavien-Dindo classification adverse effect grade < 3 (p < .001, 95%CI 2.27-18.04, OR 6.34), c-T1(ver.9) (p < .001, 95%CI 2.45-8.90, OR 4.67) and blood loss less than 1465g (p=0.04, 95%CI 1.03-3.76, OR 1.97) were significant predictive factors of long-term survival.

Conclusions: Younger age, uneventful peri and post operative course and c-T1(ver.9) were independent predictive factors of long-term survival in PM patient undergoing curative-intent surgery.

EP.14.06 Survival Analysis in Malignant Pleural Mesothelioma

H. Sürmeli
Kartal Dr. Lütfi Kirdar City Hospital, ISTANBUL/TR

Introduction: This study aims to evaluate the effect of surgical intervention, the type of surgery performed, and the administration of radiotherapy (RT) on overall survival (OS) among patients diagnosed with malignant pleural mesothelioma (MPM) between the years 2015 and 2025. Given the aggressive nature of MPM and the variation in treatment strategies, the analysis focuses on exploring survival outcomes in a real-world clinical setting.

Methods: This retrospective study included 44 patients with histologically confirmed MPM who were followed at a tertiary care center in Turkey between 2015 and 2025. Patient data were collected from hospital records, including demographic characteristics, performance status, treatment modalities (surgery, chemotherapy, radiotherapy), and clinical outcomes. Patients were categorized into subgroups based on whether they underwent surgery, received RT, and the type of surgery performed (pleurectomy/decortication [P/D] versus extrapleural pneumonectomy [EPP]). Survival time was measured from diagnosis until death or last follow-up. Kaplan-Meier survival curves were generated, and comparisons between groups were assessed using the log-rank test. A p-value of <0.05 was considered statistically significant.

Results: The median overall survival (OS) for all patients was 27.9 months (95% Confidence Interval [CI]: 16.8-39.1). Subgroup analysis revealed the following:• Operated vs. Inoperable Patients: Median OS was 20.4months versus 44.5 months, respectively (p = 0.202).• Type of Surgery: Patients undergoing P/D had a medianOS of 27.9 months compared to 20.4 months for thoseundergoing EPP (p = 0.468).• Radiotherapy: Median OS was 20.1 months for patientswho received RT versus 28.3 months for those who didnot receive RT (p = 0.461).

Conclusions: Although surgical intervention remains a key treatment modality in MPM, the study observed longer survival among non-operated patients. This unexpected finding is attributed to the non-operated group's timely and uninterrupted access to combined chemotherapy and immunotherapy regimens. Conversely, patients who underwent surgery experienced notable delays in receiving adjuvant treatments and faced irregular treatment courses, potentially compromising their clinical outcomes. These results highlight the critical importance of coordinated, multidisciplinary care and seamless transitions between treatment phases for optimizing survival in MPM patients.

EP.14.07 Applying Multi Criteria Decision Analysis in Health Care Decision Making in Egypt

A. Nagy[1], N. Ashoush[2]
[1]Ain Shams University, Cairo/EG ,[2]The British University in Egypt, Cairo/EG

Introduction: Multi Criteria Decision Analysis (MCDA) is an evidence based HTA methodology that has the capacity to assess simultaneously a set of criteria that meet the standards of MCDA process (i.e. Completeness, non-redundancy, and mutual independence) for choosing between the different drug alternatives.

Methods: An MCDA framework was developed using multiple chosen criteria for the evaluation of both pemetrexed and gemcitabine, using a numerical scoring system on a scale ranging from 1 to 3 for each criterion. A Delphi study was then used to discuss a final list of criteria with very clear definitions and a potential scoring scale. An appraisal group was formed and participants were invited to express their individual perspectives, by assigning weights to each criterion of the MCDA model. Participants then assigned individual performance scores for each medication. MCDA estimates of perceived value were then calculated by using a combination of normalized weights and scores.

Results: The present study has resulted in a preliminary rating tool for assessing mesothelioma management in Egypt. The tool is made up of 11 criteria covering context of medications, outcomes of drugs, economics and quality of evidence. The next step was determining the total aggregate score by using average weight and average score allocated to pemetrexed and gemcitabine on each of the decision criteria of the MCDA model. Pemetrexed got the highest total aggregate score (2.05) compared to gemcitabine (1.99).

Conclusions: Applying MCDA in the care of mesothelioma favours the use of pemetrexed rather than gemcitabine.

EP.14.08 Gender Difference as a Prognostic Factor in Non-Epithelioid Pleural Mesothelioma: Survival Analysis in the Retrospective SONET Study

C. Bertolina[1], L. Cerbone[1], M. Bertolotti[1], R. Mazzucco[2], S. Biasion[1], A. De Angelis[1], S. Delfanti[1], A. Maconi[1], F. Grosso[1]
[1]Azienda Ospedaliero-Universitaria SS. Antonio e Biagio e Cesare Arrigo, Alessandria/IT ,[2]Azienda Sanitaria Locale, Alessandria/IT

Introduction: Pleural mesothelioma (MP) is a rare, aggressive neoplasm with an unfavourable prognosis, the onset of which is a direct consequence, in about 80% of cases and after a long latency phase, of asbestos exposure. In Alessandria area, which was characterized in the past by the presence in Casale Monferrato of a large factory producing asbestos-cement products, the standardized incidence rates (per 100,000) of MP in the 2017-2021 period are 8.4 for women and 12.1 for men. MP is classified into three subtypes: the most frequent is the epithelioid, which is associated with better prognosis and survival, while the non-epithelioid subtypes (biphasic and sarcomatoid) have a very poor prognosis. While it is known that in patients with epithelioid MP women have better survival, less is known about the effect of gender in non-epithelioid MP. The aim of the study was to evaluate the effect of gender on survival in a cohort of patients with non-epithelioid MP who were diagnosed and treated at Alessandria University Hospital and Casale Monferrato Hospital.

Methods: A retrospective cohort study was conducted, including patients diagnosed with non-epithelioid MP between 2012 and 2020. Survival analysis was conducted using the Kaplan-Meier estimator. Hazard Ratios (HRs) and respective 95% confidence intervals (95% CIs), estimated by Cox regression model, were used to assess the effect of gender on survival, adjusting for other factors including age, histotype and treatment. In Cox models, the type of treatment was considered as a time-dependent variable.

Results: One-hundred seventeen patients were enrolled, 76% of whom were male, with a mean age of 71.5 ± 8.3 years; the biphasic histotype was the most frequently diagnosed (58%). The median overall survival time was 8.46 months (95% CI: 6.90-10.5). Log-rank test for the comparison of survival curves did not show a statistically significant difference between genders (p=0.21). Multivariate analysis confirmed the absence of a statistically significant difference in mortality between men and women, although female gender seemed to have a better survival (HR=0.94; 95% CI: 0.67-1.33). There was not a significant impact of gender on mortality neither in the group of patients with a sarcomatoid histotype nor in the one with a biphasic histotype. In the overall sample, the biphasic histotype was also found to have a better survival than the sarcomatoid one, but not statistically significant (HR=0.91; 95% CI: 0.67-1.24). Chemotherapies different from standard platinum-based and Pemetrexed are associated with a mortality decrease compared to standard chemotherapy, which was not statistically significant (HR=0.80; 95% CI: 0.50-1.30).

Conclusions: There is no evidence of a statistically significant difference on survival in non-epithelioid MPs between the genders, although the results obtained show an apparent protective effect on mortality in female gender. This relationship needs to be further explored by considering a larger sample in order to improve knowledge on these more aggressive forms of MP.

EP.14.09 Comparison Between Epithelioid Type and Biphasic Type in Pleurectomy/Decortication for Pleural Mesothelioma

K. Okabe, S. Suzuki, H. Komatsu
Bell Land General Hospital, Sakai/JP

Introduction: Immediately after the presentation of the Mesothelioma and Radical Surgery (MARS) 2 trial, it was met with harsh criticism based on a high 90-day mortality rate of 9% and a big number of serious complications after Pleurectomy/Decortication (P/D). It is said that the significance of the MARS 2 trial is that the median survival of 24.8 months in the chemotherapy-only arm is the only possible guideline for treatment. We report a comparison of the epithelioid type and biphasic type in P/D for patients with pleural mesothelioma for whom Extrapleural Pneumonectomy (EPP) is inappropriate due to past medical history, comorbidities, or advanced age.

Methods: Age, sex, affected side, operative time, blood loss, International Mesothelioma Interest Group (IMIG) pStage, and prognosis were compared in 34 cases of epithelioid type and 14 cases of biphasic type between May 2013 and February 2025. Survival analysis was performed using the Kaplan-Meier method with the Log Rank test.

Results: Median age was 72 years for epithelioid type and 68 years for biphasic type. The sex was 28 males and 6 females for epithelioid type and 14 males and 0 female for biphasic type. The affected side was 24 right and 10 left for epithelioid type and 13 right and 1 left for biphasic type. Median operative time was 8 hours 35 minutes for epithelioid type and 8 hours 43 minutes for biphasic type. Median bleeding volume was 1,655 ml in epithelioid type and 2,055 ml in biphasic type. IMIG pStage was: epithelioid type (IV+III 62%): IV 3, III 18, II 7, I 5, 6 cm in size localized type 1; biphasic type (IV+III 71%): IV 1, III 9,II 3,I 1. Epithelioid type: 2-year survival 58%, 5-year survival 16%, median survival 28 months. Biphasic type: 2-year survival 69%, 5-year survival 0%, median survival 27 months. The Kaplan-Meier survival curves (Figure) for epithelioid type and biphasic type overlapped and were not significantly different with a Log Rank test of p=0.615. 90-day mortality was 0% for both epithelioid and biphasic types, lower than the 9% in the MARS 2 trial.

Conclusions: Despite the majority of advanced cases, the median survival time for epithelioid type and biphasic type was 28 and 27 months, respectively, exceeding the median survival time of 24.8 months for the chemotherapy-only group in the MARS 2 trial. The survival curves for epithelioid type and biphasic type (Figure) overlapped, and there was no significant difference in prognosis.

EP.14.10 Role of CT Assessed in the Evaluation of Sarcopenia in Patient With Malignant Pleural Mesothelioma. Results From an Observational Study

M. Vitti[1], L. Cerbone[2], F. Boccuzzi[2], S. Delfanti[2], M. Giuseppe Antonio[3], I. Gallesio[2], F. Grosso[2]
[1]AOU ALESSANDRIA, Alessandria/IT ,[2]AOU ALESSANDRIA, AL/IT ,[3]ASL AL Ospedale Santo Spirito, Casale Monferrato/IT

Introduction: Sarcopenia is a condition characterized by skeletal muscle loss associated and it has been associated with poor clinical outcomes in oncology. Computed Tomography based assessment of sarcopenia is a non-invasive method leading to a quantitative assessment of muscle mass. The goal of this study is to explore the prognostic value of CT-assessed sarcopenia in a cohort of patients with Pleuric Mesothelioma .

Methods: 48 Patients underwent a CT scan as part of their oncologic evaluation. For each patient, total muscle area (TMA) was defined as the total area of muscle with density > 30 HU at L3 level . Sarcopenia was defined as a skeletal muscle index (SMI: TMA/Height^2) at L3 lower than 39 for female and lower than 52 for male. A survival analysis was performed using the Kaplan-Meier method.

Results: Patients were mostly male (38/48) with a median age of 72 years and a median BMI of 24. Mean TMA was 128,6 cm2 ±32.5 and mean SMI was 43,5 cm2/m2 ±9.4. 33 patients were sarcopenic. Median OS was 13 months in sarcopenic patients and wasn't reached in non-sarcopenic, but survival curves clearly separated. Median PFS was 6.4 (95%CI 2.9-22.7) months in non-sarcopenic and 6.5 months (95%CI 4.5-7.8) in sarcopenic patients. OS and PFS didn't statistically differ in patient treated with immunotherapy (p=0.8 and 0.4) or ChT (p=0.13 and 0.28).

Conclusions: Sarcopenic patient, especially those ChT treated, showed a tendency towards worse OS, though not statistically significative. Further investigation into the role of sarcopenia in PM patients in a wider prospective population is warranted.

Keywords: mesothelioma, sarcopenia, CT

EP.14.11 Comparison of Short Term Surgical Outcomes for Thymectomy With Various Minimally Invasive Approaches : A Single Center Exper

y. bae, I. Kim, J.K. Yun, S.I. Park, D.K. Kim, Y-H. Kim, H.R. Kim, S. Choi, G.D. Lee, J.Y. Kim
Asan Medical Center, Seoul/KR

Introduction: Minimally invasive thymectomy, including video-assisted thoracoscopic surgery (VATS) and robotic-assisted thoracic surgery (RATS), has gained popularity as an alternative to traditional sternotomy. However, limited studies have compared the short-term surgical outcomes of different minimally invasive approaches. This study aimed to compare the early surgical outcomes of three techniques: VATS lateral, RATS lateral, and RATS subxiphoid.

Methods: We retrospectively analyzed patients who underwent thymectomy with minimally invasive approach for anterior mediastinal mass between October 2020 and April 2024. Patients were categorized into three groups based on the surgical approach: VATS lateral, RATS lateral, and RATS subxiphoid. Baseline characteristics and perioperative outcomes were compared among the groups.

Results: A total of 292 patients were included in this study, of whom 70 (24.0%) with RATS lateral, 67 (22.9%) with RATS subxiphoid, and 155 (53.1%) with VATS lateral. Operation time was significantly longer in the RATS groups than in the VATS group (118.7 ± 42.4 min for RATS lateral, 116.7 ± 33.3 min for RATS subxiphoid, and 93.5 ± 30.2 min for VATS lateral; $P < 0.001$). No significant differences were observed in postoperative pain scores ($P = 0.154$), chest tube duration ($P = 0.165$), hospital stay ($P = 0.059$), or complication rates ($P = 0.424$) among the three groups. The rates of open conversion, R0 resection, and complications (Clavien-Dindo classification ≥ III) were comparable. No in-hospital mortality occurred in any group.

Conclusions: In this study, short-term surgical outcomes for thymectomy via three minimally invasive approaches were comparable and acceptable. These findings indicate that all three approaches are effective and adaptable options for thymectomy, enabling surgeons to select the most appropriate technique based on patient-specific factors and surgical expertise.

EP.14.12 Immune Profiles and Clinicopathological Insights in Thymomas: A Comprehensive Analysis

A. Sukla, A. Nambirajan, B. Thirunavukkarasu, S. Jain, D. Jain
AIIMS, New Delhi, New Delhi/IN

Introduction: Thymic epithelial tumors (TETs) are the most common neoplasms of the anterior mediastinum, with thymomas comprising the majority. The immune microenvironment of thymomas mirrors that of the normal thymus, varying by histological subtype. Active thymomas (AB, B1, and B2) are frequently associated with myasthenia gravis (MG), an autoimmune disorder. However, the functional significance of immune cell populations within thymomas and their prognostic implications remain unclear. This study aims to elucidate the immune landscape of thymomas, its relationship to clinicopathological factors, and potential implications for immunotherapy.

Methods: This retrospective-prospective study analyzed 55 resected thymoma cases (Type A, AB, B1, B2, B3) and 15 control thymuses from the archives of the Department of Pathology, AIIMS New Delhi. Clinical and histopathological parameters were evaluated. Immunohistochemistry was performed using 12 antibodies, with eight assessed via dual staining (DAB+ALP). Whole Slide Imaging (WSI) at 40x magnification was utilized for digital slide analysis. Three consistent regions (outer, middle, and inner) per IHC slide were selected for manual cell counting, annotated with designated color codes, and analyzed for cell density. Markers assessed included CD34, TdT, CD3, CD20, CD4, CD8, CD68, CD163, S100, FOXP3, and IDO1. PD-L1 expression was evaluated using tumor proportion scoring. The same methodology was applied to control samples.

Results: Thymomas exhibited distinct immune profiles based on histological subtype. Type AB, B1, and B2 thymomas displayed high-density immune infiltrates, predominantly immature lymphocytes, while Type A and B3 thymomas had lower immune cell density, enriched in mature lymphocytes. B1 thymomas showed a higher proportion of mature immune cells compared to B2 thymomas. Notably, AB, B1, and B2 thymomas demonstrated significantly higher TdT+, CD3+, double-positive, and CD4+ cell densities compared to Type A and B3 thymomas. PD-L1 expression increased with tumor grade, exhibiting diffuse expression in high-grade thymomas but showing no correlation with immune infiltrates or clinical outcomes. IDO1 expression was significantly higher in AB, B1, B2, and B3 thymomas compared to Type A but did not correlate with PD-L1 expression, stage, or prognosis. Thymoma-associated myasthenia gravis (TAMG) cases exhibited lower immune cell densities, except for FOXP3+ cells, though these differences were not statistically significant. In 15 control thymuses, cortical regions were enriched with immature immune cells, while medullary regions contained mature immune cells. Non-myasthenic controls had higher CD3+ and FOXP3+ cell densities, whereas myasthenic cases displayed more S100+ dendritic and IDO1+ cells. Significant differences in CD20+, double-positive lymphocytes, and IDO1+ cells were observed between thymomatous and non-thymomatous controls.

Conclusions: This study, utilizing double immunostaining and digital analysis, identified unique immunological profiles for each thymoma subtype in the Indian population. Type A thymomas resembled medullary thymus, whereas AB, B1, and B2 resembled cortical thymus. PD-L1 expression was predominantly observed in non-A subtypes and pT1b or higher-stage thymomas, indicating a potential role in immunotherapy response. IDO1 expression, absent in Type A, suggests a therapeutic target in other subtypes. Variations in immune infiltrates between TAMG and non-TAMG cases warrant further investigation for clinical implications.

EP.14.13 Utility of Visual Assessment of PET/CT for Differentiating Malignancy in Thymic Epithelial Tumors

M. Asami, M. Isaka, K. Matsushima, K. Hayasaka, T. Masuda, S. Katsumata, H. Kojima, H. Konno, N. Yokomakura, Y. Ohde
Shizuoka Cancer Center, Shizuoka/JP

Introduction: In thymic epithelial tumors, maximum standardized uptake values (SUVmax) derived from 18F-fluorodeoxyglucose(18F-FDG)PET/CT have been reported to correlate with WHO histological classification. However, since the SUVmax value varies depending on the imaging device, the reliability of quantitative evaluation is low. In contrast, the Deauville score is a five-point visual assessment scale widely used in hematologic malignancies for evaluating treatment response. It compares FDG uptake in lesions with that in the liver and mediastinum. Unlike SUVmax, the Deauville score enables consistent evaluation across multiple institutions. While the Deauville score has been reported to be useful for evaluating tumor malignancy in lung cancer, its relevance in thymic tumors remains unclear. This study investigated the relationship between the Deauville score and pathological findings in thymic epithelial tumors.

Methods: We retrospectively analyzed 126 patients with thymic epithelial tumors who underwent PET/CT and surgical resection at our institution between 2005 and 2024. To evaluate the association with the Deauville score, WHO histological classifications were categorized into the thymoma and thymic carcinoma groups. We also assessed the correlation between pathological staging using Masaoka classification and the Deauville score. Associations between variables were analyzed using Fisher's exact test.

Results: Among the 126 cases, 101 were thymomas, and 25 were thymic carcinomas. According to the Masaoka classification, 111 cases were stage I-II, and 15 were stage III-IV. There were 71 patients (56.3%) with the Deauville score ≤3 and 55 patients (43.7%) with a score ≥4. The proportion of thymic carcinoma was 2.82% in patients with Deauville scores ≤3 and 41.8% in those with scores ≥4 ($p<0.001$). The proportions of Masaoka classification III or higher were 2.82% and 24.5%, respectively ($p<0.001$). Deauville scores ≥4 were significantly more frequent in cases of thymic carcinoma and Masaoka stage III or higher.

Conclusions: In thymic epithelial tumors, the Deauville score of ≥4 was associated with thymic carcinoma and advanced Masaoka classification, suggesting its potential utility in evaluating tumor malignancy and invasiveness.

EP.14.14 Cyclophosphamide/Pegylated Liposomal Doxorubicin/Cisplatin as First-Line Treatment for Patients With Advanced Thymic Epithelial Tumors

Y. Liang[1], J. Mai[1,2], Y. Lin[1], H. Liu[1], B. Qiu[1], Q. Li[1], C. Huang[1,3], Q. Zou[1], L. Kang[1,4]
[1]Sun Yet-sen University Cancer Center, Guangzhou/CN ,[2]Jiangmen Central Hospital, Jiangmen/CN ,[3]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen/CN ,[4]Yuebei People's Hospital, Shantou University Medical College, Shaoguan/CN

Introduction: Thymic epithelial tumors (TETs) are rare tumors including thymoma and thymic carcinoma. Cyclophosphamide/Doxorubicin/Cisplatin (CAP) is the preferred first-line chemotherapy for thymoma and optional first-line chemotherapy regimen for thymic carcinoma. As a substitute for traditional doxorubicin, pegylated liposomal doxorubicin (PLD) has been widely recognized for its efficacy and safety in other malignancies. Due to the rarity of TETs, it is difficult to conduct prospective randomized controlled studies. We conducted this retrospective study to evaluate the activity and safety of Cyclophosphamide/Pegylated liposomal doxorubicin/Cisplatin (CDP) combination as the first-line treatment for patients with advanced TETs.

Methods: This study retrospectively analyzed a total of 57 patients with advanced TETs who received CDP regimen as first-line chemotherapy at Sun Yat-sen University Cancer Center from July 2013 to January 2024. Treatment consisted of intravenous cyclophosphamide (500 mg/m2 on day 1), PLD (30 mg/m2 on day 1) and cisplatin (50 mg/m2 divided into 3 days) every 3 weeks.

Results: Characteristics of the patients are shown in Table 1. A total of 57 patients were involved in this study, including 43 cases of thymoma and 14 cases of thymic carcinoma. As of the last follow-up, 43 patients with thymoma received a total of 177 cycles (median: 4, range: 2-6) , and 14 patients with thymic carcinoma received a total of 75 cycles (median: 5, range: 2-6) of the CDP regimen. Among 43 patients with thymoma, there were 0 CR, 17 PR(39.53%), 26 SD(60.47%) and 0 PD. The ORR was 39.53%, and DCR was 100%. At a median follow-up of 61 months, median PFS was 25 months [95%CI: 5.09-44.91 months], and median OS was 79 months [95%CI: 60.35-97.66 months]. Among 14 patients with thymic carcinoma, there were 0 CR, 9 PR(64.29%), 5 SD(35.71%), and 0 PD, The ORR was 64.29%, and DCR was 100%. At a median follow-up of 71 months, median PFS was 13 months [95%CI: 8.25-17.75 months], and median OS was 24 months (95%CI cannot be calculated). All patients were evaluated for toxicity. Twelve cases (21.05%) experienced grade 3/4 leukopenia, 3 cases (5.26%) experienced grade 3/4 anemia, 1 case (1.75%) experienced grade 3 thrombocytopenia, 1 case (1.75%) experienced grade 3 vomiting, and 1 case (1.75%) experienced grade 3 transaminase elevation. There was no treatment-related death.

Conclusions: This retrospective study demonstrated that the Cyclophosphamide/Pegylated liposomal doxorubicin/Cisplatin regimen exhibited both favorable efficacy and good tolerability as first-line treatment for patients with advanced thymic epithelial tumors.

EP.14.15 Patterns of Failure and Long-Term Outcomes in Patients With Thymoma Treated With Surgery and Radiation Therapy

O. Icht[1,2], I. Nardi-Agmon[3], P. Thavendiranathan[3], A. Agrawal[1,2], S. Keshavjee[4], J-M. Miro[5], G. Liu[5], J.B.C. Cho[1,2], A. Bezjak[1,2], A. Hope[1,2]
[1]Radiation Medicine Program, Princess Margaret Cancer Centre, University Health Network, Toronto/ON/CA ,[2]Department of Radiation Oncology, University of Toronto, Toronto/ON/CA ,[3]Department of Medicine, Division of Cardiology, Ted Rogers Program in Cardiotoxicity Prevention, Peter Munk Cardiac Center, Toronto General Hospital, University Health Network, University of Toronto, Toronto/ON/CA ,[4]Division of Thoracic Surgery, University of Toronto, Toronto General Hospital, Toronto/ON/CA ,[5]Department of Medical Oncology, Ontario Cancer Institute, Princess Margaret Cancer Centre, Toronto/ON/CA

Introduction: Thymic malignancies are rare tumors typically treated with surgical resection followed by postoperative radiation therapy (RT). While long-term outcomes are generally favorable, a subset of patients experience disease recurrence. This study aimed to characterize patterns of failure and identify clinicopathologic predictors of recurrence among patients treated with surgery and RT.

Methods: We conducted a retrospective cohort study of 175 consecutive patients with thymic malignancies treated with curative-intent surgery and RT between 2004-2024 at a single center. Collected data encompassed clinical characteristics, histopathology, treatment parameters, and imaging used to assess recurrence. Survival outcomes were estimated using the Kaplan-Meier method. Recurrence was defined radiographically, with location confirmed by imaging review. A univariate logistic regression model was used to assess predictors of recurrence.

Results: The cohort included patients with Masaoka stage I (4.7%), II (43%), III (33%), and IV (19.4%) disease. Histologic subtypes were type A/AB thymoma (19%), type B (60%), and thymic carcinoma (type C; 15%). Positive resection margins were present in one-third of cases. Most patients (75%) received adjuvant RT, while the remaining 25% were treated with neoadjuvant RT.

With a median follow-up of 9.7 years, the median overall survival (mOS) was not reached. The 5-, 10-, and 15-year OS rates were 92.4%, 78.8%, and 65.8%, respectively. Recurrence occurred in 62 patients (35%), with a median time to recurrence of 3.2 years. Among those with recurrence, mOS was 13.4 years; the 5-, 10-, and 15-year OS rates were 85.0%, 56.3%, and 43.6%, respectively. Recurrence was significantly associated with vessel invasion (OR 6, (2.3-15.6)), pleural invasion (OR 5.4, (CI: 2.7-10.9)), and pericardial invasion (OR 3.6, (1.8-7.3)). Positive surgical margins were also associated with recurrence (OR 2.2, (1.1-4.4)), while histologic subtype was not (OR 1.6, (0.7-3.9)). The most common site of recurrence was the pleura (76%), followed by mediastinal lymph nodes (6.5%), lung parenchyma (5%), and distant sites (5%). Only 5% of recurrences occurred within the radiation field (Image 1).

Conclusions: Patients with thymic malignancies treated with a curative intent surgery and RT demonstrate excellent long-term outcomes, with low rates of in-field recurrence. Most recurrences were pleural and occurred outside the radiation field, underscoring the effectiveness of current treatment approaches. Recurrence was associated with clinicopathologic features of local invasion rather than histologic subtype. While current RT strategies appear effective, further study is needed to define optimal management approaches for patients with high-risk invasive features.

EP.14 MESOTHELIOMA, THYMOMA, AND OTHER THORACIC TUMORS

EP.14.16 Clinical Characteristics, Surgical Risks, and Long-Term Prognosis of Good's Syndrome: A Retrospective Analysis of 108 Thymoma Cases

S. Otsuka, H. Shiiya, K. Ohtaka, A. Fujiwara-Kuroda, M. Aragaki, K.C. Hatanaka, Y. Matsuno, T. Kato
Hokkaido University Hospital, Sapporo/JP

Introduction: Good's Syndrome (GS) is a rare disorder involving thymoma and hypogammaglobulinemia, leading to a poorer prognosis due to severe infections. Complete tumor resection and appropriate management of infectious diseases have been reported to be essential for long-term survival. Advances in surgical procedure, particularly robotic-assisted thoracic surgery (RATS) and video-assisted thoracic surgery (VATS) can offer lower risks of perioperative infections and ensure complete tumor resection. However, there have been no reports on the association among surgical procedures for GS, complications, and long-term prognosis. Since 2007, we have performed thymectomies for seven patients with GS including three RATS cases. Based on data from all thymectomy cases, including those not associated with GS, we investigated peri- and postoperative outcomes, evaluating the role of surgical intervention for GS patients.

Methods: Data were retrospectively collected from patients who underwent curative surgery for thymoma at Hokkaido University Hospital between July 2007 and January 2024. Background characteristics of the patients, laboratory data, and data on surgery were collected from medical records. The pathological stage was evaluated according to both 8th and 9th editions of TNM classifications. Continuous variables were compared using the Mann-Whitney U test, and categorical data were compared with Fisher's exact test. Survival curves were estimated using the Kaplan-Meier method, and compared using the log-rank test.

Results: Out of the total 104 patients who underwent thymectomy, seven had GS. There were no significant differences in age (p=0.94), sex (p=0.07), and pathological stage (p=0.62 for TNM 8th, p=0.64 for TNM 9th) between non-GS and GS cases. All GS cases were diagnosed as type AB thymoma, whereas only 29% were type AB in non-GS group, indicating a significant difference in histological type (p=0.04). Among the patients with GS, two had median sternotomy (MS), two had VATS, and three had RATS. On the other hand, 31 underwent MS, 35 underwent VATS, and 31 underwent RATS in non-GS thymoma patients. When categorized by surgical procedure, although there was a significant bias in the number of cases, no tendency for greater blood loss or longer operation times, and no significant perioperative complications were observed in GS patients. However, no cases showed improvement in immunodeficiency, and five cases developed severe infections late postoperatively, including one patient with RATS. Two patients died with infectious disease. Furthermore, two GS cases developed extrathymic malignancies more than five years after surgery and subsequently died due to these cancers. While perioperative management could be safely achieved, the long-term risk of severe infections and developing extrathymic malignancies possibly remained. Additionally, three cases developed pure red cell aplasia one to two years following thymectomy. In survival analysis, GS patients had significantly worse prognosis (p=0.002).

Conclusions: The risk of surgery itself for GS patients is possibly not particularly high. However, regardless of the surgical procedures, even if perioperative management proceeds uneventful, there remains a risk of severe infections and development of new malignancies late postoperatively, resulting in a poor prognosis.

EP.14 MESOTHELIOMA, THYMOMA, AND OTHER THORACIC TUMORS

EP.14.17 Clinical Outcomes of Patients With Advanced Thymic Malignancies Treated With Carboplatin/Pemetrexed Vs. Pemetrexed Alone

L. Reed-Guy, B. Bleiberg, O. Elghawy, A. Barsouk, L. Sun, C. Langer, C. Aggarwal, R. Cohen, A. Singh, M. Marmarelis
University of Pennsylvania, Philadelphia/PA/USA

Introduction: Thymoma (T) and thymic carcinoma (TC) are rare malignancies with limited systemic treatment options. Pemetrexed (pem) is approved as a single agent for advanced and metastatic T and TC. In practice, pem is often given in combination with carboplatin (carbo), but the safety and efficacy of this combination has not been established in either T or TC.

Methods: We identified patients with a diagnosis of unresectable, recurrent, or metastatic T or TC who were treated with carbo/pem or pem alone at the University of Pennsylvania's Abramson Cancer Center from 2011-2024. Time to disease progression and objective response rate (ORR) were determined retrospectively using RECIST 1.1. Median progression-free survival (mPFS) and median overall survival (mOS) were estimated using Kaplan-Meier methodology and compared using the log-rank test.

Results: We identified 24 patients (n=14 T; n=10 TC). Overall, 8 patients were treated with carbo/pem and 16 with pem alone. Carbo/pem was most often used in the first-line setting for patients with T vs in later lines for patients with TC. For our total study population, mPFS was not reached (NR) with carbo/pem and 14.7m with pem (p=0.27). Among patients with T, mPFS was numerically improved with carbo/pem compared to pem (NR vs 15.6m, p=0.09). Among patients with TC, mPFS was 10.9m with carbo/pem vs 14.7m with pem alone (p=0.88). At a median follow up of 49.0m (37m for carbo/pem; 107m for pem), mOS was NR in any group. With carbo/pem, ORR was 1/8 (12.5%) with 1 partial response (PR) observed in a patient with T. With pem, ORR was 5/16 (31%) (3 PRs in T; 2 in TC). Stable disease (SD) was observed in 6/8 (75%) patients treated with carbo/pem (4 with T; 2 with TC) and in 8/16 (50%) treated with pem (6 with T; 2 with TC). The most common AEs in both groups were hematologic: 62.5% experienced hematologic toxicity of any grade with carbo/pem vs 43.8% with pem. 1 patient (12.5%) receiving carbo/pem experienced a grade 3 adverse event (AE) vs 3 patients (18.8%) receiving pem.

Conclusions: Carbo/pem was well tolerated and associated with promising PFS and OS compared to pem monotherapy, especially in patients with T. While more research is needed to determine which patients are likely to derive benefit from the addition of carbo to pem, this combination should be considered an option in the treatment of thymic malignancies.

Introduction: Myasthenia gravis (MG) associated with thymoma is a rare but serious autoimmune disorder that may arise after thymectomy, including in patients without preoperative symptoms. This study aims to explore the clinical, pathological, and therapeutic features of patients who developed MG following thymectomy.

Methods: A retrospective analysis was conducted across five national referral centers, involving patients who underwent thymectomy for thymoma. Data collected included demographics, ASA and ECOG status, TNM staging, histological subtype, surgical approach, MGFA classification, antibody status at MG onset, treatment modalities, and remission outcomes. MG-free survival was estimated using the Kaplan-Meier method.

Results: The study included 30 patients, predominantly male (60%), with a median age of 51 years at surgery. Most patients had mild systemic disease (ASA II, 43.3%) and good performance status (ECOG 0-1, 83.3%). The most common pathological stage was T1a (40%), followed by T1b and T3. Lymphadenectomy was performed in 83.3% of cases, all N0, with M0 status in 96.7%. The most frequent histological subtypes were B2 (33.3%), B1 (26.7%), and B3 (20%). Median tumor size was 6.5 cm (range: 1.0-11.5 cm). Surgical approaches included sternotomy (80%), thoracotomy (13.3%), and robotic techniques (6.7%). Median follow-up was 88.9 months (range: 6.0-294.8 months). MG developed at a median of 20.2 months after surgery (range: 1.5-197.9 months). MGFA classification showed class IIa in 23.3% and IIb in 16.7% of patients. Anti-AChR antibodies were positive in 56.7% at diagnosis. The most common treatment regimen included corticosteroids and acetylcholinesterase inhibitors. Complete remission was achieved in 13.3% of patients; the majority had persistent symptoms.

Conclusions: MG after thymectomy is an important postoperative complication with diverse clinical presentations. These findings emphasize the need for long-term follow-up and a multidisciplinary approach to management.

EP.14.19 A Single Institution Retrospective Analysis of Mediastinal Tumor Resections Utilizing Robotic-Assisted Surgery

Y. Ueda, J-i. Wakahara, S. Miyahara, Y. Masuda, H. Nakashima, T. Shiraishi, T. Sato
Fukuoka university, Fukuoka/JP

Introduction: Robotic-assisted thoracoscopic surgery (RATS) for mediastinal tumors has been covered by insurance in Japan since 2018 and is increasingly adopted as a standard practice. Our institution has three distinct robotic surgical systems: da Vinci™, Saroa™, and hinotori™. This study evaluates the feasibility and efficacy of robotic-assisted surgery, including emerging robotic platforms, for mediastinal tumor resections.

Methods: A retrospective analysis was conducted at our institution, examining patients who underwent mediastinal tumor resections utilizing the da Vinci™, Saroa™, and hinotori™ surgical systems from April 2019 to March 2025. Short-term outcomes were assessed, including intraoperative complications, operative duration, estimated blood loss, and overall feasibility and safety of robotic-assisted thoracic surgery for mediastinal tumors.

Results: Among 94 patients, robotic resections were performed using the da Vinci™ system in 85 cases, the Saroa™ system in 6 cases, and the hinotori™ system in 3 cases. Procedurally, 25 patients underwent tumor resection, while 69 underwent thymectomy. Histopathological analysis revealed 43 cases of thymoma, 31 cases of thymic cyst, 10 cases of neurogenic tumors, and additional cases of metastatic tumors, thymic hyperplasia, thymic carcinoma, and teratoma. Four patients required conversion to sternotomy due to vascular adhesions. Postoperative complications classified as Clavien-Dindo grade II or higher were not observed, except for two patients requiring intervention for arrhythmia and prolonged air leakage. No intraoperative adverse events were reported. There was no statistically significant difference in console time among the three robotic systems: 133.2 minutes for the da Vinci™, 167.5 minutes for the Saroa™, and 172.3 minutes for the hinotori™ ($p = 0.604$). Similarly, no significant differences were observed in postoperative hospital stay (6.74 days vs. 7 days vs. 5.3 days, $p = 0.412$), total operative time (208.7 minutes vs. 218.7 minutes vs. 327.7 minutes, $p = 0.474$), or intraoperative blood loss (43 mL vs. 14 mL vs. 13 mL, $p = 0.818$).

Conclusions: Our findings suggest that robotic-assisted mediastinal tumor resection is a safe and viable surgical approach. Further investigations are warranted to assess long-term oncological and functional outcomes.

EP.14.20 Whole-Exome Sequencing Study of Thymic Epithelial Tumors

Y. Zhang[1], W. Lian[1], L. Zhang[1], F. Wang[2], Y. Zhang[2], J. He[1], Y. Wang[1], W. Gao[1]
[1]The First Affiliated Hospital of Nanjing Medical University, Nanjing/CN ,[2]Nanjing Geneseeq Technology Inc, Nanjing/CN

Introduction: There is a lack of effective clinical treatment options for patients with unresectable metastatic and recurrent thymic epithelial tumors (TETs). Moreover, patients with TETs often have other comorbidities associated with various paraneoplastic syndromes, including autoimmune diseases, which severely affect their survival. Advances in whole-exome sequencing (WES) technology can help understand the mechanisms of TETs at the genetic level to explore the genetic alterations that play a key role in the pathogenesis of TETs, which could facilitate the reliable diagnosis and treatment of TETs.

Methods: From 2019 to 2024, 24 patients diagnosed to have TETs (18 patients with thymic carcinomas and 6 patients with thymomas) at the Jiangsu Province Hospital underwent WES.

Results: RHPN2 was the most mutated gene in TETs, with a mutation rate of 45.8% (n = 11), and TETs with RHPN2 mutation showed greater upregulation of the oncogenic pathways such as the Notch and WNT signaling pathways as well as a trend toward shorter survival of the patients. Twenty-one peak regions were detected in the focal copy number variation region (q-value < 0.15), which were associated with various tumors. Mutated genes in TETs were enriched in several classical tumor-associated pathways, including cAMP, Notch, PI3K-Akt, and WNT signaling pathway, as well as multiple hormone-associated pathways such as insulin secretion; Cushing syndrome; parathyroid hormone synthesis, secretion, and action; and thyroid hormone signaling pathway. Immune-related pathways, including cytokine receptors and cytokines, were also altered in patients with TETs.

Conclusions: This study indicated that RHPN2 could be a potentially valuable gene associated with the development of TETs. We also elucidated the possible key factors related to TETs development and high prevalence of paraneoplastic syndromes at multiple levels, including tumor-related signaling pathways, hormones, and cytokines. These findings could help further enhance the knowledge and research on TETs.

EP.14.21 Real-World Clinical Outcomes of Patients With Masaoka Stage Iv Thymic Carcinoma Treated With Carboplatin and Paclitaxel

M. Nakamura[1,2], K. Wakuda[1], S. Matsuda[1], T. Fujisaki[1], K. Miura[1], H. Kobayashi[1], R. Ko[1], A. Ono[1], H. Kenmotsu[1], T. Naito[1], H. Murakami[1], H. Nokihara[2], M. Hojo[2], T. Takahashi[1]
[1]Shizuoka Cancer Center, Shizuoka/JP ,[2]National Cancer for Global Health and Medicine, Tokyo/JP

Introduction: Thymic carcinoma is rare and there are few phase III trials in thymic carcinoma due to its rarity. The treatment of advanced thymic carcinoma is based on the results of phase II trials, and the carboplatin and paclitaxel (CP) regimen is widely used worldwide. Since there were few real-world data on advanced thymic carcinoma treated with CP, we evaluated the treatment efficacy and the subsequent course of CP for Masaoka stage IV patients.

Methods: We retrospectively identified 107 patients diagnosed with thymic carcinoma between September 2002 and August 2024 at Shizuoka Cancer Center. Thirteen patients with neuroendocrine tumor were excluded. Fifty-eight were Masaoka stage IV patients. Treatment efficacy was evaluated based on overall survival (OS) and progression-free survival (PFS).

Results: The treatment details of 58 patients with Masaoka stage IV were as follows; 3 patients underwent surgery, 4 received chemoradiotherapy, 7 received radiotherapy, 37 received chemotherapy, and 7 received best supportive care (BSC) alone. The time from diagnosis to death in the BSC alone group was 15.5 months (95%CI: 0.2 months-not reached (NR)). The CP regimen was administered in 30 patients (81%). Baseline characteristics in the CP group were as follows; median age was 64.5 years, 63.3% were male, 90.0% had performance status 0-1, 86.7% had squamous cell carcinoma, and 73.3% were Masaoka stage IVB. The median PFS and OS in the CP group were 5.8 months (95%CI: 4.8-8.3 months) and 28.2 months (95%CI: 22.3-63.5 months). Twenty-six patients had disease progression and 24 patients received chemotherapy. As second-line chemotherapy, lenvatinib was administered in 5 patients, amrubicin in 6, S-1 in 3, and other regimens in 10. The median PFS of lenvatinib, amrubicin, and S-1 group were 25.3 months (95%CI 3.3 months-NR), 6.4 months (95%CI: 6.2 months-NR), and 33.6 months (95%CI: 6.4 months-NR), respectively. There was no significant difference in PFS among those groups (p=0.20). The median OS of lenvatinib, amrubicin, and S-1 group were 26.3 months (95%CI: 5.9 months-NR), 18.3 months (95%CI: 12.0 months-NR), and NR (95%CI: 14.9 months-NR), respectively. There was no significant difference in OS among those groups (p=0.35).

Conclusions: This study demonstrated the CP regimen is relatively effective for Masaoka IV stage thymic carcinoma patients. Among the patients who relapsed after the CP regimen, a high proportion of the patients (92%) were able to proceed the subsequent chemotherapy.

Table: Clinical outcomes of patients with Masaoka stage IV thymic carcinoma

	The median PFS	The median OS *BSC group: the time from diagnosis to the death
First line chemotherapy Carboplatin+paclitaxel (N=30)	5.8 months (95%CI: 4.8-8.3 months)	28.2 months (95%CI: 22.3-63.5 months)
BSC (N=7)	—	15.5 months (95%CI: 0.2 months-NR)
Subsequent treatment after relapse		
Lenvatinib (N=5)	25.3 months (95%CI: 3.3 months-NR)	26.3 months (95%CI: 5.9 months-NR)
Amrubicin (N=6)	6.4 months (95%CI: 6.2 months-NR)	18.3 months (95%CI: 12.0 months-NR)
S-1 (N=3)	33.6 months (95%CI: 6.4 months-NR)	NR (95%CI: 14.9 months-NR)

EP.14.22 Intrathoracic Radiotherapy in the Treatment of Human Papillomavirus-Associated Head and Neck Squamous Cell Carcinoma Metastases

J. Ma, A. Shamseddine, Y. Yu, L. Chen, N. Riaz, S.M. McBride, D.Y. Gelblum, C.B. Simone 2nd, A.J. Wu, J.Y. Shin, R.M. Gewanter, Q. LaPlant, D. Billing, T.L. Chaunzwa, P. Iyengar, D.R. Gomez, N. Shaverdian, N.Y. Lee
Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: There is no clear consensus on optimal management of intrathoracic metastases from HPV-positive head and neck squamous cell carcinoma (HPV+ HNSCC). Furthermore, patients receive different systemic therapies, including immunotherapy, at the time of metastases. Given the diversity in treatment strategies and radiation therapy (RT) fractionation schemes and timing, we evaluated outcomes in this patient population.

Methods: This is a single-institution retrospective review of selected patients who received intrathoracic RT to gross disease from 2020-2024 for biopsy-proven parenchymal or lymph node metastases from HPV+ HNSCC. Univariable (UVA) and multivariable (MVA) logistic regression analyses were performed to identify predictors of in-field failure on both a patient level and lesion level.

Results: Patient and treatment characteristics are listed in Table 1. We identified 35 patients receiving 52 RT courses to intrathoracic metastases. The majority (31 patients; 89%) had no other sites of disease at the time of intrathoracic RT. In-field failure occurred in 6 cases (11.5%) with a median time of 42.4 months (IQR 27.2, 43.8) after RT, and 42 patients (81%) were alive at last follow-up.On UVA, patients with lung-only metastases had significantly lower odds of in-field failure (OR: 0.095, 95% CI: 0.01-0.64, p=0.015). Higher BED (≥100 Gy) trended toward lower in-field failure (OR: 0.26, 95% CI: 0.03-2.41, p=0.24). In MVA, lung-only disease (OR: 0.17, 95% CI: 0.02-1.55, p=0.12) was the only variable that remained associated with lower odds of failure, though not statistically significant. Of the 6 in-field failures, five of these lesions received a BED <100Gy. Of the 5 in-field failures with BED <100 Gy, 3 lesions were treated with 27Gy in 3 fractions, one with 45-60Gy in 15 fractions, and one with 30Gy in 5 fractions. The one in-field failure with BED ≥100 was treated with 50Gy in 5 fractions. No patient-level predictors (age, KPS), tumor size, RT dose, or systemic therapy within 3 months post-RT were significantly associated with in-field failure.

Conclusions: In this small retrospective cohort, in-field failure was infrequent and appeared less commonly among patients with lung-only metastases and those treated with higher BED. However, these trends did not reach statistical significance in MVA. These results warrant further prospective study in a larger, uniform cohort in order to guide thoracic treatment strategies for HPV+ metastatic HNSCC.

Patient Characteristic	N (%)
Male Sex	34 (94%)
Median Age	68 (IQR 60-79)
Median KPS	90 (IQR 80, 90)
Median Tumor Size	1.6 cm (IQR 1.0, 2.8)
RT Indication	
Oligometastatic	44 (85%)
Oligoprogressive	3 (6%)
Palliative	5 (10%)
Radiation Technique	
SBRT (27-50G y in 3-5 fractions)	36 (69%)
IMRT (45-60 Gy in 8-15 fractions)	11 (21%)

EP.14.23 Distinct Mechanical Responses in Psp Reveal AKT1 Mutation and Mechanical Tension Synergy in EMT

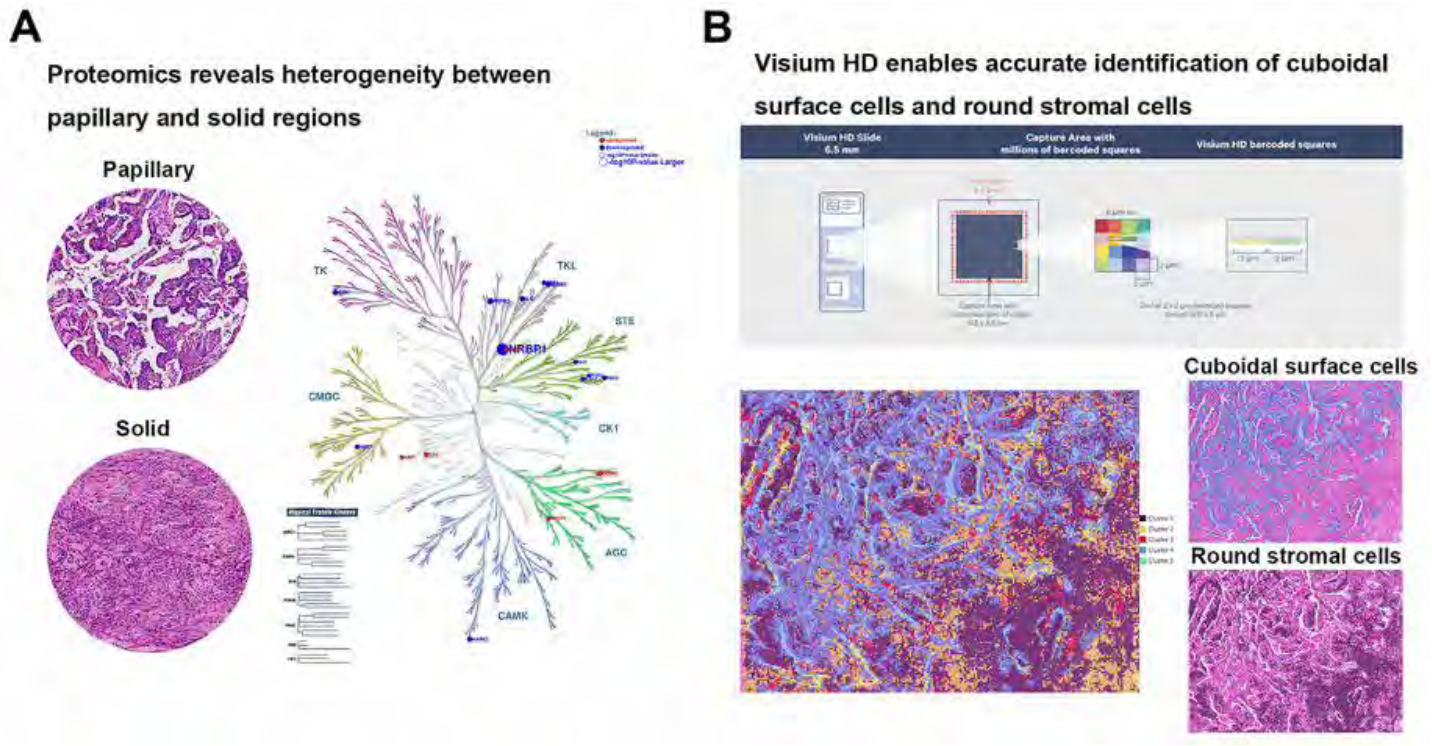
X. Qin, X. Liu, M. Li, R. Wang, X. Ai
shanghai pulmonary hospital, Shanghai/CN

Introduction: Pulmonary sclerosing pneumocytoma (PSP) is a benign lung tumor composed mainly of cuboidal surface cells (CSCs) and round stromal cells (RSCs). Despite its favorable prognosis, it may still metastasize to lymph nodes and distant sites. Studies have shown that PSP originates from primitive lung epithelium, and almost all patients carry AKT1 gene mutations. However, the mechanisms underlying PSP development and progression, particularly the characteristics and interactions between CSCs and RSCs, remain poorly understood.

Methods: In this study, formalin-fixed paraffin-embedded (FFPE) tumor and matched adjacent tissue samples from 31 PSP patients were collected, and the molecular characteristics of CSCs and RSCs were systematically analyzed using a combination of proteomic analysis and Visium HD spatial transcriptomics. We first observed significant differences between CSCs and RSCs in their responses to mechanical stimulation, a finding that led us to further investigate the biological significance of PSPs being commonly located in the lung periphery, where they may be exposed to high mechanical tension over time. To explore this, we constructed a Beas-2b cell line harboring the AKT1_E17K mutation and applied a cyclic stretch model to examine the effects of AKT1 mutation and mechanical tension on the PSP cell phenotype.

Results: Our study revealed distinct molecular characteristics of CSCs and RSCs, along with their differential responses to mechanical stimulation. Additionally, we found that the combination of AKT1 mutation and mechanical tension promoted the epithelial-mesenchymal transition (EMT) process in PSP cells, suggesting that this mechanism may play a key role in PSP progression and potential metastasis.

Conclusions: This study systematically analyzed PSP cellular heterogeneity for the first time and identified differences between CSCs and RSCs in their responses to mechanical stimulation. This observation prompted further investigation into the synergistic effects of mechanical tension and AKT1 mutation, ultimately revealing a potential mechanism for shaping the EMT phenotype in PSP. These findings not only deepen our understanding of PSP development and progression but also provide potential therapeutic implications for other lung tumors harboring AKT1 mutations.



Keywords: Pulmonary sclerosing pneumocytoma, Proteomic, Mechanical tension

EP.14 MESOTHELIOMA, THYMOMA, AND OTHER THORACIC TUMORS

EP.14.24 Report of Four Cases of Primary Pulmonary Sarcoma Experienced at Our Hospital

Y. Mishina[1,2], H. Arai[1], M. Toyoda[1], S. Nakamura[1], A. Saito[3]
[1]Kanagawa Cardiovascular and Respiratory Center, Yokohama city, Kanagawa Prefecture/JP ,[2]Yokohama city university medical center, Yokohama City, Kanagawa Prefecture/JP ,[3]Yokohama City University Hospital, Yokohama City, Kanagawa Prefecture/JP[1]

Introduction: Primary pulmonary sarcomas are very rare, accounting for about 0.5% of all primary lung malignancies, and are one of the most difficult to diagnose and treat and have a poor prognosis. The clinicopathological findings of each case are reviewed.

Methods: Over the past 26 years from 1999 to 2024, 2480 operations for lung malignancies were performed at our institution, of which 4 (0.16%) were for sarcoma. The clinicopathological findings of each case are reviewed.

Results: 1.Female(age29) with no history of smoking. She presented to her previous physician with complaints of left chest pain and bloody sputum. Chest CT scan revealed a nodular shadow on the mediastinal side of the left lower lobe and a left hematogenous pleural effusion. The patient was diagnosed as having a respiratory infection and treated with antibiotics. The nodule was subsequently reduced in size, and internal cavitation was observed. There was no elevation of tumor markers, and FDG accumulation was very slight (SUVmax=1.21) on PET-CT. The patient was followed up for about two years, and no malignant lesion was actively suspected, considering the above examination results and the fact that he was a young non-smoker. After repeated enlargement and shrinkage, he was referred to our hospital for diagnosis and treatment of malignant lesions. In addition to a nodule 30 mm in diameter, an increased pleural effusion (CT values: 30-50 HU) was observed. Intraoperative findings revealed a large amount of hematogenous pleural effusion and a tumor that had already self-destructed with persistent hemorrhage. The tumor was directly invasive to the lingual region, the left diaphragmatic nerve, and the pericardium. Rapid diagnosis suggested a non-epithelial malignant tumor, sarcoma. A left lower lobectomy was performed for hemostasis. The pathological diagnosis was synovial sarcoma, and although there was no metastasis in the accessory lymph nodes, the extension to the resection margin could not be evaluated. 2. Male(age65), SI=900, underwent total left pneumonectomy plus pulmonary angioplasty for a left hilar mass. Postoperative pathology revealed an intimal sarcoma in the main trunk of the left pulmonary artery. The patient died of tumor embolism the day after surgery. 3. Male(age55), SI=640, blood sputum, left upper lobe resection for left upper lobe lung mass.The postoperative pathological diagnosis was synovial sarcoma. The patient survived for more than 10 years after surgery. 4. Male(age65), SI=900, blood sputum, partial right lower lobe resection for right lower lobe lung mass.The pathological diagnosis was liposarcoma. Five months after surgery, local recurrence was found in the lower lobe of the right lung, and resection of the remaining right lower lobe was performed. The patient survived 7.5 years postoperatively without recurrence.

Conclusions: Pulmonary sarcoma is an extremely rare disease and has a low priority in differential diagnosis. It is also reported to be poorly sensitive to chemotherapy and radiation. In the present study, some patients achieved long-term survival after complete resection. Early detection of disease and awareness of differential diagnosis, including rare malignancies, are considered to be of utmost importance.

Keywords: Primary pulmonary sarcoma, Pulmonary sarcoma, Synovial sarcoma

EP.14 MESOTHELIOMA, THYMOMA, AND OTHER THORACIC TUMORS

EP.14.25 The Initial Outcome of Single Port Robotic Surgery for Mediastinal Tumors With 16 Cases

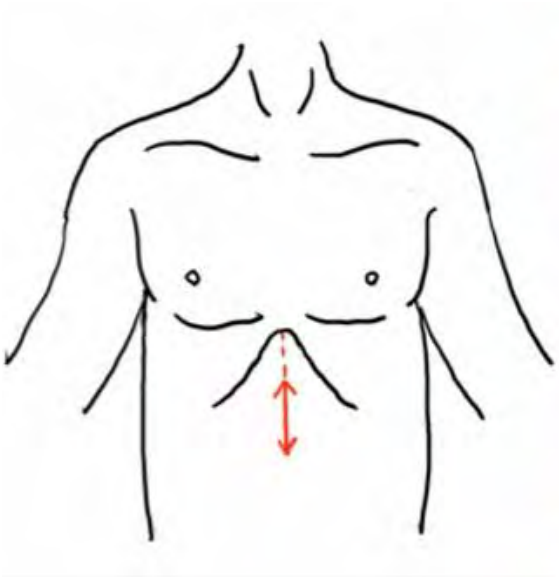
D. Ito, K. Kawaguchi, S. Kaneda, T. Kawaguchi, T. Kawaguchi
Mie University, Tsu/JP

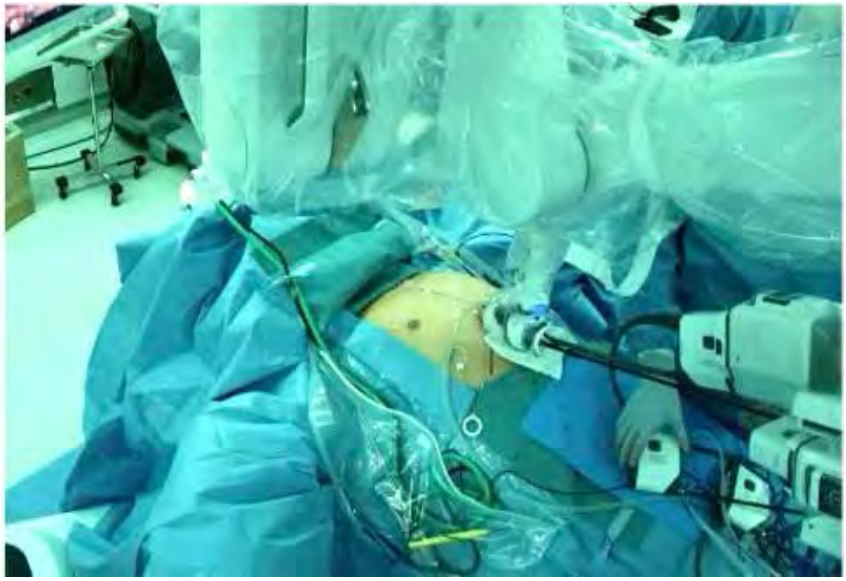
Introduction: Since February 2024, our institution has adopted the da Vinci SP® single-port robotic system for robot-assisted mediastinal tumor resection. This subxiphoid or subcostal approach demonstrates reduced invasiveness compared to conventional methods, potentially lowering postoperative pain and shortening hospital stays. The subxiphoid approach for anterior mediastinal tumors offers enhanced maneuverability over standard thoracoscopic techniques, warranting further evaluation of its safety and efficacy.

Methods: We analyzed perioperative outcomes of 16 consecutive patients undergoing SP robot-assisted mediastinal tumor resection (February 2024-March 2025). Lesion distribution included 14 anterior, 1 middle, and 1 posterior mediastinal tumors. Anterior tumors utilized a subxiphoid approach with a 3-cm midline incision 2 cm caudal to the xiphoid process. Other lesions employed a subcostal approach via a 3-cm incision along the costal margin at the 8th intercostal level. All procedures were performed through a single dedicated access port.

Results: The cohort (10 male, 6 female) had a median age of 58 years (range: 8-75). Median operative and console times were 120 minutes (85-246) and 84 minutes (48-212), respectively, with a mean blood loss of 10g. No perioperative complications occurred. Drain removal was achieved by postoperative day 1 in 15 cases and day 2 in 1 case. The median postoperative hospital stay was 5 days (5-8).Pathological examination revealed: thymoma (6 cases: 3 Masaoka stage I, 3 stage II; including 3 myasthenia gravis cases [1 MGFA class I, 2 class IIa]), thymic cysts (3 cases), neurogenic cyst (1 case), bronchogenic cyst (1 case), mature teratoma (1 case), cholesterol granuloma (1 case). All achieved R0 resection.

Conclusions: In this study, we performed mediastinal tumor resection using a single-port robotic system in 16 cases. Although the safety and efficacy of single-port robotic surgery have not yet been fully established, we were able to conduct these procedures safely at the current stage. Particularly for anterior mediastinal tumors, the approach facilitates surgery without connecting both pleural cavities, potentially reducing the risk of recurrence-related seeding and bilateral pneumothorax. Furthermore, da Vinci SP was indicated for an 8-year-old child with a posterior mediastinal tumor over 10 cm in size, and no intercostal dissection was needed. He was discharged 3 days after surgery and was able to run the same day. Da Vinci SP is also expected to make it a good indication for pediatric surgery. Accumulating further clinical cases will allow us to evaluate the effectiveness of this surgical method comprehensively.





Keywords: da Vinci SP, mediastinal tumor, single port

EP.14.26 Novel Bioengineered Drugs With Immunotherapies for Malignant Pleural Effusion

L. Chen, P. Zhan
Affiliated Hospital of Medical School, Nanjing University, Nanjing, China, Nanjing/CN

Introduction: Malignant pleural effusion (MPE), a hallmark of advanced cancers, portends poor survival due to its immunosuppressive tumor microenvironment (TME) and limited drug penetration. Conventional approaches (e.g., thoracentesis) palliate symptoms but fail to restore antitumor immunity or prolong survival. Emerging bioengineered platforms—integrating nanotechnology, gene editing, and immunotherapy—offer a paradigm shift by dual-targeting TME remodeling and immune activation. This review deciphers the molecular basis of MPE immunosuppression and evaluates novel bioengineering strategies (e.g., cytokine-loaded nanoparticles, oncolytic viruses) to overcome immune tolerance. We further discuss risks, clinical translation challenges, and future directions toward precision MPE therapy.

Methods: 1. Literature Search

Databases: PubMed, Web of Science, ClinicalTrials.gov, IEEE Xplore (2015-2024).

Keywords: “malignant pleural effusion” + (“bioengineering” OR “nanoparticle” OR “oncolytic virus”) + (“immunotherapy” OR “TME remodeling”).

Screening: PRISMA-guided selection (n=XXX studies; Fig 1).

2. Data Synthesis

Focus:

Bioengineering platforms: Nanoparticles (lipid/polymer), CRISPR-edited CAR-T, oncolytic viruses.

Immune metrics: Treg/MDSC suppression, IFN-γ/IL-12 levels, M1/M2 macrophage ratio.

Efficacy: MPE volume reduction, survival benefit.

Safety: Cytokine release syndrome, local fibrosis.

Quality Assessment: SYRCLE (preclinical), Cochrane Risk of Bias (clinical trials).

Results: 1. Bioengineering Strategies

Nanoparticles: pH-responsive carriers enhanced drug penetration (e.g., paclitaxel-loaded liposomes: 60% MPE reduction in murine models). Oncolytic Viruses: Local delivery of IL-12 boosted $CD8^+$ T-cell infiltration (3-fold vs. controls).Combinatorial Therapies: Anti-PD-1 + STING agonists doubled survival in preclinical trials.

2. Challenges

TME Barriers: Fibrosis reduced nanoparticle diffusion (efficacy dropped by 40% in high-collagen models).Safety: Grade 3 cytokine storms reported in 15% of early-phase trials.

3. Clinical Translation

Level 1 Evidence: Nanoparticle-albumin-bound paclitaxel + pembrolizumab (Phase II: 12-month survival in 55% MPE patients).Emerging Tools: AI-designed smart hydrogels enabled sustained cytokine release (preclinical validation).

Conclusions: Bioengineered immunotherapy synergizes TME reprogramming and immune reactivation, showing promise in MPE management. Key advances include nanoparticle-mediated targeted delivery and combinatorial regimens. However, clinical translation requires overcoming fibrosis barriers and cytokine toxicity. Future priorities:

Cross-disciplinary Innovation: Integrate AI, biomaterials, and immune profiling.Precision Biomarkers: Stratify patients for optimal bioengineering platform selection.

This paradigm may herald a new era of curative-intent MPE therapy.

EP.14 MESOTHELIOMA, THYMOMA, AND OTHER THORACIC TUMORS

EP.14.27 mTOr Inhibitor as Treatment Inpulmonary Epithelioid Hemangioendothelioma, a Case Series

R. Letelier Farias[1], C. Ibarra[2], F. Orlandi[2], M.P. Saavedra[2], L. Cisternas[2]
[1]Universidad Finis Terrae, Santiago/CL ,[2]Instituto Nacional del Torax, Santiago/CL

Introduction: Pulmonary epithelioid hemangioendothelioma (P-EHE) is an extremely rare vascular tumor originating from the endothelial cells of the lung. It often appears as multiple bilateral nodules, occasionally accompanied by pleural effusion, and can remain asymptomatic until advanced stages. Histologically, it is characterized by epithelioid cells positive for endothelial markers such as CD31, CD34, and ERG, commonly driven by the WWTR1-CAMTA1 fusion gene. Management strategies vary due to its low incidence and heterogeneous behavior. In some asymptomatic patients with indolent disease, watchful waiting is a viable option, whereas symptomatic or more aggressive cases may require systemic therapies like chemotherapy, immunotherapy, or antiangiogenic agents. Sirolimus has emerged as a potential additional treatment approach, exploiting its antiproliferative properties.

Methods: Three cases of patients from the National Thoracic Institute are presented. Their medical history and evaluation were collected in oncology committees over the last five years. The clinical presentation of patients and their treatments are characterized.

Results: First case: male patient, 21 years old, with back pain of two years of evolution. CT scans of the spine revealed multiple pulmonary nodules from 1-22 mm size. Suspecting disseminated tuberculosis, a biopsy of the lesion was performed, showing neoplasm CD34+, FL1+, VEGF- compatible with P-EHE. Staging show several bone metastasis. Began treatment with Pazopanib for two years. Sirolimus treatment was initiated due to poor tolerance and has successfully continued for 18 months, patient remaining asymptomatic thus far. Second case: female patient, 31 years old. Consulted for pain in the left hemithorax, but due to pregnancy, the imaging study was delayed. With persistence of symptoms, a complete study was completed 11 months after the onset of pain. CT scans showed a large mediastinal mass involving large vessels and the left bronchus, associated with adenopathic involvement and bone metastasis. The biopsy was CK AE1/AE3+, CD31+, FLI1+, confirming P-EHE. Receive mediastinal radiotherapy, followed by Carboplatin/Paclitaxel. She was referred to our center where Sirolimus was started, completing 30 months of treatment and remaining asymptomatic thus far. Third case: female patient, 80 years old, with progressive dyspnea associated with massive pleural effusion and cardiorespiratory arrest. After extubation and recovery from cardiac arrest, a pleura biopsy was taken via VTC. The biopsy showed D2-40+, CD31+, ERG+, GATA+. Reviewed in pathological anatomy, P-EHE was confirmed. She presented to the committee for the initiation of Sirolimus, however, the patient refused to start treatment.

Conclusions: The occurrence of only three cases in five years highlights the rarity of this tumor. The advanced stage at diagnosis and the symptoms resulting from its progression are consistent with previously reported cases. Treatment with chemotherapy or antiangiogenic therapies are the most described in case reports. Notably, our series demonstrates an excellent response and high tolerance to the administration of Sirolimus as a second-line treatment. Given the presentation in young patients in two of these three cases, this response facilitates the chronic management of this pathology with this drug. The question remains about how to proceed in the event of progression and observe the survival time of these patients.

EP.14.28 Three-Dimensional Reconstruction of the Sternum: A Novel Approach for Improved Surgical Outcomes

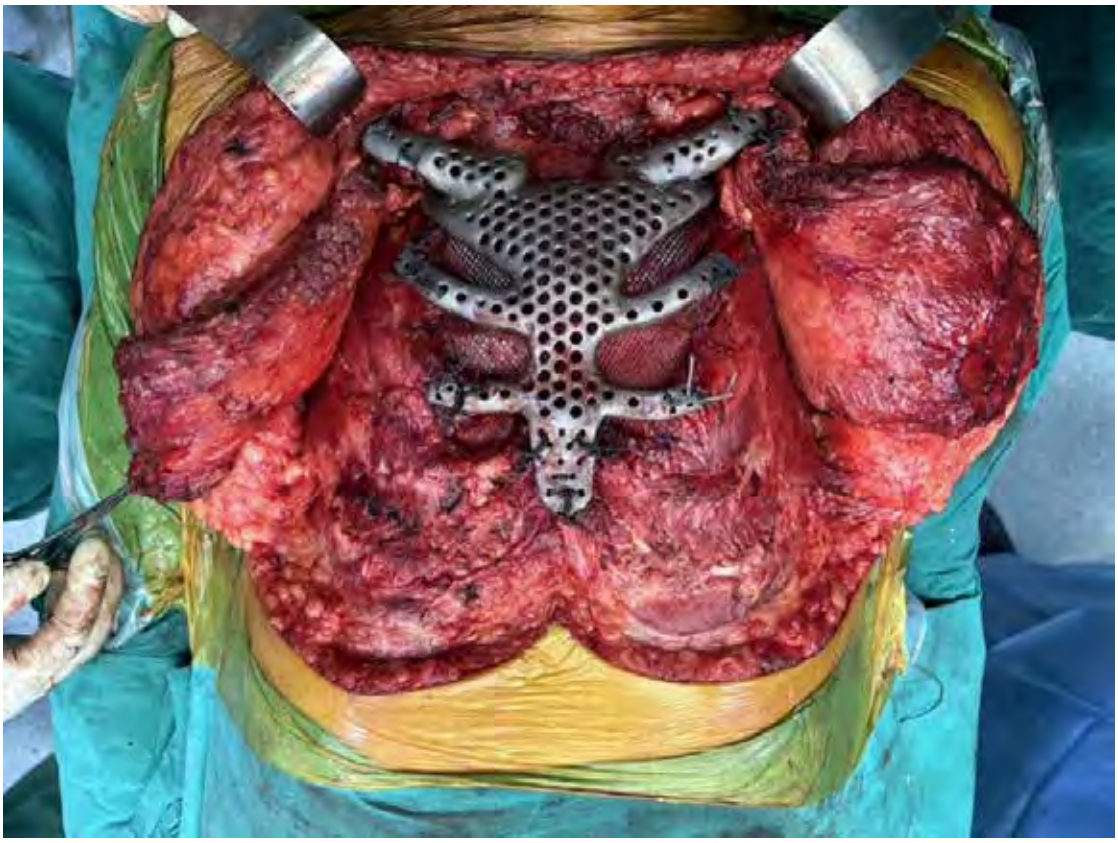
A. Jakhetiya, B. Jakhetiya, A.K. Yadav
Geetanjali medical college and hospital, Udaipur/IN

Introduction: The sternum plays a crucial role in chest stability and protection of vital organs. Sternal defects resulting from tumour resection pose significant challenges for reconstructive surgery. Traditional techniques using autologous tissue or synthetic materials have limitations in achieving optimal functional and aesthetic outcomes. Three-dimensional (3D) printing technology offers a promising solution for personalized sternal reconstruction. Here we present a case series of patients with complex sternal defects who underwent 3D-printed sternum reconstruction. We describe the preoperative planning process, surgical technique, and postoperative outcomes.

Methods: The records retrieved from a prospectively maintained database at our institute. A total of three patients were included that underwent curative surgical resection followed by reconstruction using 3D titanium implant between May 2022 and April 2024. All patients underwent preoperative contrast CT scan for preoperative planning and resection margins. Virtual 3D implant was created and after approval from operative team final customized 3D implant was prepared.

Results: The mean age was 44 years, two patients were male and one female. Two patients had chondrosarcoma and one had solitary plasmacytoma of sternum. All three underwent oncological resection with adequate margins. Customized titanium implant was used for all three. Mean duration of surgery was 240 minutes. Implant was covered with pectoralis major muscle in all cases. Mean duration of hospital stay was five days. One patient received post operative radiotherapy and tolerated well. No implant related complications observed and after median follow up of 15 months all three are alive and disease free.

Conclusions: Our results demonstrate that 3D-printed sternum reconstruction provides a customized, anatomically accurate solution with improved surgical precision and patient satisfaction compared to traditional methods. Further studies are warranted to evaluate long-term outcomes and cost-effectiveness of this innovative approach.



Keywords: Sternum, 3D reconstruction, Titanium implant

EP.14 MESOTHELIOMA, THYMOMA, AND OTHER THORACIC TUMORS

EP.14.29 A Case Study of Multiple Nodular Lesions in the Anterior Mediastinum Detected on Preoperative Imaging

k. Fujimoto, N. Kawakita, A. Baba, E. Takehara, T. Takeuchi, S. Sakamoto, N. Miyamoto, H. Sumitomo, A. Morishita, H. Toba, H. Takizawa
Tokushima University Graduate School of Biomedical Sciences, Tokushima/JP

Introduction: Multiple nodular lesions in the anterior mediastinum, either solid or cystic, are occasionally encountered on CT or MRI. We retrospectively reviewed the clinicopathological features of surgical cases with such findings identified on preoperative imaging.

Methods: Among 143 patients who underwent surgical resection for anterior mediastinal tumors at our institution between 2011 and 2023, 7 cases with multiple solid and/or cystic nodular lesions in the anterior mediastinum on preoperative imaging were included in this study.

Results: The median age was 56 years (range, 50-64), and the cohort consisted of 1 male and 6 females. CT and MRI findings were reviewed in collaboration with radiologists, and lesions were categorized as cystic type (2 cases), mixed type (3 cases), and solid type (2 cases), depending on their radiologic appearance.Six patients had underlying autoimmune diseases, including Sjögren's syndrome (n=4), rheumatoid arthritis (n=1), and systemic sclerosis (n=1). Bronchial asthma was observed in 3 patients, and one patient had a history of parotid MALT lymphoma.Surgical procedures included extended thymectomy in 5 cases and thymic and perithymic fat resection in 2 cases. Histopathological diagnoses were multilocular thymic cyst (MTC) with MALT lymphoma in 4 cases and MTC with follicular hyperplasia (FH) in 3 cases. One patient with MTC and FH experienced regrowth of residual lesions and underwent reoperation approximately 3 years and 2 months after the initial surgery. As of the most recent follow-up, which was more than 4 years after the reoperation, the patient remains recurrence-free. All four patients diagnosed with MTC and MALT lymphoma showed no recurrence during long-term postoperative follow-up. Postoperative adjuvant therapy with rituximab monotherapy was administered in one case of MALT lymphoma.

Conclusions: All patients with multiple anterior mediastinal nodules—regardless of whether they appeared cystic or solid—were pathologically diagnosed with MTC and further classified as either MALT lymphoma or FH. Notably, all cases associated with Sjögren's syndrome were diagnosed with MTC and MALT lymphoma, indicating a potential relationship.In one patient with FH, recurrence occurred even though extended thymectomy was performed as the initial surgery. The residual lesion likely remained due to anatomical constraints related to the patient's body habitus. MTC was also identified in the tissue removed during the reoperation.This case suggests that complete resection may be important to prevent recurrence when MTC is suspected. Accordingly, extended thymectomy may be a reasonable surgical option in such cases to reduce the risk of residual disease.Although differentiation between MTC, cystic thymoma, and other anterior mediastinal tumors was difficult based on preoperative CT and MRI, surgical resection provided both diagnostic and therapeutic value and was considered an appropriate approach.

EP.14.30 Clinicopathological Features and Diagnostic Challenges of Pulmonary Lymphoma: A Retrospective Review of 21 Cases

T-J. Kim
The Catholic University of Korea, Seoul/KR

Introduction: Pulmonary involvement of lymphoma can manifest in various clinical contexts, including primary pulmonary lymphoma (PPL), relapse of previously treated lymphoma, or secondary involvement from systemic lymphoma. Given the rarity and nonspecific presentation of lymphoma in the lung, accurate diagnosis is often delayed. This study aims to review cases of lymphoma diagnosed in the lung and to analyze the clinicopathological features, diagnostic approaches, and differential diagnoses, with particular emphasis on cases of PPL.

Methods: A retrospective analysis was conducted on 21 cases in which lymphoma was diagnosed in the lung at Yeouido St. Mary's Hospital, The Catholic University of Korea, between 2019 and 2025. Of these, 15 cases were classified as primary pulmonary lymphoma (PPL), while 4 cases represented relapsed lymphoma involving the lung, and 2 cases were systemic lymphomas with secondary pulmonary infiltration. Among the PPL cases, histologic subtypes included mucosa-associated lymphoid tissue (MALT) lymphoma (n=10), extranodal NK/T-cell lymphoma (n=1), classic Hodgkin lymphoma (n=1), follicular lymphoma (n=1), plasmablastic lymphoma (n=1), and T-cell/histiocyte-rich large B-cell lymphoma (n=1). The diagnoses were established via wedge resection (n=9), segmentectomy (n=2), lobectomy (n=1), and biopsy (n=3).

Results: Radiologic findings in cases of relapse or systemic involvement were often suggestive of lymphoma. In contrast, primary pulmonary lymphomas frequently mimicked benign or other malignant conditions. Among PPL cases, initial clinical or radiologic impressions included organizing pneumonia (n=6), differential diagnoses between sarcoidosis and lymphoma (n=2), suspicion of lymphoma (n=4), IgG4-related disease (n=1), and adenocarcinoma in situ (n=1). MALT lymphoma cases showed favorable outcomes, with 90% of patients achieving and maintaining complete remission following chemotherapy (mean follow-up: 34 months). In contrast, other PPL subtypes showed a more aggressive course with progressive disease.

Conclusions: Lymphomas involving the lung encompass a heterogeneous group of diseases, with primary pulmonary lymphoma being particularly prone to misdiagnosis due to nonspecific imaging and clinical features. Careful correlation of clinical, radiologic, and pathologic data is essential. When imaging findings do not align with the clinical picture or expected response to treatment, timely and adequate tissue sampling should be pursued to ensure accurate diagnosis, especially given the prognostic differences between MALT and non-MALT PPL subtypes.

Keywords: Lymphoma, Lung, MALT lymphoma

EP.14 MESOTHELIOMA, THYMOMA, AND OTHER THORACIC TUMORS

EP.14.31 Incidence Trends and Survival Outcomes of Pulmonary Langerhans Cell Histiocytosis: A National Cancer Study Using SEER

J. Arunachalam[1], B. Carpo[2], J. Arunachalam[3], K. Gunturu[4]
[1]University of Connecticut, Farmington/CT/USA ,[2]University of Connecticut Health Center, Farmington/CT/USA ,[3]Royal Shrewsbury Hospital, Shrewsbury/GB ,[4]UConn Health: Neag Comprehensive Cancer Center, Farmington/CT/USA

Introduction: Pulmonary Langerhans cell histiocytosis (PLCH) is a rare, smoking-related neoplastic lung disease arising from clonal proliferation of dendritic cells. Initially considered a reactive disorder, the discovery of recurrent BRAF V600E mutations has led to its reclassification as a neoplasm. PLCH typically presents with nonspecific respiratory symptoms or may be incidentally detected on imaging. Diagnosis is based on high-resolution computed tomography, with histologic confirmation via biopsy. Smoking cessation remains the cornerstone of treatment, although glucocorticoids and BRAF-targeted therapies are used in selected cases. This study aims to characterize the incidence trends and survival outcomes of PLCH using a large population-based dataset in the U.S.

Methods: We performed a retrospective analysis using SEER (Surveillance, Epidemiology, and End Results) Research Plus (17 registries, 2010-2021). Patients with histologically confirmed Langerhans cell histiocytosis (ICD code 9751/3) with a primary site in the lung (C34) were included. Demographic and clinical data collected included age at diagnosis, sex, race/ethnicity, stage at presentation, treatment modality, and county of residence (metropolitan vs. non-metropolitan). Incidence rates (IRs) per 100,000 were calculated using SEER*Stat and age-adjusted to the 2000 U.S. standard population. Kaplan-Meier survival analysis was performed using GraphPad Prism to evaluate overall survival (OS) and cancer-specific survival (CSS).

Results: A total of 253 patients with PLCH were identified. The cohort was 57% female and 43% male, with 73% White, 15% Black, 6% Hispanic, 3.5% Asian/Pacific Islander, and 1% American Indian/Alaska Native. At diagnosis, 73% had localized disease and 20% presented with metastases. The overall age-adjusted IR was 0.0132 per 100,000, with the highest annual IR observed in 2016 (0.0493), followed by a decline. Females had a 33% higher IR than males (0.01509 vs. 0.01138; $p = 0.028$). While Black patients had a higher incidence (0.0190) compared to White patients (0.0160), the difference was not statistically significant ($p = 0.37$). The highest IR was observed in the 55-59 age group (IR = 0.03840), which was significantly higher than in the 40-44 (IR = 0.01419; $p = 0.0004$) and 35-39 (IR = 0.01261; $p = 0.0001$) groups, though not significantly different from those aged 45-54. Nonmetropolitan counties had a significantly higher IR (0.02507) compared to metropolitan counties (0.01185; $p = 0.0004$). The 5- and 10-year OS rates were 84.38% and 60.08%, respectively, while CSS rates were 96.25% and 93.39%. Adults aged ≥60 years had a significantly shorter median OS (mOS) of 81 months compared to younger patients ($p < 0.0001$; HR 4.19, 95% CI 2.20-7.99).

Conclusions: PLCH is an extremely rare pulmonary neoplasm with excellent cancer-specific survival but modest overall outcomes, likely reflecting comorbidities or delayed diagnosis. Incidence was highest in females, adults aged 55-59, and residents of nonmetropolitan areas, suggesting demographic and geographic disparities. These findings highlight the importance of early diagnosis and smoking cessation. The potential for disease stabilization or regression following smoking cessation differentiates PLCH from other lung neoplasms and underscores the need for timely recognition and intervention. Further investigation is warranted into the molecular framework and development of targeted therapies for this rare disease.

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.01 Anorexia, an Underreported Adverse Event, Predicts Mortality in Lung Cancer Patients

A.B. Barreto[1], I. Borchardt[1], J. Lattanzi[1], G. Farias[1], G. Fraga[1], B. Sodré[1], F. Dias[1], F. Telles[1], T. Montella[1], A.C. Melo[1], C.G.M. Ferreira[1]
[1]Grupo Oncoclínicas, Rio de Janeiro/BR

Introduction: Lung cancer (LC) is often diagnosed at advanced stage. Anorexia, an underreported condition, is defined by loss of appetite, a phenotypic characteristic of cachexia, a common condition in advanced disease that affects clinical outcomes. Anorexia is graded according to changes in eating habits and weight loss following the Common Terminology Criteria for Adverse Events (CTCAE). This study aimed to assess whether the occurrence of anorexia predicts mortality in LC patients.

Methods: This is a prospective study of LC patients treated between May 2023 and December 2024 at an oncology center in Rio de Janeiro, Brazil. Clinical and demographic characteristics, and the Patient Self-Generated Global Assessment (PG-SGA) were collected to identify patients who reported anorexia on first nutritional assessment, recommended within 60 days. The chi-square test (χ^2) was used to compare categorical variables and the student's t-test for continuous variables. Overall survival was estimated using the Kaplan-Meier method and compared between groups using the Log-Rank test.

Results: A total of 134 patients with LC were included, and 49% had the first nutritional appointment before the start of treatment and 30% within 60 days after. The sample total was made up of 58% females, 90% older than 60 years, 76% advanced stage, eutrophic BMI (26 ± 4,5kg/m with a predominant treatment modality of chemotherapy combined with immunotherapy (30%), chemotherapy (25%) and targeted therapy (22%). The anorexic group (32%) was older (74.6 ± 8.7 years, p=0.03), 91% had advanced stage (n=39, p=0,041), eutrophic, but with a lower BMI (24.8 ± 3.5 kg/m, p=0.008), with a greater weight loss in the last 6 months 7.6 ± 7.7% (p<0.00), an indicator of anorexia severity, and a higher nutritional risk (PG-SGA: 12.7 ± 5.1, p=0.00). Overall survival was clinically significantly lower in the anorexia group (23.7 vs. 45.2 months, p=0.002)(Figure 1).

Conclusions: The occurrence of anorexia at the first visit was associated with lower survival, reinforcing the importance of early anorexia screening and nutritional interventions to improve clinical outcomes of advanced LC.

Anorexia	N Patients	Median Overall Survival (95% CI)
No	91	42.5 (37.7-47.2)
Yes	43	23.7 (19.8-27.5)

EP.15.02 Therapeutic Efficacy of Traditional Chinese Medicine Heat Patch Therapy for People With Lung Cancer

Y-N. Chang
Shanghai Yaning Chinese Medicine Clinic, Shanghai/CN

Introduction: Lung cancer remains a leading cause of cancer-related mortality worldwide, with complex pathogenesis involving environmental, genetic, and molecular interactions. While modern medicine focuses on targeting specific mutations (EGFR, KRAS) and signaling pathways (PI3K/AKT/mTOR), Traditional Chinese Medicine (TCM) conceptualizes lung cancer as "lung accumulation," characterized by deficiency in origin and excess in manifestation. Heat patch therapy, an external TCM treatment, combines warming properties with acupoint stimulation to regulate the tumor microenvironment through local thermal effects and transdermal drug delivery. This study investigates the antitumor effects, immunomodulatory functions, and clinical applications of heat patch therapy in the management of lung cancer.

Methods: This randomized controlled trial enrolled 60 people with stage III-IV non-small cell lung cancer, randomly assigned to either the heat patch group (n=30) or control group (n=30). Inclusion criteria included pathological diagnosis and TCM pattern differentiation of "phlegm-dampness accumulating in the lung" or "yang deficiency with cold coagulation." The treatment group received daily application of medicinal patches on acupoints BL13 (Feishu), CV17 (Shanzhong), and BL43 (Gaohuang) for eight weeks, in addition to conventional chemotherapy. The herbal composition included Cinnamomi Ramulus (15g), Sinapis Albae Semen (12g), Curcumae Rhizoma (10g), and Astragali Radix (20g). Evaluation metrics included tumor response (RECIST 1.1 criteria), serum biomarkers (CEA, PD-L1), T-cell subsets, TCM symptom scores, and safety parameters.

Results: The heat patch group demonstrated significantly higher objective response rate (36.7%) compared to the control group (30.0%, $p<0.05$). In vitro experiments revealed that herbal extracts inhibited A549 lung cancer cell proliferation (IC50=32μg/mL) and downregulated PI3K/AKT pathway phosphorylation. Immunologically, the treatment group showed improved CD4+/CD8+ ratio (from 1.5 to 1.8, $p<0.01$), 18% reduction in serum PD-L1 levels, and 25% decrease in tumor lactate concentration, suggesting reversal of the Warburg effect. Clinically, cough and shortness of breath scores decreased by 40% and 35% respectively in the treatment group ($p<0.01$), with Karnofsky Performance Status improving by 15 points and chemotherapy-related nausea reduced by 50%. Only three participants developed mild skin rash, with no hepatorenal abnormalities observed.

Conclusions: TCM heat patch therapy achieves integrated therapeutic effects through a triple mechanism of "medicinal-acupoint-thermal" action, demonstrating both local tumor-suppressing and systemic regulatory functions. This approach not only inhibits tumor proliferation and angiogenesis but also modulates the immune-metabolic microenvironment and reverses T-cell exhaustion. Clinical data confirms improved tolerance to chemoradiotherapy and significant amelioration of cancer-related fatigue and respiratory distress. This study establishes an evidence-based foundation for incorporating external TCM therapies into multidisciplinary lung cancer management, highlighting the unique value of integrating disease and pattern differentiation in precision medicine.

Keywords: Heat Patch Therapy, Traditional Chinese Medicine, Tumor Microenvironment

EP.15.03 Why Are Patients With Non-Small Cell Lung Cancer in Stage I-IIIA Considered Inoperable? A Registry Study From Denmark

T. Budolfsen[1], R.H. Petersen[1], L.B. Møller[2], J. Brabrand[1], Z. Saghir[3], M. Quist[1]
[1]Rigshospitalet, Copenhagen/DK ,[2]Department of Cardiothoracic Surgery, Aalborg/DK ,[3]Department of Medicine, Section of Pulmonary Medicine, Herlev-Gentofte Hospital, Hellerup/DK

Introduction: : Surgical resection is the first-line treatment for patients with stage I-IIIA non-small cell lung cancer (NSCLC) when feasible, offering the best chance for long-term survival. However, a significant proportion of patients are deemed inoperable despite technically resectable tumors. The decision to withhold surgery is influenced by multiple factors, including tumor burden, mediastinal lymph node involvement, and patient-specific factors, necessitating a multidisciplinary team (MDT) evaluation to determine the most appropriate strategy.

Methods: This retrospective registry-based cohort study included patients diagnosed with NSCLC in stage I-IIIA in the Capital Region of Denmark between January and December 2022. Patients were stratified into "Surgery" and "No Surgery" groups based on treatment records. Data on demographic variables, comorbidities, pulmonary function, performance status, and MDT decisions were extracted from the Danish Lung Cancer Registry and medical records. Logistic regression analyses identified predictors of non-surgical management. The one-year overall survival (OS) rate was estimated using the Kaplan-Meier method. Additionally, preoperative exercise testing was documented.

Results: Among 524 patients with NSCLC in stage I-IIIA, 178 (34%) did not undergo surgery. Advanced age (≥ 80 years, OR 1.298), poor performance status (ECOG-PS ≥ 2, OR 1.443), comorbidities (OR 1.116), and stage IIIA disease (OR 1.181) were significantly associated with non-surgical management. The primary reasons for non-operative management in MDT decisions were low pulmonary function or poor performance status (29.2%) and comorbidities (18.0%). Notably, in 19.7% of cases, no justification for "No Surgery" was recorded. Furthermore, preoperative exercise testing was not documented for any patient. One-year OS was 95.7% in the "Surgery" group versus 82.0% in the "No Surgery" group.

Conclusions: The findings of this study align with previous research, indicating that patients with stage I-IIIA NSCLC are often deemed inoperable due to comorbidities, poor performance status, or advanced age. A novel insight from this study is its documentation of the rationale for non-operative treatment, as recorded in the MDT decision-making process. Additionally, our findings indicate that exercise testing is not utilized in the assessment process, despite being recommended in current guidelines. The study also suggests a difference in overall survival between operative and non-operative treatment; however, these results should be interpreted with caution due to study limitations. Further research is needed to explore the underlying reasons for treatment decisions. Moreover, future studies could examine whether the implementation of exercise testing, as recommended, may improve the assessment of patients with lung cancer and their surgical eligibility.

EP.15.04 Lung Function Before and After Development of Checkpoint Inhibitor Pneumonitis: Insights for Risk Assessment and Recovery

S. Shivakumar[1,2,3,4], N. Vukelic[4], F. Atashrazm[4], V. Naranbhai[5], S. Parakh[1,4], J. Da Gama Duarte[4,5], N. Goh[1,2,3], T. Leong[1,2,3,4]
[1]Austin health, Melbourne/AU ,[2]University of Melbourne, Melbourne/AU ,[3]Institute for Breathing and Sleep, Melbourne/AU ,[4]Olivia Newton John Cancer Research Institute, Melbourne/AU ,[5]Monash University, Melbourne/AU

Introduction: Checkpoint inhibitor pneumonitis (CIP) presents with highly heterogenous clinical manifestations and disease trajectories, with severe cases linked to increased morbidity and mortality. Lung function testing offers a non-invasive approach to assessing the risk of CIP-related complications and potential long-term respiratory sequelae. This study investigates the relationship between lung function parameters before and after CIP diagnosis to determine their predictive and prognostic value.

Methods: A retrospective analysis was conducted of patients who received immune checkpoint inhibitors (ICIs) between 2015 and 2024 at Austin Health, Melbourne. Patients diagnosed with CIP were identified alongside a comparator cohort without CIP. Those with available pre-diagnosis lung function testing were included in the final analysis. Lung function parameters, including spirometry and diffusion capacity, were assessed in relation to CIP severity. Post-diagnosis lung function was analysed to evaluate recovery following CIP treatment.

Results: A total of 46 patients were included (21 CIP cases, 25 non-CIP cases), with a mean age of 75 years (95% CI: 69-74) and a predominance of males (n=25). Most patients had an Easter Cooperative Oncology Group (ECOG) performance status of 1 (n=30, 65.2%) prior to developing CIP. Among CIP cases, 11 patients (23.9%) developed grade 2 pneumonitis, while 6 (13%) and 4 (8.7%) developed grades 3 and 4, respectively. No significant difference in baseline lung function or diffusion capacity were observed between CIP and non-CIP cohorts. Regression modelling indicated that abnormal diffusion capacity (β = -3.273 95%CI: -5.951,-0.594; p=0.017) and ECOG performance status (ECOG 1 β= -3.625 95%CI: -6.146,-1.104); p=0.005) were predictive of increased severity of CIP. In a subset of patients with post-diagnosis lung function assessments (n=7), a significant decline in Forced Expiratory Volume in one second (FEV1) % predicted and diffusing capacity of the lungs for carbon monoxide (DLCO)% predicted was observed within the first 18 months (Figure 1).

Conclusions: CIP is associated with substantial morbidity and mortality. Within the limitations of this small retrospective study, we demonstrated that pre-diagnosis gas transfer and ECOG performance status was predictive of progression to severe forms of CIP. Persistent reduction in FEV1 and DLCO were observed in some patients , several months following initial CIP diagnosis. Larger prospective studies are required to better assess the role of lung function testing in CIP risk assessment and management.

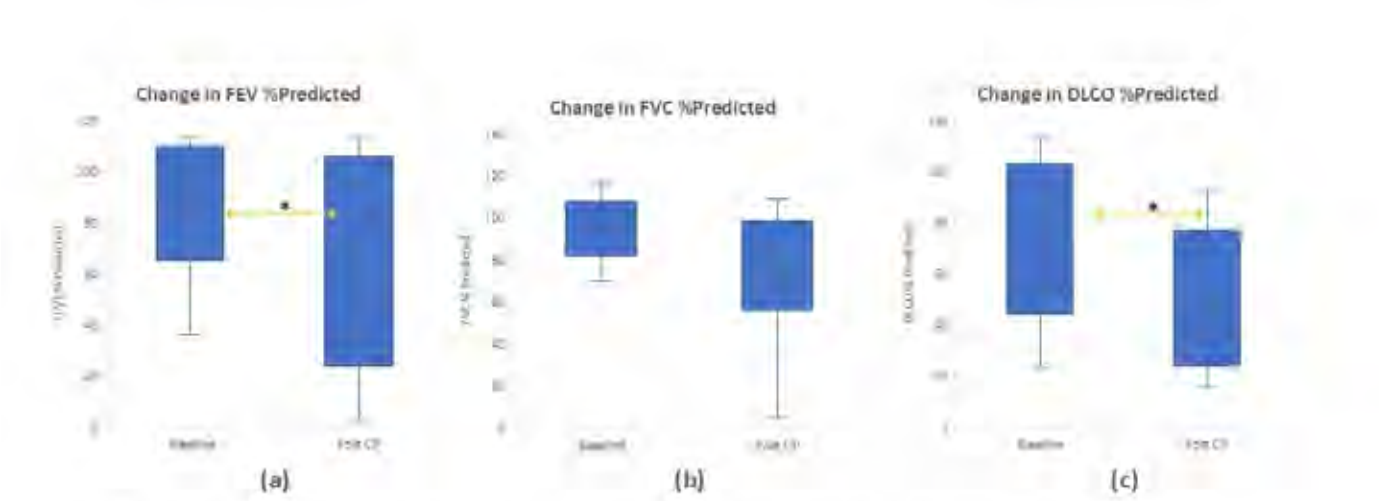

Figure 1. Box and whisker plot depicting the changes in lung function and gas transfer before and after development of CIP:

a) FEV1 %predicted: mean difference = 16.48 (95% CI: -3.69-36.64), p value of 0.046; b) FVC %predicted: mean difference = 23.35 (95% CI: -7.23-53.92), p value of 0.055; c) DLCO %predicted: mean difference = 17.33 (95% CI: -2.13-36.79), p value of 0.036.

EP.15.05 Wearable Devices and ePROs for Perioperative Continuous Monitoring in Thoracic Surgery

R. Wang[1], H. Huang[2], Q. Wang[3], W. Guo[1], Y. Li[3], M. Lin[3], L. Huang[3], Q. Zhang[3], K. Chen[3], Z. Ye[3], H. Deng[3], J. Zheng[3], Y. Jiang[4], Y. Lin[3], Y. Feng[3], Y. Huang[3], Y. Chen[3], J. He[1], H. Liang[1], Q. Zhong[1]
[1]First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]the First Affiliated of Guangzhou Medical University, Guangzhou/CN ,[3]the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[4]the First Affiliated Hospital of Guangzhou Medical University, China/CN

Introduction: Minimally invasive thoracic surgery (MITS) has improved lung cancer outcomes but requires enhanced postoperative care. Traditionally episodic care model has limited timely and multi-dimensional monitoring of patients. Recent technological advances in multimodal digital devices, including wearable device and electronic patient reported outcomes (ePROs), offer a promising solution to these challenges. However, current studies focus on only a few parameters and limited application in thoracic surgery.

Methods: We included 288 non-small cell lung cancer (NSCLC) patients from the GMU cohort, which includes 2,757 participants with various lung diseases. Digital data were collected during hospitalization using a commercial smartwatch combined an electronic patient-reported outcomes (ePROs) questionnaire, while clinical data was obtained from electronic health record (EHR). Agreement between the digital device and EHR was evaluated via Bland-Altman analysis. Time-series data were normalized for continuous outlier monitoring and threshold analysis of ePROs scores was used to explore associations across different modules.

Results: Throughout hospitalization, digital devices provided a subjective overview of the patients' recovery trajectories. Agreement analysis confirmed that wearable devices deliver accurate and clinically relevant measurement. Meanwhile, wearable devices demonstrate significant potential in outlier detection compared to episodic care model, offering accurate and sensitive monitoring of outliers between traditional measurement intervals. Using a thresholding method, we found that wearable metrics was correlated with the severity of ePROs.

Conclusions: These findings highlight the reliability and clinical potential of digital device-based multimodal system within the enhanced recovery after surgery (ERAS) framework, offering a novel approach for continuous perioperative monitoring.

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.06 Bridging the Gap: Co-Designing Tools to Improve Equity in Lung Cancer Screening Care Pathways

A. Sayani[1], A.K. Saka[2], M. Ligam[2], Z. Ladak[1], M. Khawari[1], F. Christian[3], G. Bloch[4], V. Redditt[1], V. Wright[1], A. Edwards[5], S. Dworkin[6], B. Amenu[1], H. Freedman[1], A. Pratt[1], J-C. Camus[1], V. Ramasamy[1], T. Jeji[1], A. Lofters[1], P. Selby[2]
[1]Women's College Hospital, Toronto/ON/CA ,[2]The Centre for Addiction and Mental Health, Toronto/ON/CA ,[3]Ontario Lung Screening Program, Toronto/ON/CA ,[4]St. Michael's Health Centre, Toronto/ON/CA ,[5]Canadian Cancer Society, Toronto/ON/CA ,[6]Canadian Partnership Against Cancer, Toronto/ON/CA

Introduction: Lung cancer remains the leading cause of cancer-related death in Canada due to late-stage diagnosis. Although low-dose computed tomography (LDCT) screening can reduce mortality by up to 20% among high-risk individuals, uptake remains low—especially among underserved populations facing systemic barriers, incomplete smoking history documentation, and fragmented referral pathways. In Ontario, the Ontario Lung Cancer Screening Program (OLSP) provides a pathway for LDCT screening to those at high risk, but systematic identification of eligible individuals is lacking, representing a missed opportunity for early diagnosis and timely care. The Smoking Cessation Treatment for Ontario Patients (STOP) program is Canada's largest smoking cessation initiative, with over 416,000 participants and comprehensive demographic and smoking-related data contained within an Electronic Medical Record (EMR). Leveraging STOP data to identify and refer high-risk individuals to OLSP through decision-support prompts could streamline referral workflows, improve documentation, facilitate timely care, and reduce inequities. In this study, we will leverage STOP's infrastructure to streamline the process of connecting high-risk individuals to LCS in the OLSP, thereby enhancing early detection, promoting equitable access and improving patient care pathways with a focus on structurally underserved populations.

Methods: This is a patient-partnered, interdisciplinary study that employs qualitative methods using interpretive description to co-design and implement practical screening tools. Guided by Trauma and Violence Informed (TVIC) principles, the project team will recruit and engage three stakeholder groups: healthcare providers (10), patients (10), and key informants (10) in 1:1 semi-structured interviews and virtual co-design sessions. Our research questions are: (1) What are the perspectives and needs of providers and patients regarding systematic LCS referrals initiated by the STOP smoking cessation program? (2) What patient, provider and system-level barriers and facilitators must be addressed to ensure tools are practical, equitable, and user-friendly? (3) How can a systems-level implementation plan be designed to integrate co-designed tools into the STOP program and support broader adoption across LCS and smoking cessation programs in Canada?

The project team will de-identify and analyze interview data thematically using NVivo software. Themes will focus on barriers, facilitators, and actionable insights for integrating support for LCS referrals into the STOP program. Interview findings will be presented and collaboratively analyzed during the virtual workshop sessions with the stakeholder committee and patient partner panel to refine emerging themes and co-create provider-facing prompts, patient-facing scripts, an implementation plan outlining how to integrate the tools into STOP workflows, and training requirements and scalability considerations.

Results: This study will produce co-designed trauma-informed referral tools, including provider prompts embedded within the STOP EMR, patient-facing scripts to guide the referral process in a patient-centric and accessible way, and a comprehensive implementation plan that is feasible and ready for implementation into the STOP program.

Conclusions: This project promotes timely and equitable access to LCS for high-risk individuals by bridging gaps between smoking cessation and lung cancer care. The project can improve provider workflows, patient-provider communication, and referral processes. It can also directly increase LCS access among underserved populations and potentially reduce lung cancer mortality and treatment burden by facilitating earlier diagnosis.

Keywords: Smoking Cessation, Lung Cancer Screening, Co-design

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.07 Living With Lung Cancer-A Qualitative Exploration of Its Psychosocial Impact

T. Reddy[1], S. Sinde[2]
[1]osmania medical college, HYDERABAD/IN ,[2]Gandhi medical college, hyderabad/IN

Introduction: In India , Lung cancer is the most common cancer in men and the most common cause of cancer related deaths. A recent study reported that Lung cancer contributes significantly to the global cancer burden, with tracheal, bronchus, and lung(TBL) cancer accounting for approximately 20.4% of total cancer related deaths and 18.3% of disability adjusted life years(DALY). Beyond its physical burden, the patients are prone to psychological, social and emotional stress; thus, negatively affecting their quality of life. Given these complexities, individuals with lung cancer often struggle with uncertainty, lifestyle adjustements,stigma associated with the disease and burden of managing a long -term illness. The main objectives of the study are to assess the psychological experiences and challenges faced, to understand how the disease impacts daily life and the financial burden imposed.

Methods: Study setting was in a tertiary care hospital where patients came for admission due to complications, follow-up or those who participated in clinical trails. Study design is a qualitative study which was conducted through in-depth interviews through a semi-structured questionnaire which consisted of questions related to demographic information and social, emotional and mental aspects of the disease. After obtaining informed consent, the interviews were conducted and audio-recorded. Initially 6 patients were interviewed, data saturation was observed as most of the themes were repititive. Additionally, 2 interviews were conducted to confirm the data saturation. Each interview lasted for about 25-30 minutes and was transcribed in the local language. After identifying the quotations, it was translated to English. Codes and then later themes were developed by deductive thematic analysis method.

Results: After analysis, 4 main themes and 10 sub themes were developed. The first theme was psychological turmoil and emotional impact which had the sub-themes: " why me", fear of future and uncertainty, persistant stress. The second theme developed was socioeconomic impact which had the sub-themes: financial burden, embarrassment, isolation. The third theme was lifestyle disruption which had the sub-themes: change in body image perception, changes in sleep pattern. The fourth theme was support systems and coping strategies which had support from friends and family, coping mechanisms as sub-themes.

Conclusions: This study highlights the multidimensional psychosocial burden of lung cancer. Understanding this is essential for developing comprehensive strategies that provide holistic support including mental health care, patient education and emapthetic healthcare interactions. Some of the strategies we propose are patient education and self empowerment, promoting positive outlook, enhancing healthcare provider support, community and policy level interventions, peer mentorship and group therapy and psychological support.

Keywords: LUNG CANCER, PSYCHOSOCIAL IMPACT, QUALITATIVE STUDY

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.08 The Lived Experience of Dyspnea and Quality of Life Before and After Lung-Sparing Surgery

M. Culligan[1], A. Tod[2], M. Regan[3], N.J. Klinedinst[3], J.S. Friedberg[1], K. Mooney-Doyle[3]
[1]Temple University Hospital, Philadelphia/PA/USA ,[2]University of Sheffield, Sheffield/GB ,[3]University of Maryland, Baltimore, Baltimore/MD/USA

Introduction: Pleural Mesothelioma (PM) is a rare, incurable malignancy of the pleura. The most common symptoms experienced include dyspnea, pain, fatigue, anorexia, early satiety and anxiety. Lung-sparing surgery for PM is considered investigational and involves resection of pleura, pericardium, diaphragm, depending upon the extent of disease. While the primary goal of surgery is to prolong survival, palliation of symptoms and improvement in quality of life (QOL) are taken into consideration when offering surgery. Beyond the standard quantitative measures used to determine successful surgical outcomes, an understanding of an individual's perception of the impact surgery has had on their symptom burden and QOL has not been reported in the literature. The primary aim of this study was to explore the lived experience of dyspnea and QOL before and after lung-sparing surgery.

Methods: The philosophical approach to this study was grounded in hermeneutical phenomenology which combines the interpretive focus of hermeneutics with the exploration of lived experiences and consciousness of phenomenology. Participants underwent in-depth semi-structures interviews, before and 3-4 months after surgery. Interviews were transcribed using NVivo and transcripts were analyzed according to Interpretive Phenomenological Analysis, focusing on detailed examinations of lived experience, the meaning of the experience to participants and how participants make sense of and describe that experience.

Results: The Group Experiential Themes (GETs) before and after surgery included Psychological: Mind supports body in the world; Physiological: Body fighting, enduring, adjusting and adapting in the world; Social: Others sharing and supporting body in the world; Existential: Facing an uncertain future of body living in the world. The emotional impact a diagnosis of PM has on a person is multidimensional and involves elements of time, internal psychological struggles and learning to deal with the reality of the diagnosis. The physical impact of living with mesothelioma can disrupt a person's normal routine and interactions with the world as they perceive it. An individual's interaction with others during an illness experience such as PM can influence the perception of the lived experience for both the individual and others in their world. Facing a serious illness such as PM was disruptive to individual normal bodily routines and interactions with the world.

Conclusions: The results of this study provide valuable insight regarding the essence of the experience of living with mesothelioma, enduring lung sparing surgery and coping with the symptom of dyspnea. This enriched understanding of the experience comes from the voice of the experiencer, not from the usual measures used to determine success of surgery, mitigation of symptoms and optimization of QOL. The lived experience of dyspnea and QOL before and after lung-sparing surgery is a continuum influenced and impacted by physical, psychological, social and existential factors that vary for each individual but are most certainly present at some level. This study provides qualitative evidence that perceptions of dyspnea and QOL play an impactful role in the patient experience, before and after surgery. Healthcare teams must look beyond what is measurable and visible and consider what patients are experiencing physically, emotionally, socially and existentially.

Keywords: pleural mesothelioma, quality of life, dyspnea

EP.15.09 Clinical Decision Flowchart for Optimizing the Use of EGFR Tyrosine Kinase Inhibitors in Non-Small Cell Lung Cancer: Real-World Data

G. Gosi[1], G. Fraga[1], I. Borchardt[1], T. Alencar[1], M. Marinho[1], F. Dias[1], F. Telles[1], C.G. Ferreira[1]
[1]Oncoclinicas CTTB, Rio de Janeiro/BR

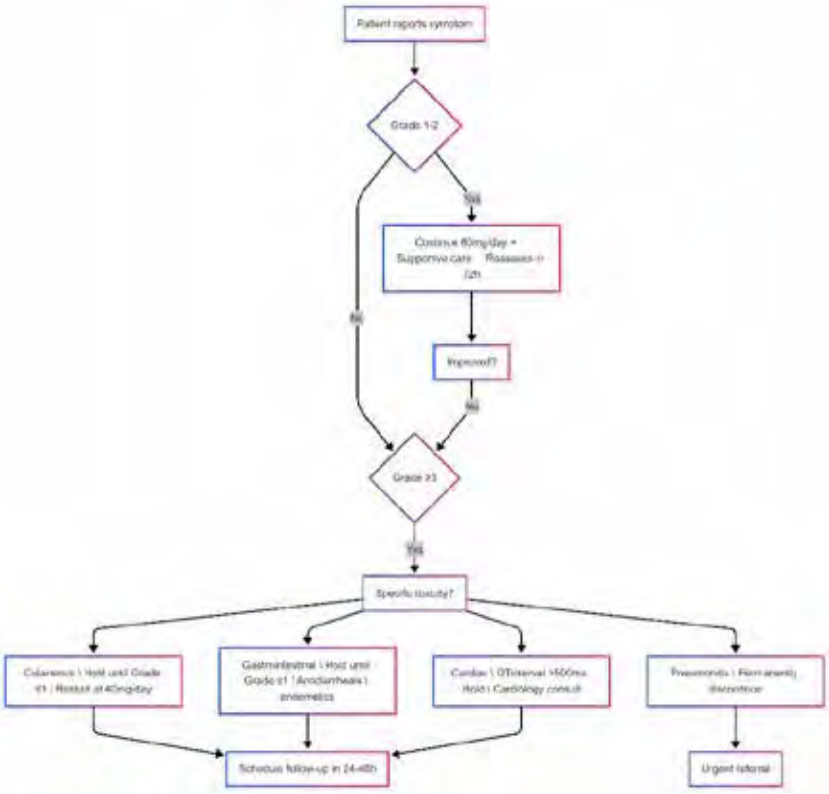
Introduction: Osimertinib represents a significant advance in the treatment of non-small cell lung cancer (NSCLC) with EGFR mutations. The management of related toxicities remains a complex challenge in oncology practice, requiring innovative approaches that combine technology and patient-centered care. While osimertinib has significantly improved outcomes for EGFR-mutated lung adenocarcinoma patients, its toxicity profile often leads to treatment interruptions and reduced quality of life. Current care models frequently lack efficient systems for early toxicity detection and intervention, highlighting the need for more integrated and innovative approaches, incorporating telemonitoring and the role of the multidisciplinary team.

Methods: This is a retrospective cross-sectional study carried out in a private cancer center in Brazil. The data consisted of clinical and epidemiological variables, as well as the detection and intervention of AEs by the multidisciplinary team. AEs were classified according to the Common Terminology Criteria for Adverse Events (CTCAE), and the data were presented descriptively.

Results: We retrospectively analyzed data from 24 patients with NSCLC and EGFR mutations, 84% of whom were stage III-IV, treated with osimertinib at a dose of 80 mg/day for an average of 19 months. The population was predominantly female (83%), with a mean age of 64 years. AEs occurred in 54% of cases, with 37.5% requiring dose adjustment. The most frequent toxicities were cutaneous (44.4%), gastrointestinal (33.3%), hepatic (11.1%), and pneumonitis (11.1%). Management included a dose reduction to 40 mg, which was effective in 100% of cutaneous cases and 66.7% of gastrointestinal cases. Discontinuation was necessary in one case of grade 3 pneumonitis. Patients over 70 experienced severe gastrointestinal toxicities, while cardiac comorbidities increased cardiovascular risk. Symptom management was carried out by a nurse navigator. AEs were grade 1-2 (20%) and 80% of patients had grade 3, with only 4% requiring hospitalization (due to pneumonitis). A flowchart was created to design the management (Figure 1).

Conclusions: The study proposes a clinical decision flowchart integrated into a telemonitoring model, with nursing associated with a multidisciplinary team, allowing for early identification and intervention, thereby reducing the time between symptom manifestation and intervention. The results reinforce the need for active telemonitoring, particularly in the elderly and patients with comorbidities, and highlight the crucial role of advanced practice nursing in patient navigation and the timely implementation of osimertinib treatment adjustments.

PS: We use AI with Mermaid Live Editor to build the flowchart.



Keywords: Telemonitoring, Oncology Nursing, Osimertinib

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.10 Do Enhanced Recovery After Lung Cancer Surgery Programs Risk Putting Primacy of Caring at Stake?

M. Missel, P.O. Donsel
Copenhagen University Hospital, Copenhagen/DK

Introduction: Since nurses play a key role in overcoming implementation barriers in enhanced recovery after surgery programs, successful implementation depends on their care approach during the surgery pathway. To gain insight into nursing in an enhanced recovery after surgery program for lung cancer, we explored its meaning for nurses in a thoracic surgery unit.

Methods: A hermeneutic approach inspired by Gadamer guided the research. Sixteen thoracic surgery nurses participated in focus group interviews. Benner's primacy of caring theory enhanced understanding of the findings.

Results: The thoracic surgery nurses compared the streamlined trajectory in the lung cancer program to working in a factory. Shifting focus away from a dialogue-based, situated care practice compromised their professional nursing identity. The program made combining scientific evidence with lung cancer patients' lifeworld perspectives challenging. Although the nurses recognized that the physiological processes and positive outcomes promoted recovery, they felt each patient's life situation was not sufficiently considered. To meet the program's professional nursing responsibilities and provide comprehensive lung cancer care, specialized thoracic nursing should continue after discharge to allow professional care while meaningfully engaging with the patient's situatedness and lifeworld.

Conclusions: Primacy of caring risks being compromised if accelerated treatment is implemented uncritically. If care is based on the dominant rational justifications underpinning thoracic surgical nursing, living conditions, and patient values might be overlooked, affecting how disease, illness, and health are managed. Our findings focus on obvious unintended consequences of enhanced recovery after surgery programs. To avoid dehumanizing patients, surgical lung cancer programs must adopt a humanistic attitude in a caring practice guided by the moral art and ethics of care and responsibility.

Keywords: NSCLC, Surgery, Nursing

EP.15.11 Patterns of Care and Outcomes in Patients With Advanced Lung Cancer in a Hospital Palliative Care Unit: A Single-Center Retrospective Study

S. Barban[1,2], R. Leporati[1,2], L. Trudu[1,2], L. Scarabelli[1], S.C. Bonilauri[1,2], M. Argento[1,2], L. Casadei[1,2], E. Cabitza[1,2], G. Guaitoli[1], K. Di Emidio[1], F. Bertolini[1], M. Dominici[1,2], C. Fiorani[1]
[1]Modena University Hospital, Modena/IT ,[2]University of Modena and Reggio Emilia, Modena/IT

Introduction: Palliative care is essential for managing patients with advanced lung cancer, yet real-world data on their end-of-life care are scarce. This study evaluates patient characteristics, treatment approaches, and clinical outcomes in a specialized palliative care unit within a university hospital, an uncommon setting that allows for a detailed analysis of hospice care. Patients were assessed using the Palliative Prognostic (PaP) score, Edmonton Symptom Assessment System (ESAS), and PERSONS tool to systematically evaluate symptom burden and palliative needs.

Methods: A retrospective analysis was conducted on patients with advanced thoracic malignancies admitted to the Palliative Care Ward of Modena University Hospital between January 2022 and September 2024. Clinical and demographic data, prior oncologic treatments, symptom burden, palliative interventions, and overall survival from admission were collected. Descriptive statistics summarized patient characteristics, and Kaplan-Meier analysis estimated survival.

Results: A total of 144 patients (42.4% female, median age 75 years) were included, representing 20% of all admissions during the study period. The majority had non-small-cell lung cancer (68.1%), followed by small-cell lung cancer (15.3%) and mesothelioma (2.1%). Seventeen patients (11.8%) lacked a histological diagnosis due to clinical deterioration and non suitability for active treatments. All had stage IV disease, with a median of three metastatic sites. In the 30 days before admission, 79 patients (54.9%) had not received oncologic treatments. Among the 65 treated patients, 45 (31.3%) received systemic therapy, 9 (6.3%) had radiation therapy, and 5 (3.5%) received both. Of note, 72% of patients were not receiving active home-based palliative care at the time of admission. The median time from diagnosis to palliative care admission was 4.8 months, and from the first oncology referral to admission was 4.1 months. Most patients (73.6%) were transferred from other hospital wards, while 22.2% were admitted from home or residential care. The most common reasons for admission were dyspnea (50%), pain (24.3%), and neurological symptoms (19.4%). Median hospitalization duration was 14 days (range 1-73). By discharge, 34% of patients returned home or to other facilities, while 66% died in the unit. PaP scores indicated high (>70%) mortality risk in 26.8% of patients, intermediate (30-70%) in 41.3%, and low (<30%) in 31.2%. The mean ESAS score was 30.7, with dyspnea (38.2%) and pain (13.2%) being the most frequently reported symptoms. Palliative sedation was necessary in 38.9% of cases, primarily for refractory dyspnea (62.2%) and agitation (56.8%).

Conclusions: This study highlights the role of hospital-based palliative care units in managing patients with advanced thoracic malignancies. Despite late referrals, multidisciplinary care provided effective symptom management and dignified end-of-life support. The fact that 31% of patients received systemic therapy within one month of admission raises concerns about the appropriateness of late-line treatments in this population. Notably, 11.8% of patients lacked a histological diagnosis, underscoring the need to better identify those presenting at an advanced stage who are unable to receive oncologic treatment. Strengthening early palliative care integration and timely patient identification can improve quality of care and ensure that even those without a formal diagnosis receive appropriate symptom management and support.

Keywords: lung cancer, palliative care, hospital-based palliative care unit

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.12 Virtual Personalized Exercise Program for Subjects With Lung Cancer: A Feasibility Study

M. Neumann[1], S. Maltser[1], E. Alpert[1], M. Akerman[2], S. Khanijo[2], J. Scanlon[3], T. Green[3], L. Crichton[2], A. Pemmaraju[2], S. Chen[1], K. Sullivan[1], N. Seetharamu[1]
[1]Northwell Health, New York/NY/USA ,[2]Northwell Health, Manhassett/NY/USA ,[3]Northwell Health, Lake Success/NY/USA

Introduction: With improved outcomes, cancer is increasingly viewed as a chronic disease, highlighting the need for exercise programs to enhance survivors' quality of life (QOL). Unlike heart disease, diabetes, and pulmonary disease, where exercise has long been recommended, guidance for cancer patients has lagged. Exercise and rehabilitation interventions clearly benefit cancer survivors by improving outcomes, treatment tolerance, delaying progression, and reducing new primary cancer risk. Despite support from societies such as IASLC, exercise programs remain underutilized in lung cancer treatment plans.

Methods: This single-arm, investigator-initiated feasibility study evaluates a virtual exercise platform for patients with non-small cell lung cancer (NSCLC) undergoing surgery with or without peri-operative chemoimmunotherapy (cohort A); radiation ± chemo (cohort B); or systemic treatment only (cohort C). Potentially eligible subjects are referred to physiatry for evaluation, enrollment, and individualized virtual exercise prescription, accessible via personal electronic devices. The primary objective is feasibility, targeting 50% program completion at 12 months. Secondary objectives include satisfaction, measured via patient and provider questionnaires [i.e., System Usability Scores (SUS), Technology Acceptance Model (TAM) Perceived Usefulness (PU) and Perceived Ease of Use (PEOU), and Net Promoter Score (NPS)]. Exploratory outcomes include Pulmonary Function Test (PFT), Six Minute Walk Test (6MWT), and Sit to Stand Test (STS) obtained at the start and 12 months, and QOL changes, measured by FACT-L at baseline and every three months. Descriptive statistics (mean, SD, median, IQR, minimum, maximum for continuous variables; frequencies/percentages for categorical variables) were calculated at months 1, 3, and 6.

Results: Twenty-one patients have consented to the study to date. Two (9%) were subsequently deemed ineligible by PM&R, and eight have withdrawn consent or missed deadlines, leaving ten active patients in the study. Retention among those seen by PM&R was 80%. Compliance increased significantly after a study navigator was recruited in late November. Since then, nine new patients have consented, and the average monthly compliance of all enrolled patients has increased from ~10% to ~40%. The average time from oncology referral to PM&R visit was 11 days. The two eldest participants both aged 77 have shown the highest engagement. SUS suggested fair usability at 100%, 80%, and 75% at months 1, 3, and 6, respectfully. Median TAM PU scores were 4.39, 5.57, and 4.32 at months 1, 3, and 6; PEOU remained 4.07 throughout and NPS was 75 at month 3, which is an excellent rating.

Conclusions: This pilot study demonstrates that a virtual exercise platform is feasible in a lung cancer population. Larger validation studies are needed to demonstrate impacts on QoL and treatment outcomes. Clinicaltrials.gov ID: NCT06540495

Keywords: Non-Small Cell Lung Cancer, Exercise, quality of life

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.13 Pilot Study of Exercise Program and Monitoring by a Lung Cancer Patient Navigator During Chemoradiotherapy for Stage III Lung Cancer

P.L. Chia , C.S.T. Heng, S.Y. Kok, Y.Y. Chea, C.J. Wong
Tan Tock Seng Hospital, Singapore/SG

Introduction: Stage III locally advanced non-small cell cancers (NSCLC) patients are treated with definitive chemoradiation (chemoRT) followed by maintenance immunotherapy (durvalumab). Specialized multidisciplinary approach combining medical oncology management with symptom management, nutritional support and exercise plans to improve physical functioning in lung cancer patients are increasingly explored and shown to be beneficial. The use of patient navigators may help patients with the necessary support throughout their cancer journey to connect the patient with the necessary community and hospital resources. We conducted a feasibility study incorporating supervised exercise program in lung cancer patients receiving definitive chemoRT with the assistance of lung cancer patient navigator throughout the program.

Methods: Patients≥ 21 years old, diagnosed with stage III NSCLC seen at the Tan Tock Seng Hospital oncology clinic who will be initiated on definitive chemoRT between June 2023 to August 2024 were eligible. The exercise program will span 8 weeks duration. On the first visit, the patient will be assessed by the exercise physiotherapist and cancer rehabilitation physician (6 mins. walk test). Patients will be taught exercises that they can self-administer at home. A care navigator will contact patient weekly to check for compliance and discuss any difficulties faced by patient with the exercises. The patient will continue with self-administered home exercises with the care navigator contacting patient weekly until the last week 8 where patient will return for review assessment by physiotherapist and rehabilitation physician.

Results: We screened and invited 28 stage III lung cancer patients who are planned for definitive chemoRT and only 5 patients agree to participate and are recruited to the pilot exercise study (acceptance rate of only 17.9%). There is high screened fail rate, and the common factors include high dyspnoea score, comorbidities unsuitable for exercise, presence of thrombosis, sequential chemo then radiation and falls history. Two patients have withdrawn midway through the exercise program in view of inability to complete the exercises due to prolonged admissions and medical issues. 6MWT improved with the program albeit not statistically significant. All of patients had experienced fatigue and breathlessness during the exercises and had to reduce their exercise duration/intensity; however, they managed to continue some physical activity during the chemoRT period. Patients shared subjectively that it improved their well-being and helped them to relax during the chemoRT treatment.

Conclusions: The low uptake of exercise program in stage III lung cancer patient in this single institution in Singapore has shown a huge discrepancy in level of acceptance for exercise during chemoRT compared to the prior reported literature in Caucasian populations. Many of the stage III lung cancer patients are already having difficulty adjusting to the chemotherapy and daily RT, leading to a low uptake despite active screening by the nurse coordinator during this 1-year period. The study provides insight into the barriers to recruitment for exercise programs in Asian patients who may have different concerns and physical capacities for ongoing physical workout during their treatment course. This will inform future trial designs concerning rehabilitation programs peri-chemoRT period for lung cancer patients.

Keywords: Exercise program, lung cancer nurse navigator, stage III lung cancer

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.14 Empowering Lung Cancer Care: The Role of AI Chatbots to Promote Exercise Oncology

T. Franchina[1], F. Omero[1], M. Santarpia[1], I. Passalacqua[2], S. Parisi[3], R. Soffitto[1], D. Macheda[1], D.A. Restivo[4], M. Berretta[1]
[1]Medical Oncology Unit, Department of Human Pathology "G. Barresi", University of Messina, MESSINA/IT ,[2]Medical Oncology Unit, University Hospital "G. Martino", MESSINA/IT ,[3]Department of Biomedical, Dental, Morphological and Functional Imaging Sciences, University of Messina, MESSINA/IT ,[4]Department of Clinical and Experimental Medicine, University of Messina, MESSINA/IT

Introduction: Exercise oncology has demonstrated significant benefits in improving the physical and psychological well-being of patients with lung cancer. Involving patients in personalized exercise programs can improve their quality of life, minimize the side effects related to treatment, and improve general resilience during the lung cancer journey. Limited information and adherence of cancer patients to physical exercise is a significant concern in cancer care. Despite the well-documented benefits of exercise, such as improved quality of life and general resilience, enhanced physical function, and potentially better treatment outcomes, there remains a gap in awareness and understanding among patients regarding the importance of incorporating exercise into their treatment regimen. Simultaneously, AI chatbots have emerged as a transforming tool in oncological care, providing immediate access to credible information, facilitating communication and support for behaviour change. These chatbots can also monitor the physical activity levels of patients, offering feedback and motivation in real time, which can reinforce adherence to exercise regimes. The objective of this research is to evaluate and compare the accuracy of several popular free AI chatbots when responding to specific questions concerning the impact of exercise on lung cancer patients.

Methods: We reviewed a range of commonly available tools for patients and selected the most frequently used free chatbots for our analysis: ChatGPT, Google Gemini, Microsoft Copilot, and Claude. We therefore posed five questions to AI chatbots regarding the role of physical exercise in patients with lung cancer, the anticipated benefits, and the timing and methods involved in performing physical exercise.

Results: The results of our analysis are summarized in Table 1.

	Google Gemini	Microsoft Copilot	Claude	Chat GPT
Is exercise contraindicated in lung cancer patients?	Exercise is not contraindicated for lung cancer patients	Exercise is not universally contraindicated for lung cancer patients. However, there are specific situations where exercise might need to be modified or avoided	The relationship between exercise and lung cancer patients is complex, and the recommendations can vary depending on the type and stage of cancer	Exercise is generally not contraindicated for most lung cancer patients and can offer many benefits
How can exercise improve the quality of life for lung cancer patients?	Reducing cancer-related fatigue; enhancing mental wellness; increasing muscle strength and improving management of specific side effects	Reducing fatigue, and enhancing physical function during cancer treatment	Improving physical function and quality of life, reducing fatigue and depression	Reducing fatigue, depression, anxiety; increasing muscle strength, cardiovascular fitness and immune function
How many times a week should a lung cancer patient exercise?	Both aerobic and resistance exercise 2-3 times a week is a good general guideline	3-5 times a week, depending on the individual's energy levels and treatment stage. Additionally, incorporating resistance training at least 2 days a week and stretching exercises is recommended	2-3 times per week of moderate-intensity exercise. This can be gradually increased as the patient tolerates it	At least 3-5 times a week of physical activity, with adjustments made based on how they feel and their specific treatment or recovery needs
What type of exercise is recommended for a lung cancer patient?	A combination of aerobic, resistance, flexibility, and balance exercises	A combination of walking, yoga, swimming, tai chi, stretching	A combination of aerobic exercise like walking and cycling, flexibility like yoga and Tai Chi and balance exercises	Low-impact activities like walking, swimming, cycling, or yoga

Although the positive impacts of exercise on the well-being of oncology patients are well-documented, the responses indicate the limited information about how tailored exercise regimens can be effectively implemented with adapted physical activity programs. The absence of specific indications related to the expertise of kinesiologists in this setting suggests that their contributions to developing individualized exercise plans are not sufficiently recognized or understood within the context of cancer care.

Conclusions: As research continues to explore the effectiveness of these integrations, it is crucial to evaluate the precision and reliability of AI chatbots' responses. By incorporating more specific exercise recommendations in chatbot functionalities, patients could receive more specific information about exercise oncology. These evaluations will be vital to ensure that improved services with AIs align with evidence-based oncology practices.

Keywords: Exercise oncology, AI chatbots information, supportive care

EP.15.15 Lived Experiences and Needs of People Living Long-Term With Metastatic Non-Small Cell Cancer: A Qualitative Study

R. Urquhart, S. Scruton, C. Hovey, C. Kendell
Dalhousie University, Halifax/NS/CA

Introduction: Until recently, persons diagnosed with metastatic non-small-cell lung cancer (mNSCLC) faced a dire prognosis. In 2016, the IASLC Lung Cancer Staging Project reported a worldwide 5-year overall survival of about 6% for persons with mNSCLC. However, advances in precision oncology have substantially improved the prognosis for specific subtypes of mNSCLC patients. For example, people with anaplastic lymphoma kinase (ALK)-translocations have achieved a 5-year overall survival of 62.5% with first line targeted therapy. Yet, beyond the view of cancer-directed treatment, we have a limited understanding of how to support and care for this growing population. Worldwide, less than a handful of studies have explored the lived experiences of persons with mNSCLC who are on targeted or immunotherapies. In the care setting, the services and supports designed for persons post-treatment without active disease may not be well suited for people living long-term with disease. Given this context, we sought to: (1) explore the lived experiences and needs of persons receiving targeted therapy agents or immunotherapies for mNSCLC and (2) identify key components of ongoing care and supports to design future interventions.

Methods: Guided by qualitative description, we conducted semi-structured, one-on-one interviews with persons with mNSCLC who are receiving long-term targeted therapy agents or immunotherapies. Recruitment occurred via community-based approaches. Interviews explored participants' experiences living with mNSCLC, including their physical, emotional, and practical needs, and their views on services and supports that would help meet their needs and optimize their quality of life. All interviews were conducted by the same researcher experienced in qualitative methods, audiotaped, and transcribed verbatim by an experienced transcriptionist. Data analysis involved constant comparative analysis, a technique commonly used in descriptive qualitative research. Team meetings were held to review, question, and clarify findings.

Results: Nine individuals (3 male, 6 female) participated in this study. Participants identified significant gaps in care, including delays in biomarker testing, limited disease-specific information, and concerns about accessing treatment beyond first line therapies. Physical challenges included fatigue, cognitive issues, and pain, while emotional needs centered on anxiety, stigma, finding meaning, and uncertainty about the future. Practical barriers, such as financial strain, travelling for treatments, and insurance limitations, complicate the long-term management of one's disease. Participants emphasized the need for improved provider communication and collaboration, automated referrals to supportive care services, and ongoing, multidisciplinary care (versus the short-term, fragmented, and episodic services many participants described experiencing). Suggested interventions included accessible and trustworthy informational resources and integrated healthcare services and programs tailored for persons living long-term with metastatic cancer.

Conclusions: Existing cancer survivorship services were designed for persons without active disease and may not meet the needs of persons living with metastatic cancer, a growing population worldwide. One example is the short-term nature of many survivorship services, which are less suitable for people living with persistent symptom burden and uncertain prognosis. The information gained from this study is informing the co-design of services to better support persons with mNSCLC who are living long-term in the era of targeted and immunotherapies.

Keywords: metastatic cancer, qualitative inquiry, lived experiences

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.16 Patient's Understanding of Follow-Up Post Curative Primary Lung Cancer Surgery

P.W.J. Barton[1],[2], M. King[2], E. Wassell[2],[3], J. McAdam[3]
[1]Manchester University NHS Foundation Trust, Manchester/GB ,[2]Royal Papworth Hospital NHS Trust, Cambridge/GB ,[3]The Shrewsbury and Telford Hospital NHS Trust, Shrewsbury/GB

Introduction: Follow up is an important part of patient care post primary lung cancer resection due to the possibility of cancer recurrence or the development of a new primary lung cancer. We aim to explore post operative patient's with a lung cancer understanding of follow-up and how we can implement and support this practice.

Methods: Between 01/08/2023 and 31/08/2023 every curative intent surgical patient was given a questionnaire to complete whilst attending follow-up clinics. This was rolled out over three UK thoracic surgical centers/Diagnostic centers and targeted patients with lung cancer undergoing follow-up post curative primary lung cancer surgery (excluding carcinoids, recurrence). 148/155 questionnaires were returned, collecting information on demographics, smoking status, operation performed, follow-up period post-surgery and patient understanding of follow-up. The responses were collated, compared and interpreted by the authors

Results: 148/155 (96%) patients responded. 62% female, 36% male. 80% Ex-smokers, Lobectomy most common operation 64%. 97% of patients' aware follow-up was required, and 72% identified that this would be for 5 years. 68% knew their diagnosis prior to surgery and 58% their final staging, 9% understood TNM. 58% knew their lung cancer nurse specialist (LCNS) and 54% when radiological investigations would be performed. 57% recall being given advice on improving their health and wellbeing, from (LCNS) 30%. 45% recalled a healthcare professional discussing recurrence. 34% knew the potential signs and symptoms of recurrence.

Conclusions: This study has identified a gap in patients' knowledge and understanding of follow-up: The necessity of follow-up; TNM stage relevant to individuals; Schedule and frequency of radiological tests; Signs and symptoms suggestive of lung cancer recurrence. The development of a information leaflet patients with lung cancer by LCNS aims to address this need.

Keywords: Surgery, Follow-up, Communication

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.17 The Role of Pneumonia in Mortality Among Hospitalized Patients With Advanced Lung Cancer

X. Gao, Y. Pei, J. Liu, M. Zhang, Y. Liu
Beijing Arion Cancer Center, Beijing/CN

Introduction: Patients with lung cancer are are at high risk of developing pneumonia, particularly those with advanced and terminal-stage disease. Analyzing the occurrence of pneumonia in deceased hospitalized lung cancer patients would deepen the understanding of prognostic characteristics in advanced lung cancer, refine the treatment strategies, and ultimately improve the quality of life and extend survival time for these patients.

Methods: A retrospective analysis was conducted on hospitalized patients with primary lung cancer who died in the Lung Cancer Department of Beijing Arion Cancer Center from February 2021 to February 2025. Demographic and clinical variables were extracted from the electronic medical record system.

Results: 52 patients met the inclusion criteria, including 43 males and 9 females, with a mean age at death of 66.36±11.23 years. Pathological types included adenocarcinoma (26, 50%), squamous cell carcinoma (18, 34.61%), small cell carcinoma (5, 9.61%), large cell carcinoma (1, 1.92%), and mixed type (2, 3.84%). At the final hospitalization, 43 patients (82.69%) had an Eastern Cooperative Oncology Group performance status (ECOG PS) score >2. Metastases were present in one or more sites in 91.2% of the patients, and 82.3% had received second-line or subsequent treatment. A total of 36 patients (69.23%) died directly or indirectly from pneumonia. Sputum samples from these patients underwent microbiological testing, yielding 103 isolated strains. Gram-negative bacilli accounted for 59 strains (57.28%), predominantly Pseudomonas aeruginosa (22.03%), followed by Klebsiella pneumoniae, Escherichia coli, and Acinetobacter baumannii, which showed sensitivity to third-generation cephalosporins, aminoglycosides, and carbapenems. Gram-positive cocci comprised 16 strains (15.53%), primarily coagulase-negative staphylococci (10.08%), followed by Staphylococcus aureus and Enterococcus faecium, with sensitivity to vancomycin and linezolid. Fungi constituted 28 strains (27.18%), predominantly Candida albicans (14.23%), followed by Candida tropicalis and Candida glabrata, which were sensitive to voriconazole and amphotericin B. Antibiotic therapy was administered to all 36 patients with pneumonia. Among them, pneumonia was temporarily controlled in 7 patients (19.44%), with a duration from the last pulmonary infection to death exceeding 30 days. For the remaining 29 patients (80.55%), the mean duration to death was only 9.86±7.71 days, with the shortest interval being 1 day.

Conclusions: Pneumonia is a major complication and leading cause of death in patients with advanced lung cancer. Gram-negative bacilli are the primary pathogens, but fungal infections require vigilant monitoring. Early detection of pneumonia and integration of pneumonia-specific effective therapy into palliative care would systematically improve outcomes for advanced lung cancer patients.

Keywords: Pneumonia, Advanced lung cancer, Mortality

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.18 Characteristics and Clinical Outcomes of Hispanic Patients With Thoracic Malignancies Requiring ICU Admission: A Single Center Experie

S.I. Martinez Jaramillo, A. Cardona
CTIC, Bogota/CO

Introduction: Patients with thoracic malignancies (TMs) admitted to the intensive care unit (ICU) face challenges owing to advanced disease, comorbidities, and organ failure risk. Lung cancer (LC) is the leading cause of cancer-related mortality worldwide and often requires ICU admission. Recent therapeutic advancements have improved survival rates but increased complication risks. This study aims to delineate the clinical characteristics, comorbidities, interventions, and outcomes of TM patients admitted to the ICU while examining differences based on cancer subtype and mutation status.

Methods: This retrospective study included patients diagnosed with TMs who were admitted to the ICU of a Latin America reference hospital between July 2022 and December 2024. Demographic, clinical, treatment, and hospital outcome data were extracted from the medical records. Statistical analysis, including bivariate analysis, was conducted to evaluate the associations between clinical features, lung cancer subtypes, mutations, and outcomes, with significance set at $P < 0.05$.

Results: We analyzed 41 patients with TM admitted to the ICU (57 ICU admissions). The median age was 65 years (r, 45-80), with 60% male. Predominant LC subtypes were non-small cell lung cancer (NSCLC) (70%) and small cell lung cancer (SCLC) (30%), followed by pleural mesothelioma (MPM) (9.8%), thymic tumors (TT) (7.3%), and neuroendocrine thoracic tumors (NETs) (7.3%). Molecular testing found EGFR mutations (20%), KRAS mutations (15%), and ALK rearrangements (10%) among the subgroup of patients with adenocarcinoma. NSCLC patients had lower ICU mortality (55%) than SCLC (70%). Among NSCLC patients, EGFR mutations showed lower mortality (40%) than KRAS (65%) and ALK (60%). The 30-day mortality rate was 30%, varying by subtype: SCLC (100%), NSCLC (40%), NET (20%), and TT (0%). For the general population, the post-ICU overall survival (OS) was 11.7 months (95%CI 3.7-18) and 8.7 months (95%CI 3.3-24.3) for NSCLC patients. Comorbidities were observed in 78% of the patients with cardiovascular diseases (45%) and chronic lung conditions (33%). Invasive ventilation was needed in 65% of cases, and 60% required vasoactive support. Primary complications were respiratory failure (50%) and sepsis (30%), which were caused by respiratory infections in 60% of cases. Higher mortality was significantly associated with infections of any origin ($P = 0.0027$), sepsis ($P = 0.00079$), and the requirement of a high-flow nasal cannula ($P = 0.0056$) or vasoactive agents ($P = 0.02$).

Conclusions: Hispanic patients with lung cancer admitted to the ICU experienced high mortality, particularly those with SCLC and NSCLC-harboring KRAS mutations. Conversely, patients with EGFR mutations and ALK rearrangements exhibit better outcomes. Identifying the clinical and molecular factors associated with a poor prognosis can inform tailored ICU care and early palliative interventions. Further research is warranted to optimize management strategies for high-risk patients.

EP.15 MULTIDISCIPLINARY CARE: NURSING, ALLIED HEALTH AND PALLIATIVE CARE

EP.15.19 Patients With Advanced-Stage Lung Cancer in Intensive Care Unit, a Retrospective Observational Study Assessing Their Prognosis

M.A. Hila[1], L. Pirard[1], P. Bulpa[1], A. Robert[1], I. Michaux[1], F. Duplaquet[1], S. Ocak[2]
[1]Université catholique de Louvain, CHU UCL Namur (Godinne Site), Namur/BE ,[2]UCLouvain, Institut de Recherche Expérimentale et Clinique (IREC), Bruxelles/BE

Introduction: The admission of patients with advanced-stage lung cancer to the intensive care unit (ICU) is often a matter of debate. However, little is known about their prognosis since the era of immune checkpoint inhibitors (ICIs) and targeted therapies. In this study, we aimed to evaluate the mortality rate of patients with advanced-stage lung cancer admitted to ICU and the characteristics of those who died in ICU.

Methods: We conducted a retrospective monocentric study which included patients with metastatic or locoregionally-advanced-stage lung cancer (according to UICC eighth edition) admitted to ICU of CHU UCL Namur (Godinne) (academic institution) from August 2018 to August 2023, aiming to evaluate their mortality rate and characteristics of those who died in ICU in an era with availability of ICIs and targeted therapies. Following patient data were collected : general clinico-pathological characteristics, reasons for admission to ICU, and delivery of intensive care. The study was approved by the Ethical Comittee of CHU UCL Namur (Godinne).

Results: Over this period, 82 patients with a metastatic or locally-advanced-stage lung cancer were urgently admitted to ICU. Majority of patients were admitted to ICU for respiratory issues (57%) and cancer-related reasons (44%). Median age was 72 years. Majority (72%) were men with an ECOG performance status >2 (68%). Non-small cell lung cancer (NSCLC) was observed in 81% and small cell lung cancer (SCLC) in 17% of patients. Majority were receiveing a first-line anti-cancer treatment (59%) or had not yet initiated it (34%). Twenty-nine% died in ICU, 43% died in hospital but outside ICU, and 70% died within a year. Fourty-five% of patients (n=37) received an anti-cancer treatment after their stay in ICU. Average SAPS II and APACHE II scores were respectively 43 and 20 at admission. Half (51%, n=42) of patients had mechanical ventilation, one quarter (24%, n=20) high-flow nasal oxygenation, and one quarter (24%, n=20) non-invasive ventilation. Half (48%, n=39) of patients received vasoactive or inotropic support and 35% developed acute renal failure, but only two patients were hemofiltered. Main factors for mortality in ICU were severity scores (APACHE II median score at 17 in the ICU survival group (SG) versus 25 in the ICU mortality group (MG) and SAPS II median score at 38 in the ICU SG versus 59 in the ICU MG, p-value<0,01), mechanical ventilation (38% in the ICU SG versus 83% in the ICU MG, p-valu<0,01), and acute renal failure (24% in the ICU SG versus 63% in the ICU MG, p-value<0,01). However, in a one-year analysis, only the ECOG performance status at baseline, before admission in ICU, was identified as a poor prognosis factor (84% of patients who died at 1 year had an ECOG > 2 versus 32% in the group still alive at 1 year, p-value<0,01).

Conclusions: In this study ICU mortality was linked to the severity of the illness bringing them to ICU, while long-term mortality was related to the performance status. Further studies, prospective and involving a larger number of patients, are warranted.

EP.16 PATIENT ADVOCACY

EP.16.01 Is Follow Up for Lung Cancer Surgery Evidence Based Within the UK - a Critical Review of Protocols

P.W.J. Barton[1], J. McAdam[2], T. James[3], S. Gomez[4], J. Morley[5], P. Dalrymple[6], C. Smith[7], S. Ivey[8]
[1]Manchester University NHS Foundation Trust, Manchester/GB ,[2]The Shrewsbury and Telford Hospital NHS Trust, Shrewsbury/GB ,[3]Wye Valley NHS Trust, Hereford/GB ,[4]University Hospital Bristol and Weston NHS foundation Trust, Bristol/GB ,[5]Sherwood Forest Hospitals NHS Foundation Trust, Mansfield/GB ,[6]Inverclyde Royal Hospital, Greenock/GB ,[7]Cambridge University Hospitals NHS Foundation Trust, Cambridge/GB ,[8]Frimley Health NHS Foundation Trust, Frimley/GB

Introduction: Our aim is to look at surgical follow-up protocols in different UK trusts to critically review and see if follow up varies post-surgical patient with lung cancer.

Methods: A literature review around this topic was conducted to establish if there was an evidence-based approach. We collected follow up protocols from 10 trusts in the UK and applied 6 questions to each to allow us to compare the results. Responses were collated, compared and interpreted by the authors.

Results: Our literature review highlighted there is limited evidence to support how lung cancer patients should be followed up post-surgery. Overall, the literature supports CT based imaging although no specific period is supported. From the protocols reviewed there were common themes identified. Post-surgical follow-up was predominantly nurse led, face to face appointments or mixed with virtual were more common. Frequency of follow-up varied between 3 and 8 months, but apart from one site was consistently over 5 years. Similarly, radiology modality predominantly used CT scan either solely or mixed with chest x-rays. Only one site only used chest x-rays to follow up patients

Conclusions: Both the literature review and critical review of protocols highlight that further research would be beneficial, looking at a wider population of protocols could help encourage a more standardised approach across the UK to ensure optimum care for patients.

EP.16.02 Lung Cancer Patients' Involvement and Support Preferences and Needs: Insights From a Global Patient Experience Survey

K. Clayton[1], M. Daniels[2], J. Fox[3], B. Gaspar[4], M. Hennink[5], J. Mayans[4], K. O'Hagan[6], L. Pretorius[2], M. Rigney[7], K. Tong[8], M. Dohr[9]
[1]Lung Cancer Nursing UK, London/GB ,[2]Campaigning for Cancer, Randburg/ZA ,[3]Roy Castle Lung Cancer Foundation, Liverpool/GB ,[4]Asociación Española de Afectados de Cáncer de Pulmón, Valencia/ES ,[5]Longkanker Nederland, Utrecht/NL ,[6]Irish Cancer Society, Dublin/IE ,[7]GO[2] Foundation for Lung Cancer, Washington, D.C./DC/USA ,[8]Cancer Information Network, Hong Kong/HK ,[9]Incisive Health, London/GB

Introduction: The Global Lung Cancer Coalition (GLCC), a partnership of 43 patient organisations across 31 nations, reaffirms in its charter the right of all lung cancer patients to be treated with dignity and respect and to have informed self-determination. Understanding patients' preferences and needs for involvement and support is essential to ensure that their physical, emotional and practical needs are met. This survey examines patients' preferences for involvement with their treatment and support teams in different situations. It also aims to explore where lung cancer patients currently seek support, where they would prefer to receive support and what kind of assistance they need most.

Methods: For its sixth annual survey, GLCC commissioned Censuswide to conduct a global survey of lung cancer patients. The survey is currently in the field across 18 countries (Australia, Argentina, Brazil, Canada, Greece, Hong Kong, Hungary, Ireland, Israel, Italy, Japan, Mexico, Portugal, South Africa, Spain, Taiwan, UK, USA). As part of this survey, the GLCC included questions about patients' preferred method of involvement with their treatment and support teams at different points in their care journey. Additionally, the survey assesses where patients are currently seeking help to cope with their disease, where they would prefer to receive support, and the most important type of support patients need at the current stage of their journey.

Results: Results will be available for presentation. The results will provide insights into how lung cancer patients worldwide would like to communicate with their care teams, and whether their preferences vary by country, age, or gender. The survey also assesses the sources of support patients currently rely on and how these match or differ from their preferred sources of support. Finally, the survey results will include insights into the most pressing support needs of lung cancer patients.

Conclusions: It is anticipated that this survey will provide valuable insights for healthcare providers, patient organisations, and policy makers by identifying where patients seek help, their preferred methods of involvement with their treatment teams, and their most pressing support needs. The findings can help tailor care and support services to better meet the needs of lung cancer patients, ultimately improving their experience of care and quality of life.

Questions	Answer options															
What do you think is the best way to have a conversation with your treatment and support team in the following situations? (Matrix. Rows provided are: • Finding out the diagnosis • The first consultation • Regular check ups • If there is a change to treatment • If there is a change in my disease • If I'm worried about something	Video	Telephone	Face-to-face	Not sure												
a) Where do you get help to cope with your disease? b) Where would you like to get help to cope with your disease? Please tick all that apply:	Family and Friends	Healthcare Professionals (Doctors, Nurses, etc.)	Patient organisations	In-person support groups	Virtual support groups	Online support groups /social media communities	Peer matching services / one-to-one peer support	Helplines/chats /text services for support, information and referral	Education programme (for example chemo education)	Counselling or therapy	Spiritual or religious communities	Work colleagues	Physical therapy	Respiratory therapy	Other [open text box]	Nowhere/I do not do this
What is the most important help you need at the moment? [Ranking scale]	Emotional support – I need counselling, mental health support, or someone to talk to	Medical care – I need better access to doctors, treatments, or pain management	Financial assistance – I need help covering medical costs, travel expenses, or daily living costs	Information and education – I need clearer information about my condition, my treatment, side effects, or what to expect	Practical support – I need help with transportation, childcare, or other daily tasks	Social support – I need connection with support groups, family, or community	Carers support – I need support in looking after my children/parents/o their family members while dealing with my diagnosis and/or treatment	Other [open text box]	Nowhere/I would not want this

EP.16 PATIENT ADVOCACY

EP.16.03 Characterization of a Real-World Data Set of EGFR+ NSCLC Patients

B.N. Nichols, M. Reiss, A. Ciupek
GO² for Lung Cancer, Washington/DC/USA

Introduction: Since the introduction of the first targeted therapy for thoracic malignancy, the field of personalized medicine and oncologic genetics has undergone rapid expansion. Though great strides have been made, there is still much we do not know about the different subgroups of people impacted by genetic drivers and personalized medicine. While mutations in the Epidermal Growth Factor Receptor (EGFR) gene are reported as the driver mutation in approximately 32% of non-small cell lung cancer (NSCLC) cases represent a larger proportion in the GO2 for Lung Cancer LungMATCH database, at about 60%. Using patient and caregiver-reported data, we sought to better understand characteristics shared amongst these individuals.

Methods: GO2 for Lung Cancer, a non-for-profit organization, runs a concierge-style treatment and clinical trial navigation service (LungMATCH) for people affected by lung cancer and their loved ones. LungMATCH collects self-reported data from patients/caregivers utilizing the service. For this analysis, we examined all contacts from the period of 01/01/2018 to 09/30/2024 to identify individuals with an EGFR driver mutation who had reported receipt of targeted therapy, and, after removing duplicate entries, analyzed their health and demographic data for commonalities and outliers.

Results: Between 01/01/2018 and 09/30/2024, 113 unique EGFR-positive (EGFR Exon 19 deletions, L858R mutation, L861Q, L718Q, or Exon 20 insertions) individuals who had received targeted therapy (or their loved ones) contacted the LungMATCH program. Patients contacted GO2 after a median of 2 lines of therapy and the median age at diagnosis was 58. Most patients (79%) were female, which aligns with the current literature, highlighting the prevalence of EGFR mutations in women. Cases were predominately adenocarcinoma (97%) and the most common co-mutations in this population were EGFR T790M (14%) and TP53 (12%). Other than targeted therapy, the most common treatments received were chemotherapy (46%) and radiation (32%). A third-generation TKI (tyrosine kinase inhibitor) was the most common first-line treatment (49%), followed by surgery (14%). Prevalent second-line treatments were third-generation TKIs (31%) or radiation (16%). Of note, 98.1% of patients presented with late-stage (stage IV) disease at the time of first LungMATCH contact. The most frequently reported sites of lung cancer metastasis were bones (30%), brain (26%), and lymph nodes (16%). For navigation services, 4% requested biomarker testing navigation, 49% requested treatment navigation, and 29% sought clinical trial navigation. 82% of calls regarded the next steps after progression on a 3rd generation EGFR-targeted therapy.

Conclusions: People diagnosed with EGFR-positive lung cancer represent a distinct subset of the NSCLC population. This real-world data analysis highlights the pervasiveness of third-generation EGFR inhibitor resistance. Once progression occurs, patients and their loved ones are unsure of how to proceed, and what options remain. Providing an individualized support service, such as the treatment and trial navigation offered through LungMATCH, can help to bridge this gap. In addition, using platforms such as LungMATCH to gather real-world, patient-reported data can help to broaden our understanding of what these groups require and how we can adapt to their changing needs.

EP.16 PATIENT ADVOCACY

EP.16.04 Relationship Between Telomere Length and Pulmonary Toxicity in Patients With Locally Advanced Unresectable Lung Cancer

A. Marín-Muñiz
Bellvitge University Hospital - IDIBELL. University of Barcelona, L'Hospitalet de Llobregat/ES

Introduction: Telomere length (TL) is involved in tissue repair. Pulmonary toxicity (PT)due to radiotherapy (RT) is a complication of non-small cell lung cancer (NSCLC)treatment, being a risk factor under study.Our objective is to analyze the relationship between TL and PT due to RT in patients with locally advanced unresectable NSCLC treated with concurrent chemoradiotherapy and immunotherapy (IT) in PDL-1 positive patients.

Methods: A unicenter prospective study of 90 patients enrolled between 2018and 2021. Clinical, analytical, tumor, treatment data and TL were collected. TL was obtained from buccal samples. Patients were classified in percentiles according to z-score and were divided into two groups according to the severity of PT: G1-G2 (mild)/G3-G5 (severe).

Results: Ninety (90%) were men with a mean age of 72 years (SD 6.3). Predominanthistology was squamous (54%) and 40% received IT. In relation to PT, 81% developed G1-G2 toxicity and 19% G3-G5 with significant differences between groups only in dosimetric variables; V20: 20Gy vs. 26Gy (p=0.002) and in V5: 46Gy vs. 54Gy (p=0.006). No significant difference was observed between PT and TL, according to the univariate analysis. In the subgroup analysis by IT treatment, lower PT was observed in patients with TL above the 25th percentile (Figure 1). TL was shorter in our population compared to general population, done by indirect comparation.

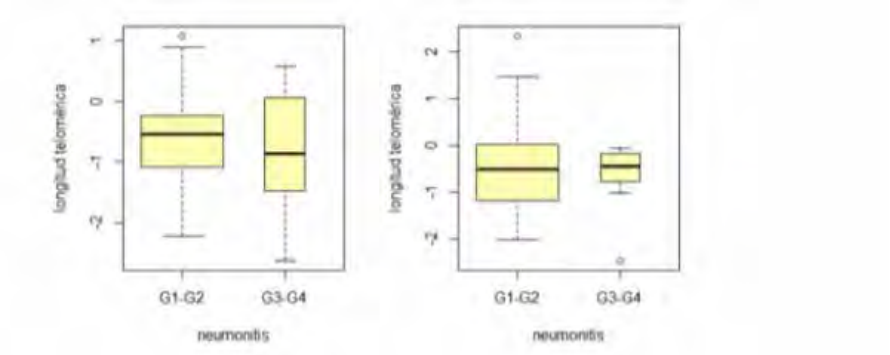

Figure 1. Boxplot of pneumonitis and telomere length in both groups (Left, without IT. Right, with IT). p-value 0.045.

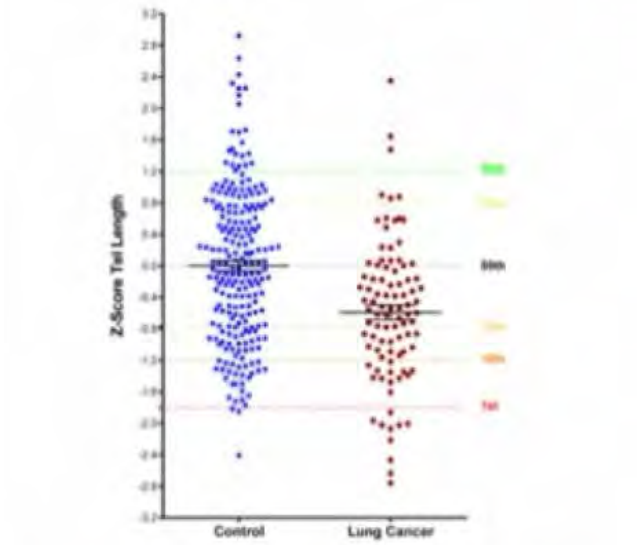

Figure 2 TL Distribution in our series compared to general population

Conclusions: No relation was found between LT and PT development. However,patients with TL above 25 th percentile treated with IT had lower risk of developing severe PT. Further studies are needed to validate the findings and think about therapeutic implications.

Keywords: Cancer, Pneumonitis, Telomere

EP.16 PATIENT ADVOCACY

EP.16.05 Expectations and Quality of Life of Lung Cancer Patients During the Care Process

E. Pataki
National Koranyi Institute of Pulmonolgy, Budapest/HU

Introduction: Lung cancer affects an increasing number ofpeople worldwide. Mortality and incidence rates are traditional public healthindicators, but these indicators are difficult to interpret at the individuallevel. The experiences of those affected in the care system and during thepatient journey can provide important feedback.

Methods: A quantitative questionnaire-basedcross-sectional study examining patients' self-reported clinical data and theirexperiences during the patient journey, in two selected institutions (in total,n=122). The qualitative method focuses on feedback on personal experiences(focus groups n=7).

Results: The patients average age was 66.8 years,and their general health was good according to their self-reporting. In termsof stage: 51% of the patients were in stage I-II, 20% in stage III. and 29% instage IV. Over 90% wereunaware of biomarker positivity, although it was at the base of subsequenttreatments.Half of thepatients were identified through screening, 10% were included in the LDCTprogram.In terms of transparency in the patientjourney, public information on early symptom recognition, improving therelationship between primary care physicians and patients, and more in-deptheducation about lung cancer were considered useful by 85%. Reducing waitingtimes was considered important by 60%, and clear information about diagnosticprocesses was considered particularly important by 77%.In theirsuggestions, 91% of patients identified the accessibility of the medical teamand 86% of professionals' communication skills as areas for improvement. Intotal, 89% found the communication reassuring.

Conclusions: Patients willtrust clinical decisions when they are provided with sufficient information andunderstanding during treatment so that their overall quality of life issatisfactory regardless of the outcome of treatment. Clearcommunication with patients during the whole examination and treatment promotesthe quality of life and sence of security.Patientsexperience difficulties in accessing primary care and early information at thebeginning of their journey, and the time to diagnosis seems long, which ispartly a justified observation. The feedback on the work of the care teamand the information received and the quality of care is satisfactory. However,the quantity and quality of communication is not entirely reassuring. This maybe due to the known capacity and staff shortage, which means that the team isoverloaded.

Keywords: QoL, Communicaton, patient perspective

EP.16 PATIENT ADVOCACY

EP.16.06 Health Literacy Leads to Health Equity; a Best Practice Approach From a Lung Cancer Organization

C. Estrin-Lebovic, A. Kampschroeder, H. Law, D. Hicks, N. Phipps, R. Botello, M. Reiss, M. Rigney
GO² For Lung Cancer, Washington/DC/USA

Introduction: Health literacy is defined as the ability to find, understand, and use information to make health-related decisions. In the US, health literacy is a stronger predictor of health outcomes than income, employment status, education level, and racial or ethnic background. With nearly 9 out of 10 Americans experiencing limited health literacy and lung cancer being the leading cause of cancer deaths, addressing this issue is critical. Recognizing this, health literacy guidelines were integrated into all educational materials and the Lung Cancer Registry (LCR) with the goal of improving health outcomes, and supporting health equity within lung cancer communities.

Methods: After extensive research and advanced training in health literacy best practices, the content and design features of all educational materials were reviewed and revised to align with these guidelines. The same best practices were also integrated into the Lung Cancer Registry (LCR), an online platform where individuals with lung cancer and caregivers can provide updates on treatment and disease status. Created to track the journey from diagnosis through treatment and survivorship, the LCR helps researchers assess treatment effectiveness, side effects, quality of life, outcomes, and quality of care.

Adaptations to the LCR included making it easier for individuals to understand the informed consent, survey descriptions, and registry questions. Feedback was gathered from community members living with lung cancer to ensure the registry platform and educational materials were clear, easy to understand and accessible.

Results: Along with the language and design of the LCR, nearly 50 individual educational materials were reviewed and revised with input from multiple audiences, including people living with lung cancer, healthcare professionals, and the general public. Valuable feedback was gathered, including the need for the LCR to avoid the phrase 'Advance lung cancer research,' as it closely resembles 'advanced lung cancer,' which could unintentionally exclude some individuals. Once feedback and health literacy guidelines were incorporated, lung cancer community members confirmed that the information was clearer and more engaging. By incorporating health literacy guidelines such as plain, person-first language, shorter sentences and structuring content with bullet points and other design elements - the accessibility and readability of lung cancer materials were significantly improved to best meet the needs of the population.

Conclusions: Integrating consistent health literacy best practices fosters equitable health outcomes. With significant advances in lung cancer, vital information has grown increasingly complex, making clear communication about lung cancer more urgent than ever. Engaging a multidisciplinary group to provide feedback and confirming the final draft with lung cancer community members, was highly effective in improving the health literacy of our content. Additionally, using shorter sentences, bullet points, and person-first language are simple strategies that others can implement in order to positively impact health outcomes and survivability.

Established in 2021, the IASLC Language Guide reminds us that thoughtful language "respects the dignity of those diagnosed with lung cancer and their families." We have created a model for improving health literacy across all aspects of lung cancer care that can be replicated anywhere around the world.

EP.16 PATIENT ADVOCACY

EP.16.07 Addressing Unmet Needs of the Lung Cancer Community: The Journey to Find and Implement Mind Over Matter

S. McHale, M. Rigney, A. Doty
GO² for Lung Cancer, Washington/DC/USA

Introduction: People with lung cancer experience high levels of distress and have great unmet psychological and physical needs. Their loved ones often also have high rates of distress, anxiety, and depression. Many cancer centers lack comprehensive psychosocial programs, and where services are offered, there are often barriers to participation such as waitlists, ill health, and transportation issues. Research confirms the effectiveness of psycho-oncology interventions to address these needs. Specifically, studies have found benefits of mindfulness- and cognitive behavioral-based group interventions for those impacted by lung cancer, Implementation of interventions from research to practice is rare, and can take up to 17 years. In a quest to help address the psychosocial needs of the US lung cancer community, we began the search for an intervention to implement.

Methods: From October 2022 to June 2023, our efforts were three-fold. As we completed a literature review, we conducted five key formal and informal interviews with behavioral researchers, providers of psychosocial services, and an implementation scientist. We then formulated six key requirements for the intervention: 1. suitable for both those diagnosed and their loved ones; 2 the participant burden needed to be low, to allow those in active treatment and busy caregivers to join; 3. licensing constraints meant that it had to be skills based, not therapeutic; 4. as stress and anxiety affect those across the continuum, it needed to be relevant at any point in the journey, including for long-term survivors; 5. for anyone in the US to join, it had to be virtual; and 6. we needed assurance that it was evidence-based.

Results: Mind Over Matter (MOM), is a five-week group psychosocial coping skills training developed by Inova Peterson Life with Cancer™. MOM teaches “ tips and tools to deal with the fears, worries, and sadness that can come with a cancer diagnosis.” We discovered MOM in June 2023 and found it met our requirements. We attended facilitator training in November 2023, hired a MOM-specialist social worker in May 2024, and began recruitment that June. We “soft” launched MOM in August 2024, marking the first time it was offered at the national level and the first exclusive to the lung cancer community. At the end of 2024, two full classes had been completed, with post-attendance surveys indicating that MOM provided helpful information to change behaviors and learn coping skills. We are expanding our recruitment efforts and expect to have data from three additional classes by September. We are also initiating an enhanced intake process and plan to offer a MOM class just for lung cancer caregivers.

Conclusions: In under two years, we researched, identified, and launched a unique virtual psychosocial intervention, available to anyone affected by lung cancer in the United States. MOM has the potential to meet the global need for coping skills as well. Thus far, it has been adapted and translated into Spanish and the feasibility and acceptability of MOM is under study with African American/Black women. Interestingly, providers from Latvia joined Life with Cancer’s most recent facilitator’s training.

EP.16 PATIENT ADVOCACY

EP.16.08 Preliminary Study of Culturally Adapted Approaches to Enhance Lung Cancer Education for Hispanic/Latino Population

R. Botello[1], C.D. Clark[2], P. Rios[3], M. Reiss[1]
[1]GO[2] for Lung Cancer, Washington/DC/USA ,[2]Hi Cal Consulting LLC, Gainesville/FL/USA ,[3]Behavioral and Clinical Services Institute, Gainesville/FL/USA

Introduction: Effective lung cancer education for Hispanic/Latino populations requires a strategic adaptation to address cultural preferences in material engagement, an understanding of the barriers to care access within the community and insight into how this population interacts with medical information in daily life. Nuestra Gente, a health education initiative from GO2 for Lung Cancer, developed a series of videos designed to bridge linguistic and cultural gaps in lung cancer education for Hispanic/Latino communities in the U.S. This qualitative review examines the perceptions, knowledge, and relevance of these audiovisual materials, assessing their effectiveness in conveying critical lung cancer information and their ability to address health communication disparities.

Methods: Our qualitative analysis is based on responses from an in-person, structured focus group conducted in February 2024 with Spanish-speaking Hispanic/Latino adults (ages 30-60 years, n=4). Participants engaged in a structured discussion of the Nuestra Gente video library to assess the knowledge gained and effectiveness of the Spanish-language materials developed by GO2 for Lung Cancer. The analysis also examined participant engagement, accessibility of media format, and comprehension of the medical information presented.

Results: Preliminary findings revealed that while the information was considered useful, there is a need for visual reinforcements within the videos and improved accessibility measures for video distribution. Specifically, the use of traditional medical terminology without sufficient context posed a challenge. Focus group analysis also indicated that language, pacing, and the integration of supplementary educational materials (such as infographics) significantly influenced participants' comprehension and retention of information.

Conclusions: Leveraging a more deliberate approach towards lung cancer education is essential to ensure that the information is both accessible and culturally relevant for Hispanic/Latino populations. Future efforts should focus on refining educational tools to better align with the cultural, linguistic, and health literacy needs of the community. Enhancing engagement, incorporating visual reinforcements, and improving accessibility can help ensure that members of the Hispanic/Latino community receive information in meaningful and actionable ways. Our analysis highlights the need for clear explanations of medical terminology, improved pacing, and the integration of supplementary materials to support comprehension and retention. Applying these insights can help healthcare organizations develop new, more effective materials that not only inform but also empower individuals to make more confident decisions about their care. To further guide best practices and the development of educational resources, additional data collection and a larger-scale analysis are needed to confirm these findings and assess the long-term impact of culturally tailored lung cancer education initiatives.

EP.17 GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS

EP.17.01 Identifying Barriers to Timely Initiation of Oral Anti-Cancer Medication in Patients With Non-Small Cell Lung Cancer

A. Hicks[1,2], S. Monestime[3], K. Dumais[2], H.W. Powery II[2], C. Granville[3], L.E. Raez[2,4]
[1]Florida A&M University, Davie/FL/USA ,[2]Memorial Cancer Institue, Pembroke Pines/FL/USA ,[3]GO[2] for Lung Cancer, Washington/DC/USA ,[4]Florida Atlantic University, Boca Raton/FL/USA

Introduction: Delays in initiating therapy in patients diagnosed with non-small cell lung cancer (NSCLC) can worsen outcomes. Therefore, the timely initiation of oral anti-cancer medication (OAM) is paramount. A previous study demonstrated that time to treatment initiation (TTI) of less than 45 days was associated with improved outcomes, and 37.2% of patients experienced treatment delays. The cost of OAMs, requirements of prior authorization (PA), and need of patient assistance programs (PAP) can all contribute to delays. This study aims to evaluate the timeliness of OAM initiation in patients with advanced NSCLC with EGFR mutations or ALK translocations.

Methods: A retrospective observational cohort study was conducted at the Memorial Cancer Institute (MCI), a large multi-site community cancer center. Medical records were reviewed for patients diagnosed with advanced NSCLC prescribed preferred first-line therapy between January 1, 2020, and December 31, 2023. TTI was defined as the number of days from initial diagnosis to the first dose of OAM. A delay in TTI was defined as initiation occurring more than 45 days after diagnosis. Descriptive statistics were used to summarize patient demographics, insurance status, type of specialty pharmacy, and quantify the duration of each step in the medication access process. The Mann-Whitney U test was used to compare TTI between patients who received PAP support and those who did not.

Results: Of the 150 patients identified, 34 were included in the analysis. The mean age was 64.8 years (SD 13), and the majority were female (n=23, 67.6%), White (n=27, 79.4%), Hispanic (n=18, 52.9%), and had stage IV NSCLC (n=33, 97%). A total of 24 patients (70.6%) obtained their medication through an internal specialty pharmacy, and 31 patients (91.2%) had insurance coverage. Overall, 52.9% of participants utilized PAP support, while 47.1% did not. The mean processing times for each step were as follows: 2.2 days (SD 2.4) from prescription to PA submission, 2.9 days (SD 3) for PA approval, 1.1 days (SD 1.5) for PAP approval, and 9.7 days (SD 5.6) from written prescription to patient receipt. Overall, the mean TTI—from diagnosis to patient receipt of medication—was 26.5 days (SD 15.5), with 11.76% (n=4) of patients experiencing a delay defined as TTI exceeding 45 days.

Conclusions: Majority of patients with NSCLC receiving OAM from MCI received timely treatment from diagnosis, and the use of PAP was not associated with delays in treatment. These findings may reflect the efficiencies of coordinated medication access processes at MCI. Given the impact of delayed diagnosis and treatment initiation on clinical outcomes, future research should assess generalizability and evaluate both patient-specific and system-level contributors to treatment delays across diverse care environments.

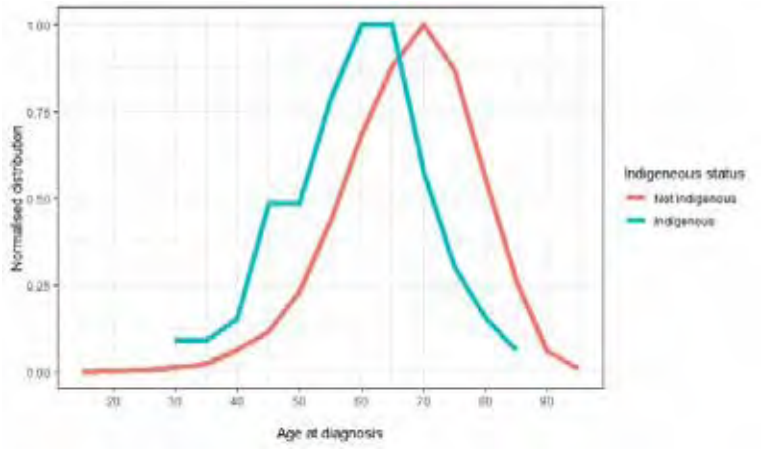
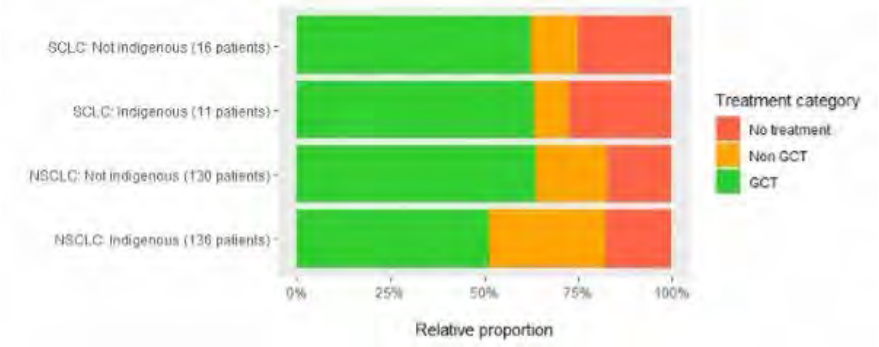
Introduction: Indigenous Australian lung cancer patients are known to have poorer survival outcomes, later stage at diagnosis, and significant comorbidities. Socioeconomic disadvantage, cultural awareness and access to healthcare are key factors that impact outcomes of indigenous populations. Our goal was to explore risk factors, patterns of management and survival outcomes in Indigenous compared to non- Indigenous Australian patients using the Victorian Lung Cancer Registry (VLCR).

Methods: A retrospective observational cohort study, using data collected on primary lung cancer patients in the VLCR between January 2011 and January 2024. Multivariate Cox regression and propensity matched survival analysis was performed to assess impacts of patient and clinical variables on survival.

Results: We included 171 Indigenous and 17,343 non-Indigenous Australian patients. Indigenous lung cancer patients were younger in age (<60 years: 41% vs 17.2%, p<0.001), had lower socioeconomic status, were more likely to be current smokers (99% vs 87%, p<0.001) and had higher levels of respiratory comorbidity (36% vs 23%, p<0.001) Figure 1. Indigenous patients had lower receipt of guideline concordant treatment (53% vs 59%, p=0.084) Figure 2. Survival outcomes were not statistically significant but slightly lower for Indigenous compared to non-Indigenous Australian lung cancer patients (median survival 1.3 vs 1.6 years, HR=1.13, p=0.2).

Conclusions: We found lung cancer patients of Indigenous status were more likely to have demographic disadvantage and clinical risk factors that contributed to poorer management and survival outcomes compared to patients of non-Indigenous status. 16% of the Indigenous population were aged <50 at diagnosis posing eligibility concerns for the upcoming National Lung Cancer Screening Program. Identifying barriers to healthcare and treatment in the Indigenous Australian population is an important research priority to improve disparities between the two populations.





Keywords: Indigenous population, Lung cancer registry, Disparity and inequity

EP.17.03 Disparities in Lung Cancer Treatment for Older Adults

R.S. Kailar[1], F. Liu[2], D. Yammani[3,4], Y. Raghuwanshi[1], A. Dowlati[2,3], M.L. Hsu[2,3], Q. Wang[2,3], M. Mirsky[2,3], L. Chiec[2,3]
[1]University Hospitals Cleveland Medical Center, Cleveland/OH/USA ,[2]Case Western Reserve University School of Medicine, Cleveland/OH/USA ,[3]University Hospitals Seidman Cancer Center, Cleveland/OH/USA ,[4]Case Comprehensive Cancer Center, Cleveland/OH/USA

Introduction: Older adults are disproportionately affected by non-small cell (NSCLC) and small cell lung cancers (SCLC), with most patients diagnosed over age 65. Treatment depends in part on functional status, generally measured by ECOG performance status, however other factors associated with treatment receipt are less clear. Here, we investigate whether differences in treatment exist for older adults with lung cancer, and explore factors associated with receipt of frontline treatment.

Methods: Clinical data was obtained from an institutional cancer registry (including academic and community sites) for patients with stage IV lung cancer diagnosed between 2018-2022. Social determinants of health data were obtained from the national LexisNexis database. Older adults were defined as ≥65years. Chi-square and Fisher's exact tests were used to evaluate associations between categorical variables, including treatment receipt and baseline characteristics across age groups and subgroups. For continuous or ordinal variables, the Wilcoxon rank-sum test was used for assessing normality and comparing differences between groups for skewed distributions.

Results: For younger and older adults, there were no differences in baseline features (Table 1) or receipt of any systemic treatment (p=0.49). Older adults were more likely to be treated with immunotherapy alone (p=0.006). Younger adults survived longer than older adults (p<0.01, median survival 352 vs 217 days). For all patients, ECOG 0-2 was associated with increased likelihood of treatment; for older adults only ECOG 0-1 showed this association (p<0.01). For all patients (p=0.005) and older adults specifically (p=0.013), having SCLC was associated with increased likelihood of treatment compared to NSCLC. There was no difference in hospitalizations between younger and older adults, although the proportion of patients hospitalized after diagnosis was high in both groups (76 vs 67%, p=0.80). There were no differences in treatment receipt based on wealth index or college attendance. There were significant differences in the household structures of older and younger adults, suggesting potential differences in caregiving dynamics and family support structures by age, however total household members, and their age, were not associated with receipt of treatment.

Conclusions: Older adults are as likely to receive frontline systemic therapy for stage IV lung cancer as younger adults, but more likely to receive immunotherapy alone and less likely to receive treatment if ECOG 2. Younger adults have longer survival times after diagnosis compared to older adults. Household support structures vary by age, with future research to be focused on personalizing support for older adults based on their unique needs.

Table 1: Baseline Demographics

	Younger Adults (n = 120)	Older Adults (n = 188)	p-value
Median Age in Years (IQR)	59 (56-62)	74 (69-79)

EP.17.04 Social Vulnerability as a Determinant of Disparities in Lung Cancer Management and Survival

P. Duarte D'Ambrosio[1], P.B. Costa[1], R.M. Terra[2], P.M. Pêgo-Fernandes[1]
[1]Instituto do Coracao, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo/BR ,[2]Instituto do Cancer do Estado de Sao Paulo, Faculdade de Medicina FMUSP, Universidade de Sao Paulo, Sao Paulo/BR

Introduction: Social vulnerability significantly influences lung cancer outcomes, contributing to disparities in diagnosis, treatment, and survival. This study evaluates the impact of the Índice Paulista de Vulnerabilidade Social (IPVS -São Paulo Index of Social Vulnerability) on clinical characteristics, treatment access, and survival among patients with lung cancer in São Paulo.

Methods: A retrospective cohort of 6,835 treated patients diagnosed with lung cancer (stages I-IV) between 2000-2013 was analyzed. Patients were stratified by IPVS categories, ranging from very low (IPVS 1) to very high (IPVS 4-6) vulnerability. Clinical and demographic disparities across PVS groups were evaluated using ANOVA and chi-square tests. Survival outcomes were assessed using Kaplan-Meier analysis and Cox regression models, adjusted for confounders such as stage at diagnosis and treatment modality.

Results: Significant disparities were observed across IPVS groups. Patients in the most vulnerable categories (IPVS 4-6) were older (27.3% aged ≥70 years), had lower educational attainment (10.4% illiterate; only 2.8% with higher education), and were more frequently diagnosed at advanced stages (33.2% at stage IV). Treatment access also declined with higher IPVS levels, with a treatment rate of 85.5% in IPVS 4-6 versus 89.4% in IPVS 1 ($p<0.001$). Survival outcomes mirrored these disparities: mean survival times were 18 ± 19 months for PVS 1, 15 ± 17.3 months for IPVS 2, and 13.2 ± 15.8 months for IPVS 4-6 ($p<0.001$). In multivariate Cox regression, high social vulnerability independently predicted poorer survival (HR for IPVS 4-6 vs. IPVS 1=1.32, 95% CI: 1.22-1.43, $p<0.001$), even after adjusting for stage and treatment. Advanced clinical stage and non-surgical treatment also contributed to worse outcomes.

Conclusions: The Índice Paulista de Vulnerabilidade Social is a powerful predictor of disparities in lung cancer diagnosis, treatment, and survival. Higher social vulnerability correlates with delayed diagnosis, reduced access to treatment, and significantly worse survival outcomes.

EP.17 GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS

EP.17.05 Association of Social Vulnerability With Prognosis of Lung Cancer in Japan

Y. Seki[1], A. Ichikawa[1], S. Uchiyama[1], Y. Matsui[1], J. Araya[2]
[1]The Jikei University Katsushika Medical Center, Tokyo/JP ,[2]The Jikei University Hospital, Tokyo/JP

Introduction: Lung cancer remains the leading cause of cancer-related deaths worldwide. Prognosis is often determined by clinical factors such as tumor stage and response to treatment. Outcome of cancer care is also influenced by social and economic factors. Some studies have suggested that social isolation may be associated with an increased risk of mortality in cancer patients, as it can lead to a reduction in treatment intensity and promote behaviors that hinder treatment continuation. However, the impact of social vulnerability on survival outcomes on lung cancer care has not been sufficiently explored. Socially vulnerable populations, including individuals with low socioeconomic status, limited healthcare access, and social isolation, face unique challenges that can detrimentally affect their prognosis. This study aims to investigate the influence of social vulnerability on the survival outcomes of lung cancer patients.

Methods: We performed a retrospective cohort analysis of 71 socially vulnerable lung cancer patients diagnosed between 2021 and 2023. Data were extracted from cancer registries and patients were identified as welfare recipients or extreme elderly (range, 85-98 years) . The primary outcomes evaluated were overall survival (OS), availability of active treatment, and whether they received the treatment plan they desired. Data, including patient demographics, tumor characteristics, treatment details, and clinical outcomes, were collected from medical records. Reasons for not receiving active treatment, such as chemotherapy or molecular targeted therapy, were also examined. Statistical analyses including survival and subgroup analyses were performed to summarize the data.

Results: In socially vulnerable lung cancer patients, median overall survival (mOS) was 14.6 months, considerably worse than historical survival data for lung cancer patients. The prognosis for extreme elderly group had very poor of mOS of 7.1 months. The group that received active treatment, including surgery, chemotherapy, and/or radiotherapy had a better mOS of 20.4 months. Of all patients studied, 65.7% were not eligible for curative therapy, chemotherapy, or molecular targeted therapy. The main reasons for not receiving these treatments were deterioration of general condition in 22.5% and the patient's will in 21.1%. Notably, patients who received early diagnosis and treatment before their performance status (PS) declined significantly had improved survival, underscoring the importance of early diagnosis and timely medical intervention.

Conclusions: Our findings indicate that socially vulnerable lung cancer patients have considerably worse survival outcomes compared to historical data, even after accounting for clinical factors. Addressing the needs of this high-risk group through systems for regular lung cancer screening and facilitating early access to treatment may improve their prognosis. Further research is required to identify the underlying causes of these disparities and develop targeted interventions to enhance survival rates for socially vulnerable populations.

EP.17.06 Evolving Trends in Lung Cancer Epidemiology in India: A Shift in Patterns and Clinical Insights

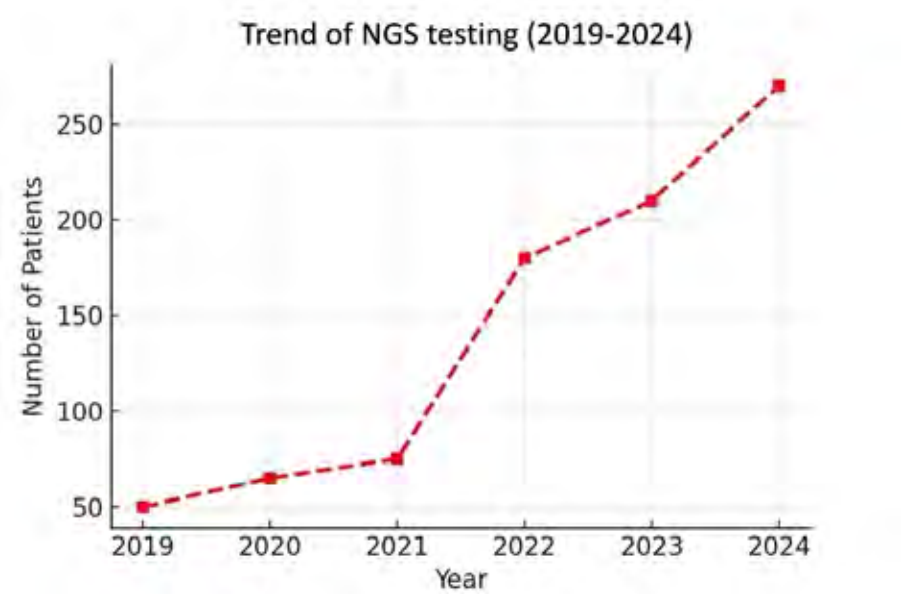
U. Batra[1], M. Sharma[1], R. Choudhury[1], S. Nathany[2], R. Sachdeva[1], V. Krishna[1], A. Patel[3], M. Wadhwa[4], K. Gupta[4], A. Dewan[1], S. Choudhary[1], V. Batra[5], A. Mehta[1], P. Venkataraman[1]
[1]Rajiv Gandhi Cancer Institute & Research Centre, New Delhi, Delhi/IN ,[2]Fortis Memorial Institute and Research Institute, Gurugram, Gurugram/IN ,[3]Malnad Hospital and Institute of Oncology, Shivamogga, Karnataka/IN ,[4]Center for Quality Improvement and Patient Safety and Faculty, Indian Institute of Public Health, Gandhinagar/IN ,[5]SGT Medical College, Gurugram/IN

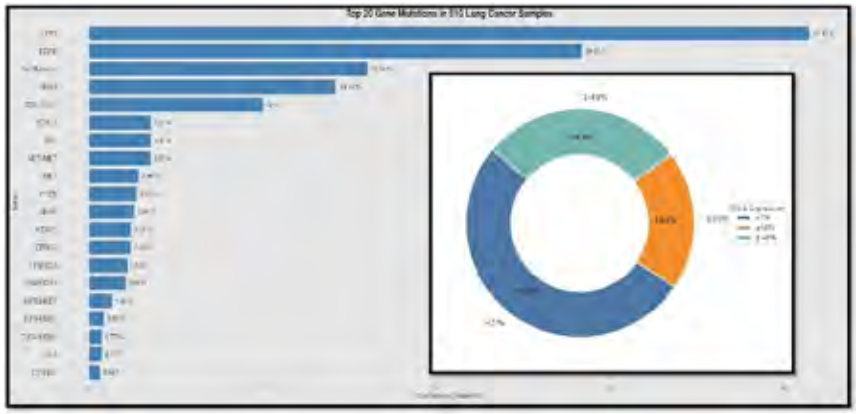
Introduction: Lung cancer in India is rising due to increasing air pollution and lifestyle changes, with more cases among females, non-smokers, and younger patients and a declining co-existing tuberculosis. There exist significant differences in the molecular landscape of NSCLC between the western and Indian population. This study aims to examine the changing epidemiology and molecular profile of lung cancer in India.

Methods: We collected patient data from the Thoracic Oncology OPD at RGCIRC. Relevant clinical and demographic variables including age, gender, histological subtype, tuberculosis status, smoking history, ECOG PS, metastatic disease and NGS/ PDL1 was included. Analysis was conducted using JAMOVI software, version 2.6.

Results: A total of 1,714 patient data was analysed. The findings indicated prevalence of lung cancer was 32.3% in females. Furthermore, only 7.1% of the total cases were empirically treated with ATT in the 6 months prior to diagnosis . However, once diagnosed with NSCLC, high number of patients underwent hot spot NGS and PDL1 testing with a higher NGS positivity in the female group.

Conclusions: This study reveals evolving trends in the epidemiology of lung cancer in India. Our data suggests a rise in trend among nonsmoking, females and decrease in the trend of TB. The PDL1 positivity rates and incidence of EGFR /ALK/Ros mutations is also different from western and far east population. This study highlights the importance of real world data and global participation in clinical trials so as to ensure that treatment strategies are tailored to the unique genetic and epidemiologic characteristics of different populations, ultimately improving patient outcomes.





Keywords: molecular classification, real world data, heterogeneity of cancer

EP.17 GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS

EP.17.07 Using COM-B Behavioural Change Framework to Implement Lung Cancer Pathway for Primary Care Physicians

z. otty[1], s. sabesan[1], r. evans[2], a. brown[1], s. larkins[2]
[1]townsville university hospital, townsville/AU ,[2]james cook university, townsville/AU

Introduction: To improve care of people with suspected lung cancer in Northern Australia, we developed an online 'Health Pathway' called the Townsville lung cancer referral pathway (TLCRP). TLCRP outlines the recommended investigations and appropriate referrals for a person with suspected lung cancer. Implementation of evidence-based practices like the TLCRP depends on successful behavioural change interventions. Here, we describe the implementation of TLCRP using the COM-B behavioural change framework.

Methods: The COM-B model proposes three necessary components for any behaviour (B) to occur. Through assessing capability (C), opportunity (O), and motivation (M), targeted interventions can be created that lead to effective change (figure 1)

Results: Interventions that were useful in TLCRP implementation based on the COM-B framework 1. Education- Team of clinicians who regularly educate local GPs, nurses and medical students about TLCRP.....

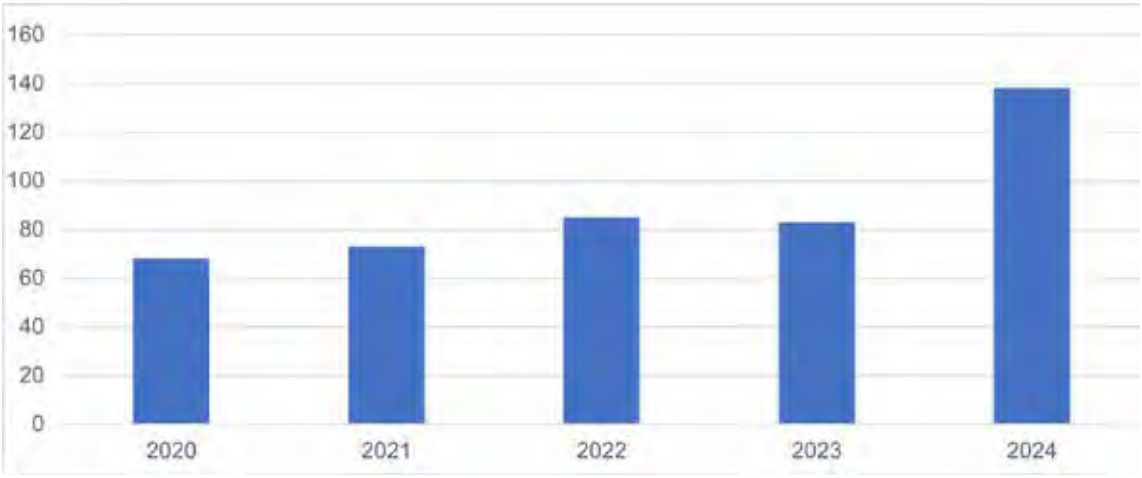
2. Persuasion-Increased engagement with GPs who don't use TLCRP and resolve the barriers for using it.....

3. Incentivisation- RACGP (Royal Australasian College of General Practitioners) provides CPD (continuous professional development) points for using TLCRP.....

4. Training- Training for new GPs and practice managers to use the TLCRP portal.....5. Restriction- Respiratory physicians not accepting referrals that do not include all the required information. ..... 6. environmental restructuring-TLCRP is easily accessible - on the desktop as well as mobile devices. ..... 7. Modelling-Positive feedback from specialists and patients. ..... 8. Enablement- Prompt technical support for use of the website.....

Policy categories that were useful in TLCRP implementation based on the COM-B framework: 1.Communication/ marketing- The local Primary Health Network actively promotes use of TLCRP through flyers and newsletters.....
2. Guidelines- Cancer Australia lung cancer management protocols. .....3. Fiscal- 'Health Pathways' software provided free to all the GP practices. ..... 4. regulation- Establishing agreements on GP specialist referrals.....5. Legislation-Governement policy to encourage the use of Health Pathways and online referrals..... 6.Environmental/social planning- Ensuring adequate clinical staff and diagnostic facities .....7. Service provision- Employing a team of clinicians and administration personnel to implement and support TLCRP.

Conclusions: IThe COM-B model for behavioural change is a useful tool to implement Health Pathways for primary care physicians. use of TLCRP increased from 2020 to 2024 (figure 1).



Keywords: lung cancer, health pathways, COM B framework

EP.17 GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS

EP.17.08 Ready or Not: Assessing Provider and Facility Preparedness for Bispecific Therapy in Extensive Stage-Small Cell Lung Cancer

J.T. Fathi, A. Ciupek, S. Ulloa, A.S. Boyd
GO² for Lung Cancer, Washington/DC/USA

Introduction: Small Cell Lung Cancer (SCLC) is aggressive with 94% of cases extending outside the lung (ES-SCLC), leading to poor 5-year survival rates. Until recently, limited therapeutic options were available to treat SCLC and its associated poor outcomes. A new T-cell engager immunotherapy that targets delta-like ligand 3 (DLL3) and CD3 T-cell co-receptors for cytotoxic T-cell activation (bispecific therapy (BT)) has been shown to improve overall survival for ES-SCLC. However, BTs carry an adverse side effect (AE) profile requiring enhanced monitoring after certain doses. This study aimed to define healthcare provider knowledge gaps related to BT and measure their preparedness for its implementation as an effective treatment for ES-SCLC.

Methods: A survey was distributed to assess facility demographics, populations served, and provider characteristics; BT awareness, preparedness, barriers, likelihood of offering or referring, and interest in further education. Emails were sent to GO2 Centers of Excellence (COE; n=94) and non-COE (n=48). Additionally, 435 emails were distributed nationwide, including providers in various geographic locations and health professional shortage areas (HPSAs).

Results: Participant Population Sixty-nine participants completed the survey, representing a diversity of professional roles: physicians (28%), Advanced-Practice Registered Nurses (APRNs; 25%), oncology navigators (16%), nurses (9%), healthcare administrators (4%), and clinical healthcare staff (2%). These participants served Urban (61%) and Suburban (25%) populations, while fewer served Rural (10%) and Healthcare Professional Shortage areas (HPSA; 1%). Of note, 63% of rural or HPSA participants were oncology navigators or nurses. Familiarity with Therapy 74% of participants reported familiarity with BT for SCLC management. However, most nurse and health administrator respondents reported no familiarity, including approximately 25% of APRNs. Only 50% of respondents from rural or HPSA areas reported familiarity. Additionally, all nurse respondents, most healthcare administrators, approximately 40% of oncology navigators, and approximately 30% of APRNs reported no familiarity with the therapy's mechanism of action. Similar patterns appeared for other BT-related topics, including administration route, time-bound AEs, and extended monitoring requirements. Systems Preparedness Overall, 27% of respondents felt their facility was very highly prepared to offer BT for ES-SCLC, and 24% felt highly prepared. In rural or HPSA areas, 25% reported very little and 38% reported no preparedness. Notably, half of rural and HPSA participants reported no confidence in their ability to order or obtain BT or IL-6R antagonist therapy for AE management.

Conclusions: These results show a generally high level of familiarity with BT for ES-SCLC and readiness to offer it. However, they also reveal a pronounced gap in familiarity and preparedness of nurses, oncology navigators, and APRNs (regardless of facility location or type) compared to other professionals. This underscores the need for targeted education and training for nurses, oncology navigators, and APRNs, including those in rural and HPSAs, to ensure equitable readiness across patient-facing roles for optimal and widespread implementation. Further study is needed to examine systemic differences across facility types and better understand gaps in knowledge of BT characteristics and administration by role.

EP.17.09 Pulmonary Nodule Burden in Melbourne: A Snapshot Pre-Australian Lung Cancer Screening Rollout

C.L. Leong[1], K. Tang[1], A. Hocking[1], M. Yao[1], H. Buzacott[1], A. Baker[1], S. Knight[1], T. Leong[1]
[1]Austin Health, Melbourne/AU

Introduction: The Australian National Lung Cancer Screening Program launches on 1st July 2025. It is anticipated that demand for pulmonary nodule diagnostic and management services will increase. To date, there is a lack of understanding of the prevailing pulmonary nodule burden in Australia. Therefore, there is a need to characterise the nodule landscape before the implementation of the screening program so that services can be appropriately upscaled to deliver high-quality, patient-centered and efficient nodule care. This study has commenced at a single large tertiary centre and will expand to involve two further tertiary institutions that will encompass northern, southern and central regions of the state (Victoria).

Methods: This is a retrospective review of electronic and scanned medical records to assess the burden of new pulmonary nodules referred to both the respiratory and thoracic surgery departments in a metropolitan-based, university-affiliated tertiary centre in Melbourne between 1st July 2023 to 1st August 2024. Known pulmonary nodules undergoing surveillance or associated with underlying known malignancy before study duration were excluded.

Results: A total of 1,338 cases were reviewed with 535 new referrals (288 males and 247 females) identified for further evaluation of new pulmonary nodules across the respiratory and thoracic surgery departments. 231 (43.6%) patients were referred by a primary care physician. Within the cohort, 134 (25.1%) patients were current smokers, 215 (40.3%) were former smokers and 170 (31.9%) were lifelong non-smokers. 158 (31.7%) pulmonary nodules were identified in the right upper lobe. 422 nodules (85.6%) had a solid component, 26 (5.3%) were semi-solid whilst 45 (9.1%) nodules were ground glass in nature. 99 (19.9%) nodules were spiculated, 44 (8.9%) were lobulated and 37 (7.4%) nodules had cavitations. 325 (63.9%) patients underwent subsequent positron emission tomography (PET) scans and 159 (29.7%) nodules were biopsied. 113 (21%) nodules were diagnostic for malignancy with 61 (54%) cases being adenocarcinoma. 161 (30%) patients had more than 1 nodule identified.

Conclusions: Based on documented international experience from national lung cancer screening programs, there is an anticipated increase in pulmonary nodule burden which would lead to a proportionate rise in demand in resource utilization and will need adequate planning to ensure delivery of high-quality, timely care to patients and ensure patient adherence to the program.

Keywords: Pulmonary nodule, Lung cancer screening, Lung nodule

EP.17.10 Opportunities and Challenges of Lung Cancer Diagnosis, Care and Treatment in Western Kenya

A.L. Murunga
AMPATH-MOI TEACHING AND REFERRAL HOSPITAL, ELDORET/KE

Introduction: The incidence of lung cancer generally remains low in Africa despite high mortality. According to the Kenya National Cancer Control Strategy 2017-2022, lung cancer accounted for 794 cases with 729 deaths and a prevalence of 1.75 per 100,000 translating to a case fatality of 92%. Diagnosis, care, and management of lung cancer in the western region have presented disparities in the outcomes due to multiple factors including; unique biological characteristics of patients, socio-economic and health systems factors. This has conferred opportunities and challenges we wish to share.

Methods: The study employed a retrospective review of records of all patients with a histological diagnosis of primary lung cancer at MTRH AMPATH Oncology Clinics from January 2018 to January 2021. Data on demographics, history, signs and symptoms, the outcome of investigations, treatment, and status at the end of the period were analyzed.

Results: Out of 153 patients, 79(51.60%) were male, 74(48,40%) were female (n = 153). The median age at diagnosis was 59 years (range:20-95 years) with 44(29.30%, n = 150) as active smokers. Of the active smokers, 36(81.82%) were males. Majority had non-small cell lung cancer 143(94.10%, n = 152) with 103(74.10%) adenocarcinoma and 36(25.90%, n = 139) squamous cell carcinoma. Most had advanced disease with 130 (89.10%, n = 146) in stage III or IV and 12(8.20%) not stagged. Chemotherapy 149(97.40%, n =153) was the most common treatment modality. 124 (81.04%) deaths were reported.

Conclusions: Lung cancer is a significant Public Health problem in western Kenya that calls for a screening/case-finding program to enable early diagnosis. The majority of patients with Lung Cancer in Western Kenya have never smoked tobacco. Adenocarcinoma is the predominant subtype of non-small cell lung cancer. A referral system with feedback from the community to the facility will improve early referral and prompt diagnostic interventions.

Keywords: Retrospective review of records, Adenocarcinoma, Non-Small Cell Lung Cancer

EP.17 GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS

EP.17.11 Integrating Prevention and Screening of Tobacco-Related Diseases Including Lung Cancer Screening: Results of a Pilot Program

M. Lemonnier[1], C. Buton[2], R. Timricht[1], N. Ghourchidian[1], X-B. D'journo[1], D. BOULATE[1]
[1]Assistance Publique - Hôpitaux de Marseille, Marseille/FR ,[2]Computational Pharmacology and Clinical oncology, CRCM, Inserm, Inria, Marseille/FR

Introduction: Active smoking and tobacco-related diseases (TOREDI) such as cardiovascular diseases, cancers and chronic obstructive pulmonary diseases (COPD) are limiting the net benefit of lung cancer screening (LCS). The feasibility of an integrated clinical program for transversal prevention and screening of TOREDI has been poorly reported. Our monocentric pilot program includes smoking cessation with brief structured intervention and follow-up, cardiovascular risk factor evaluation, spirometry in case of COPD symptoms, in addition to lung cancer screening in case of eligibility. The objective of the study is to report our monocentric experience in implementing a pilot clinical program for the prevention and screening of TOREDI in addition to LCS in an academic hospital.

Methods: We performed a retrospective analysis of the patients' medical folders that were included in the pilot TOREDI program from 11/2023 to 12/2024. The study was approved by the local Internal Review Board (CSE25-30). We analyzed the number of 1st planned visit, 1st visit, visits per patient, the proportion of visits performed by nurses (vs. physicians) and performed by phone calls (vs. in person). We evaluated smoking cessation after the first visit among smokers, as well as the rate of known, screened and uncontrolled or unknown cardiovascular risk factors and COPD. History of cancer and active cancer were reported as well as the rate of participants undergoing LCS. Age was presented as mean ± standard deviation and categorial variables as median [IQR], ratio were presented as %, while smoking cessation probability was evaluated by Kaplan-Meier analysis.

Results: Among 346 planned 1st visit, 300 were actually performed in person. Mean age was 55 ± 13, sex ratio (men/women) was 148/152. Among 283 available folders for smoking cessation, 244 (86.2%) were active smokers; 965 visits were performed for smoking cessation including 548 (57%) nurse driven visits, 409 (42%) physician driven visits and 8 (1%) unknown; a median of 5 [3; 7] visits was performed per active smoker; 562 (58%) visits were performed in remote by phone. The median delay for smoking cessation was 120 days. Among 300 1st visits, 290 folders were available for TOREDI evaluation, we found known history of atheromatous cardiovascular disease in 82 (28.3%), hypertension in 78 (26.9%), blood pressure evaluation in 173 (59%) identifying untreated or undertreated hypertension in 21 (7.2%); known history of dyslipidemia in 89 (30.7%), dyslipidemia evaluation in 57 (19.7%) identifying 16 (5.5%) untreated or under treated dyslipidemia; known history of diabetes in 30 (10.3%), diabetes evaluation in 64 (22.0%) and untreated or undertreated diabetes in 8 (2.8%). Out of 290, 85 (29.3%) presented history of cancer including, 22 (7.6%) with active cancer; we performed LCS in 139 (47.9%) and 209 had available lung CT (72%); 25 (8.6%) had a diagnosed COPD, 128 (44%) without known COPD presented symptoms and underwent spirometry, 31 (10.6%) presented airway obstruction defined by Tiffeneau index < 70%.

Conclusions: Integrating smoking cessation, cardiovascular risk factors evaluation, COPD screening and lung cancer screening is possible in an integrated transversal program mainly driven by nurses and including remote visits by phone.

Keywords: lung cancer, tobacco, screening

EP.17 GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS

EP.17.12 Utility of CT Scans & Blood Tests After Maintenance Durvalumab Post Chemort in Stage III NSCLC Patients

A. Muñoz-Lerma[1], D. Cano Gil[2], M. Davidson[3], C. Milner-Watts[3], A. Minchom[3], S. Popat[4], J. Bhosle[3], M. O'Brien[3]
[1]Hospital de Jerez, Jerez de la Frontera/ES ,[2]Hospital Marina Baixa, Villajoyosa/ES ,[3]Royal Marsden Hospital, Sutton, London/GB ,[4]Royal Marsden Hospital, Chelsea, London/GB

Introduction: The phase 3 PACIFIC trial established the benefit of one year of durvalumab maintenance following chemoradiotherapy (chemoRT) in stage III non-small cell lung cancer (NSCLC) patients, with imaging every 8 weeks during treatment and every 12 weeks thereafter. While imaging follow-up is in guidelines, blood test surveillance remains undefined.This retrospective study evaluated the frequency and clinical impact of follow-up CT scans and blood tests in stage III NSCLC patients treated at The Royal Marsden Hospital, London. We analyzed adherence to 3-monthly (3M) CT scans, correlation with progressive disease (PD) or death, and the utility of post-treatment blood tests. Secondary objectives included assesing scan findings´ impact on clinical decisions.

Methods: Patients with stage III NSCLC diagnosed from March 2019, who received ≥1 cycle of adjuvant durvalumab and completed one-year post-treatment, were included. Sixty patients were identified. A >20% rate of CT scans prompting intervention was set as a threshold for maintaining current practice.Adherence to 3M blood tests, including full blood count (FBC), urea and electrolytes (U+E), liver function (LFT), and thyroid function tests (TFTs), was recorded. Seventy-two patients had a complete baseline panel. Clinically significant abnormalities requiring intervention during follow-up were also documented.

Results: Of 60 patients, 4 showed progression on baseline CT, leaving 56 in the 3M follow-up. Compliance was high (92.8%). At 3 months, 14.2% of scans led to further imaging, decreasing to 11.5% at 6 months and 4% at 9 months. PET-CT was the most common additional test. Medication changes and specialist referrals ranged from 4% to 9.6%.

None of the patients with unspecified baseline CT changes progressed, but up to 50% of those with suspected tumor regrowth, pneumonitis, or pleural effusions had PD. At 3 months, 2/4 patients with pneumonitis progressed; at 6 months, 1 patient with suspected tumor growth progressed at 9 months. At 12 months, no patients had PD.

Regarding blood tests, 72 patients had a baseline panel. At 3 months, 79% had follow-up tests, with 45% showing clinically significant results requiring intervention. At 6, 9, and 12 months, follow-up rates dropped to 51%, 32%, and 39%, with 54%, 74%, and 53% of tests showing abnormalities, respectively. In total, 52% of all tests revealed significant abnormalities. Blood test follow-up was irregular (75%), with only 20% receiving routine 3M monitoring.

Conclusions: Adherence to 3M CT scans post-durvalumab was high (93%). The 10% scan pickup rate aligns with PACIFIC trial relapse rates (PFS 12-24 months). As this is below our 20% threshold, scan frequency will be reduced to 6 months. Blood test follow-up was poorly adhered to, yet when performed, it identified significant abnormalities, supporting its continuation.

Keywords: NSCLC, stage III, follow-up

EP.17 GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS

EP.17.13 Healthcare Professionals' Perceived Barriers and Facilitators of Risk-Stratified Follow-Up Care in Lung Cancer

N. Moss[1], N. Billingy[1], I. Maassen[1], A. Becker-Commissaris[2], M. Broeders[1], R. Hermens[1], I. Walraven[1]
[1]Radboudumc, Nijmegen/NL ,[2]Amsterdamumc, Amsterdam/NL

Introduction: Routine follow-up of lung cancer patients involves thoracic computed tomography (CT) scans every 3-6 months for the first 2 years, followed by yearly CT-scans up to 5 years. This 'one-size-fits-all' approach poses immense pressure on current healthcare facilities. Therefore, a risk-stratified strategy, tailoring follow-up frequency and imaging modality per patient, is needed to reduce the number of unnecessary scans and ensure high-quality follow-up. This study aims to identify healthcare professionals' (HCPs) barriers and facilitators for the implementation of a risk-stratified follow-up in lung cancer care.

Methods: A qualitative study was performed, involving 14 semi-structured interviews with a heterogenous group of HCPs engaged in lung cancer care. Inductive and axial coding of the transcripts was performed to categorize barriers and facilitators using the Grol & Wensing framework.

Results: Overall, HCPs stated that risk-stratified follow-up may help to organize follow-up care more accurately. Key identified barriers included the fear of missing disease progression when extending follow-up intervals for low-risk patients and the potentially increased healthcare burden from more intensive follow-up schedules for high-risk patients. Conversely, a key facilitator was that depicting the most accurate imaging modality and frequency for each patient could reduce the number of necessary follow-up scans. Another identified facilitator was that risk-stratified follow-up may pose an opportunity to increase the involvement of specialized nurses during follow-up.

Conclusions: This study shows that HCPs are generally willing to adopt a risk-stratified follow-up in lung cancer care. Nonetheless, the approach should be feasible and cost-effective, and its safety and effectiveness should be proven before implementation.

Keywords: Risk-stratification, Follow-up care, Lung cancer

EP.17.14 Concordance Between Clinical and Radiological Diagnoses of Pneumonitis: Retrospective Cohort Review From Regional Health Service in Australia

D. Dua
Central Gippsland health, Sale/AU

Introduction: Background:

Pneumonitis is a clinically challenging and potentially life-threatening condition, often presenting with non-specific respiratory symptoms that overlap with other pulmonary diseases. In regional healthcare settings, the limited availability of timely radiological support further complicates diagnostic accuracy. Although clinical guidelines for pneumonitis exist, evidence supporting clinical diagnosis without radiological confirmation remains sparse. This audit investigates the level of diagnostic agreement between clinical assessments and radiological findings in a regional Australian health service and evaluates the impact of imaging on clinical decision-making.

Aims:

- To assess concordance between clinical and radiological diagnoses of suspected pneumonitis.
- To evaluate the necessity of radiological imaging in guiding treatment decisions.
- To inform local clinical protocols for diagnosing pneumonitis when imaging is not readily available.

Methods: This retrospective audit reviewed patient presentations to Central Gippsland Health from 1 January to 31 December 2024. Patients included were those assessed for suspected pneumonitis based on presenting symptoms. Data collected from electronic medical records included demographics, clinician-documented diagnoses, and corresponding radiological interpretations. Diagnostic concordance was defined as agreement between the initial clinical impression and radiological findings and was expressed as a percentage. Data were de-identified and analysed using descriptive statistics.

Results: Thirty-four eligible cases were identified. Clinical and radiological diagnoses aligned in 50% of cases. In 25% of cases, imaging either confirmed or challenged the clinical impression, influencing final diagnosis. However, in the remaining 25%, radiological imaging did not affect patient management, indicating that clinical judgment alone may be adequate in some cases. These findings are particularly relevant in resource-limited settings, where immediate access to radiology is not feasible.

Conclusions: Conclusion:

This study highlights a critical gap in evidence regarding the utility of imaging in diagnosing pneumonitis, particularly in rural and regional contexts. The moderate level of concordance observed suggests that with enhanced clinical criteria and structured assessment tools, diagnosis and initial treatment may be possible without immediate imaging. These findings support the development of localised, evidence-informed diagnostic pathways aimed at improving efficiency without compromising patient care. Further prospective studies are warranted to validate these findings and assess long-term outcomes in settings with constrained access to radiology.

Keywords: pneumonitis, regional, concordance

EP.17.15 Tackling the Lung Cancer Crisis in Canada: Co-Creating a National Strategy to Reduce Lung Cancer Mortality by 30% Action Plan?

C. Finley[1], A. Edwards[2], J. Nordlund[2], S. Lafond[2], A. Mullin[3], E. Porfilio[3]
[1]McMaster University, Hamilton/ON/CA ,[2]Canadian Cancer Society, Toronto/ON/CA ,[3]Shift Health, Toronto/ON/CA

Introduction: Lung cancer is the leading cause of cancer death in Canada, claiming more lives annually than breast, colorectal, and prostate cancers combined. Despite advancements in care, inequities in access, diagnosis, and outcomes persist—especially among underserved populations. To address this, the Canadian Cancer Society (CCS), with guidance from a National Steering Committee of diverse stakeholders, developed the 2025-2035 Pan-Canadian Lung Cancer Action Plan. The plan's overarching goal is to reduce lung cancer deaths by 30% over the next decade through coordinated, equity-focused national action.

Methods: The Action Plan was developed through a multi-phase, community driven process. Inputs were gathered from environmental scans, active engagement, and a national Lung Cancer Summit held in late 2024. The Summit convened over 100 interest holders from across the lung cancer ecosystem, including people with lived experience, cancer charities, clinicians, researchers, advocates, policymakers, and representatives from equity-deserving communities. A modified Delphi approach using an adapted form of the James Lind Alliance priority setting partnership was used. This enabled structured dialogue and consensus-building to identify and validate key priorities across the continuum of lung cancer care, from prevention through to survivorship and research.

Results: The Action Plan is built around four strategic priorities: 1. Reduce exposure to carcinogenic inhalants: National education campaigns will increase awareness of lung cancer risk factors, including radon and occupational exposures. The plan calls for enhanced tobacco control policies, improved product labelling, and advocacy for stricter air quality and workplace safety standards. 2. Detect lung cancer earlier: Actions include the development of national screening guidelines with expanded eligibility, scaling screening programs in all provinces and territories, and improving access to diagnostics, particularly in rural and remote areas and launching culturally competent awareness campaigns. 3. Improve access to timely, best-in-class care: The plan supports equitable access to genomic and molecular testing, faster regulatory approval and reimbursement of new therapies, expanded navigation services, and greater integration of trauma informed and culturally appropriate care. 4. Accelerate lung cancer research: Key actions include advocating for funding proportionate to disease burden, establishing national research priorities with increased investment in clinical trials, supporting early career researchers, and improving health data and biospecimen sharing across jurisdictions.

Each strategic area includes clear progress indicators. By 2035, the plan aims for earlier detection of lung cancer, consistent access to high-quality screening and testing, shorter diagnostic and treatment wait times, and increased research investment and innovation.

Conclusions: The 2025-2035 Pan-Canadian Lung Cancer Action Plan outlines a bold, coordinated path forward to reduce lung cancer mortality and address longstanding inequities in care. Grounded in community engagement, evidence, and a shared commitment to health equity, the plan provides a roadmap to improve outcomes and transform the lung cancer landscape across Canada over the next decade.

Footnote: ChatGPT was used to consolidate the existing original non-AI generated Action Plan in the first draft of this abstract.

Keywords: Action Plan, Strategy, Consensus

EP.17.16 Improved Concordance to Clinical Practice Guideline: Analysis Of Multidisciplinary Team Discussed Patients With Stage III Lung Cancer

X. Cheng[1], Z. Li[1], X. Cai[1], H. Zhang[1], P. Cui[2], B. Yin[2], J. Cai[3], C. Mao[3], S. Zhang[3], M.T. Campos[4], H. Naqvi[5]
[1]Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai JiaoTong University School of Medicine, Shanghai/CN ,[2]VINTURA, Baarn/NL ,[3]Astrazeneca, Shanghai/CN ,[4]Astrazeneca, Barcelona/ES ,[5]Astrazeneca, Gaithersburg/MD/USA

Introduction: China has a vast lung cancer disease burden due to the high incidence of 1.02 million new cases annually, accounting for 40% of the world total. The management of lung cancer - especially stage III - patients is complex due to the tumor severity, patient health status, and treatment feasibility. Meanwhile, guidelines from organizations like ASCO, ESMO, and CSCO are available, yet research on patient guideline concordance post-MDT is limited. This study aims to assess stage III lung cancer patient concordance to CSCO guidelines post-MDT and its impact on diagnosis and treatment outcomes.

Methods: This retrospective study assessed the impact of remote MDT discussions on diagnostic accuracy and treatment guideline concordance for lung cancer. The study included 77 patients from lower-tier hospitals discussed in 20+ remote MDT sessions with Shanghai Chest Hospital (2024-2025). Eligible patients had histologically confirmed lung cancer and underwent CT imaging and biopsy before MDT discussions, with 70% diagnosed at stage III, given the complexity of lung cancer at later stage. Data from electronic medical records and MDT logs included pre-MDT diagnosis and treatment plans, MDT recommendations, and post-MDT decisions. Outcomes analyzed were treatment guideline concordance, diagnostic modifications, genetic testing rates, and treatment changes. Descriptive statistics assessed MDT impact on clinical decision-making in lower-tier hospitals.

Results: Prior to MDT discussions, only 42% of stage III patients had undergone genetic testing. Following MDT recommendations, an additional 20% were advised to complete molecular testing to enable precision diagnostics. Diagnosis was revised in 22% of cases, and 11% of initially deemed unresectable cases were reclassified as potentially resectable. Regarding treatment optimization, 45% of stage III cases had their treatment plans modified post-MDT, leading to better alignment with national guidelines. The most significant adjustments included a shift from systemic therapy alone to multimodal approaches: a). Systemic + radiotherapy increased from 16% to 35%, b). Systemic + radiotherapy + surgery increased from 11% to 20%. These findings highlight the role of MDTs in ensuring more standardized and evidence-based management of stage III lung cancer.

Conclusions: This study demonstrates the significant role of MDT discussions in refining diagnoses and optimizing treatment strategies for stage III lung cancer. MDT participation enhances guideline adherence and promotes evidence-based decision-making, particularly in lower-tier hospitals. Future research should focus on long-term clinical outcomes, patient survival, and quality of life metrics to further assess MDT effectiveness. Additionally, expanding MDT networks and integrating digital platforms could strengthen multidisciplinary collaboration and improve lung cancer care in resource-limited settings.

Keywords: Stage III Lung Cancer, Remote MDT, Guideline concordance

EP.17 GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS

EP.17.17 Availability of PD-L1 and Ngs Results at Initial Medical Oncology Consultation in Patients With Non-Small Cell Lung Cance

J. Martin[1], S. Brule[1,2,3], S. Moore[1,2,3], P. Wheatley-Price[1,2,3]
[1]The Ottawa Hospital Research Institute, Ottawa/ON/CA ,[2]University of Ottawa Division of Medical Oncology, Ottawa/ON/CA ,[3]The Ottawa Hospital Cancer Centre, Ottawa/ON/CA

Introduction: PD-L1 and next-generation sequencing (NGS) testing are essential for guiding treatment choices in non-small cell lung cancer (NSCLC), influencing decisions on targeted therapy and immunotherapy. Delays in obtaining these results at the time of initial medical oncology consultation may impact timely treatment initiation and patient care. This quality improvement (QI) project aimed to assess the availability of PD-L1 and NGS results at initial consultation and their effect on patient care and treatment decisions.

Methods: With an ethics board waiver for QI projects, we reviewed 100 consecutive patients with newly diagnosed NSCLC seen in medical oncology consultation at The Ottawa Hospital Cancer Centre, a Canadian tertiary academic cancer centre with an in-house molecular testing laboratory, starting October 1, 2024. Molecular testing is initiated by the pathologist in our institutions workflow policies. PD-L1 is routinely ordered in all cases, and NGS in all non-squamous NSCLC cases. Data collected included patient demographics, staging, PD-L1 and NGS result availability, and treatment decisions.

Results: Among 100 patients (median age 71 years, 51% male), 3% had stage I, 13% stage II, 33% stage III, and 52% stage IV disease. Histological subtypes included 75% adenocarcinoma and 24% squamous cell carcinoma. PD-L1 and NGS testing were ordered reflexively by the pathologist before the initial medical oncology consultation in 96% of cases. PD-L1 testing was performed on 99/100 patients. At the time of consultation, PD-L1 results were available for 80/99 (81%) patients. NGS was performed on 77 patients and only 43/77 (56%) had NGS results at the time of consultation. The time between PD-L1 results becoming available and medical oncology consultation ranged from -150 to +20 days, with a median of 7 days before (IQR -16 to +4). For NGS, this range was -146 to +26 days, with a median of 1.5 days before consultation (IQR -16.6 to -1). Due to unavailable results, 39 patients required additional visits, with 36 needing one extra appointment, 1 requiring two, and 2 needing three additional visits. Despite this, only 5 patients had treatment initiated before obtaining PD-L1 and/or NGS results. No patients required a complete change in treatment upon result availability, though 2 had pembrolizumab added once results were available.

Conclusions: Overall, many NSCLC patients lack complete molecular testing results at their initial medical oncology consultation, particularly NGS. This delay often necessitates additional clinic visits, potentially delaying treatment initiation, although did not result in incorrect treatment in any cases. The efficiency of initial 1 hour consultations and subsequent 15-20 minute follow up appointments is impacted based on clinical discussions reliant on those results. These are complex issues, and oncology wait times and laboratory turn-around-times are also important variables. Given that most patients did not start treatment before results were available, this study helps inform whether scheduling the initial consultation after PD-L1 and NGS results are received may improve efficiency in clinical decision-making and reduce unnecessary visits. Our centre is currently piloting oncologist review of referrals to identify cases that can safely wait for initial consultation until results are ready.

Keywords: NGS, PD-L1, NSCLC

EP.17.18 Refining Lung Cancer Diagnosis Through Multidisciplinary Team Collaboration

X. Zhang[1], C. He[1], G. Liang[1], K. Ye[1], L. Kang[1], C. Shi[1], P. Cui[2], H. Wang[1]
[1]The Affiliated Cancer Hospital of Zhengzhou University/Henan Cancer Hospital, Zhengzhou/CN ,[2]VINTURA, Baarn/N

Introduction: Lung cancer remains a leading cause of cancer-related mortality worldwide, in part due to challenges in achieving accurate tumor-node-metastasis (TNM) staging. Multidisciplinary team (MDT) approaches have demonstrated the potential to refine staging accuracy and optimize treatment. In China, the disparity between top-tier Centers of Excellence (CoEs) and resource-limited lower-tier hospitals often hampers comprehensive diagnostic reviews. Remote MDT consultations, facilitated by digital platforms, aim to bridge this gap by enabling real-time collaboration across institutions. This study assesses whether MDT discussions can improve clinical TNM staging and resectability determinations in patients with lung cancer, providing a foundation for broader implementation aligned with established guidelines.

Methods: An observational approach was adopted across a Center of Excellence (CoE) - Henan Cancer Hospital and lower-tier hospitals. 102 real-time patient cases with lung cancer were discussed via remote MDT sessions, among which 99 were patients with Stage III and beyond. During each MDT review, imaging results, pathology findings, and clinical variables were reassessed, and any resulting modifications in TNM classification, clinical staging or resectability status were recorded.

Results: Among the 99 cases, 10% of patients exhibited a change in either their TNM classification or clinical stage after MDT review. Of these, 7% experienced modifications in TNM components, while the remainder had changes in overall clinical staging. In the group with modified TNM classifications, the shift was more frequently downward than upward. Closer analysis indicated that T and N statuses underwent changes more often than M. One example involved downgrading a patient from T3 to T1 following enhanced radiologic assessment; in other instances, N status was revised after comprehensive lymph node evaluations. With respect to clinical staging, alterations were relatively modest overall. Stage IIIA and IIIC decreased, whereas IIIB and IV showed a slight uptick in patient numbers. Collectively, these modifications in TNM components and clinical staging yielded a 9% increase in the proportion of patients deemed resectable. Furthermore, after MDT, 30% of patients have changed their treatment plan, with more people switched from no therapy at all, or chemotherapy only to a combination between radiotherapy, chemotherapy and immuno-therapy. Crucially, these improvements stem from more precise clinical decisions made at lower-tier hospitals once they received valuable remote MDT input from the CoE (Henan Cancer Hospital). By providing specialized diagnostic and treatment insights, the CoE helped align final staging determinations with recognized guidelines and enhanced consistency across diverse clinical settings.

Conclusions: These findings underscore the value of MDT participation—particularly when CoE expertise is combined with remote digital platforms—in refining lung cancer staging and improving resectability and other treatment determinations. While most clinical diagnoses remained unchanged, the observed modifications highlight the importance of thorough, collaborative review. Improved identification of T, N, or M status facilitates more precise treatment planning, which is especially beneficial in lower-tier hospitals that may lack advanced imaging and pathology capabilities. Broadening the reach of MDT frameworks across facilities with vastly different infrastructures can ultimately help standardize guideline-based care and enhance outcomes for patients with lung cancer.

Keywords: Refining TNM Staging, Remote MDT

EP.17.19 Quality Control and Analysis of Standardized Diagnosis and Treatment of Lung Cancer

Z. He
Affiliated Cancer Hospital of Zhengzhou University&Henan Cancer Hospital, Zhengzhou/CN

Introduction: Lung cancer is the most common malignancy in China in terms of morbidity and mortality. Benefiting from the improvement of etiological prevention awareness, the promotion of screening work and the continuous improvement of comprehensive diagnosis and treatment level, the 5-year survival rate of lung cancer patients in China has been greatly improved, but there are still significant differences in the diagnosis and treatment level of lung cancer in different regions, which is also one of the key factors restricting the further improvement of survival of lung cancer patients. The quality control is conducive to promoting the standardization and homogenization of lung cancer diagnosis and treatment, and improving the level of diagnosis and treatment in primary hospitals, which is of great significance to improve the survival rate and quality of life of lung cancer patients.

Methods: From August 20 to September 20, 2024, a survey was conducted on the diagnosis and treatment status of lung cancer in the department heads of secondary and above medical institutions in Henan Province, and relevant information was collected by questionnaire. SPSS software (23.0 version) was used for statistical analysis.

Results: The quality control of standardized diagnosis and treatment of lung cancer covers 18 cities and 136 districts in the province, including 194 medical institutions; A total of 278 valid questionnaires were collected in this survey. The pathological diagnosis rate of lung cancer patients before the first non-surgical treatment was 100 (81.5-100) %. The average proportion of newly diagnosed and treated NSCLC undergoing genetic testing in 2021-2024 is shown in Table 1. We further investigated the factors affecting the submission of genetic testing, and 86.3% of the participants believed that “patients or family members give up” was the main factor. The average clinical TNM stage diagnosis rate of lung cancer patients before the first anti-tumor treatment was 99 (80-100) %.18.3% of the participants had no MDT team in their hospital, and 22.3% of the participants could not carry out radiotherapy in their hospital.

Table1. The average proportion of newly diagnosed and treated non-small cell lung cancers undergoing genetic testing in 2021-2024.

	2021	2022	2023	2024
LUAD	70 (45-90)	81 (60-95)	90 (70-100)	95 (80-100)
LUSC	17 (5-34)	16.5 (5.25-40)	20 (7-50)	20 (8.25-50)
LUASC	26.5 (7.75-80.00)	40 (10-80.75)	52 (11-89)	61.5 (11.25-95)

LUAD, lung adenocarcinoma; LUSC, lung squamous carcinoma; LUASC, lung adenosquamous carcinoma.

Conclusions: Thvrough the quality control and analysis of lung cancer diagnosis and treatment, we found that there are still problems including insufficient related equipment and configuration in some primary hospitals, low pre-treatment genetic testing delivery rate, and insufficient evaluation of adverse reactions after treatment: Strengthening standardized training and multidisciplinary cooperation may help to reduce the occurrence of misdiagnosis, missed diagnosis and improper treatment, and ultimately reduce the mortality rate of lung cancer.

Keywords: quality control, lung cancer

EP.17.20 Natural Language Processing in Rapid Evaluation of Suspicious Lung Findings: Impact on Lung Cancer Outcomes

N. Tamam Shenholz[1], K. Hod[2,3], L. Toderis[2,4], E. Dudnik[2,5]
[1]Faculty of Health Sciences, Joyce & Irving Goldman Medical School, Ben Gurion University of the Negev, Beer Sheva/IL ,[2]Assuta Medical Centers, Tel Aviv/IL ,[3]School of Health Sciences, Ariel University, Ariel/IL ,[4]Ariel University, Ariel/IL ,[5]Faculty of Health Sciences, Joyce & Irving Goldman Medical School, Ben Gurion University of the Negev, Beer Sheva/IL

Introduction: Lung cancer represents the leading cause of cancer-related mortality, making early diagnosis and prompt treatment initiation imperative. This study assessed the Natural Language Processing (NLP)-assisted rapid evaluation protocol, which employs chest CT report analysis as an opportunistic screening tool to identify suspicious lung findings necessitating further investigation, and evaluated its impact on prognosis and diagnostic work-up timelines for patients with lung cancer.

Methods: Consecutive lung cancer patients (n-200) diagnosed at Assuta Medical Centers (AMC) between January 2019 and December 2022 were retrieved from the AMC electronic database using the MDClone platform. The participants were divided into 2 groups: Group A (NLP-assisted rapid evaluation, n=100) and Group B (traditional referral for rapid evaluation by community physicians, n=100). Stage at diagnosis, time from initial imaging to biopsy, - histological verification, - molecular subtype determination, and - treatment initiation were assessed.

Results: The implementation of the NLP-assisted protocol resulted in a significant stage shift, with a higher percentage of patients diagnosed at Stage I (47.5% in Group A vs. 26.8% in Group B, p=0.013, Figure 1). While Group B exhibited a shorter median time to biopsy, this difference was not clinically significant. Other diagnostic work-up timelines were comparable between both groups; however, Group A demonstrated reduced variability in these timelines (Table 1).

Figure 1. Stage distribution at diagnosis by study group

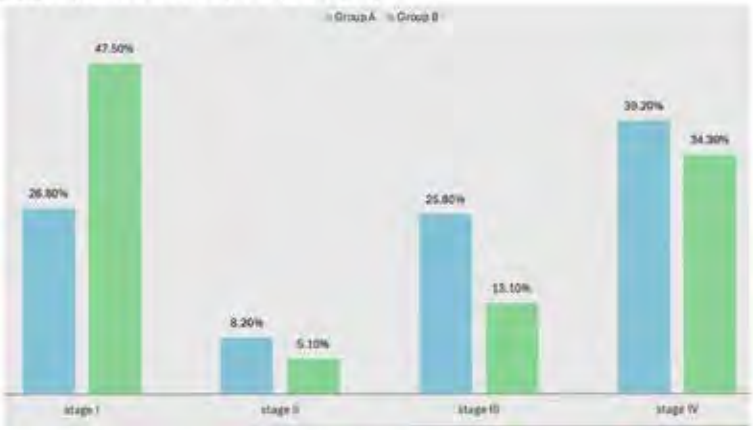

Table 1. Time from performance of the first imaging study demonstrating any cancer-related finding to biopsy, - histological verification, - molecular subtype determination, and - treatment initiation.

	Group A	Group B	P value
Time to biopsy performance, weeks			
Mean ± SD	9.31 ± 7.83	8.89 ± 10.87	0.05
Median, 95% CI	6.428 (1.1-50)	6 (0-54.9)	
Time to histological diagnosis verification, weeks			
Mean ± SD	11.37 ± 10.07	9.87 ± 9.14	0.39
Median	7.142 (2.9-63.4)	7.857 (1.4-55.7)	
Time to molecular subtype determination, weeks			
Mean ± SD	14.75 ± 7.66	20.90 ± 32.44	0.53
Median	13 (5.9-41.9)	11.928 (0-173.4)	
Time to definitive treatment initiation, weeks			
Mean ± SD	15.39 ± 10.73	15.71 ± 17.31	0.08
Median	12.785 (3.1-65.4)	10.571 (1.6-123.6)	

Conclusions: The incorporation of an NLP-assisted diagnostic approach facilitates opportunistic screening, promoting a stage shift towards earlier stages at diagnosis and potentially enhancing diagnostic efficiency along with the timeliness of interventions in lung cancer patients. ChatGPT AI tool was used to finalize the abstract.

EP.17.21 A Digital Health Solution for Monitoring Pulmonary Symptoms in Cancer Treatment

E. Piault[1], G. Beran[2], L. Cecconi[3], K. Bernatowicz[3], L. Kurkinen[4], D. Zoumplis[5], E. Sartor[6]
[1]Evinova, South San Francisco/CA/USA ,[2]Evinova, Macclesfield/GB ,[3]Evinova, Barcelona/ES ,[4]Evinova, Gothenburg/SE ,[5]Evinova, Gaithersburg/MD/USA ,[6]Astrazeneca, Wilmington/DE/USA

Introduction: Pulmonary toxicities such as pneumonitis or interstitial lung disease (ILD), are associated with significant morbidity and can hinder patient outcomes of immunotherapy, chemotherapy, and targeted therapies through required treatment delays, dose reduction, or treatment discontinuation. Clinical providers are expected to monitor for and promptly investigate respiratory signs and symptoms for drugs associated with fatal cases of ILD. A digital application that supports capture, transfer and visualization of patient-reported new or worsening respiratory symptoms is a pragmatic tool for health care providers to meet label or protocol requirements.

Methods: Clinical consensus from a panel of oncologists (n=4), pneumonologists (n=2), and radiologist using a qualitative Delphi methodology, in addition to the review of published literature and AE adjudication charters (n=3) informed the content of this digital application. Interfaces for data collection (patient) and access (clinician) were designed with a focus on user-engagement and clinical relevance to inform the likely occurrence of ILD. Patients receiving anticancer therapies and clinicians (oncologists and nurses) participated in 1:1 qualitative user testing of the overall application's content and design. Prototypes of the patient app were implemented in clinical trials (n=484 patients) to inform patients' engagement.

Results: Based on clinical consensus, the patient app enables reporting of onset or worsening of the cardinal (cough, dyspnea, pain) and secondary symptoms of ILD (fever, fatigue) and the capture of blood oxygenation (SpO2), pulse and respiration rate collected at rest or during mild exertion (walking at normal pace for 3 minutes). Data collection uses a gated approach to foster daily symptom report while minimizing burden. The clinician portal provides easy to access chronological data visualizations in addition to alerts for symptom-worsening. As we could not achieve a consensus on an SpO2 threshold, the solution enables clinical staff to set a threshold adapted to the patient's health status and prompt investigation. Qualitative testing and early quantitative data from trial implementation support sustained patients' engagement (275 patients compliant over at least 5 weeks) to provide relevant data for the monitoring of the risk of ILD.

Conclusions: Leveraging digital interfaces provides a solution for clinicians to monitor patients at risk of ILD in between clinic visits while filling in a gap in evidence to support algorithm development for patient triaging or diagnosis (with added imaging). As both the patient and the clinician interfaces are implemented in 5+ clinical trials in various tumors, data and evidence of clinical validity and utility are expected within the next year or so.

Keywords: Remote Monitoring, ILD, Digital symptom monitoring

EP.17.22 The Burden of Lung Cancer in Nigeria's Capital City: Findings From the Population Based Cancer Registry

V. Igbinomwanhia[1], F. Omonijo[2], T. Olukomogbon[2], N-B. Dirisu[2], I. Ambi[2], S. Israel-Isah[2], A. Ademola[2], C. Mba[2], O. Onisile[2], F. Egaga[2], G. Harrison-Osagie[2], F. Igbinoba[3], C. Mensah[1], P. Dakum[1], G. Oko-Oboh[4]
[1]Institute of Human Virology, Nigeria, Abuja/NG ,[2]International Research Centre of Excellence, Institute of Human Virology Nigeria, Abuja/NG ,[3]Abuja Cancer Registry, Abuja/NG ,[4]Tempere University, Finland, Tempere

Introduction: Globally, lung cancer is the most frequently diagnosed malignancy responsible for about 2.5 million new cases and a mortality of 1.8 million in 2022. There is a rising incidence in sub-Saharan Africa with Nigeria having about 1,789 new cases and 1,643 deaths annually and projected to increase to 2.4 and 1.4 million respectively by 2040. The causes, types and survival trend vary in different populations. It is important to understand these characteristics in order to proffer plausible interventions for prevention and treatment. This study seeks to describe the lung cancer burden in Nigeria through analyses of data from the Abuja population based cancer registry (PBCR).

Methods: We conducted a retrospective analyses of lung cancer cases recorded in the Abuja Cancer Registry between 2009 and 2024. Key variables analyzed included age, sex, tumor morphology, diagnosis type, marital status, religion, and vital status. Data cleaning and transformation were performed using Python and R. We derived the incident year from the date of diagnosis and categorized age into three groups. Descriptive statistics were computed, and cross-tabulations with chi-square tests and t-tests were used to examine associations between sex and other variables. Trends in lung cancer incidence were visualized by year.

Results: A total of 98 lung cancer cases were reported to the Abuja Cancer Registry. The mean age at diagnosis was 56.8 (SD = 12.4) years, ranging from 29 to 83 years. Majority were married (89.8%), and Christains (77.6%) with a higher proportion of women with lung cancer [54 55.1%]. The morphological verification percent is 98%, the most common morphological type was Bronchio-alveolar carcinoma mucinous, representing 67.3% of cases, followed by Adenocarcinoma NOS (20.4%). Regarding diagnostic type, most cases were diagnosed through asymptomatic presentation (43.9%), symptomatic presentation (41.8%), and screening programs (14.3%). Out of all patients, 88 (89.8%) were alive at the time of data collection, giving a case fatality rate of 10.2%. A year-on-year trend analysis showed fluctuating incidence with no significant consistent increase or decline between the years captured in the dataset.

Conclusions: The data from the PBCRs in Abuja highlights the demographic and clinical characteristics of lung cancer cases. We observed a majority of cases occurring in older adults with a slight female predominance. The high proportion of diagnoses through asymptomatic presentation suggests the lack of early detection efforts. Although a low fatality rate may suggest a high survival of patients with lung cancer, a follow up assessment of vital status is recommended. The findings underscore the need for improved lung cancer surveillance. Research into the early diagnosis, screening, socio-economic and environmental factors that may predispose to lung cancer will prove beneficial. Findings from this registry study will be compared to other PBCRs in Nigeria.

EP.17.23 Demographic Profile and Patient Journey of Early-Stage NSCLC Patients in a Brazilian Public Reference Center: A Real-World Study

R.M. Terra[1], P.P. Fernandes[1], C.P. Marcelino[2], P.d.M. Batista[2], L.P. Leonel[3], P. Pungartnik[3], M.A.d.C. Rego[2], C. Parisi[2], L.L. Lauricella[1]
[1]ICESP - HCFMUSP, São Paulo/BR ,[2]MSD Brazil, São Paulo/BR ,[3]IQVIA Brazil, São Paulo/BR

Introduction: Early-stage non-small cell lung cancer (NSCLC) poses unique challenges in diagnosis and treatment, particularly in asymptomatic patients. This study describes the demographics, patient journey, and healthcare resource utilization (HCRU) of early-stage NSCLC patients at the Instituto do Câncer do Estado de São Paulo (ICESP), Brazil. Insights into these aspects are vital for improving patient outcomes and resource allocation.

Methods: A retrospective study was conducted on early-stage NSCLC patients treated at ICESP from January 2010 to January 2022. Inclusion criteria encompassed patients with histologically confirmed early-stage NSCLC (stages I, II, and IIIA) who underwent tumor resection, excluding those treated with immunotherapy. Data collection continued until January 2024, with the surgery date as the index date.

Results: Among 606 early-stage NSCLC patients, most were over 65 years old (52%), female (54%), and white (78%), with a median BMI of 26. Most were former or current smokers (74%), with squamous histology in 19%. Stage distribution was 56% stage I, 23% stage II, and 18% stage IIIA (AJCC 8th edition). The mean age at diagnosis was 63 years, with common comorbidities including hypertension (53%), COPD (44%), and previous malignancy (40%). Median time from symptom onset to histological diagnosis was 241 days (SD 391), and from diagnosis to surgery was 145 days (SD 114). Surgery only was predominant in stage I (93%), stage II (67%), and stage IIIA (51%), while surgery combined with adjuvant treatment was received by 4%, 31%, and 47%, respectively. Most patients (84%) underwent lobectomy. Recurrence rates were 19% for stage I, 37% for stage II, and 43% for stage IIIA. Recurrence-free survival (RFS) ranged from 47 months (SD 27) in stage I to 28 months (SD 28) in stage IIIA, with a mean of 39 months (SD 29). Regarding HCRU, non-invasive staging tests were common, including thorax CT (87%) and PET scan (83%). Invasive tests were less frequent, with EBUS performed in 24%: 16% in stage I, 38% in stage II, and 35% in stage III. Molecular exams were conducted in only 28% of patients. Postoperative care involved ICU admissions for 49%, with a median stay of 4 days. Stage IIIA patients had the highest rates (69%) and longest ICU stays (mean: 21 days; SD: 26). The median inpatient stay post-surgery was 4 days, with stage IIIA patients requiring longer stays (mean: 8.0; SD: 9.1).

Conclusions: This real-world study characterizes the demographic and clinical profiles, treatment patterns, and HCRU of early-stage NSCLC patients undergoing curative-intent surgery at a major public cancer center in Brazil. Notably long-time intervals were observed, with a median of over 7 months from symptom onset to diagnosis and nearly 5 months to surgery. Despite surgical treatment being the primary approach, recurrence rates were significant, especially in stages II and IIIA, with diminishing RFS. The variability in staging and molecular tests and high rates of intensive postoperative care underscore the complexities of managing early-stage NSCLC and the need to improve diagnostic timeliness, standardize staging practices, and strengthen postoperative follow-up within the public healthcare system.

EP.17.24 Clinicopathological Features of Lung Cancer: A Study From a Tertiaryreferral Center in Georgia

A. Geguchadze[1], A. Tsereteli[1], I. Kiladze[1,2]
[1]Caucasus Medical Centre, Tbilisi/GE ,[2]Ilia State University- School of Medicine, Tbilisi/GE

Introduction: Lung cancer (LC) is one of the leading causes of mortality in Georgia. This study is first such kind in Georgia aiming to analyze the clinicopathological characteristics of patients with confirmed LC.

Methods: Between 2023 and 2024, data from 255 LC patients, including demographic and clinicopathological characteristics, were analyzed at a tertiary referral center in Tbilisi, Georgia.

Results: The median age was 67 years (range 31-88), with 200 patients (78.4%) older than 60, 86% were male and 88% smokers. Among current smokers, the male-to-female ratio was 2:1 and 47% were heavy smokers (>1 pack/day).Cough and shortness of breath were the most common presenting symptoms (28%), followed by fatigue (22%) and hemoptysis (16%).Bronchoscopy was performed in 125 (49%) patients for diagnosis. Only 40 patients (16%) had a PET-CT for staging, likely due to limited access to this procedure in a resource-limited setting. Non-small cell lung cancer cases (NSCLC) were 82% and small cell lung cancer (SCLC) 18%. Among NSCLC cases, 51% were adenocarcinoma, 38% squamous cell carcinoma, and 11% other subtypes. With biomarker testing, 14.5% of cases were EGFR-positive and 10% ALK/ROS1-positive, with higher rates in nonsmokers and those with non-squamous histology. For PD-L1 expression, 37% had TPS <1%, 35% TPS 1-49%, and 28% TPS >50%.Distant metastases were observed in 171 (67%) patients. Among NSCLC cases, 64.7% (136/210) were stage IV, while 80% of SCLC cases had extensive-stage disease.Bone and contralateral lung (29%) were the most common metastatic sites, followed by brain and pleura. Only 13 (5%) of patients were diagnosed at stage I or II.A family history of cancer was found in 39 patients (15%), and notably, 13 patients (5%) had a family history of LC.We found a significant correlation between smoking and histology, with non-smokers mostly having adenocarcinoma (p=0.009). No correlation was found between PD-L1 status and smoking.

Conclusions: Most LC cases present at advanced stages, leading to poor outcomes. Adenocarcinoma is prevalent in nonsmokers and driver mutations occur in one-quarter of NSCLC cases, which shows the need for biomarker testing. Implementing preventive programs and LC screening could help reduce mortality rates.

EP.17.25 The Transition of Treatment Choice for First-Line Treatment for Advanced or Recurrent NSCLC and the Patients' Characteristics

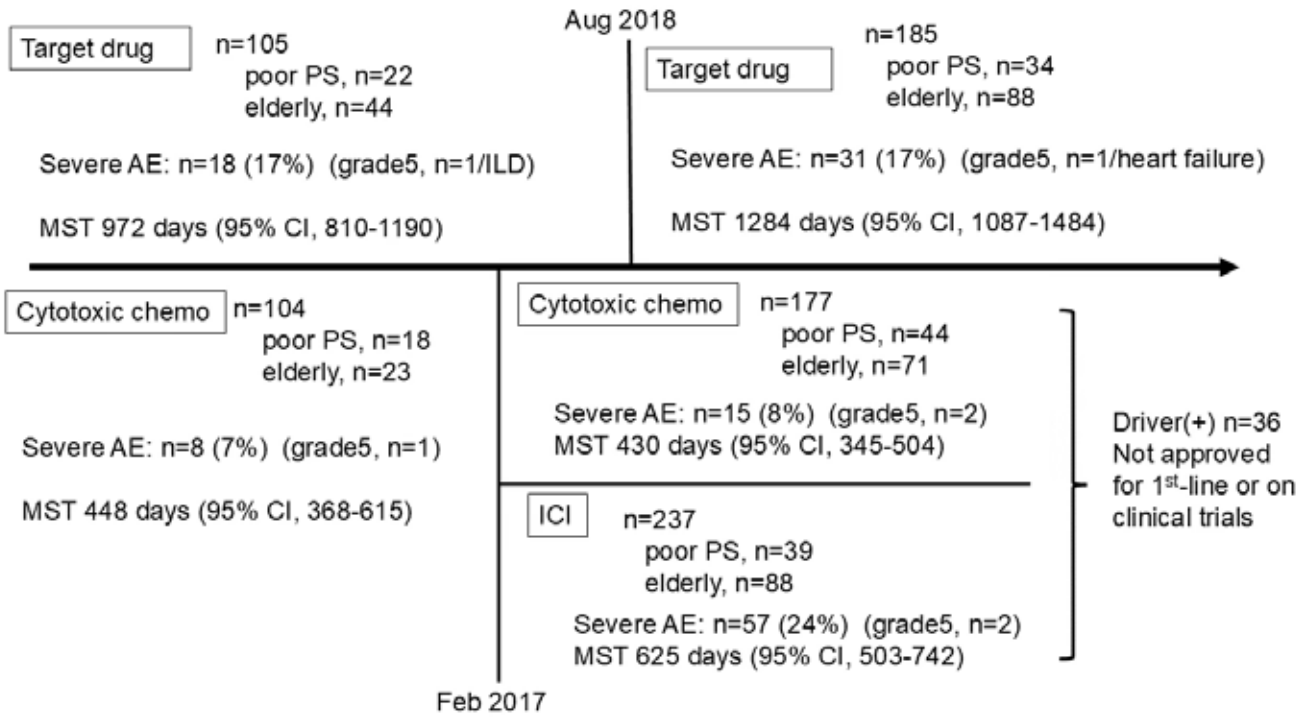
Y. Akazawa[1], A. Kubota[2], Y. Mihashi[1], R. Nishijima[1], Y. Yano[1], M. Mori[1], J. Uchida[1]
[1]Osaka Toneyama Medical Center, Toyonaka/JP ,[2]Kyoto University Graduate School of Medicine, Kyoto/JP

Introduction: The introduction of targeted therapies and immune checkpoint inhibitors (ICIs) has enhanced survival rates for patients with advanced or recurrent NSCLC. However, anticancer medications with new mechanisms of action can sometimes lead to unforeseen adverse events (AEs). In this retrospective analysis, we aimed to assess the efficacy and adverse events associated with anticancer treatments, categorized by treatment era and the types of drugs used.

Methods: In this retrospective single-center analysis, we planned to assess the transitions of treatment strategies for first-line treatment for advanced or postoperative recurrent patients with NSCLC and the incidence of AE stratified by treatment era and drugs. We accessed the data of patients who started first-line therapy in our institute between April 2014 and February 2024. Treatment eras for patients with targeted therapy for first-line treatment were divided into two periods by August 2018, when osimertinib was approved for first-line therapy. Treatment eras for patients who did not receive targeted drug were divided in February 2017, when pembrolizumab was approved for first-line treatment.

Results: The ratio of the patients with poor performance status (PS) score of 2-4 was 16-17% in the target therapy group, the ICI group, and the chemotherapy group prior to the ICI era, whereas the chemotherapy group post ICI era included 25% of poor PS. The incidences of AE were consistent in both periods in the target therapy group (17%) and in the cytotoxic agent group (7-8%). ICI regimen caused the highest incidence of AE (24%), and endocrine disorders were the most common. Six cases of grade 5 occurred (EGFR-TKI, n=1; cytotoxic chemotherapy, n=3; ICI, n=2). Even after the approval of ICI for first-line therapy, patients with ILD as comorbidities, the elderly or poor PS tended to choose a cytotoxic regimen due to the concern of AE.

Conclusions: This research had several limitations due to its retrospective nature. Our data included only the patients who received anticancer drugs, and we did not collect the details of subsequent treatment. However, many patients who received cytotoxic chemotherapy may have reaped the benefit of survival by later-line administration of ICI. Some targeted drugs, e.g., sotorasib and TdX-D, are approved for late-line therapy. Due to the aging society of Japan, the ratio of the elderly has increased. The treatment decision for patients with underlying conditions places more importance for oncologists.



EP.17.26 Survival in Advanced NSCLC Patients With PD-L1 =50% Treated With ICIs : A Multicenter, Retrospective Real-World Study in Georgia

A. Tsereteli[1], I. Kiladze[1,2], A. Iovashvili[3], K. Bibichadze[4], A. Matitashvili[5], T. Makharadze[6], A. Geguchadze[1]
[1]Caucasus Medical Centre, Tbilisi/GE ,[2]Ilia State University - School of Medicine, Tbilisi/GE ,[3]Iv.Bokeria University Hospital, Tbilisi/GE ,[4]Krystyna Kiel Oncology Center, Kutaisi/GE ,[5]Mardaleishvili Medical Centre, Tbilisi/GE ,[6]Consilium Medulla Multiprofile Clinic, Tbilisi/GE

Introduction: ICIs are standard for aNSCLC with high PD-L1 expression(≥50%) and no genomic aberrations. Real-world survival outcomes often differfrom clinical trial results, with shorter overall survival (OS) reported in severalstudies. This study aimed to assess real-world OS and progression-freesurvival (PFS) in patients with aNSCLC and high PD-L1 expression treatedwith ICIs, comparing outcomes with clinical trials.

Methods: A retrospective analysis was conducted on 49 patients withaNSCLC, PD-L1 tumor proportion score (TPS) ≥50%, and no drivermutations, treated with ICIs between January 2019 and September 2024 atfour centers in Georgia. All patients received either pembrolizumab oratezolizumab without chemotherapy as first- or second-line treatment. Dataon patients' clinicopathological characteristics (see Table #1). Kaplan-Meierestimates were used to calculate PFS and OS, and treatment responses andadverse events were assessed.

Results: The median age was 69 years (range: 44-84), with 93% male. 26patients (53%) had non-squamous carcinoma, while 23 patients (47%) hadsquamous cell carcinoma. The majority (88%) had stage IV disease, and 92%received pembrolizumab. The median follow-up duration was 16 months (2-36), with a median of 7 (1-37) treatment cycles. The best response waspartial response (46%), disease stabilization (24%), and disease progression(24%). The median PFS was 10.0 months (95% CI: 6.7-13.2 months), andthe median OS was 22.0 months (95% CI: 17.8-26.1 months). Adversereactions were reported in 70% of patients, with 24.4% experiencing grade3-4 events. Two patients had fatal immune-related adverse events (irAEs).

Conclusions: Study shows the effectiveness of using ICIs monotherapy inreal-world setting in patients PD-L1 TPS ≥50% aNSCLC. Our results clearlystate that the overall survival benefit is consistent with clinical trial data,although PFS was slightly lower. It might be useful to briefly acknowledge

limitations (e.g., retrospective design, sample size) or implications for futureresearch.

EP.17.27 Real-World Impact on Overall Survival of High-Cost Targeted and Immunotherapies in Lung Cancer Patients Under Chile's DAC Program

R. Letelier Farias[1], F. Orlandi[2], M.P. Saavedra[2], C. Ibarra[2], L. Cisternas[2], S. Zapata[2], R. Bugueño[2]
[1]Universidad Finis Terrae, Santiago/CL ,[2]Instituto Nacional del Tórax, Santiago/CL

Introduction: Lung cancer remains among the leading cancers in incidence and mortality worldwide, including Chile. Advances in cancer therapy, notably immunotherapy and targeted therapies, have substantially improved patient quality of life and overall survival. However, the high cost of these drugs generates significant access disparities, challenging the Chilean public health system's ability to provide them equitably. To address this, in 2019, Chile's Ministry of Health established the High-Cost Drugs Program (DAC), which evaluates and finances selected high-cost oncologic therapies for public health patients. This study assesses the survival impact of treatments funded by DAC among lung cancer patients treated at Instituto Nacional del Tórax (INT).

Methods: We retrospectively analyzed survival data of lung cancer patients enrolled in the DAC program at INT. Patients were evaluated according to the medication received (immunotherapies: Pembrolizumab, Nivolumab; and tyrosine kinase inhibitors: Osimertinib, Alectinib, Crizotinib). Mean survival with 95% confidence intervals, median follow-up, overall mortality rate, and survival rates at 12 and 24 months were calculated. Time of survival consider from indication of therapy from oncology committee. This analysis did not stratify by histology, cancer stage, age, or other relevant clinical variables.

Results: A total of 76 patients were included. Overall, patients showed a mean survival of 16.41 months (95% CI: 13.68 - 19.13 months) and a median follow-up of 13.5 months. The observed mortality rate was 32.9%.Survival rates at specific intervals indicated that 51.3% of patients remained alive at 12 months, decreasing to 23.7%at 24 months. Treatment-specific mean survival results were:• Alectinib: 19.16 months (95% CI: 14.59 - 23.73 months)• Osimertinib: 20.20 months (95% CI: 11.36 - 29.04 months)• Nivolumab: 15.67 months (95% CI: 7.86 - 23.47 months)• Pembrolizumab: 13.59 months (95% CI: 9.78 - 17.39 months)• Crizotinib: 43.00 months (single patient; no CI available)

Conclusions: The analysis demonstrates improved survival outcomes for patients enrolled in the DAC program compared to historical survival rates for lung cancer in Chile. However, important limitations must be acknowledged. Notably, this analysis did not adjust survival outcomes for crucial prognostic factors such as tumor histology (e.g., adenocarcinoma versus squamous cell carcinoma), clinical stage, patient age, or comorbidities, all of which significantly influence survival outcomes. This limitation may partially explain variations observed in survival between immunotherapy-treated patient groups and should be considered when interpreting these results.The presence of heterogeneous histologies (adenocarcinoma and squamous cell carcinoma) among patients treated with immunotherapy could influence differential responses and survival outcomes, highlighting the need for future, more detailed subgroup analyses. Additionally, age and cancer staging are critical factors known to influence survival significantly and should be included in subsequent analyses to provide a clearer interpretation of the impact of DAC-funded treatments.Despite these limitations, the data confirm the clinical relevance of DAC by facilitating access to high-cost drugs and underscore the importance of conducting comprehensive, locally-relevant cost-effectiveness and clinical studies to guide future policy decisions.

EP.17.28 Duration of Systemic Therapy in Patients With Metastatic EGFR-Mutated NSCLC and Brain Metastases: First vs Third Generation TKIs

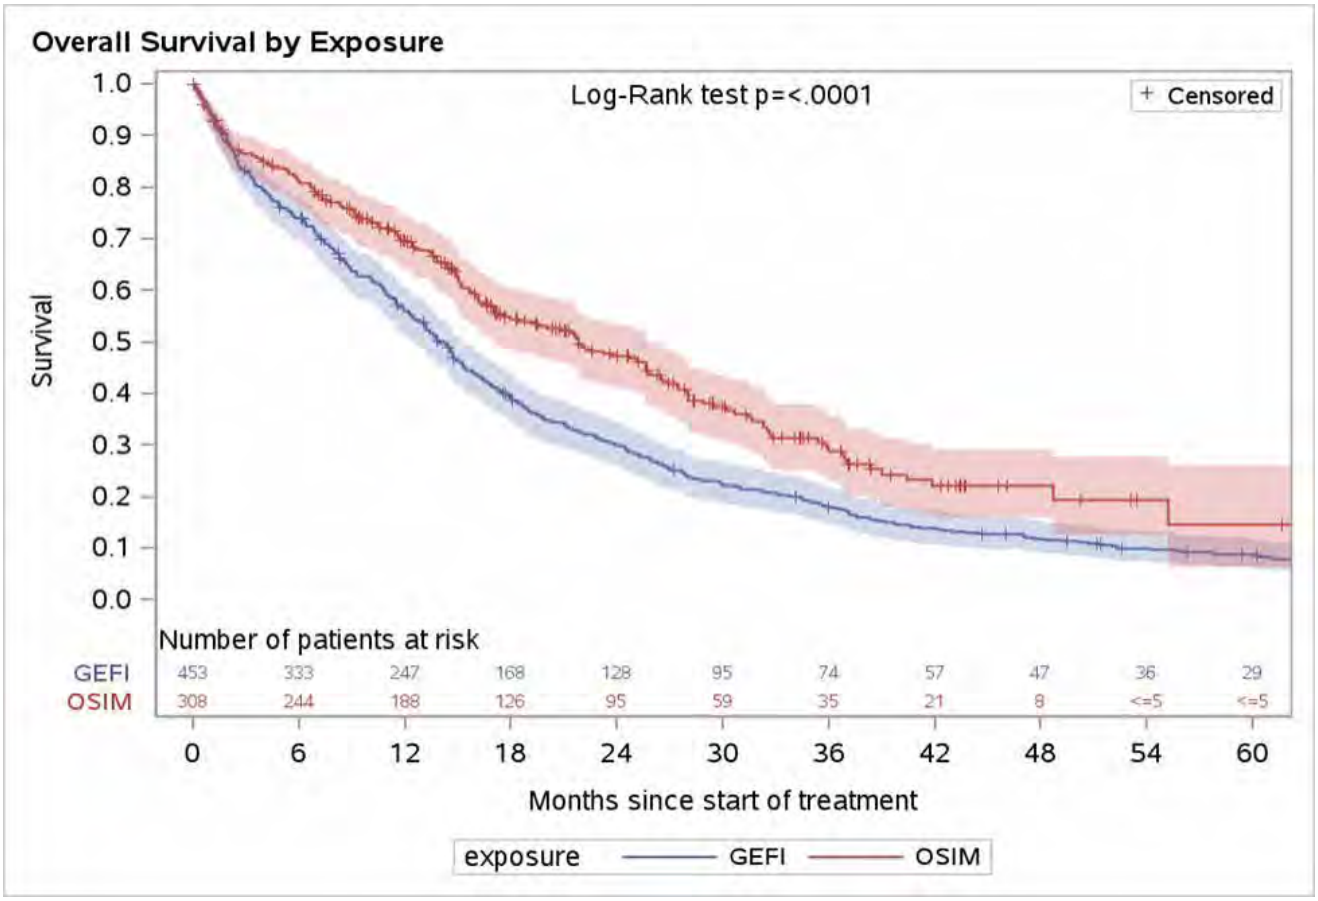
A. Parmar[1], L. Nguyen[2], N. Coburn[1], A. Louie[1]
[1]Sunnybrook Health Sciences Centre, Toronto/ON/CA ,[2]Institute of Clinical and Evaluative Sciences, Toronto/ON/CA

Introduction: New-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs), such as Osimertinib, demonstrate high central nervous system (CNS) activity in EGFR-mutated non-small cell lung cancer (NSCLC). Clinical guidelines recommend TKI monotherapy as an effective option for small, asymptomatic brain metastases (BM). We hypothesize that patients receiving Osimertinib remain on therapy longer than those on first- or second-generation TKIs. This study evaluates treatment duration in a real-world setting using a healthcare administrative database.

Methods: We analyzed data from the Institute for Clinical Evaluative Sciences (ICES), a provincial health administrative database, identifying patients diagnosed with non-squamous NSCLC from 2002 to 2022. Eligible patients received first-line EGFR-targeted therapy with either Gefitinib or Osimertinib. Brain radiotherapy receipt was used as a surrogate for BM presence. Patients under 18 or those with a prior cancer diagnosis within five years were excluded. The primary outcome was the duration of first-line systemic therapy. Overall survival (OS) was estimated using the Kaplan-Meier method. Propensity score matching adjusted for baseline factors influencing systemic therapy duration, including age, sex, rurality index, Charlson and Elixhauser comorbidity indices, income quintile, and treatment year.

Results: Among 3,088 screened patients with EGFR-mutated NSCLC, 1,243 received Osimertinib and 1,845 received Gefitinib as first-line therapy. A total of 761 patients had BM while receiving systemic therapy and met inclusion criteria (Osimertinib: 308; Gefitinib: 453). The median first-line systemic therapy duration was significantly longer in the Osimertinib cohort (327 vs. 190 days, $p < 0.001$). Median OS was also higher with Osimertinib (21.8 vs. 14.0 months, $p < 0.001$) (Figure 1). After propensity score matching (n = 168, 84 in each cohort), patients on Osimertinib first line had a median duration of 390 days vs. 154 days per patients receiving Gefitinib. There was no longer a significant difference in OS, with a median OS of 16.2m vs. 14.7m in the same respective cohorts ($p = 0.36$).

Conclusions: Patient with brain metastases treated with Osimertinib remained on this line of systemic therapy longer than patients treated with Gefitinib. These findings remained consistent after propensity score matching. These findings suggest that despite BM, patients on Osimertinib may have sustained efficacy in this patient population.



Keywords: Brain Metastases, Osimertinib, EGFR

EP.17.29 Real-World Effectiveness of Immunotherapy for Advanced Non-Small Cell Lung Cancer (NSCLC) Without Oncogenic Driver Alteration

C. Horugsa[1], S. Sawasdisara[1], L. Thamlikitkul[1]
[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok/TH

Introduction: Immune checkpoint inhibitor (ICI) is the standard of care for non-oncogene-addicted advanced NSCLC. ICIs used either in frontline (1L) or second-line (2L) setting improved patient survival, compared to chemotherapy alone. Unfortunately, ICIs are not reimbursable in many countries due to financial constraints. While the cost of ICIs used in the 1L setting is higher than the 2L one, the comparative effectiveness is unknown.

Methods: Medical records of advanced NSCLC patients receiving ICIs or chemotherapy at Siriraj Hospital, Bangkok, Thailand from 2016 to May 2023 were reviewed. Progression-free survival of 1L treatment (PFS) and overall survival (OS) of patients receiving 1L-ICIs, 2L-ICIs, and chemotherapy alone were compared using Kaplan-Meier method and log-rank test. Hazard ratio (HR) was calculated using Cox proportional hazard model. OS was defined as the duration from 1L treatment initiation until death.

Results: Both 1L-ICIs and 2L-ICIs significantly improved OS, compared to chemotherapy alone. However, no OS difference was observed between 1L-ICIs and 2L-ICIs (p=0.45).

Conclusions: Real-world evidence confirmed that ICIs significantly improved OS compared to chemotherapy alone. However, OS was similar for ICIs used in 1L and 2L settings. These results will be used for cost-utility analysis to identify the most cost-effective scenario for ICI reimbursement.

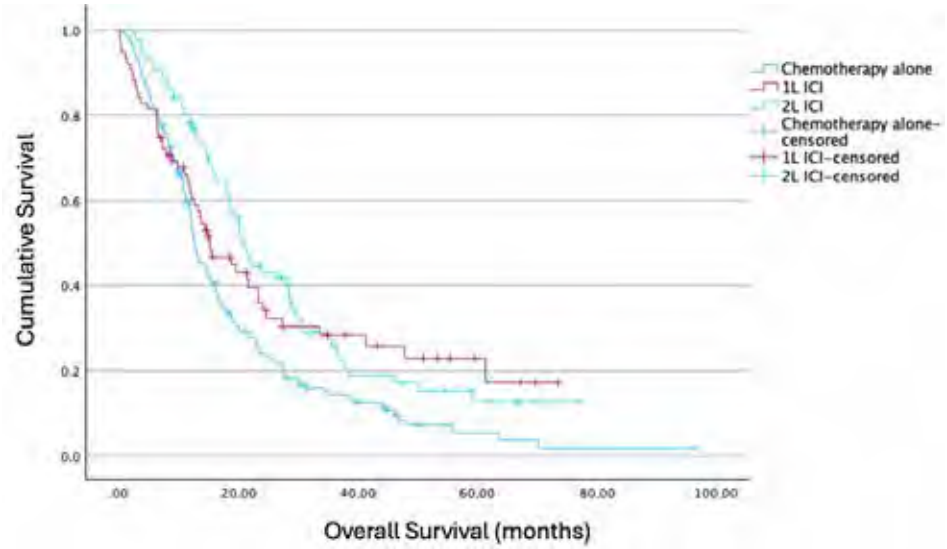


Table 1. Baseline characteristics

	Chemotherapy alone (n=156)	1L-ICIs (n=75)	2L-ICIs (n=87)	p-value
Male (%)	102 (65.4)	54 (72.0)	59 (67.8)	0.60
Age – Mean (SD)	62.7 (10.8)	69.6 (10.4)	64.7 (10.2)	< 0.001
Smoker – n (%)	82 (52.6)	44 (58.7)	53 (60.9)	0.05
Adenocarcinoma – n (%)	127 (81.4)	60 (80)	72 (82.8)	0.14
ECOG 0-1 (%)	137 (87.8)	54 (72.0)	79 (90.8)	0.001
Brain metastasis – n (%)	21 (13.5)	9 (12.0)	13 (14.9)	0.86
PD-L1 – n (%)				< 0.001
Negative	52 (33.3)	15 (20.0)	38 (43.7)	
Low (TPS 1-49%)	15 (9.6)	17 (22.7)	27 (31.0)	
High (TPS ≥ 50%)	9 (5.8)	33 (44.0)	17 (19.5)	
Unknown	80 (51.3)	10 (13.3)	5 (5.7)	

Table 2. Survival outcomes

Treatment	Median PFS (months)	Hazard ratio for PFS [95% CI]	p-value
Chemotherapy alone	8.9	Reference	
1L ICIs	24.6	0.35 [0.24-0.50]	<0.001
2L ICIs	7.2	1.18 [0.90-1.55]	0.23
Treatment	**Median OS (months)**	**Hazard ratio for OS [95% CI]**	**p-value**
Chemotherapy alone	19.4	Reference	
1L ICIs	27.1	0.70 [0.50-0.96]	0.027
2L ICIs	28.7	0.60 [0.45-0.80]	<0.001

EP.17.30 Rising Incidence of Early Onset Thoracic Malignant Tumors: Real-World Data From Two Hospitals in Brazil

B.V. Miyamura, D.V. Markus, L.S. Pernomian, D.R.O. Pereira, G.M. Andriatte, G. Schvartsman, F.C. Maluf, O. Smaletz, J.R. Beal, P. Taranto, J.P. Batista, D.C.O.S. Lopes, P.L.S. Uson Junior, F.S. Moura
Hospital Israelita Albert Einstein, Sao Paulo/BR

Introduction: A rising number of early onset cancers have been observed worldwide in the last two decades. In lung cancer, the population of early onset cancer has conflicting data as far as risk factors, such as tobacco exposure, family history and female gender. In Brazil, tobacco consumption has decreased over the last two decades, while other lifestyle risks have increased, such as obesity, pollution exposure and use of electronic nicotine delivery systems. Moreover, the increase in early onset cancers holds substantial personal and societal consequences, including greater disease burden, loss of potential working years, and long-term health complications throughout the life course. There has been published data in other populations of this phenomena, however, there is a notable scarcity of data regarding this trend in Brazilian population. This study aims to evaluate the increase of number of early onset thoracic solid malignant tumors in two Hospitals in Brazil.

Methods: Retrospective data from Hospital Israelita Albert Einstein and Hospital Municipal Vila Santa Catarina in Sao Paulo, Brazil were queried from the period of 2018 to 2023. The study assessed patients with the diagnosis of thoracic solid malignancies according to the International Statistical Classification of Diseases and Related Health Problems 10th Revision (ICD-10). Search included C33 - malignant neoplasm of trachea, C34 - malignant neoplasm of bronchus and lung and C37 - malignant neoplasm of thymus. Early-onset cancer was defined as cases diagnosed in adults between 18 and 49 years. Data extraction was automated, utilizing precision medicine sources to obtain information related to ICD codes, demographics, and medical history.

Results: Our analysis observed 954 cases of malignant solid thoracic neoplasms, divided into 933 cases of lung and bronchus cancer, 20 cases of malignant neoplasm of thymus and 1 case of malignant neoplasm of trachea. From the total, 871 patients (91%) were aged 50 years or older, while 83 (9%) were between 18 and 49 years old. Smokers or former smokers were majority in both populations, but less common in the early onset population (68%) when compared to 50 years or older (82%), with statistical significance (p-value 0.002). In the early onset population, female gender was numerically more prevalent with 58% versus 42% of males and more common when compared to 51% in the 50 years or older, but with no statistical significance (p-value 0.3). Proportion of localized or locally advanced disease was similar in both populations. Incidence in early onset cancer increased from 0.16 cases per 10,000 people in 2018 to 0.49 per 10,000 people (p-value 0.001), with an increase in variation of 200% in the early onset population versus 18% in the 50 years or older.

Conclusions: Rising number of early onset thoracic solid cancers appears to be trend observed worldwide and was also saw in our sample with Brazilian patients. Even though our study does not have the power to fully represent the population, this trend deserves further studies to better understand it, so we can better characterize risk factors and access best screening opportunities for this younger population.

Keywords: early onset cancer, rising incidence, thoracic tumors

EP.17.31 Temporal Trends and Prognostic Factors in Lung Cancer Patients: Analysis Of a 25-Year Cohort of 2,488 Cases

B.B.d. Rezende[1], L. Assumpção[2], S. Jamnik[1], I. Santoro[1], L. Lauricella[3], R. Terra[4]
[1]Federal University of São Paulo, São Paulo/BR ,[2]State University of Rio de Janeiro, Rio de Janeiro/BR ,[3]University of São Paulo, São Paulo/BR ,[4]Hospital Israelita Albert Einstein, São Paulo/BR

Introduction: Lung cancer remains the leading cause of cancer-related mortality worldwide. Clinical and epidemiological factors such as sex, smoking, histological type, staging, functional performance (ECOG), and recurrence pattern directly influence patient survival. This study aims to demonstrate temporal changes in the Brazilian patient profile over the past 25 years.

Methods: This is a retrospective cohort study involving 2,488 lung cancer patients at three hospital institutions in São Paulo between 1999 and 2024. Variables analyzed included sex, smoking status, ECOG, histological type, recurrence, and survival. Statistical tests were applied according to data type and distribution (Wilcoxon, Shapiro-Wilk, Kruskal-Wallis, chi-square, and Cochran-Armitage trend tests).

Results: There was a decrease in the proportion of male patients (from 75% in 1999 to 41.7% in 2024) and an increase in the number of women diagnosed with lung cancer. Prevalence of non-smokers rose from 13.6% (2000) to 40.1% (2024), and probability of developing lung cancer as a non-smoker increased from 6.3% to 34.2% during the period. Smoking cessation after diagnosis dropped from 69.3% in 2013 to 38.6% in 2024. Probability of quitting smoking post-diagnosis showed a downward trend (from 57.1% in 1999 to 53.2% in 2024). Men were more frequently former smokers (65.3%), while women predominated among non-smokers (37.3% vs. 12.9%). Proportion of current smokers was similar between sexes (21.3% in men vs. 20.2% in women). Adenocarcinoma increased in prevalence from 62.5% (1999) to 67% (2024), while squamous cell carcinoma decreased from 37.5% to 8.2%. Although there was no statistically significant increase in adenocarcinoma among women ($p = 0.1433$), it was significantly associated with active smoking. A significant increase in the proportion of patients diagnosed at stage I was observed, especially after 2015, reaching 83.5% in 2024 ($z = 22.7$; $p < 0.001$).

Stage IV cases dropped from 50% in 1999 to less than 2% in 2024 ($z = -20.0$; $p < 0.001$). Being diagnosed at stage I increased from 26.9% (before 2010) to 61.2% (2015-2019), reaching 79.4% between 2020-2024, while stage IV diagnosis decreased from 24.6% to 5.2% in the same period ($p < 0.001$). Median survival was 25.3 months in patients with local recurrence, 20.0 months with distant recurrence, and 15.83 months in patients without recurrence overall. Women with local recurrence had the best survival outcomes (33.7 months). ECOG 2-3 associated with smoking correlated with worse survival (1.5 months in men; 1.08 months in women).

Conclusions: There has been a transformation in the profile of lung cancer patients in this Brazilian cohort over the past 25 years, with an increase in cases among non-smokers and a higher proportion of affected women.

There was a decrease in squamous cell carcinoma and a rise in adenocarcinoma.

The percentage of patients diagnosed at stage I increased, while stage IV cases declined over the years.

Survival is influenced by sex, type of recurrence, functional status, and smoking, with women showing more favorable prognoses. Smokers with high ECOG scores have worse survival.

Prospective national-level studies are needed to better understand lung cancer behavior and trends in the coming years.

EP.17.32 Real-World Disease Impact in First-Line Treated Patients With Advanced Non-Small Cell Lung Cancer With PD-L1 Expression =50%

D. H.Owen[1], M. Sebastian[2], H. Kenmotsu[3], S. Viswanathan[4], S. K. Mhatre[4], I. K. Dhillon[5], C. Hogea[4], S. Ding[5], T. Hill[6], H. Bailey[6], D. Rodríguez-Abreu[7]

[1]James Cancer Hospital and Solove Research Institute, Columbus/OH/USA ,[2]Goethe University Frankfurt, Frankfurt/DE ,[3]Shizuoka Cancer Center, Shizuoka/JP ,[4]Gilead Sciences, Inc, Foster City/CA/USA ,[5]Gilead Sciences Europe, Stockley Park, London/GB ,[6]Adelphi Real World, Macclesfield/GB ,[7]Hospital Universitario Insular de Gran Canaria, Las Palmas de Gran Canaria/ES

Introduction: Given the evolving treatment landscape globally in patients with advanced non-small cell lung cancer (aNSCLC), PD-L1 ≥50% and without actionable genomic alterations (AGA), there is a need to better understand impact of symptoms and comorbidities on overall functioning to support treatment choice. This study assessed disease burden in patients prescribed first-line (1L) immunotherapy monotherapy or immunotherapy + chemotherapy across Europe (EU), United States (US), and Asia.

Methods: Data were derived from the Adelphi NSCLC Disease Specific ProgrammeTM: a comprehensive multifaceted systematic approach involving multi-country, cross-sectional surveys of physicians and patients across EU (France, Germany, Spain, Italy, UK), US, and Asia (China, Japan) between Dec 2023-May 2024. This included data from medical charts of patients (alive at the time of the study) on symptoms, comorbidities and patient-reported impairment on activities of daily living during treatment, as well as hospitalizations (excluding routine visits) 12 months prior to data collection (recent). All analyses were descriptive.

Results: Of 512 patients (EU: n=369; US: n=53; Asia: n=90) with PD-L1 expression ≥50% and without AGAs, median (IQR) age across regions was 69 years (64-74) with majority (75%) treated at a public hospital. Overall (n=430), 44% experienced a recent hospitalization. Symptoms were similar for 1L immunotherapy + chemotherapy (n=116) and 1L immunotherapy monotherapy (n=340) across regions, with the most common being cough (66% and 62%), fatigue (53% and 42%), dyspnoea (35% each), loss of appetite (28% each), chest pain (24% and 26%), and persistent cough (30% and 20%). On a severity scale, cough and persistent cough were reported severe by a higher proportion of 1L immunotherapy + chemotherapy patients (11%, n=76 and 9%, n=35) than 1L immunotherapy monotherapy patients (1% each, n=211 and n=67), respectively. A higher proportion of patients with squamous histology, history of smoking, and ECOG 1+ experienced symptoms during 1L treatment than patients with non-squamous histology, never smokers, and ECOG 0, respectively. When examining by duration of 1L treatment (median: 8 months; n=216), a lower proportion of patients with ≥6 months experienced cough (60%), wheezing (23%) and persistent cough (23%), than with <6 months (71%, 38%, and 36%). Chronic pulmonary disease (25% and 23%) and diabetes without chronic complications (17% and 18%) were the most common comorbidities for immunotherapy monotherapy and immunotherapy + chemotherapy, respectively. From patient-reported aNSCLC-related impairment (n=148), patients receiving 1L immunotherapy monotherapy (n=88) and 1L immunotherapy + chemotherapy (n=36), reported moderate-severe impairment of overall general health (38% and 44%), overall level of physical function (33% and 44%), quality of life (33% and 53%), ability to work (50% and 47%), ability to socialize (27% and 28%) and emotional well-being (33%, each), respectively.

Conclusions: Considerable symptom burden and impairment on patient health due to aNSCLC was found during 1L treatment in patients with PD-L1 ≥50% and without AGAs, regardless of treatment received across all regions. This highlights a persistent unmet need in the current treatment landscape over the past decade to reduce symptom burden and understand drivers of treatment choice as combination therapies continue to evolve.

EP.17.33 Evolving Treatment Patterns in Early-Stage Non-Small Cell Lung Cancer in the United States

J.E. Gray[1], K. Thoele[2], A.M. Gilligan[2], M. Richey[3], N. Boualam[3], E. Brechtelsbauer[2], K.M. Sheffield[2]
[1]H. Lee Moffitt Cancer Center and Research Institute, Tampa/FL/USA ,[2]Eli Lilly and Company, Indianapolis/IN/USA ,[3]Flatiron Health, New York/NY/USA

Introduction: The standard of care for patients (pts) with early-stage non-small cell lung cancer (esNSCLC) is surgery combined with systemic therapy. Recent approvals of immunotherapies (IO) and targeted therapies (TT) offer new options for pts with early-stage disease. This study evaluated evolving trends in the adoption of TT and IO among pts with resected esNSCLC in the US.

Methods: This retrospective observational study included pts diagnosed with esNSCLC (stages IB-IIIA) who underwent surgical resection between 1/1/2019 and 12/31/2023, with follow-up through 9/1/2024. Data were extracted from nationwide Flatiron Health electronic health records-derived de-identified database. Demographics, clinical characteristics, neoadjuvant, adjuvant and perioperative treatment patterns, and time to treatment discontinuation (TTD) of adjuvant IO and TT were reported.

Results: Among 14,638 pts who met the eligibility criteria (median age 70 years [IQR: 64, 75]; 53.3% female), 32.1% were diagnosed with stage IB, 39.2% with stage II, and 27.7% with stage IIIA disease, 87.1% had a history of smoking, and 22.9% were treated in an academic setting. From 2019 to 2023, use of platinum-based chemotherapy remained steady, while use of IO and TT increased (Table). Among pts who underwent surgery in 2023 and treated with IO (n=1,024), the majority (72.4%) received IO as adjuvant therapy, 17.1% as neoadjuvant therapy, and 10.6% as perioperative therapy. IO use was observed across all PD-L1 subgroups. In 2023, 28.8% of pts with PD-L1 <1%, 39.7% of pts with PD-L1 1-49%, and 52.8% of pts with PD-L1 ≥ 50% received IO as a component of their curative regimen. Pts without pathologic complete response after neoadjuvant chemotherapy with IO (ChemoIO) received adjuvant IO (33.5%), ChemoIO (7.4%), chemotherapy (6.5%), other treatment (6.2%), or no adjuvant treatment (46.5%). Median TTD for adjuvant IO (pembrolizumab, durvalumab, and atezolizumab) was 10.5-11.4 months. Median TTD for adjuvant osimertinib was 35.1 months.

Table: Systemic therapy in patients with resected esNSCLC from 2019 to 2023*

	Stage IB-IIIA N=3,256	**Stage IB-IIIA** N=2,950	**Subgroup: Stage II/IIIA** N=2,241	**Subgroup: Stage II/IIIA** N=1,947
	2019	**2023**	**2019**	**2023**
Any systemic therapy, %	54.6	63.0	66.1	77.1
Any platinum-based chemotherapy, %	47.9	48.5	60.9	62.9
Any IO, %	6.5	34.7	8.5	48.6
Any TT, %	1.2	7.8	1.2	7.2
Neoadjuvant IO, %	0.2	5.9	0.3	8.5
Adjuvant IO, %	6.1	25.1	8.0	34.8
Perioperative IO, %	0.2	3.7	0.2	5.3

*Treatment patterns were assessed by surgery year.

Conclusions: The clinical landscape in esNSCLC has rapidly evolved following paradigm-changing clinical trials, with growing adoption of adjuvant IO and TT. Approximately half the pts with stage II/IIIA disease received IO in 2023, with adjuvant therapy as the dominant curative paradigm. However, FDA approvals of perioperative IO occurred at the end of the study period; ongoing assessment of uptake is warranted.

EP.17.34 Real-World Survival Outcomes in Non-Small Cell Lung Cancer: Insights From UK Ehr-Derived Data

A. Samani[1], Q. Zhang[2], A. Sujenthiran[1], S. van Bömmel-Wegmann[3], B. Adamson[2]
[1]Flatiron Health UK, London/GB ,[2]Flatiron Health, New York/NY/USA ,[3]Flatiron Health Germany, Berlin/DE

Introduction: Non-small cell lung cancer (NSCLC) treatment has evolved significantly in recent years with the introduction of immune checkpoint inhibitors and targeted therapies. However, understanding real-world testing patterns, treatment patterns, and outcomes remains challenging due to limited availability of comprehensive, longitudinal datasets. We evaluated biomarker testing, treatments, and overall survival (OS) outcomes in the UK health care setting using a novel NSCLC dataset derived from the electronic health records (EHRs) of patients in the UK.

Methods: The study used the UK Flatiron Health Research Database and included anonymised, longitudinal data from patients diagnosed with NSCLC in the UK from January 1, 2016, to September 30, 2024. Structured and unstructured data were curated through technology-enabled abstraction and manual review. Key variables included patient demographics, clinical characteristics, biomarker testing (eg, programmed death-ligand 1 [PD-L1] and epidermal growth factor receptor [EGFR]; anaplastic lymphoma kinase [ALK]; B-Raf proto-oncogene, serine/threonine kinase [BRAF]; and Kirsten rat sarcoma viral oncogene homolog [KRAS] mutations), treatment regimens, and OS. Kaplan-Meier methods were used to estimate OS, stratified by stage of disease at diagnosis.

Results: Of the patients with metastatic disease at diagnosis (n = 946), >50% were tested for standard of care biomarkers (ALK, BRAF, EGFR, KRAS, and PD-L1). Of those tested, the rate of positive tests align with literature findings for patients with NSCLC (ALK, 5%; BRAF, 1%; EGFR, 11%; KRAS, 33%; PD-L1, 57%). The 3 most commonly used drugs in the metastatic setting were carboplatin (31%), pemetrexed (22%), and pembrolizumab (17%). For the entire cohort (n = 2674), OS stratified by stage at diagnosis showed plausible relationships, with higher stage associated with shorter median OS: 5.8 years (Stage I), 3.0 (Stage II), 2.9 (Stage III), 2.2 (IIIA), 0.9 (IIIB), 1.0 (IIIC), and 0.4 (Stage IV).

Conclusions: By addressing gaps in longitudinal data availability, the EHR-derived UK NSCLC dataset offered valuable insights into real-world testing patterns, treatment patterns, and outcomes. Observed biomarker prevalence aligns with established literature and treatment patterns, and survival outcomes align with typical clinical expectations, supporting the reliability, and representativeness of the dataset. Ongoing efforts to expand analyses of treatment patterns and key clinical endpoints, such as disease progression, will further enhance its role in supporting research on real-world patient care and outcomes in the UK.

EP.17.35 Treatment-Associated Interstitial Lung Disease in Extensive-Stage Small Cell Lung Cancer

G.S. Calip[1,2], Y.C. Choi[1], M. Chen[1], S. Crawford[1], P. Hingorani[1], S. Yue[1], O. Ogunyankin[1], T. Palenski[1], C. Ferlini[1], A.M. McNeill[1,3]
[1]AbbVie, North Chicago/IL/USA ,[2]University of Southern California, Los Angeles/CA/USA ,[3]University of North Carolina at Chapel Hill, Chapel Hill/NC/USA

Introduction: Interstitial lung disease (ILD) is a clinically significant adverse event associated with systemic cancer treatment, including chemotherapy and immunotherapy. Our objective was to describe rates of ILD in patients with extensive-stage small cell lung cancer (ES-SCLC) receiving first-line (1L) chemotherapy with and without a checkpoint inhibitor (CPI) and subsequent second-line (2L) monotherapy.

Methods: We conducted a retrospective cohort study using Optum's de-identified Market Clarity Data (Optum® Market Clarity). Patients diagnosed with ES-SCLC between 2019 and 2023 initiating 1L with platinum (cisplatin/carboplatin) and etoposide chemotherapy with and without CPI (atezolizumab/durvalumab) were included. Secondary analyses included patients initiating 2L with lurbinectedin, topotecan, or irinotecan. Cumulative incidence of ILD was estimated using an adapted algorithm of inpatient and outpatient diagnostic codes. Patients were followed from treatment initiation until the first of incident ILD, death, treatment discontinuation or end of study follow-up (June 2024). Fine-Gray regression models were used to calculate multivariable-adjusted sub-distribution hazard ratios (sHR) and 95% confidence intervals (CI).

Results: In a cohort of 1,608 ES-SCLC patients initiating 1L (median age: 67 years; interquartile range 61-73) with median treatment duration of 3.3 months, 740 received platinum/etoposide and 868 received platinum/etoposide plus CPI. Patients that received only platinum/etoposide had greater comorbidity at baseline, including higher prevalence of autoimmune disease, congestive heart failure, and chronic pulmonary disease, whereas those that received platinum/etoposide plus CPI had higher prevalence of brain, bone, and liver metastases and were more likely to receive thoracic radiation. Overall, 158 (9.8%) patients had incident ILD events during 1L treatment. More patients receiving platinum/etoposide plus CPI experienced an ILD event compared to platinum/etoposide alone (12.1% vs. 7.2%, P=0.001). After accounting for greater comorbidity and competing risks of death, platinum/etoposide plus CPI was associated with higher risk of ILD that was not statistically significant overall (sHR 1.20, 95% CI 0.85-1.70) but was consistently elevated throughout CPI maintenance (Figure). Among 224 patients initiating 2L, 23 (10.3%) experienced ILD during follow-up with greater incidence observed with topotecan versus lurbinectedin (18.3% vs. 8.1%, P=0.034), while no events occurred with irinotecan. Prior receipt of thoracic radiation was similar between those that did and did not develop ILD. However, the majority (87.0%) of ILD events during 2L occurred following prior immunotherapy.

Conclusions: In this real-world study of patients with ES-SCLC, more ILD events were observed among patients receiving platinum/etoposide plus CPI versus platinum/etoposide alone, and most ILD events in 2L occurred among those with prior CPI treatment.

Figure 1. Cumulative incidence of ILD among patients with previously untreated ES-SCLC initiating (A) 1L platinum/etoposide or platinum/etoposide plus checkpoint inhibitor and (B) 2L monotherapy with lurbinectedin, topotecan, or irinotecan

EP.17.36 Disparities in Survival Outcomes of Primary Pulmonary Diffuse Large B-Cell Lymphoma: A SEER Database Analysis

J. Arunachalam[1], J. Arunachalam[2], G. Nabeta[3], K. Gunturu[4]
[1]University of Connecticut, Farmington/CT/USA ,[2]Royal Shrewsbury Hospital, Shrewsbury/GB ,[3]University of Connecticut Health Center, Farmington/CT/USA ,[4]Hartford HealthCare Cancer Institute, Plainville/CT/USA

Introduction: Primary pulmonary diffuse large B-cell lymphoma (DLBCL) is a rare extranodal non-Hodgkin lymphoma involving the lung, accounting for only 0.5 - 1% of primary pulmonary malignancies. Given its rarity, survival outcomes and the influence of sociodemographic disparities in this population remain poorly understood. This study aimed to evaluate the impact of age, sex, race/ethnicity, marital status, geographic location, and median household income on survival outcomes in patients with primary pulmonary DLBCL using a national database.

Methods: We conducted a retrospective cohort study using data from the Surveillance, Epidemiology, and End Results (SEER) Research Plus database (17 registries, 2000-2021). We included adults aged ≥20 years with histologically confirmed DLBCL and a primary tumor site in the lung, identified using ICD codes 9680/3 and C34. Descriptive statistics were used to summarize patient characteristics. Survival outcomes, including median overall survival (mOS) and cancer-specific survival (mCSS), were analyzed using the Kaplan-Meier method. Survival differences were assessed using the log-rank test, and hazard ratios (HR) with 95% confidence intervals (CI) were calculated. A p-value of <0.05 was considered statistically significant.

Results: A total of 1,524 patients were identified. At diagnosis, 65% were aged >65 years, 51% were female, and 75% were White, 11% Hispanic, and 7% Black. Most patients (88.5%) lived in metropolitan areas, and 45% had a median household income below $75,000. Metastatic disease was present in 38% at diagnosis. The mOS was 66 months, and mCSS was 220 months. Patients aged >65 had significantly worse mOS (30 months) compared to those aged 20-64 years (171 months; p<0.0001; HR 2.54, 95% CI 2.23-2.89). mOS was 70 months in females and 55 months in males (p=0.09). No significant survival differences were observed across racial and ethnic groups (p=0.62). By stage, mOS was 94 months (regional), 83 months (localized), and 45 months (metastatic) (p=0.0003). Among patients with metastatic disease, those <65 had a mOS of 135 months versus 26 months in those ≥65 (HR 0.45, 95% CI 0.36-0.55; p<0.0001). Rural residents had shorter mOS (47 months) compared to urban residents (67 months), though not statistically significant (p=0.0511). Survival did not differ significantly by income (p=0.1467). Married patients had a mOS of 82 months versus 41 months in unmarried patients (p=0.0001; HR 0.77, 95% CI 0.68 - 0.89).

Conclusions: In this population-based study of primary pulmonary DLBCL, older age, metastatic disease, and unmarried status were associated with significantly worse survival. Race/ethnicity, income, and residence location were not statistically significant predictors. These findings highlight the importance of age and social support as prognostic factors and underscore the need for early psychosocial risk screening and supportive care interventions in this rare population.

EP.17.37 Assessing the Hidden Risk From 1990-2021: Radon-Attributable Tbl Cancer Burden Across the European Union

J.D. Doshi[1], G. Luthra[2], A. Aleem[3], H.A. Sami[4], D. Vaghani[5], S. Sekar Lakshmisai[6], H.D. Desai[7]
[1]University Hospital Lewisham, Lewisham & Greenwich NHS Trust, London/GB ,[2]Internal Medicine, Central Michigan University, , MI, USA, [48602], Pulmnology, Saginaw/MI/USA ,[3]Internal Medicine Central Michigan University CMU School of Medicine Mount Pleasant, MI [48859], Mount Pleasant/MI/USA ,[4]Internal Medicine , Trinity Health Oakland/Wayne State University, Pontiac, Michigan, USA, [48341], Pontiac,/MI/USA ,[5]Internal Medicine, MGM Medical College, Aurangabad, Maharashtra, India,[431003], Aurangabad/IN ,[6]Department of Medicine, SRM Prime Hospital, Chennai, Tamil Nadu, India, [600087], Chennai/IN ,[7]Gujarat Adani Institute of Medical Sciences, Affiliated to K.S.K.V University, Bhuj/IN

Introduction: Tracheal, bronchus, and lung (TBL) cancer is a leading cause of death in the European Union, with residential radon exposure recognized as a major environmental risk factor. As a radioactive gas that accumulates indoors, radon contributes significantly to the lung cancer burden, especially among non-smokers, underscoring the need for targeted prevention and mitigation efforts.

Methods: We estimated deaths, disability-adjusted life years (DALYs), and years lived with disability (YLDs) due to TBL-cancer attributable to RR across age, sex, year, and location in the European Union from 1990-2021 using the standardized Global Burden of Disease-2021 tool. Temporal trends were assessed using estimated annual percentage change(APC), with results presented as absolute counts and age-standardized rates per 100,000 population.

Results: From 1990 to 2021, the total number of deaths increased from 12,635 (95% UI: -6,113 to 33,583) to 15,816 (-7,648 to 41,686). DALYs rose from 317,832(-153,698 to 840,975) to 340,698 (-163,261 to 899,744), while YLDs increased from 3,056(-1,479 to 8,377) to 4,441 (-2,032 to 12,208). The highest APC in age-standardized mortality rate (ASMR) was observed in Romania(0.73%), followed by Bulgaria(0.45%), while the rest of the EU showed a declining trend over the same period. Age-wise, individuals aged 55 and above showed increasing APC in ASMR in Romania(1.33%), Bulgaria(0.9%), Portugal(0.31%), and Greece(0.07%), whereas all countries showed a declining trend in those under 55. Regarding gender, females experienced a greater increase in burden, with ASMR increasing in all countries except Lithuania, Latvia, Denmark, and Estonia; in contrast, most countries saw a declining trend in males, except for Romania(0.5%) and Bulgaria (0.23%).

Conclusions: In 2021, the EU accounted for 19.25% of all global TBL cancer deaths attributable to residential radon, representing 5.84% of all TBL cancer deaths in the region—highlighting the urgent need to implement widespread radon testing and mitigation policies to reduce this preventable burden.

EP.17.38 Intersecting Determinants of NSCLC Outcomes in Brazil: The Roles of Histology, Socioeconomic Status, and Healthcare Sector Disparities

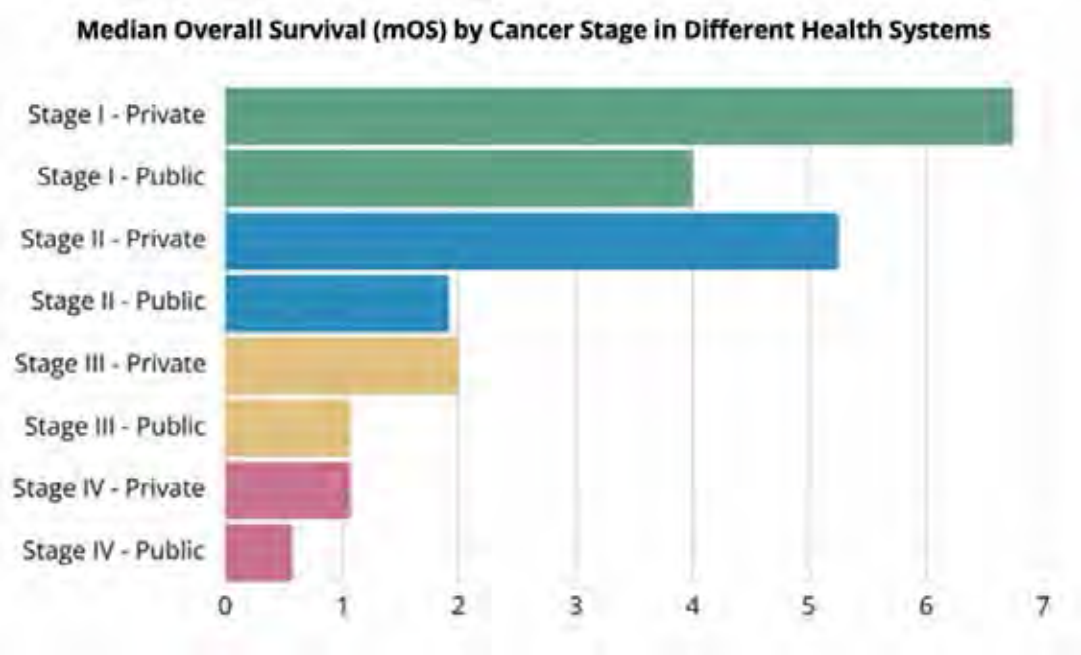
F. Malucelli Favorito[1], B. E Wilson[2,3], F. Ynoe de Moraes[2,3]
[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, São Paulo/BR ,[2]Queen's University, Kingston/ON/CA ,[3]Queen's Cancer Research Institute, Kingston/ON/CA

Introduction: While socioeconomic status (SES) is globally linked to cancer outcomes, Brazil's unique healthcare landscape — combining public and private sectors amid stark regional inequities — remains understudied. This study examines how histological subtype, SES, and healthcare coverage influence diagnosis stage, treatment access, and survival in NSCLC over a 20-year period.

Methods: A retrospective cohort of 37,606 adults (≥18 years) with pathologically confirmed NSCLC (2000-2020) was analyzed using data from the Fundação Oncocentro de São Paulo (FOSP). Histology (adenocarcinoma vs. non-adenocarcinoma NSCLC), SES (education level, municipal GDP per capita), and healthcare sector (public vs. private) were evaluated. Trends in diagnosis stage, treatment patterns, and diagnosis-to-treatment intervals were assessed. Survival analyses used Kaplan-Meier curves and log-rank tests.

Results: The cohort comprised 61% males, with 87% treated in the public healthcare system. Most patients (82%) presented with advanced-stage disease (III/IV). Adenocarcinoma (47% of cases) was associated with modestly earlier diagnosis and longer median overall survival (mOS) compared to non-adenocarcinoma NSCLC (53% of cases). Public-sector patients had significantly worse survival than private-sector patients (mOS: 0.83 vs. 2.00 years; p<0.0001), a disparity persisting across all stages (e.g., stage I: 4.00 vs. 6.75 years; p=0.0032). Higher SES correlated with private-sector access (4.4% in lowest GDP regions vs. 8.8% in highest GDP regions), earlier diagnosis (p<0.001), and improved survival: university-educated patients had the highest mOS (0.99 years) versus unschooled patients (0.58 years; p=0.0037).

Variable	Public System	Private System	No Schooling	University Education	Lowest GDP	Highest GDP	Adenocarcinoma	Carcinoma
Median age (yrs)	-	-	-	-	-	-	63	65
% Female	41.4	44.5	36	44	37.7	39.1	45	32
% Stage I	10.9	25.0	7.9	19.7	8.9	11.7	12	9.9
% Stage IV	57.5	50.2	50.1	54.6	54.5	55.6	62.6	48.4
Median OS (yrs)	0.83	2.00	0.58	0.99	0.65	0.76	0.74	0.72
% Waiting >60 days	43.4	26.9	29	21.4	27.5	29.5	29.6	27.0
% Receiving IO	0.43	3.22	0.18	1.42	0.8	0.43	0.60	0.50



Conclusions: NSCLC outcomes in Brazil are shaped by intersecting factors: tumor biology, healthcare infrastructure, and SES. Public-sector patients and those with lower education or income face delayed diagnoses, limited treatment access, and poorer survival — even at early stages. These findings underscore the urgent need for policy reforms to address systemic inequities in cancer care, prioritizing resource allocation and access within Brazil's public health system.

EP.17.39 Carbon Footprint of Lung Cancer Management and Impact of Lung Cancer Screening Implementation

V. Héluain1, I. Récoché1, A. Grand2, M. Lescouzères1, B. Collotte3, L. Molinier4, S. Liva-Yonnet4, A. Rabeau1, A. Didier1, L. Bigay-Game1, N. Guibert1, L. Brouchet1, J. Mazières1

Introduction: Health care is a key contributor of national greenhouse gas (GHG) emissions in western countries. Climate change directly threatens populations health around the world, undermine the past 50 years of gains in public health and threatens heath system ability to deliver high quality care. Reducing GHG emissions has become an urgent and significant issue to limit climate change, air pollution and health system dependence to fossil energies. Individual benefit of lung cancer (LC) screening is now well established: it reduces LC mortality in a heavy smoker population about 20% and increases the diagnosis rate of localized and treatable stages. The aim of this study was to evaluate LC management carbon footprint across different stages (localized vs metastatic diseases)

Methods: We performed a comparative environmental study to assess the carbon footprint of LC management in a thoracic oncology centre (Toulouse University Hospital) at different stages (localized vs metastatic stages). This project has been made in partnership with Monde Nouveau, a design office specialized in carbon and environmental footprint accounting. The methodology used is based on Bilan Carbone® methodology coupled with the Life Cycle Assessment (LCA) steps principle. The Base Empreinte® database was used to evaluate emission factors and a specific calculator has been made by the design office leaning on a flow mapping for the different health trail. Data from global results of GHG emissions of Toulouse University Hospital (year 2022) and specific data (drugs prescription, medical devices use, and visitors shift) from patients treated for LC in Toulouse University Hospital (year 2022) were used. Direct and indirect GHG emissions (scopes 1, 2 and 3) were taken into account.

Results: A total of 1293 patients treated for LC in 2022 were included. 245 patients underwent thoracic surgery for localized LC and 566 patients were treated for metastatic disease. The carbon footprint of stage I lung cancer patients who have undergone curative thoracic surgery was estimated at 2.7 tCO2e/patient/year (year of surgery). GHG emissions from the systemic treatment of metastatic cancers (stage IV) were estimated at 9.5 tCO2e/patient/year. The uncertainty interval was 22%. A very large majority of the carbon footprint was linked to the purchase and use of medicines and medical devices (respectively 94% and 77% for stage I and IV). GHG emissions due to LC screening were estimated in our institution at 0.02 tCO2e/patient/year.

Conclusions: The management of stage I LC appears to emit 3.5 less atmospheric CO2 in comparison to metastatic diseases. Considering that the majority of operated LC are cured, this difference is likely to increase considerably during follow-up. GHG emissions related to LC screening by low-dose computed tomography appear much lower than emissions related to LC treatment. LC screening could therefore effectively reduce the carbon footprint of LC management, which in turn would be beneficial for the health of the general population.

Keywords: lung cancer, carbon footprint, climate change

EP.18 CLINICAL TRIALS IN PROGRESS

EP.18.01 The Beneficial Value of 18F FDG PET/CT in the Follow-Up of Stage III Non-Small Cell Lung Cancer Patients (NVALT31-PET Study)

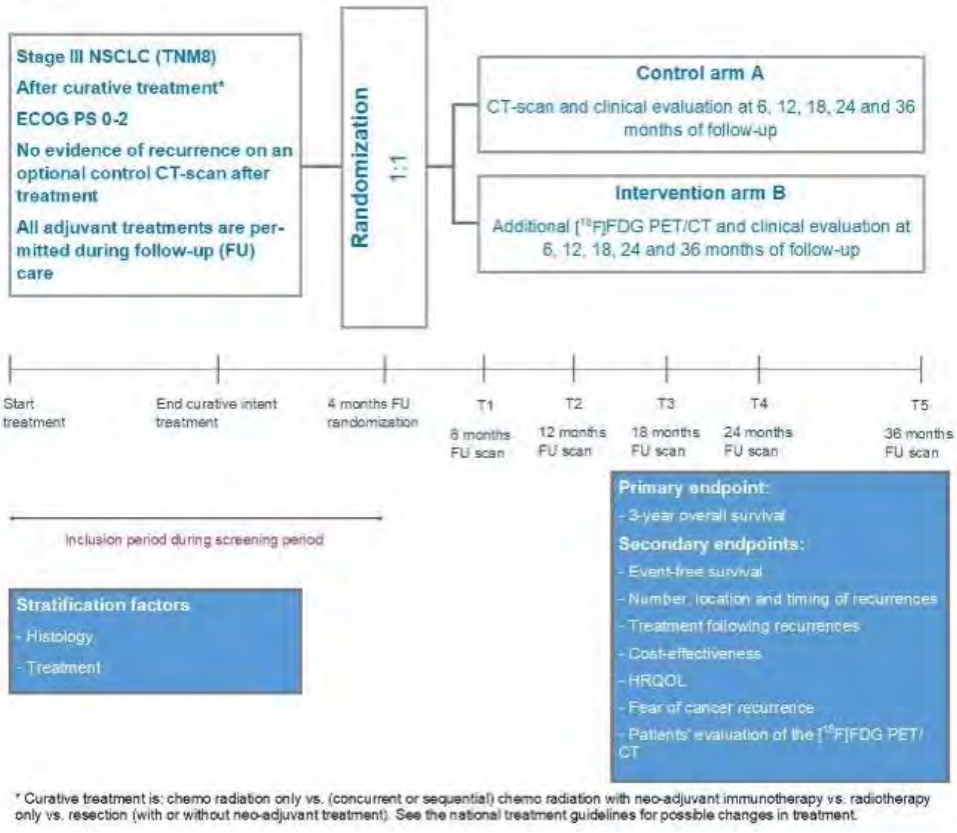
N. Billingy[1], C. Verberkt[1], M. Hassing[1], J. Schoorlemmer[1], M. Sarioglu[1], S. Senan[2], E. Aarntzen[1], W. Kievit[1], S. Teerenstra[1], C. Jacobs[1], A. Keijser[3], I. Bahce[2], M. van den Heuvel[1], A. Becker-Commissaris[2], I. Walraven[1]
[1]Radboudumc, Nijmegen/NL ,[2]Amsterdam UMC, Amsterdam/NL ,[3]Netherlands Cancer Institute, Amsterdam/NL

Introduction: Stage III non-small cell lung cancer (NSCLC) patients have a high risk of developing a recurrence after curative-intent treatment. As more effective treatments are now available, especially for patients with oligometastatic disease, earlier detection of recurrences utilizing [18F]FDG PET/CT (PET/CT) may prolong survival and health-related quality of life (HRQOL).

The Dutch multicenter NVALT31-PET randomized controlled trial aims to evaluate the effect of PET/CT versus only CT on 3-year overall survival (OS) in stage III NSCLC patients during FU surveillance. Secondary aims are to compare the rate of detected recurrences, type of treatment following recurrence, event-free survival, cost-effectiveness, HRQOL, patients' fear of cancer recurrence and the role of circulating tumor DNA (ctDNA) in the detection of recurrences during FU surveillance.

Methods: This study randomizes 690 patients at 4 months post curative intent treatment to either the intervention group or the control group. Eligible patients (>18yrs) have stage III NSCLC and are starting FU care, (which may include adjuvant therapies) with an ECOG Performance Status 0-2. The control group (n=345) receives usual care CT-based FU surveillance and HRQOL surveys at 6-, 12-, 18-, 24-, and 36-months FU. The intervention group (n=345) receives usual care, with additional whole-body PET-scans, blood samples and HRQOL surveys at the same intervals (Figure 1). Intention-to-treat analysis will be conducted to assess the intervention effect of PET/CT on 3-year OS using Kaplan-Meier curves.

Figure 1. Flow chart



Results: Patient recruitment and data collection commenced in March 2024. Currently, 27 hospitals have initiated patient recruitment with over 167 patients enrolled as of Apr. '25 (control group n = 85; intervention group n = 82). The mean age is 66.9 years (SD 7.5) and 54.5% is male. See Table 1 for a short overview of the baseline characteristics. The first results are anticipated by the end of 2029..$$graphic_{C8DC5DE5-97B1-44F9-BE3B-23CA1C17B538}$$

EP.18.02 Multicenter, Prospective Study on the Precise Diagnosis and Treatment of Shape-Sensing Robotic-Assisted Bronchoscopy

X. Zhang, Y. Gu, C. Su
Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Interventional bronchoscopy is a major tool for airway examination, diagnosis of airway lesions, therapeutic aspiration of airway secretions, and transbronchial needle biopsy for the diagnosis of pulmonary nodules. However, traditional bronchoscopes are too large in outer diameter to reach the peripheral lung, and although transthoracic needle biopsy has a high diagnostic rate, it also has a high risk of pneumothorax. In recent years, robotic bronchoscopes such as shape-sensing robotic-assisted bronchoscopy (e.g. ION system) can perform biopsies on peripheral pulmonary nodules, improving the biopsy diagnostic rate while achieving a low complication rate. Compared with existing technologies (ENB electromagnetic navigation technology, etc.), they have the advantages of high clinical performance and high stability.

Methods: This study intends to be based on the new generation ION system in a multicenter, prospective clinical cohort study to explore the precise diagnosis and treatment plan for thoracic tumors using robotic bronchoscopes. We aim to enroll 327 patients with pulmonary nodules who will undergo robotic bronchoscopy in three medical centers and conduct a follow-up for no less than 6 months. For patients with pulmonary nodules, the navigation success rate, biopsy success rate, diagnostic sensitivity for malignant tumors, and overall complication rate will be statistically analyzed and compared with the performance of existing technologies. For patients with malignant tumors who are intolerant of surgery or refuse to surgery for various reasons, a new microwave ablation technology using robotic bronchoscopes will be carried out and optimized in 32 patients.

Keywords: shape-sensing robotic-assisted bronchoscopy, Ion system, pulmonary nodules

EP.18.03 Neoadjuvant Toripalimab for Stage Ii-Iiib Resectable NSCLC With EGFR Mutation and PD-L1 Positive Expression (TOPLINE)

Y. Han[1], R. Jin[1], M. Du[1], J. Fan[1], J. Xiang[1], X. Yan[2], Y. Liao[3], F. Yang[4], J. Chen[5], W. Zhong[6], H. Li[1]
[1]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN ,[2]Tangdu Hospital, Air Force Medical University, Xi'an/CN ,[3]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN ,[4]People's Hospital, Peking University, Beijing/CN ,[5]Tianjin Lung Cancer Institute, Tianjin Medical University General Hospital, Tianjin/CN ,[6]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangdong/CN

Introduction: The optimal neoadjuvant treatment strategy for EGFR-mutant (EGFRm+) non-small cell lung cancer (NSCLC) remains unclear. Current strategies using either chemotherapy or EGFR tyrosine kinase inhibitors (TKIs) demonstrate modest efficacy, with major pathological response (MPR) rates approximating 10%. Preliminary data suggest neoadjuvant chemoimmunotherapy can achieve MPR rates exceeding 40% in EGFRm+ and PD-L1-positive (PD-L1+) NSCLC patients. This study aims to assess the safety, feasibility, and efficacy of neoadjuvant toripalimab (anti-PD-1) in patients with EGFRm+, PD-L1+ resectable stage II-IIIB NSCLC (NCT06269211).

Methods: This open-label, multicenter, prospective single-arm trial will employ Simon's optimal two-stage design, initially enrolling 10 patients with EGFRm+, PD-L1+ stage II-IIIB (N2) NSCLC, with trial continuation to an additional 19 patients upon observing ≥2 MPR cases in the first stage. To ensure balanced representation, patients will be stratified 1:1 based on PD-L1 tumor proportion score (TPS) (1-49% vs. ≥50%). All enrolled participants will receive three cycles of neoadjuvant toripalimab (240mg Q3W) prior to surgical resection. Postoperatively, adjuvant therapy will be determined based on pathology and minimal residual disease (MRD) status, with options including EGFR-TKIs and/or platinum-based doublet chemotherapy. The primary endpoint is the MPR rate. Secondary endpoints include other short-term oncologic outcomes (pathological complete response [pCR] rate, objective response rate [ORR]), as well as safety, feasibility, and long-term oncologic outcomes.

Results: Currently, two patients have been enrolled and have completed neoadjuvant therapy and surgery—one with a PD-L1 TPS of 1% and the other with ≥50%. Both experienced treatment-related hypothyroidism and diarrhea; however, no grade ≥3 treatment-related adverse events were observed. Neither patient achieved an MPR.

Conclusions: No optimal neoadjuvant treatment exists for EGFRm+, PD-L1+ NSCLC, and we hope that the findings of this study will contribute to the development of more effective treatments in this context.

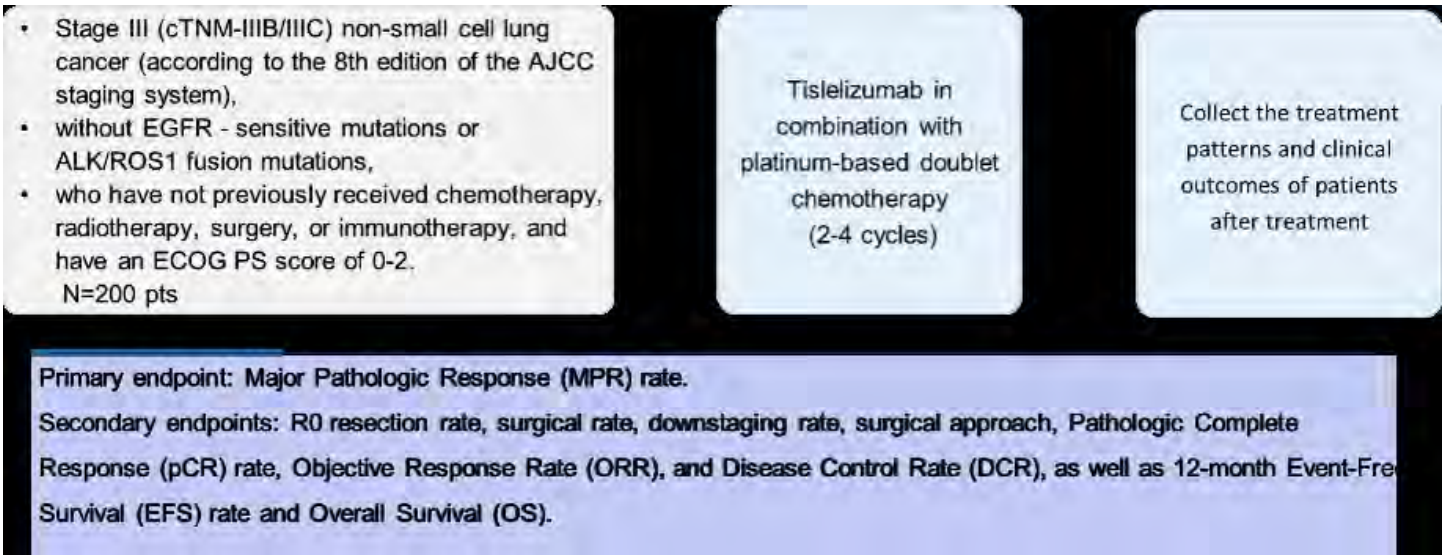
EP.18 CLINICAL TRIALS IN PROGRESS

EP.18.04 CLOG-0004 Clinical Outcomes of Tislelizumab Combined With Chemotherapy as Induction Therapy in Stage III (cTNM-IIIB/IIIC) NSCLC

T. Wang[1], Q.h. Zhou[2], Y.S. Wang[2]
[1]Lung Cancer Center, West China Hospital, Sichuan University, Chengdu, Sichuan, China, Cheng du/CN ,[2]Department of Thoracic Surgery, West China Hospital, Sichuan University, Cheng du/CN

Introduction: In patients with resectable stage II-IIIA non-small cell lung cancer (NSCLC), neoadjuvant tislelizumab plus chemotherapy showed clinically meaningful improvements in major pathological response (MPR) and pathological complete response (pCR) rates compared to chemotherapy alone. However, the clinical benefit of tislelizumab plus chemotherapy for potentially resectable stage IIIB/IIIC NSCLC remains to be determined.

Methods: Participants were recruited from August 2020 to June 2026 from dozens of large tertiary hospitals in China, enrolling patients with Stage III (cTNM-IIIB/IIIC) non-small cell lung cancer (according to the 8th edition of the AJCC staging system). The aim is to assess the Clinical Outcomes of Tislelizumab Combined with Chemotherapy As Induction Therapy in Stage III (cTNM-IIIB/IIIC) NSCLC



Keywords: Stage III (cTNM-IIIB/IIIC) NSCLC, Clinical Outcomes, Tislelizumab

EP.18 CLINICAL TRIALS IN PROGRESS

EP.18.05 Tislelizumab Combined With Low-Dose Chemotherapy in Previously Treated Advanced Squamous NSCLC

B. Ling, X. Wang, C. Chen
The affiliated cancer hospital of NanJing medical university, Nanjing/CN

Introduction: The standard second-line treatment for advanced squamous non-small cells lung cancer (SQ-NSCLC) typically involves single-agent chemotherapy or single-agent immunotherapy with the median progression-free survival (mPFS) approximately 3 months. Compared to monotherapy, using the combination of immunotherapy and chemotherapy as second-line treatment, may achieve better therapeutic outcomes. Conventional chemotherapies are administered at maximum tolerated doses (MTD) to maximize tumor cytoreduction. However, this high-dose may paradoxically impair treatment efficacy by directly cytotoxic effects on immune cells, leading to immunosuppression. Recent evidence suggests that low-dose chemotherapy may upregulate PD-L1 expression, stimulate an anti-tumor immune response, and enhance immune memory, thereby synergistically enhancing the therapeutic effects of immune checkpoint inhibitors. The aim of this study was to explore the value of low-dose chemotherapy combined with tislelizumab, an anti-PD-1 monoclonal antibody, in the later-line treatment of advanced SQ-NSCLC.

Methods: All eligible patients received low-dose chemotherapy, either nedaplatin (NDP) at 50 mg/m^2 or gemcitabine (GEM, for patients who had prior NDP exposure) at 1000 mg/m^2 on day1, combined with tislelizumab at 200 mg on day 2. The treatment was administered every 3 weeks for 6 cycles, followed by maintenance of tislelizumab for up to 2 years or disease progression. The primary endpoint was the 6-month progression-free survival (PFS) rate. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), 1-year OS rate, and safety.

Results: From August 2022 to June 2024, a total of 13 local advanced or advanced SQ-NSCLC patients who had failed first-line systemic treatment were enrolled in this study. Median age was 65 years(range 51-74), 12 (92.3%) male, 11 (84.6%) stage IV, 8 (61.5%) had previously received immunotherapy. Efficacy was evaluated in 11 patients,with median follow-up for all patients was 27 months. 6-month PFS rate 63.6% met the primary study endpoint; 4 pts achieved PR, 4 pts achieved SD, 3 pts PD, ORR was 36.4%, DCR was 72.7%; median PFS 9.0 months, 1-year PFS rate was 36.4%; median OS had not reached, 1-year OS rate was 72.7%. In safety analysis set, 2 patients occurred ≥ grade 3 adverse events (AEs), including 1 grade 4 thrombocytopenia, and 1 grade 3 thrombocytopenia combined with grade 4 leukopenia.

Conclusions: Low-dose chemotherapy combined with immunotherapy as second-line treatment for SQ-NSCLC was safe and effective, which deserves further investigation.

Keywords: Squamous non-small cells lung cancer, Immunotherapy, Low-dose chemotherapy

EP.18 CLINICAL TRIALS IN PROGRESS

EP.18.06 ML44840: A Multicenter Prospective Cohort Study of the Patient-Reported Outcomes in Chinese Patients With ALK+ Advanced NSCLC

C. Zhou[1], F. Zhou[1], Z. Song[2], H. Wang[3]
[1]Shanghai East Hospital, Shanghai/CN ,[2]Zhejiang Cancer Hospital, Hangzhou/CN ,[3]Henan Cancer Hospital, Zhengzhou/CN

Introduction: The development of tyrosine kinase inhibitors (TKIs) targeting ALK rearrangements has dramatically improved the treatment outcome of patients with ALK-positive Non-Small Cell Lung Cancer (NSCLC). Based on the results of the phase III Alesia study (Zhou et al. 2024), the 7-year overall survival rate in patients treated with Alectinib was 56.0%, which means ALK+ NSCLC gradually became a chronic disease. Poor quality of life is a severe challenge faced by the majority of lung cancer patients. Patients with ALK gene rearrangements usually require longer treatment courses of ALK-TKI, indicating that these patients could be at the highest risk of adverse drug reactions (ADR). The tolerability and toxicity profiles differ considerably between ALK-TKIs. Patient-reported outcomes (PROs) can provide important patient perspectives on the disease and the treatment received, capturing the impact of adverse reactions on patient well-being. ML44840(ALK PRO DCT, NCT06586801) aims to evaluate the PROs and safety profiles of patients with ALK-positive advanced NSCLC who received ALK-TKIs as first-line treatment in China real world practice.

Methods: Decentralized trial (DCT) mode is applied in this study. Approximately 800 patients with ALK-positive locally advanced or metastatic NSCLC will be enrolled into 3 parallel cohorts from both traditional sites and Direct to Patient (DTP) Pharmacies: Alectinib Cohort(n=400), Lorlatinib cohort(n=200) and other approved ALK-TKIs cohort(n=200), by the treating physician's decision. Key eligibility includes locally advanced and metastatic NSCLC, ALK-positive diagnosed by local standard methods, planned to receive ALK-TKIs as 1st line treatment and asymptomatic CNS metastasis allowed. The PRO follow-up will be continued until new anti-cancer therapies start, death, loss to follow-up, withdrawal of consent, or study termination by Sponsor, whichever occurs first. The data collection period for an individual patient was approximately 12 months. PRO data will be collected using the instruments of EORTC QLQ-C30,EORTC QLQ-LC13,selected items from the PRO-CTCAE and EORTC-IL46 by APP on the smart phone. Patients are required to report the outcome at Cycle 1, (baseline, Day 1±7days except IL46), Cycle 3(Day 1±7days), Cycle 5(Day 1±7days), Cycle 7(Day 1±7days), Cycle 9(Day 1±7days), Cycle 11(Day 1±7days) and Cycle 13(Day 1±7days). One cycle=28 days. The primary endpoint is PRO related outcome. The secondary endpoint is safety.

Results: NA

Conclusions: NA

EP.18.07 Aumolertinib Combined With Lomustine as First-Line Treatment for EGFR-Mutant NSCLC Patients With Brain Metastasis

T. Cheng, Z-G. Chen, L. Zhang, P. Zhang
Shangrao People's Hospital, Shangrao/CN

Introduction: As is known to all, EGFR-mutant NSCLC patients with brain metastasis are inclined to have worse efficacy and prognosis. According to subgroup analyses from registration clinical trials, the mPFS of the third-generation EGFR-TKI as first-line treatment for NSCLC with brain metastasis was 5.6-7.2 months longer than that of the control group (the first-generation EGFR-TKI). In addition, at least 95% of the enrolled patients of all registration clinical trials were evaluated as ECOG 0-1. How to further improve efficacy of EGFR-mutated NSCLC patients with brain metastasis is of great meaning in clinical practice. Lomustine is a fat-soluble drug that can be delivered effectively across the blood-brain-barrier to the brain and therefore, it has been the standard therapy for primary brain tumors or brain metastasis for its potent intracranial efficacy. Aumolertinib, targeting EGFR mutations, has been proved efficacious and well-tolerated for advanced NSCLC patients, especially with brain metastasis. Consequently, we conducted a phase II, single-arm, prospective study to verify the efficacy and safety of the combined therapy.

Methods: A total of 131 NSCLC patients with brain metastasis harboring EGFR mutation without prior anti-tumor treatment will be continuously recruited in th study. Patients with an ECOG≥3 or estimated survival lifetime less than 12 weeks will be excluded. All the participants will be orally treated with aumolertinib (110mg QD) plus lomustine (100-130/m2 at a draught, every 6 weeks) till disease progression or intolerance. The primary efficacy endpoint is PFS by investigator assessment as defined by RECIST1.1. The secondary endpoints comprise of iPFS, iORR, iDCR, OS and safety. Our study is the first trial to evaluate the efficacy and safety of third-generation EGFR-TKI plus traditional oral chemotherapy drug and the "all-oral" regime will be the key to guarantee compliance of patients resulting in lower admission rate and less hospitalization-related infection.

Keywords: EGFR-mutant NSCLC, brain metastasis, oral regime

EP.18 CLINICAL TRIALS IN PROGRESS

EP.18.08 Adebrelimab as Consolidation Therapy in Limited-Stage Small Cell Lung Cancer After Hyperfractionatedradiotherapy Combined With Chemotherapy

Y. Liu, Y. Zhou, Y. Yu, L. Zhao, X. Zhou, Y. Chen, F. Yu, S. Gong, S. Cheng, M. Li, L. Wang, L. Wang, Y. Ai
Beidahuang Industry Group General Hospital, Harbin/CN

Introduction: Concurrent chemoradiotherapy remains the standard treatment for limited-stage small cell lung cancer (LS-SCLC). However, most patients experience disease relapse within two years of treatment initiation. Hyperfractionated radiotherapy (45 Gy in 30 fractions) has shown improved long-term survival by reducing total treatment time. Adebrelimab, an anti-programmed death ligand-1 (PD-L1) antibody, demonstrated survival benefits in extensive-stage SCLC in the CAPSTONE-1 trial. The proposed study aims to assess the efficacy and tolerability of adebrelimab as consolidation therapy in LS-SCLC patients without disease progression after hyperfractionated radiotherapy combined with chemotherapy.

Methods: In this single arm, open-label, phase II trial, 36 patients with histologically or cytologically confirmed LS-SCLC as per Veterans Administration Lung Study Group staging system and without receiving prior systemic therapy are anticipated to be enrolled. Eligible patients are aged 18-80 years old with an ECOG performance status of 0 or 1, have a life expectancy of at least 12 weeks, and adequate organ function. Patients will be excluded if they have active or previous autoimmune disease, evidence of uncontrolled concomitant diseases or active infection or symptomatic interstitial lung disease. Patients will receive hyperfractionated radiotherapy at a dosage of 45 Gy (1.5 Gy bid, 5 days a week for 3 weeks) in combination with etoposide (100 mg/m2, iv, q3w) and platinum drugs (cisplatin 75 mg/m2 or carboplatin AUC 5, iv, q3w) followed by maintenance with adebrelimab (1200 mg, iv, q3w) and etoposide/platinum drugs for up to 24 months. The chemotherapy consists of a total of four cycles. The primary endpoint is 12-month progress-free survival (12-month PFS) rate, and the secondary endpoints are objective response rate, disease control rate, PFS, overall survival, safety and quality of life. Based on an estimated improvement in 12-month PFS from 42% to 65% (one-sided α=0.05, 80% power) with a 24-month follow-up, a total of 36 evaluable patients are required assuming a 10% dropout rate. The trial is currently recruiting.

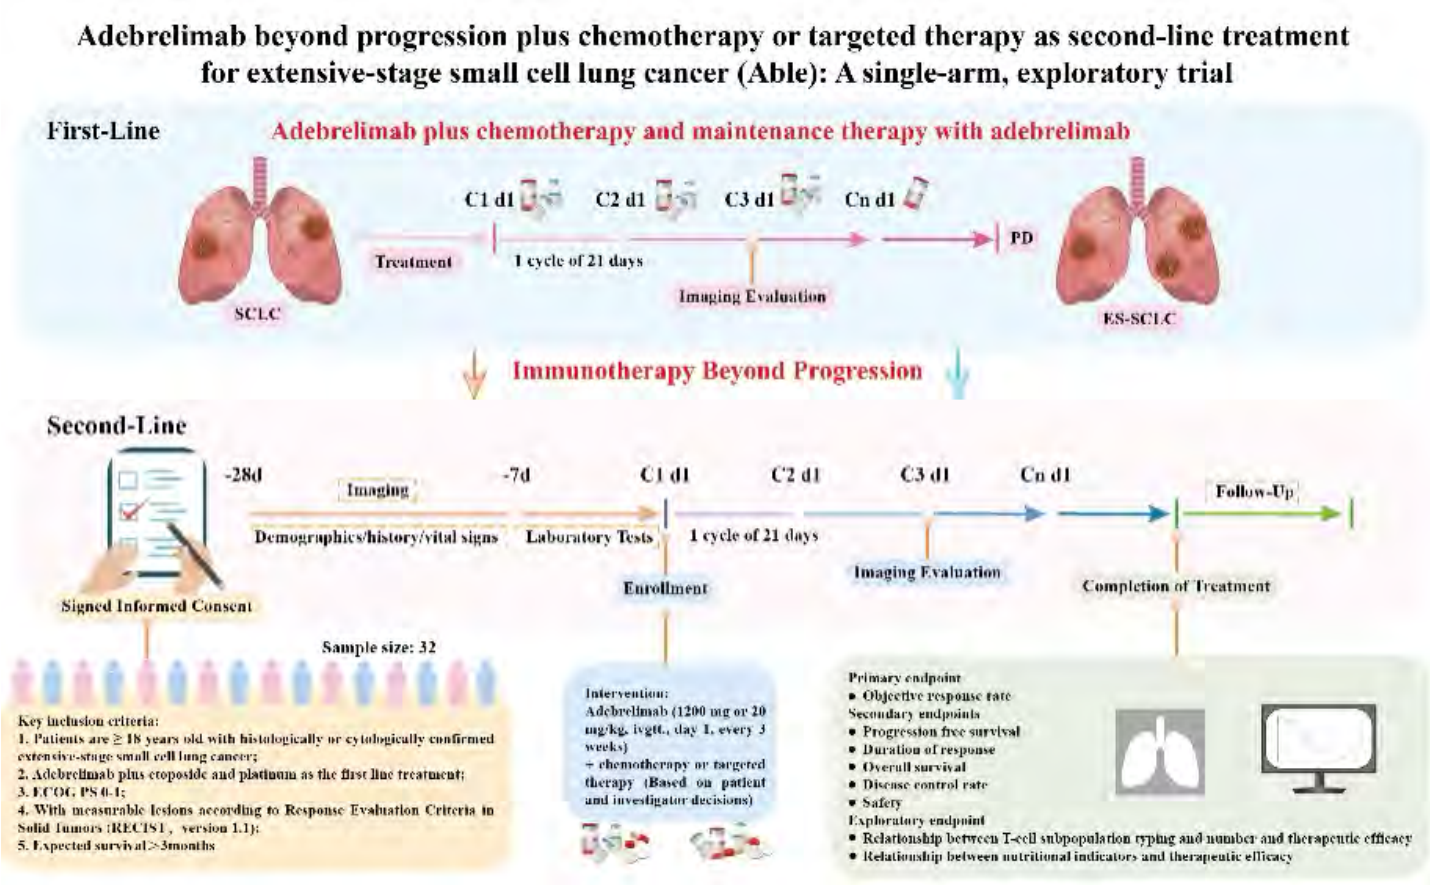
Keywords: Adebrelimab, LS-SCLC, Hyperfractionated Radiotherapy

EP.18.09 Adebrelimab Beyond Progression Plus Chemotherapy or Targeted Therapy as Second-Line Treatment for Extensive-Stage Small Cell Lung Cance

J-l. Li, Z-z. Liu, Y-z. Diao, F. Li, D. Wang, J. Zheng, C-y. Hong, Y. Liang
Liaoning Cancer Hospital & Institute, Shenyang/CN

Introduction: The phase III IMfirst study (EudraCT: 2019-002784-10) showed that compared with no follow-up therapy and other treatments, atezolizumab beyond progression tends to prolong overall survival. Twenty-four-point-four percent of patients in the ASTRUM-005 trial continued to receive serplulimab after disease progression, which may be one of the key factors contributing to a lower overall survival hazard ratio (HR) of non-head-to-head comparison to the IMpower133, CASPIAN, and CAPSTONE-1 trials (HR 0.62 vs 0.76, 0.71, 0.73, respectively). According to the Cancer-Immunity Cycle theory, adding immune checkpoint inhibitors to chemotherapy or targeted therapy may enhance anti-tumor efficacy. Currently, the efficacy of second-line monotherapy for ES-SCLC is limited, and there are no clinical studies on combining adebrelimab beyond progression with chemotherapy or targeted therapy as second-line treatment for ES-SCLC.

Methods: This is a prospective, single-arm, exploratory trial. The population included in the study is adult patients with ES-SCLC who have cancer progression after receiving first-line treatment with adebrelimab plus chemotherapy. Patients must meet Eastern Cooperative Oncology Group Performance Status 0-1, have measurable lesions according to Response Evaluation Criteria in Solid Tumors version 1.1, and have adequate organ function. The primary endpoint is the objective response rate. The secondary endpoints include disease control rate, duration of response, progression-free survival, overall survival, and safety. Additional indicators include the relationship between T-cell subpopulation typing and number and therapeutic efficacy and the relationship between nutritional indicators and therapeutic effectiveness.



Keywords: Small cell lung cancer, Beyond progression, Immune checkpoint inhibitor

EP.18 CLINICAL TRIALS IN PROGRESS

EP.18.10 Phase II Study: Efficacy and Biomarker Exploration of Anlotinib Plus Penpulimab in ES-SCLC After Failure of Platinum-Based Chemotherapy

Y. Zhang[1], n. Yang[2]
[1]Hunan Cancer Hospital, Changsha/CN ,[2]Brain Hospital of Hunan Province, changsha/CN

Introduction: The Phase II ALTER1202 trial demonstrated improved progression-free survival (PFS) and overall survival (OS) in patients receiving anlotinib after failing ≥2 systemic chemotherapy regimens compared to placebo. To further optimize outcomes for extensive-stage small cell lung cancer (ES-SCLC) patients refractory to first-line platinum-based chemotherapy, this study investigated the combination of anlotinib (a multi-target tyrosine kinase inhibitor) and penpulimab (a novel PD-1 inhibitor).

Methods: This open-label, single-arm, multicenter, phase II exploratory trial enrolled ES-SCLC patients with disease progression after platinum-based chemotherapy. Patients received penpulimab (200 mg intravenously every 3 weeks) plus oral anlotinib (10 mg daily, administered in a 2-week-on/1-week-off cycle) until disease progression, unacceptable toxicity, or withdrawal. Primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included disease control rate (DCR), PFS, OS, and safety.
